- Exclude IP/mask: if any mask is defined that is not 0.0.0.0, it might prevent the error message from being sent.

Enable FAM as S-TAP is installed with default value of `fam_installed` as 0 so the FAM does not load and is disabled.

To enable FAM, follow the applicable instructions:

For Shell installation on the database server

In the `guard_tap.ini` S-TAP configuration file, update the value of `fam_installed` and `fam_enable` parameters to 1 and then restart the server.

For GIM S-TAP bundle installation

Update the value of `STAP_FAM_INSTALLED` and `STAP_FAM_ENABLED` parameters to 1 and then restart the server.

TLS 1.3 and FIPS 140-3 not supported on Solaris operating system

IBM Security Guardium does not support Transport Layer Security (TLS) 1.3 in Guardium Data Protection version 12.0 and later on the Solaris operating system.

IBM Security Guardium does not support FIPS 140-3 cryptographic providers in Guardium Data Protection version 12.1 on the Solaris operating system.

Db2 for IBM i S-TAP

You can use the Guardium Db2 for i S-TAP to monitor and report on any database access on IBM i. This includes any programs, such as RPG, that use native database I/O operations or SQL access.

You can use information gathered by the Guardium Db2 for i S-TAP to create activity reports, help you meet auditing requirements, and generate alerts of unauthorized activity. Detailed auditing information includes:

- Session start and end times
- TCP/IP address and port
- Object names (for example, tables or views)
- Users
- SQLSTATEs
- Job and Job numbers
- SQL statements and variables
- Client special register values

- Interface information, such as ODBC, ToolboxJDBC, Native JDBC, .NET, and so on

The S-TAP receives data from two sources:

- SQL Performance Monitor (otherwise known as database monitor) data for SQL applications
- Audit entries from the QSYS/QAUDJRN audit journal for applications using non-SQL interfaces

Data from these sources includes:

- Any SQL access whether it is initiated on the IBM i server or from a client
- Any native access that is captured in the audit journal

The S-TAP sends this data to the Guardium® system in real time.

Note: The Db2 for IBM i S-TAP supports basic S-TAP features only. Features such as blocking, query rewrite, and FAM are not supported.

For more information about the Db2 for i S-TAP and related topics, see:

- [IBM i developer overview](#)
- [IBM i on IBM Docs](#)

i S-TAP for encryption, load balancing, and failover

The IBM i S-TAP supports TLS encryption and S-TAP session load balancing/failover.

Note: i S-TAP TLS support and load balancing is supported only for IBM i 7.1 and 7.2.

Similar to UNIX S-TAPs, i S-TAP configuration parameters are saved in a `guard_tap.ini` file in the `/usr/local/guardium` directory on the IBM i server.

Administrators configure the S-TAP is done using the same APIs and UI (S-TAP Control) as other UNIX S-TAPs. When the GUI or API is used to make a change to the S-TAP configuration, the Guardium sniffer sends a message to the S-TAP, which backs up the old `.ini` file, saves the configuration to the new `.ini` file and then restarts itself.

Administrators can set up encrypted communication between the S-TAP and the appliance using the S-TAP configuration controls as well as set up various load balancing options.

Using S-TAP failover and load balancing

The failover and load balancing options for the i S-TAP are similar to what exists for UNIX S-TAPs. Use the `participate_in_load_balancing` parameter to determine whether to use failover or load balancing behavior, and use the SQLGuard sections of your S-TAP to set up primary, secondary, and tertiary Guardium hosts.

One difference is that there is no need for `participate_in_load_balancing=3`; because of the way the I S-TAP communication is architected, complete session information is available on each message. This means that even before the enhancements delivered in this patch, you could have used hardware balancing (such as F5) with `participate_in_load_balancing=1` and a virtual IP address in the primary SQLGuard section of the configuration file.

In a failover configuration, the S-TAP is configured to register with multiple collectors, but only send traffic to one collector at a time (`participate_in_load_balancing=0`). The S-TAP in this configuration sends all its traffic to one collector unless it encounters connectivity issues to that collector that triggers a failover to a secondary collector.

How to use AppEvent from IMS

The data holding user information of an APP_EVENT DLI call needs to have similar syntax as GuardAppEvent api.

The first two bytes represent ccsid of the encoding of the following bytes. For example, 0x04B8 stands for ccsid 1208. The following bytes need to have the syntax as below:

SELECT

```
'GuardAppEvent:Start',
'GuardAppEventType:type',
'GuardAppEventUserName:name',
'GuardAppEventStrValue:string',
'GuardAppEventNumValue:number',
'GuardAppEventDateValue:date'
```

FROM DUAL

For further reference for type, name, string, number, date, check GuardAppEvent API.

Currently, only UTF8 encoding is supported.

- [Monitoring strategy](#)

Make your monitoring and auditing effective and efficient by developing a strategy that recognizes and fulfills your regulatory and other requirements.

- [Installing the S-TAP for IBM i](#)

The S-TAP software is a shell script that you must run from IBM i, within the Portable App Solutions Environment (PASE) environment. Take the following steps to upload the S-TAP software to the IBM i Integrated File System (IFS) and then install it.

- [Uninstalling the S-TAP](#)

- [Upgrading the S-TAP from 10.x to 11.x for IBM i](#)

- [Defining the S-TAP for IBM i](#)

After you install the S-TAP, ensure that it can communicate with the Guardium system.

Monitoring strategy

Make your monitoring and auditing effective and efficient by developing a strategy that recognizes and fulfills your regulatory and other requirements.

After you know what data you need, develop a strategy for collecting it with as little extraneous data as possible. Monitoring and logging data that you do not need uses up disk space and processing power, and generates extra network traffic. There are several areas where you can implement your strategy:

Database monitoring

The global SQL monitor captures SQL information and puts it into a queue for the S-TAP. You can use the filtering capabilities of the monitor to control which types of users and objects are queued. By default, these types of entries are not forwarded from the S-TAP to the Guardium® system:

| SQL Abbreviation | Meaning |
|------------------|--|
| AD | ALLOCATE DESCRIPTOR |
| CL | CLOSE |
| DA | DEALLOCATE DESCRIPTOR |
| DE | DESCRIBE |
| EX | EXECUTE (the SQL statement executed is audited) |
| FE | FETCH |
| FL | FREE LOCATOR |
| GD | GET DIAGNOSTICS |
| GS | GET DESCRIPTOR |
| HL | HOLD LOCATOR |
| PR | PREPARE (except authorization errors are captured) |
| RE | RELEASE |
| RG | RESIGNAL |
| SC | SET CONNECTION |
| SD | SET DESCRIPTOR |
| SG | SIGNAL |

Audit journal

You can configure the system audit journal to capture only those entries that concern objects of interest or users of interest. By default, entries of these types are sent from the S-TAP to the Guardium system:

| SQL Abbreviation | Meaning |
|------------------|------------------------------|
| ZR | Read object |
| ZC | Change object |
| CA | Authority change |
| AD | Auditing change |
| AF | Authority failure |
| CO | Create object |
| DO | Delete object |
| SV | System Value change |
| GR | General purpose audit record |
| OM | Object moved or renamed |
| PG | Primary group change |
| PW | Invalid password or user ID |
| OW | Change owner |
| OR | Object restored |
| RA | Restore authority change |
| RO | Restore owner change |
| RZ | Restore primary group change |

Only those entries that relate to database objects are forwarded:

- *FILE (a table, view, index, logical file, alias, or device file)
- *SQLUDT (an SQL user-defined type)
- *SQLPKG (an SQL package)
- *PGM (a procedure, function, or program)
- *SRVPGM (a procedure, function, global variable, or service program)
- *DTAARA (an SQL sequence)

On the Guardium system

You can define policies that control which information that is received from the S-TAP is ignored, and what actions to take based on other items.

Ignoring data after it has been sent over the network is inefficient. Wherever possible, filter out information that you do not need before it is queued for the S-TAP.

Installing the S-TAP for IBM i

The S-TAP software is a shell script that you must run from IBM i, within the Portable App Solutions Environment (PASE) environment. Take the following steps to upload the S-TAP software to the IBM i Integrated File System (IFS) and then install it.

Before you begin

- Review the minimum requirements from the following location: [Guardium and Db2 for i - technical resources](#)
- Review the Db2 for IBM i PTF Group Schedule for your version of IBM i: [Db2 for i - Technology Updates](#).
- Make sure that you have the following special authorities: *ALLOBJ, *JOBCTL, and *SECADM.
- Verify that license program 5722SS1-33 Portable App Solutions Environment (PASE) is installed on your IBM i system.

- If you use FTP to upload S-TAP software to IFS, ensure that you have access to the 5250 emulator software to connect to the IBM i system remotely. To use the IBM i Access Client Solutions (ACS) tool, download ACS from the following location: [IBM i Access Client Solutions](#).
- Download the S-TAP for the IBM i platform.
- Identify the IP address of the Guardium® system to which this S-TAP connects.
- Ensure that the following ports are open between the Guardium system and IBM i:
 - Port 446: The default port for data source connectivity via JDBC.
 - Port 16016: the port for sending encrypted traffic to the Guardium collector.

Note: In general, connections to the following IBM i ports are required:

- 449
- 446/448(TLS/SSL)
- 8471/9471(TLS/SSL)
- 8476/9476(TLS/SSL)

However, depending on the version of the IBM i server and the version of the jt400.jar JDBC driver that Guardium uses, the required ports might vary. See the [IBM i Documentation](#) to check the IBM i well-known ports. For more information about port requirements for IBM i, see [TCP/IP Ports Required for IBM i Access and Related Functions](#).

- Use the IBM i Verify TCP/IP Connection (PING) command to verify that IBM i can establish a TCP/IP connection to the IP of the Guardium system that the S-TAP must communicate with.

Procedure

1. Upload the S-TAP software to the IBM i Integrated File System (IFS) by using FTP or the graphical IBM i Access Client Solutions (ACS) tool.

To upload via FTP, use the following steps:

- Use the 5250 emulator software to connect to IBM i remotely and enter the following command to open the PASE shell: **call qp2term**.
- In the PASE shell environment on the IBM i, create a temporary directory to store the S-TAP installation script. Example: /tmp/username.
- Use the start TCP/IP File Transfer (FTP) command and move the S-TAP installation shell script to that temporary directory.

To upload by using ACS, use the following steps:

- Within the ACS tool, use the IFS to create a temporary directory and navigate to it.
- Use the GUI to select and upload the S-TAP software.

2. In the temporary directory, run the following command:

```
<S-TAP_shell_script.sh> --sqlguardip <guardium_host_IP> -u |  
-overwrite-existing [--tls force | none]
```

Where:

- --sqlguardip: a mandatory parameter that indicates the IP address of the Guardium system with which the S-TAP communicates.
- If an IBM i S-TAP installation exists, you must enter one of the following parameters:
 - -u: an optional parameter to keep the existing configuration parameters and update the S-TAP configuration with the parameters that were entered in the command.
 - -overwrite-existing: an optional parameter to overwrite the existing installation and create a new guard_tap.ini file with default parameters.
- --tls force: an optional parameter to use TLS encryption. If a secure protocol cannot be obtained when you connect, the S-TAP can fall back to using a nonsecure protocol.
- --tls none: an optional parameter to indicate that the connection is not encrypted. This parameter is selected by default if TLS is not specified.

The program installs in the following location: /usr/local/guardium.

3. Optional: When you install the S-TAP, it not only installs the necessary components and configurations, but the S-TAP also starts with the factory default configuration. Therefore, the S-TAP immediately starts capturing all database activity for all users and processes. You can stop the S-TAP immediately after installation, establish filtering rules, and then restart the S-TAP.

To stop the S-TAP, use the IBM i Run SQL command. For example,

```
RUNSQL SQL('CALL SYSPROC/SYSAUDIT_END()') COMMIT(*NONE)
```

Tip: You must establish a filtering rule that matches your database activity monitoring strategy and requirements. As an example, if you use only the Guardium policy to establish filtering, the S-TAP on IBM i might transfer and store more activity details than needed on the Guardium collector.

4. On the Guardium system's GUI, go to Manage > System View > S-TAP Status Monitor and confirm that the S-TAP status is green. A green status indicates that the S-TAP is communicating with the collector. If the S-TAP monitor is not showing green, review the details within the following IFS stream files:

- /usr/local/guardium/install_out.txt
- /usr/local/guardium/guard_itap.stderr.1.txt

Tip: You can ignore the Inspection Engine status column. Inspection engines are not used for Db2 for i S-TAP.

Uninstalling the S-TAP

Procedure

To stop and uninstall the S-TAP, run the following commands:

```
RUNSQL SQL('call SYSPROC/SYSAUDIT_End') COMMIT(*NONE)  
CALL QR2TERM  
cd /usr/local/guardium/  
uninstall  
F3  
RMVDIR DIR('/usr/local/guardium') SUBTREE(*ALL)
```

Upgrading the S-TAP from 10.x to 11.x for IBM i

About this task

Procedure

1. Use FTP to save the 11.3 itap onto iSeries using binary mode. For example,

```
ftp <server name>
username/password
cd /usr/diver
binary
put itap-11.3.sh
```

2. Stop the v10.0.0 itap audit server in the 5250 terminal with:

```
RUNSQL SQL('CALL SYSPROC/SYSAUDIT_END( )') COMMIT(*NONE)
```

3. Upgrade the i S-TAP

```
CALL QP2TERM
$ 
> cd /usr/diver
$ 
> itap-11.3.sh --sqlguardip guardclient.rch.stglabs.ibm.com -u
Verifying archive integrity... All good.
Uncompressing guard-itap.....
Checking whether Audit Server has been stopped. (This call may take a minute.
Please wait.)
Uninstalling.
Creating /usr/local/guardium directory.
Using sqlguard_ip=guardclient.rch.stglabs.ibm.com
Starting Audit Server.
```

\$
The upgrade is successful.

4. Verify the upgrade.

- a. In the 5250 terminal, verify that this string appears: /istap log_file=

```
> ps -ef
UID PID PPID C STIME TTY TIME CMD
qsecocr 10 8 0 Dec 03 - 0:23 /QOpenSys/QIBM/ProdData/JavaVM
qsys 58 1 0 Dec 03 - 14:07 /QIBM/ProdData/OS/SLP/bin/lslp
ruiyu 754 753 0 Feb 18 - 0:00 /QOpenSys/usr/bin/-sh -i
qlwsvr 857 1 0 Feb 26 - 4:39 /QOpenSys/QIBM/ProdData/JavaVM
qlwsvr 858 1 0 Feb 26 - 10:21 /QOpenSys/QIBM/ProdData/JavaVM
qlwsvr 859 1 0 Feb 26 - 0:40 /QOpenSys/QIBM/ProdData/JavaVM
qlwsvr 860 1 0 Feb 26 - 0:33 /QOpenSys/QIBM/ProdData/JavaVM
4294770734 861 1 0 Feb 26 - 0:44 /QOpenSys/QIBM/ProdData/JavaVM
richoj 1102 988 0 17:56:33 - 0:00 /QOpenSys/usr/bin/-sh -i
richoj 1243 1236 0 17:57:53 - 0:00 ./istap log_file=
richoj 1244 1102 0 17:58:35 - 0:00 ps -ef
$
```

- b. In the 5250 terminal, verify that you see the 11.3x.0.swidtag

```
> cd /usr/local/guardium/
> ls
LICENSE.TXT istap sqsh
guard_itap.stderr.1.txt istap_console.socket sqsh_write_file
guard_tap.ini just_send swidtag
install_out.txt libprotobuf.a uninstall
$ 
> cd swidtag
$ 
> ls
ibm.com_IBM_Security_Guardium_Data_Protection-11.3.0.swidtag
$
```

- c. In the Guardium S-TAP Control page, verify that the 11.x itap connections are green for iSeries 7.4 (SQ740) and iSeries 7.3 (UT28P55).

Defining the S-TAP for IBM i

After you install the S-TAP, ensure that it can communicate with the Guardium® system.

Before you begin

You must know the log-in credentials for the IBM i system.

About this task

The high-level steps to configure the S-TAP are:

1. Define Db2 for i as a recognized data source to IBM® Guardium and test the connection.
2. Populate the Guardium system with information from the configuration file on IBM i that was created when you installed the Db2 for i S-TAP, using the Custom Table Builder process.
3. Create a Db2 for i configuration report. It is from this report interface that you can invoke the Guardium APIs that enable you to start and stop the monitoring process, get status information, and update configuration parameters, including filtering values.

Procedure

1. Click Setup > Tools and Views > Datasource Definitions to open the Datasource Builder.
2. In the Datasources Definitions page, click . The Create Datasource dialog opens.
3. Fill in values:
 - Application Type: Custom Domain.
 - Database Type: Db2 FOR i.
 - all other fields: as relevant for your system.
4. Click Save.
5. Click Test Connection to ensure that the configuration succeeded.
6. Click Comply > Custom Reporting > Custom Table Builder.
7. Select Db2 for i S-TAP Configuration, and then click Upload Data.
8. Click Add Datasource.
The Select datasource window displays a list of Db2 for i S-TAPs
9. Select your Db2 for i data source from the list and click Save.
10. On the Import Data page, ensure the Db2 for i data source appears. Click Apply and then click Run Once Now.
A message appears that the operation ended successfully with one row inserted.
11. Click Comply > Custom Reporting > Custom Query-Report Builder.
12. From the Queries-Reports list, click Db2 for i S-TAP configuration, then click Open original.
13. Click Add to My Custom Reports.
14. Click Reports > My Custom Reports, and open the Db2 for i S-TAP configuration report, which now displays the IBM i report row. Right-click a row in the report and select Invoke. A list of APIs appears.
15. Select update_istap_config.
The parameters for that API are displayed. You can change any values.
16. Change the value of the start_monitor parameter to 1.
17. Click Invoke Now.

Results

Using the data that you have entered, the [update_istap_config](#) API performs these tasks:

- Creates the message queue that is used to send entries from the S-TAP to the Guardium system and starts a global database monitor using a view with an INSTEAD OF trigger, which sends the entries to the message queue.
- Starts PASE and the S-TAP.
- Receives journal entries from QAUDJRN and adds them to the message queue.

- [S-TAP for IBM i APIs](#)

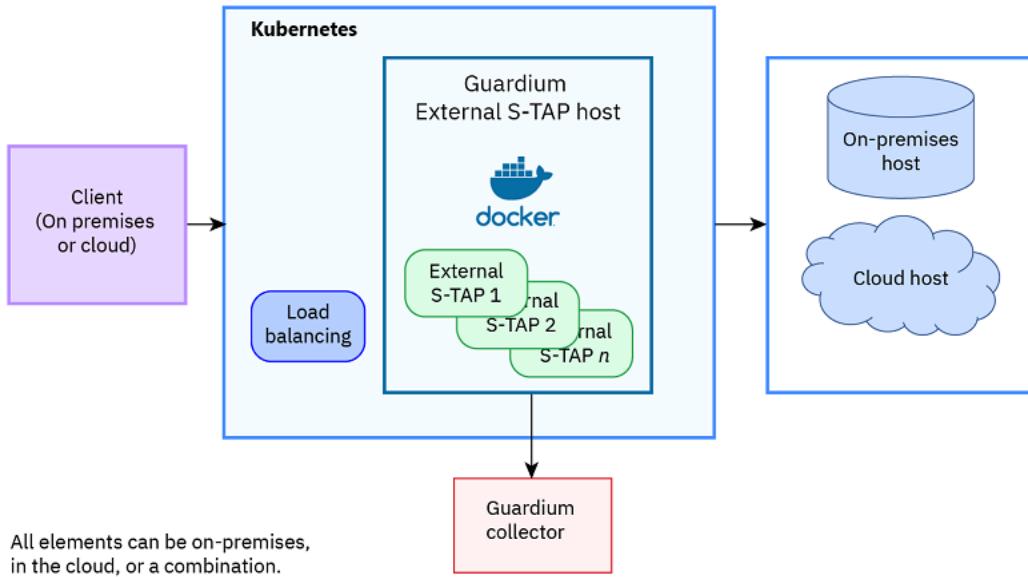

External S-TAP

IBM® Guardium® External S-TAP is a component of Guardium that can intercept traffic for cloud and on-premises database services without installing an agent on the database server. You can either deploy an External S-TAP with Kubernetes on the OpenShift® platform or manually (without Kubernetes).

External S-TAP intercepts traffic between clients and the database server, and forwards a copy of the traffic to a Guardium collector for analysis and policy application. After your External S-TAPs are installed and running, your External S-TAPs support many S-TAP policies, including redaction, S-GATE, and S-TAP Terminate. For more information about applying policy rules, see [Policy rule actions](#).

As shown in [Figure 1](#), you can use External S-TAP with Kubernetes with either cloud and on-premises databases. If your site does not use Kubernetes, you can deploy External S-TAPs manually, as shown in [Figure 2](#). For more information, see [External S-TAP requirements](#).

Figure 1. External S-TAP overview with Kubernetes

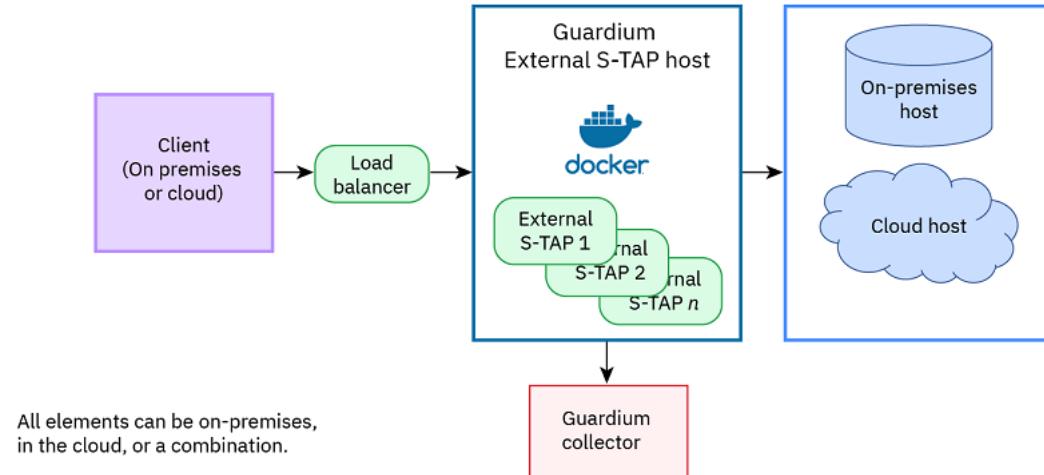

As shown in [Figure 1](#), all elements of a Guardium system that use External S-TAP can be either on premises or in the cloud. If your site uses Kubernetes, then Kubernetes takes care of many housekeeping issues such as balancing the software load and managing Docker containers. In the Kubernetes deployment configuration, specify the Docker image to use for the pods. To verify the collector certificates, as described in [Verify collector certificates \(optional\)](#), specify your private repository along with the derived Docker image name and tag. If your site does not use Kubernetes, you need to download the External S-TAP Docker container and deploy a load-balancing solution through a hardware appliance or software. For more information, see [Load balancer scripts](#).

As an alternative to deploying the External S-TAP with Kubernetes, you can use Helm charts to simplify the deployment. For more information, see [Deploying External S-TAP with Helm](#).

For information about installing External S-TAP without Kubernetes, see [Deploying External S-TAP manually](#).

Figure 2. External S-TAP overview, manual installation

As shown in [Figure 2](#), all elements of a Guardium system that use External S-TAP can be either on premises or in the cloud. External S-TAP is highly configurable. During deployment, you can configure most options, as discussed in [External S-TAP deployment scripts](#). Balancing the load can either be done through a hardware appliance or software. For more information about deploying a load-balancing solution, see [Load balancer scripts](#).

The Guardium External S-TAP Docker container

Docker containers provide a way to package software solutions so that you can easily download and manage them. Depending on your site configuration, a Guardium External S-TAP Docker container can either be downloaded directly from the IBM Cloud Container Registry (icr.io) or for computers without internet access, from a private image repository.

A Docker container runs an image, which is a packaged software solution (in this case, an External S-TAP) that can be installed on your host database. You can install multiple containers on the machine that serves as the External S-TAP host.

You can choose to derive the Docker container image by using a Dockerfile. By deriving the image, you can specify a single Guardium collector certificate (or set of related certificates) that you can use to deploy the External S-TAP. For more information, see [Verify collector certificates \(optional\)](#).

Before you deploy an External S-TAP

Assuming that your site is already using Guardium, the following steps are needed for each database where you want to run an External S-TAP container.

- If your site manages encrypted traffic (that is, is SSL-enabled), you need to work with a certificate authority (CA) to prepare the Guardium collector with the appropriate security certificates. This step can take some time, since you need to work with an outside company (the CA). For more information, see [SSL certificates for External S-TAP](#). If your environment is not SSL-enabled, you can skip this step.
- Make sure that a Linux® environment is available. Docker must be installed and running under Linux. For more information, see <https://www.docker.com/> and [Download the Docker container](#).
- Prepare to deploy an External S-TAP:
 - If your site uses Kubernetes, you can deploy an External S-TAP via the user interface. To deploy with Kubernetes from the Guardium UI, use one of the following services:
 - Amazon Elastic Container Service for Kubernetes (Amazon EKS)
 - Microsoft Azure Kubernetes Service (AKS)
 For more information, see [Deploying External S-TAP from the Guardium UI](#).
 - If your site does not use Kubernetes, you need to run scripts to deploy both a load balancer and the External S-TAP. Skip the section on deploying the External S-TAP with Kubernetes and go directly to [Deploying External S-TAP manually](#).

After you deploy the External S-TAP, it runs automatically. You can manage the External S-TAP from the Guardium UI. For more information, see [The External S-TAP user interface](#).

- [External S-TAP requirements](#)**

To use External S-TAP with your IBM Guardium system, your site must meet the following requirements.

- [SSL certificates for External S-TAP](#)**

To help protect SSL-enabled systems, the Guardium External S-TAP requires that you acquire a Secure Socket Layer (SSL) digital certificate for a TLS-encrypted database. If your database environment is not SSL-enabled, you can skip this step.

- [Deploying External S-TAP with an operator](#)**

Use Kubernetes with a computer assisted software engineering (CASE) operator to deploy your External S-TAPs. You can deploy External S-TAP as a stand-alone service, similar to installing and running the External S-TAP from Cloud Pak for Data v 4.0.

- [Deploying External S-TAP with Helm](#)**

Use Kubernetes with Helm to automate your External S-TAPs deployment.

- [Deploying External S-TAP from the Guardium UI](#)**

If your site uses Kubernetes, you can deploy an External S-TAP directly from Guardium.

- [Deploying External S-TAP manually](#)**

Deploy an External S-TAP with Docker and the External S-TAP scripts.

- [The External S-TAP user interface](#)**

Use the External S-TAP instances page to create, monitor, start, stop, and configure Guardium External S-TAPs.

- [Best practices for using External S-TAPs with on-premises databases](#)**

To use External S-TAPs with on-premises databases, you need to take a few steps to prepare both your database and the External S-TAP. Examples are shown using PostgreSQL.

- [Configuring AWS HA for External S-TAPs](#)**

Include External S-TAPs in your existing Amazon AWS high availability (HA), or failover, configuration.

- [Configuring Google BigQuery for External S-TAPs](#)**

Include External S-TAPs in your Google BigQuery configuration for Guardium.

- [Troubleshooting External S-TAP issues](#)**

Check for solutions if something goes wrong with your External S-TAPs.

External S-TAP requirements

To use External S-TAP with your IBM® Guardium® system, your site must meet the following requirements.

For more information about supported platforms for External S-TAP, see [IBM Guardium System Requirements and Supported Platforms](#).

Use Kubernetes on the Red Hat OpenShift platform to manage containers for External S-TAP. However, you can manually manage Docker containers by using the script that is described in [External S-TAP deployment scripts](#). A load-balancing solution is also required, which can be provided as part of your cloud service provider's Kubernetes services. If your site does not use Kubernetes, Guardium provides a sample script to help you configure your load-balancing solution. For more information, see [Load balancer scripts](#).

Important: The CN that you specify to create the certificate signing request (CSR) for the External S-TAP must match the DNS name to which the clients are connecting. For External S-TAP, the CN is the DNS name for the load balancer. If the client database requires that the DN (Designated Name) match the DNS entry, then all the properties in the CSR (such as CN= or OU=) must also match the DNS entry.

For administrators, you can redirect the clients to the External S-TAP by adjusting the DNS resolution. If you change the DNS resolution, be sure to use the DNS name that is visible to the client (that is, the name of the database server).

The External S-TAP can listen to only one port per container.

External S-TAP supports both unencrypted (plain text) and SSL/TLS-encrypted session flows. Other types of encrypted workflows (such as TDGSS and Oracle Native Encryption) are not supported.

If the External S-TAP container host is an on prem or virtual machine, the host must meet the following requirements:

- An x86_64 processor.
- Minimum RAM memory 500 MB and 2 GB storage.
- Linux® kernel version 3.10 or higher (latest version is recommended).
- Iptables 1.4 or higher.
- Docker Desktop.
- Minimum 2 virtual CPUs.
- Ability to use UNIX domain sockets.

Important: For on-premises installations, enable pubkey authentication for the user who starts the containers on the host systems. The deployment script calls `ssh` for the host systems multiple times; pubkey authentication simplifies the process.

You can include persistent volumes for storage to keep External S-TAP information after the Docker or Kubernetes container has exited. To use a persistent volume,

- For Kubernetes, configure the storage to appear inside any containers at `/persistent`. For more information, see [Deploy External S-TAP window](#).

- For container_mgmt.sh, use the **--persistent** flag to specify the name of the Docker volume to use. For more information, see **--persistent** in [External S-TAP deployment scripts](#).

All installations, either on prem or in the cloud, must meet the following requirements:

- For Docker, make sure that the installing user has the necessary privileges to create a container across systems.
- Make sure that network access is available to the IBM Cloud Container Registry (icr.io) where IBM releases the External S-TAP images.
- Database clients must be able to use TCP to connect to the External S-TAP host and the External S-TAP host must be able to connect to the database server.
- Locate all External S-TAP hosts in the network topology in such a way that they can be placed between the client and database host. Ideally, the latency between the client, the External S-TAP host, and the database service is as brief as possible.
- Be sure that access to the External S-TAP host is secured.
- Docker uses the kernel core pattern of the host to determine where to place core files. On some systems, the default path is not appropriate from the container's perspective. To make sure that core files are stored correctly, use the following pattern:

```
'/tmp/core.%t.%e.%p'
```

For example, on the External S-TAP host where a container runs, enter the following command to set the core pattern:

```
echo '/tmp/core.%t.%e.%p' | sudo tee /proc/sys/kernel/core_pattern'
```

Microsoft Azure users: The Azure SQL database connection policy is set to Redirect by default. You need to set the policy to Proxy. For more information, see [Azure SQL Connectivity Architecture](#) in the Microsoft Azure documentation.

In addition, to connect to the database, you need to update the `/etc/hosts` file for your system to add the following entry:

<External-IP> <your DB host>

- For Windows, add this entry to `\windows\system32\drivers\etc\hosts`.
- For Linux or UNIX, add this entry to `/etc/hosts`.

AWS Network Load Balancer users: AWS Network Load Balancer does not support listening on multiple public IP addresses. You can't listen twice on the same port for the same IP. Therefore, if your site is using multiple IP addresses, you must use a separate load balancer for each IP address.

Active directory database: For databases with active directory authentication, update the `/etc/hosts` file for your client system to add the following entry:

<External-IP> <your DB host>

- For Windows, add the entry to `\windows\system32\drivers\etc\hosts`.
- For Linux or UNIX, add the entry to `/etc/hosts`.

Note: When you deploy External S-TAP with the AWS load balancer, AWS load balancer can have multiple IP addresses. Make sure that you use the **<External-IP>** that can connect to the load balancer.

SSL certificates for External S-TAP

To help protect SSL-enabled systems, the Guardium® External S-TAP requires that you acquire a Secure Socket Layer (SSL) digital certificate for a TLS-encrypted database. If your database environment is not SSL-enabled, you can skip this step.

With External S-TAP there are two ways in which you can configure SSL certificates for your Guardium system:

- Recommended: [Configure on-demand certificate generation](#) by storing an intermediate certificate on the Guardium central manager or collector. Guardium can use that certificate to automatically generate certificates for every External S-TAP container.
- [Manually create a certificate signing request](#) and then store the certificates on any Guardium collectors that use External S-TAP.

Note: Guardium does not provide CA services.

After you configure the certificates for the central manager, you can use the [pull_external_stap_keystore](#) GuardAPI to copy the keystore from the central manager to one or more managed units.

- [Configure on-demand certificate generation](#)**

Configure Guardium External S-TAPs to automatically generate certificate signing requests (CSRs) that are signed by an intermediate certificate.

- [Manually create a certificate signing request](#)**

Create a certificate signing request (CSR) for each Guardium External S-TAP you want to manually deploy for an SSL-enabled database. Within the generated CSR, this procedure also creates the token (the shared secret) that you need to install the External S-TAP.

- [Verify collector certificates \(optional\)](#)**

You can help ensure that your External S-TAP connects only to an authorized collector by verifying the collector's certificate before connecting to the External S-TAP.

- [Verifying client and server certificates](#)**

To provide an extra level of security, you can store server or client certificates in a custom keystore, explicitly include or exclude known certificates in the keystore, or both.

- [Importing a custom certificate](#)**

To integrate External S-TAP for a server with server verification or mutual authentication if your database uses a custom certificate (that is, a trusted root certificate signed by a certificate authority [CA]), then External S-TAP must import the custom certificate. To do so, you need to build a container image, and then manually import the custom certificate.

- [Configuring mutual authentication](#)**

If your database settings are configured for mutual authentication, you can configure the External S-TAP, to verify the certificate that is set from both the data store server and client.

- [Configuring certificate mirroring](#)**

Certificate mirroring allows an External S-TAP to automatically generate copies of client and server key pairs from an existing signing key pair. Use certificate mirroring to provide mutual authentication for sites with more than one client certificate.

- [Preparing SSL certificates for client applications](#)**

To use client applications with External S-TAP, you might need to update the database client by specifying a new database endpoint and port from External S-TAP.

Configure on-demand certificate generation

Configure Guardium® External S-TAPs to automatically generate certificate signing requests (CSRs) that are signed by an intermediate certificate.

About this task

Store an intermediate certificate on a Guardium collector to allow External S-TAP instances to sign a certificate request from an External S-TAP that uses your common name (CN) to create an on-demand certificate for encrypted traffic. In this case, the CSR and the signed certificate carry the public key.

Note: If your database configuration requires a CN match, specify the name of either the server or the load balancer as the CN.

Procedure

1. Obtain an intermediate signing key and certificate pair from your certificate authority.

Note that Guardium does not provide certificate authority.

2. Use the following CLI command to store the signing key and signing certificate on the Guardium system as an intermediate certificate:

```
store certificate_external_stap_signing
```

At the prompts, enter the requested information, exactly as it shows in your certificate. Only the common name (CN=) is required.

3. The command generates a token that is required to deploy the External S-TAP. The token is the certificate secret, which you provide in either the Guardium GUI or the deployment script. Record the token because you will need it to deploy External S-TAPs in the future.

Note: You can view the token by calling **show certificate external_stap_signing**. To create a new token, delete the certificate by using **delete certificate external_stap_signing** and then store it again.

- In the GUI, enter the details in the Container tab of the Deploy External S-TAP window.
- In the deployment script, enter the details in the --proxy-secret and --proxy-csr-name parameters (along with any other parameters that you include).

What to do next

After the intermediate certificate is stored on the collector, it can automatically create a certificate for each new External S-TAP container.

- [Deploy External S-TAP window](#)

Manually create a certificate signing request

Create a certificate signing request (CSR) for each Guardium® External S-TAP you want to manually deploy for an SSL-enabled database. Within the generated CSR, this procedure also creates the token (the shared secret) that you need to install the External S-TAP.

About this task

Take the following steps to create a certificate request and token and then store the certificate in the External S-TAP keystore.

Procedure

1. Enter the following CLI command:

```
create csr external_stap
```

2. When prompted, enter an alias for the certificate, which can be the hostname, or any meaningful name:

```
host.example.com
```

3. At the prompts, enter the following information, exactly as it displays in your certificate:

- The common name (CN=) for this certificate, which must be the fully qualified domain name of the load balancer. If your site uses Kubernetes, you can find the domain name of the load balancer in the Kubernetes console as External endpoint. For example,

```
example.yourdomain.com
```

- The organizational unit (OU=), for example **external_stap**.
- The name of your organization (O=), for example **IBM**.
- The name of your city or locality (L=), for example **Boston**.
- The code for your state or province (ST=), for example **Massachusetts**.
- The two-letter country code for the unit (C=), for example **US**.
- The encryption algorithm to use (1 = DSA, 2 = RSA [default]), for example, **2**.

4. After you enter the requested information and press **Enter**, the certificate request process begins. When prompted, enter the following information:

- The keysize to use (1 = 1024, 2 = 2048 [default]), for example **2**.
 - Up to 99 SANs (Subjective Alternative Names) in fully qualified domain name format. To continue without entering a SAN, press Enter.
5. The system generates and displays the CSR.
6. Copy and paste the entire certificate signing request (CSR) into a file (in an editor such as Notepad).
Note: The CSR output includes an alias in the format **CN proxy_keycert token**. You need the alias to store the certificate.
7. Then, copy and paste the certificate request into a file to send to the CA. The certificate request is all of the information between (and including) the BEGIN and END statements. That is, be sure to include all of the text, starting with the following line:

```
-----BEGIN NEW CERTIFICATE REQUEST-----
```

And ending with the following line:

```
-----END NEW CERTIFICATE REQUEST-----
```

What to do next

After the certificate is returned from the CA, you can store it on the Guardium collector or a Guardium central manager (CM), as follows:

1. Store the root and intermediate certificates from the CA with the following command:

```
store certificate keystore_external_stap
```

2. Store the signed certificate on the collector or central manager with the following command:

```
store certificate external_stap
```

Note: If the certificate is not already in PEM format, use OpenSSL or another third-party tool to convert it.

For example, to convert from PKCS7 format to PEM, use the following OpenSSL command:

```
openssl pkcs7 -print_certs -in certificate.p7b -out certificate.pem
```

3. When prompted, enter the alias for the signed certificate, which was included in the CSR output file.

Note: If you do not remember the alias, use the **show certificate external_stap** command to display the certificate information. For more information, see [Certificate CLI Commands](#).

4. You can now deploy the External S-TAP:
 - If your site uses Kubernetes, see [Deploying External S-TAP from the Guardium UI](#).
 - If your site does not use Kubernetes, see [Deploying External S-TAP manually](#).

Related concepts

- [Certificate CLI Commands](#)

Verify collector certificates (optional)

You can help ensure that your External S-TAP connects only to an authorized collector by verifying the collector's certificate before connecting to the External S-TAP.

About this task

To verify the collector's certificate, provide the External S-TAP CA certificate and the CN for the collector's certificate. If your site uses Kubernetes, specify your private repository along with the derived Docker image name and tag as the image to use for the pods in the deployment configuration.

Procedure

1. Create and store a certificate signed request (CSR) on the collector with the **create csr sniffer** CLI command as described in [Configuring Guardium-S-TAP communication using an SSL certificate](#).
2. Instead of downloading a Docker image from the IBM Cloud Container Registry (icr.io), derive the Docker container image from the icr.io to add the CA certificate to the /etc/guardium/guardium_ca.crt file. For example, to derive the latest version of the External S-TAP Docker container, add the following commands to your Dockerfile:

```
FROM icr.io/guardium-insights/guardium_external_s-tap:latest
COPY ./guardium_ca.crt /etc/guardium/guardium_ca.crt
```

Note: The entire COPY path is required: **/etc/guardium/guardium_ca.crt**.

3. From the derived container, run the **docker build** command create a new docker image. For example:

```
docker build -t localhost/<my_image_name>:latest .
```

4. When you deploy a new External S-TAP, provide the derived image and configure the External S-TAP to expect the CN of the collector's certificate. You can deploy the External S-TAP in multiple ways:

- From the user interface in the Advanced tab under the Deploy External S-TAP tab:
 - Select Verify certificate
 - In Collector CN, provide the collector's certificate CN. You can use a regular expression to verify multiple certificates.

For more information, see [Deploy External S-TAP window](#)

- From the **container_mgmt.sh** script in non-interactive mode, provide the collector's certificate CN in the --sqlguard-cert-cn parameter. For more information, see [External S-TAP deployment scripts](#).

- From the **container_mgmt.sh** script in interactive mode, enter the collector's certificate CN in response to the following question:

Enter the CN to match when verifying the Guardium Collector's Certificate

What to do next

After you deploy the External S-TAP, the External S-TAP starts. You can make sure that it is running from the External S-TAP instances pane.

Verifying client and server certificates

To provide an extra level of security, you can store server or client certificates in a custom keystore, explicitly include or exclude known certificates in the keystore, or both.

Configure client and server certificates for the External S-TAP

In this scenario, you want to use the External S-TAP custom keystore verify that the External S-TAP communicates only with trusted clients and servers.

1. Configure the External S-TAP to trust your data store server certificate, you need the one of the following certificates:

- The signed certificate from your data store server, along with the token that was provided to create the certificate signing request (CSR). In this case, use the following CLI command to store the signed certificate in a custom keystore on the External S-TAP:

```
store certificate custom_keystore_external_stap
```

When prompted, supply the following information:

- The alias for the signed certificate, which was included in the CSR output file.
- The token that was provided to create the CSR.
- A self-signed certificate from your data store server. In this case, you can store the certificate directly into the allowlist, as described in [Certificate allowlists and blocklists](#).

2. Configure the data store client to trust the External S-TAP certificate, by taking one or both of the following steps:

- If the client can accept a trusted certificate, then store the signed External S-TAP certificate on the client data store.
- If the client can trust a certificate based on allowlist, you can also store the External S-TAP directly.

Note: If your site is using PostgreSQL for both the client and server data stores, you can additionally configure the server to trust the External S-TAP certificate to create a mutual authentication scenario. For more information, see [Configuring mutual authentication](#).

Certificate allowlists and blocklists

In addition to using certificates to verify communication with the External S-TAP, you can use allowlists and blocklists to explicitly define which certificates your site can, or cannot, trust. The lists are stored in the custom keystore.

You can add one or more certificates to an allowlist to explicitly trust the certificates on a client or server machine. In addition, you can explicitly exclude, by using a blocklist, certificates that you know can no longer be trusted.

Note: Certificates can be added only one at a time.

Use the following CLI command to add a certificate to a trusted list (an allowlist):

```
store certificate allowlist_external_stap
```

Use the following CLI command to explicitly exclude a certificate (a blocklist):

```
store certificate blocklist_external_stap
```

When you add a certificate to either an allowlist or a blocklist, you are prompted for the following information:

- The alias for the signed certificate, which was included in the CSR output file.
- The token that was provided to create the CSR for the External S-TAP certificate.

Note: For an added level of security, you can optionally use the certificate that you created to verify the collector's certificate. For more information, see [Verify collector certificates \(optional\)](#).

Other certificate CLI commands

To delete one or more certificates from the keystore, use the following CLI command:

```
delete certificate external_stap
```

A numbered list of all of the certificates in the keystore displays. Select the certificates to delete, by their number. To delete multiple certificates, separate each number with a comma.

To show details about the certificates in the keystore, use the following CLI command:

```
show certificate external_stap
```

For each certificate, useful information such as alias name, entry type, owner, and valid dates displays.

For more information about certificate-related CLI commands, see [Certificate CLI commands](#).

Note: To determine the actions to take when Guardium encounters an invalid certificate, set the actions in either the External S-TAP tab or the deployment script. For more information, see [External S-TAP tab](#) or the --invalid-cert-disconnect and --invalid-cert-notify parameters in [Table 3](#).

Importing a custom certificate

To integrate External S-TAP for a server with server verification or mutual authentication if your database uses a custom certificate (that is, a trusted root certificate signed by a certificate authority [CA]), then External S-TAP must import the custom certificate. To do so, you need to build a container image, and then manually import the

custom certificate.

Procedure

1. Download the External S-TAP image from the IBM Cloud Container Registry (icr.io). Derive the docker container image from the *icr.io* to add the ca.cert custom CA certificate to the /etc/ssl/certs/ca-bundle.trust.crt file.

For example, to derive the latest version of the External S-TAP docker container, add the following commands to your Dockerfile:

```
FROM icr.io/guardium-insights/guardium_external_s-tap:latest
COPY ./ca.crt /etc/ssl/certs/ca-bundle.trust.crt
```

2. From the derived container, run the **docker build** command create a new docker image, for example:

```
docker build -t localhost/guardium_external_s-tap:v12.0 . -f Dockerfile
```

3. When you deploy a new External S-TAP, provide the derived image and configure the External S-TAP to verify the database server certificate. You can use one of the following methods:

- From the container_mgmt.sh script, edit the following parameters:

```
--invalid-cert-disconnect
--invalid-cert-notify
```

- With a helm chart, edit the following information:

```
# Verify certificates and disconnect if they are invalid
# Optional, default is 0 (no)
disconnect_on_invalid_certificate: true

# Verify certificates and send a message to the STAP event log
# if they are invalid
# Optional, default is 0 (no)
notify_on_invalid_certificate: true
```

- Configure the On invalid certificate parameter in the Guardium UI (from the External S-TAP tab in the Edit External S-TAP group page).

Configuring mutual authentication

If your database settings are configured for mutual authentication, you can configure the External S-TAP, to verify the certificate that is set from both the data store server and client.

About this task

For the External S-TAP, Guardium supports mutual authentication through an External S-TAP custom keystore. In this scenario:

1. The data store client successfully verifies the certificate in the External S-TAP custom keystore.
2. The External S-TAP verifies the data store server certificate.
3. If mutual authentication is enabled on both the client and the server, the client sends the client certificate to the External S-TAP. The External S-TAP parses that message and verifies the certificate on behalf of the server.
4. If the client certificate is trusted, External S-TAP sends the External S-TAP certificate to the PostgreSQL server so that the PostgreSQL server can verify the certificate from the External S-TAPs.

To provide mutual authentication with multiple client certificates, you need to use certificate mirroring. For more information, see [Configuring certificate mirroring](#).

Procedure

1. To configure the External S-TAP to trust your data store client certificate, you need the CA-signed certificate (or certificates) from the client data store.

Note: Make sure that all certificates (for the External S-TAP, the client, and the server) are signed by the same certificate authority.

Use the following CLI command to store the signed client certificate into the External S-TAP custom keystore:

```
store certificate custom_keystore_external_stap
```

When prompted, supply the following information:

- The alias for the signed certificate, which was included in the CSR output file.
- The token that was provided to create the CSR for the External S-TAP certificate.

2. To verify a client certificate on a PostgreSQL server, import the External S-TAP certificate onto the server.

Note: In some configurations, the server certificate is the default certificate, rather than a certificate signed by a trusted CA. In that case, you can add that certificate to an allowlist, which explicitly adds that certificate to the custom keystore, as described in [Certificate allowlists and blocklists](#).

What to do next

If you know that a certificate can no longer be trusted, you can add it to a blocklist in the custom keystore. For more information, see [Certificate allowlists and blocklists](#).

Configuring certificate mirroring

Certificate mirroring allows an External S-TAP to automatically generate copies of client and server key pairs from an existing signing key pair. Use certificate mirroring to provide mutual authentication for sites with more than one client certificate.

Before you begin

Before you load the certificate and signing key pair into Kubernetes, make sure that your system meets the following prerequisites.

- Make sure that the signing key pair is a certificate and private key pair with the following attributes:

```
[ v3_intermediate_ca ]
subjectKeyIdentifier = hash
authorityKeyIdentifier = keyid(always,issuer)
basicConstraints = critical, CA:true, pathlen:0
keyUsage = critical, digitalSignature, cRLSign, keyCertSign
```

These attributes mark the key pair as a certificate authority (CA), an issuer, and an entity with the ability to sign new key pairs. The attributes for your environment might vary, but the key pair must be able to sign new key pairs that are trusted by both the client and backend.

- You need a functional Kubernetes deployment cluster that meets the following requirements:
 - You have an accessible Docker repository (public or private) with the External S-TAP image.
 - The database backend is configured with TLS.
 - You have a trusted signing certificate and key pair in a Kubernetes secret. For more information, see the Kubernetes documentation about secrets.
 - All of the trusted certificates are stored in a bundle within the Kubernetes secret.

About this task

Use certificate mirroring to support monitoring services that use certificate-based mutual authentication, since client certificates are duplicated and provided to the backend service.

In a certificate mirroring scenario, you provide a signing key pair to External S-TAP. Guardium® uses the signing key pair to sign new key pairs that are based on the certificates that are sent by the client and backend. To the client and the server, it appears as if they are directly connected to each other over TLS.

To ensure that only trusted certificates are mirrored, you can concatenate all of the trusted certificates into a PEM-formatted bundle, and set the STAP CONFIG PROXY DISCONNECT ON INVALID CERTIFICATE configuration parameter to 1.

These precautions cause any connections that provide an untrusted certificate to be disconnected and not mirrored.

Procedure

1. Load the signing certificate and private key (in PEM format) into a Kubernetes secret.
 2. Load the Kubernetes secret into the External S-TAP container as a file.
 3. In the Kubernetes deployment yaml file, provide the file path in the External S-TAP configuration parameter STAP_CONFIG_ROOT_CA_PEM_PATH.

Example

The following example shows a sample Kubernetes yaml file with the External S-TAP deployment with certificate mirroring enabled.

```
apiVersion: v1
kind: Secret
metadata:
  # This secret needs to contain the base 64 encoded signing certificate and key in pem format
  name: signing-key

Preparing SSL certificates for client applications

To use client applications with External S-TAP, you might need to update the database client by specifying a new database endpoint and port from External S-TAP.

About this task

To deploy an External S-TAP, you need to prepare a private key (proxy.Key) and certificate (proxy.pem) that is signed by the trusted root certificate (rootCA.pem). You can store the certificate in a Guardium® collector, a persistent volume, or Kubernetes secret. If the database uses TLS/SSL, then you also need to distribute the root certificate (rootCA.pem) to the database client.

Procedure

1. Set up the database client.

You might need to update the database client by specifying a new database endpoint and port from External S-TAP. To enable TLS or SSL on connection, specify the following driver setting in the jdbc url connection string for your database:

- SQL Server - sqlserver (encrypt=true)
- PostgreSQL - postgresql (ssl=on)
- MongoDB - mongodb (tls=true)

2. Configure certificates for Java™ applications.

You can configure access to certificates in your application with the following mechanisms:

- The Java virtual machine (JVM) truststore and JVM keystore.
 - A client-specific truststore and keystore.
- a. Configure the JVM truststore by adding the following parameters,
- javax.net.ssl.trustStore - The path to a truststore that contains the certificate of the signing authority.
 - javax.net.ssl.trustStorePassword - The password to access the truststore that is defined in javax.net.ssl.trustStore.
- b. Run the following keytool commands to import the rootCA.pem certificate to the keystore,

```
keytool -importcert -trustcacerts -file <path to CA file that External S-TAP uses>
-keystore <path to trust store> -storepass <password>
```

- c. Configure the JVM keystore. Use an application that initiates TLS or SSL requests to set the following JVM system properties to ensure that the client presents a TLS/SSL certificate to the database server,
- javax.net.ssl.keyStore - The path to a keystore that contains the client's TLS/SSL certificates.
 - javax.net.ssl.keyStorePassword - The password to access the keystore that is defined in javax.net.ssl.keyStore.

3. Create a keystore by using the keytool or OpenSSL. From the keytool, enter the following command,

```
keytool -keystore clientkeystore -genkey -alias client
```

What to do next

Note: By default, the driver ensures that the hostname included in the server's TLS/SSL certificates matches the provided hostnames. You can choose to disable hostname and server certificate verification, then you do not need to create a client-side certificate. To disable these verification methods, set the connection URL property trustServerCertificate=true.

By default, the driver ensures that the hostname included in the server's TLS/SSL certificates matches the provided hostnames. If you need to disable hostname verification or server certificate verification, change the driver properties.

To restrict your application to use the TLS 1.x protocol only, set the jdk.tls.client.protocols system property to TLSv1.x.

Deploying External S-TAP with an operator

Use Kubernetes with a computer assisted software engineering (CASE) operator to deploy your External S-TAPs. You can deploy External S-TAP as a stand-alone service, similar to installing and running the External S-TAP from Cloud Pak for Data v 4.0.

Before you begin

Ensure that the cluster meets the minimum requirements for installing External S-TAP. For more information, see [External S-TAP requirements](#). Verify that a cluster administrator completed the following tasks:

1. The project where you plan to install External S-TAP exists.
2. Optional but recommended, export the following environment variables:

Note: Make sure that the CASE_VERSION is correct for your implementation. Run the following command to check the CASE versions:

```
>oc ibm-pak list --case-name ibm-estap
* Versions listing for ibm-estap *
CASE      Version   App Version
ibm-estap  1.0.0    1.0.0
ibm-estap  1.0.1    1.0.1
ibm-estap  1.1.0    1.1.0
ibm-estap  1.1.1    1.1.1
ibm-estap  1.1.2    1.1.2
```

The following example shows CASE_VERSION=1.1.1. However, make sure to use the version that matches your app version.

```
# Set the working directory to use
export WORKDIR=$HOME
# Set the IBM-PAK working directory
export IBMPAK_HOME=$WORKDIR
# Set the name of the CASE
export CASE_NAME=ibm-estap
# Set the version of the CASE
export CASE_VERSION=1.1.1
# Set the namespace of the Cloud Pak for Data instance
export CPD_NAMESPACE=cpd-inst-01
```

3. Use the following command to download the CASE:

```
pushd $WORKDIR; oc ibm-pak get $CASE_NAME --version $CASE_VERSION; popd
```

4. For environments that use a private container registry, such as air-gapped environments, the External S-TAP software images are mirrored to the private container registry. For more information, see [Mirroring images to your private container registry](#).
5. The cluster is configured to pull the External S-TAP software images. For more information, see [Configuring the cluster to pull images](#).
6. The Guardium External S-TAP catalog source exists. For more information, see [Creating catalog sources](#).
7. The Guardium External S-TAP operator subscription exists. For more information, see [Creating operator subscriptions](#).

If these tasks are not complete, the External S-TAP installation will fail

About this task

After you have completed the previous steps, you can deploy the External S-TAP container. For details about deploying the External S-TAP container, see [Enabling the External S-TAP provisioning UI](#).

- [Mirroring images to your private container registry](#)
Guardium External S-TAP images are accessible from the IBM Cloud Container Registry. In many situations, Guardium recommends that you mirror the necessary software images from the IBM Cloud Container Registry to a private container registry.
- [Configuring the cluster to pull images](#)
If you are using a private registry, you need to update your cluster configuration to ensure that your cluster can pull External S-TAP software images. If you are using IBM Cloud Container Registry, you can skip this step.
- [Creating catalog sources](#)
If you are using a private container registry, you must create the catalog source for each service that you plan to install.
- [Creating operator subscriptions](#)
An operator subscription tells the cluster where to install a given operator and gives information about the operator to Operator Lifecycle Manager (OLM).
- [Enabling the External S-TAP provisioning UI](#)
After all of the prerequisites are met, a project administrator can enable provisioning UI for the External S-TAP container.
- [Provisioning an instance of External S-TAP](#)
Before you can use the External S-TAP service, you must provision an instance service. Each provisioned instance corresponds to a certain cloud database that you want to proxy through Guardium Data Protection.

Mirroring images to your private container registry

Guardium® External S-TAP images are accessible from the IBM Cloud® Container Registry. In many situations, Guardium recommends that you mirror the necessary software images from the IBM Cloud Container Registry to a private container registry.

Important: If your cluster is air-gapped (also called an offline or disconnected cluster), then you must mirror the necessary images to your private container registry. Even if your environment is not air-gapped, consider using a private container registry if you want to:

- Run security scans against the software images before you install them on your cluster.
- Ensure that you have the same images available for multiple deployments, such as development or test environments and production environments.

IBM suggests that you pull images directly from the IBM Cloud Container Registry if your cluster is not air-gapped, your network is extremely reliable, and latency is not a concern. However, if your system does not meet all of those requirements, mirror the images to a private container registry for predictable and reliable performance.

Define the environment variables

The first step is to define the environment variables that describe your private registry. For example:

```
export REGISTRY_IMAGE=docker.io/library/registry:2.7
export REGISTRY_HOST=`uname -n`
export REGISTRY_PORT=5000
export REGISTRY_USERNAME="user"
export REGISTRY_PASSWORD="pass"
```

Create a private registry (optional)

An example of how to create an insecure registry on a bastion node follows.

1. Define the environment variables for the registry that you want to create. For example:

```
REGISTRY_IMAGE=docker.io/library/registry:2.7
export REGISTRY_NAME=docker-registry
export REGISTRY_HOST=`uname -n`
export REGISTRY_PORT=5000
export REGISTRY_DIR=/root/registry
export REGISTRY_TLS_CA_SUBJECT="/C=US/ST=New York/L=Armonk/O=IBM/CN=IBM CA"
export REGISTRY_TLS_CERT_SUBJECT="/C=US/ST=New York/L=Armonk/O=IBM/CN=$REGISTRY_HOST"
export REGISTRY_TLS_CERT_SUBJECT_ALT_NAME="subjectAltName=IP:127.0.0.1,DNS:localhost,DNS:$REGISTRY_HOST"
export REGISTRY_USERNAME="user"
export REGISTRY_PASSWORD="pass"
```

2. Prepare the persistent storage:

```
mkdir -p $REGISTRY_DIR
mkdir -p $REGISTRY_DIR/data
mkdir -p $REGISTRY_DIR/auth
mkdir -p $REGISTRY_DIR/certs
echo $REGISTRY_HOST > $REGISTRY_DIR/hostname
```

3. Configure authentication:

```
dnf install httpd-tools
htpasswd -bBc $REGISTRY_DIR/auth/htpasswd $REGISTRY_USERNAME $REGISTRY_PASSWORD
```

4. Generate the certificate:

```
openssl genrsa -out ${REGISTRY_DIR}/certs/ca.key 4096
openssl req -new -x509 -days 365 -sha256 -subj "${REGISTRY_TLS_CA_SUBJECT}" -key "${REGISTRY_DIR}/certs/ca.key" -out
"${REGISTRY_DIR}/certs/ca.crt"
openssl req -newkey rsa:4096 -nodes -subj "${REGISTRY_TLS_CERT_SUBJECT}" -keyout "${REGISTRY_DIR}/certs/server.key" -out
"${REGISTRY_DIR}/certs/server.csr"
openssl x509 -req -days 365 -sha256 -extfile <(printf "${REGISTRY_TLS_CERT_SUBJECT_ALT_NAME}") -CAcreateserial -CA
"${REGISTRY_DIR}/certs/ca.crt" -CAkey "${REGISTRY_DIR}/certs/ca.key" -in "${REGISTRY_DIR}/certs/server.csr" -out
"${REGISTRY_DIR}/certs/server.crt"
```

5. Start the registry:

```
podman run --name "${REGISTRY_NAME}" -p ${REGISTRY_PORT}:5000 --restart=always \
-v ${REGISTRY_DIR}/data:/var/lib/registry:z \
-v ${REGISTRY_DIR}/auth:/auth:z \
-v ${REGISTRY_DIR}/certs:/certs:z \
-e REGISTRY_AUTH=htpasswd \
-e REGISTRY_AUTH_HTPASSWD_REALM=RegistryRealm \
-e REGISTRY_AUTH_HTPASSWD_PATH=/auth/htpasswd \
-e REGISTRY_HTTP_TLS_CERTIFICATE=/certs/server.crt \
-e REGISTRY_HTTP_TLS_KEY=/certs/server.key \
-d ${REGISTRY_IMAGE}
```

6. Store the certificate for the registry in a configmap in the openshift-config namespace:

```
oc create configmap registry-cas -n openshift-config --from-
file=${REGISTRY_NAME}.${REGISTRY_PORT}=${REGISTRY_DIR}/certs/server.crt
```

7. Add the new configmap to the trust store for the OpenShift cluster:

```
oc patch image.config.openshift.io/cluster --patch '{"spec": {"additionalTrustedCA": {"name": "registry-cas"}}}' --type=merge
```

Cloud Pak for Data images

IBM Cloud Pak software uses the following prefixes to identify images. These publicly available images are provided by IBM. The images do not require an entitlement key to download.

- `cp.icr.io/cpopen` - IBM Cloud Pak® for Data images.
- `icr.io/guardium-insight` - IBM® Guardium Insights images.

Ensure that:

- Your private container registry is configured to allow these prefixes.
- The credentials that you use to push images to the private container registry can push images with these prefixes.

Methods for mirroring images

There are several ways that you can mirror images from the IBM Cloud Container Registry to your private container registry. Choose the most appropriate method for your environment:

| Method | Description | Connected clusters | Air-gapped clusters |
|-------------------------|--|--------------------|---------------------|
| Portable compute device | Example: A laptop that you can move behind your firewall is a portable compute device.
High-level process using a portable compute device: <ol style="list-style-type: none">1. Create an intermediary container registry on a portable compute device that is connected to the internet.2. From the portable compute device, mirror images from the IBM Cloud Container Registry to the intermediary container registry.3. Bring the device behind your firewall and mirror the images from the intermediary container registry to the private container registry that is accessible from the Red Hat OpenShift Container Platform cluster. | | ✓ |
| File transfer | Example: You can either use a portable storage device, such as a USB drive, or use <code>scp</code> or <code>sftp</code> to move images behind your firewall.
High-level process using a file transfer: <ol style="list-style-type: none">1. Create an intermediary container registry. If you are using a portable storage device, create the intermediary container registry on the storage device.2. From a workstation that can connect to the internet and the intermediary container registry, mirror the images from the IBM Cloud Container Registry to the intermediary container registry.3. Move the files and or the storage device behind your firewall.4. Set up a workstation behind the firewall to mirror the images to the private container registry that is accessible from the Red Hat OpenShift Container Platform cluster. | | ✓ |
| Bastion node | Example: A server with access to both the public internet and the private container registry that is accessible from the Red Hat OpenShift Container Platform cluster.
If you use a bastion node, replicate the images from the IBM Cloud Container Registry to the private container registry that is accessible from the Red Hat OpenShift Container Platform cluster. | ✓ | ✓ |

Pull and mirror images

Note: **Best practice:** You can run the commands in this task exactly as written if you set up environment variables that are described in step 2 of [Deploying External S-TAP with an operator](#). Run the environment variable script before you run the commands in this task.

Take the following steps to mirror the images to a private registry.

1. Generate the mirror image list from a machine that can access the IBM Cloud Registry (icr.io):

```
pushd $WORKDIR; oc ibm-pak generate mirror-manifests $CASE_NAME MIRROR --version $CASE_VERSION; popd
```

2. Download the images:

a. Create a directory to store the mirrored images:

```
mkdir -p $WORKDIR/.ibm-pak/data/mirror/export
```

b. Download the images to the local directory:

```
pushd $WORKDIR ; while read MAPPING; do SOURCE="docker://`echo $MAPPING | cut -d '=' -f1`"; DEST="dir:$WORKDIR/.ibm-pak/data/mirror/export/`echo $MAPPING | cut -d '=' -f2 | sed "s/^.*\///"; echo "Copying $SOURCE -> $DEST" ; skopeo copy $SOURCE $DEST --remove-signatures --src-tls-verify=false --dest-tls-verify=false ; done < $WORKDIR/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt ; popd
```

3. From a system that has access to the private container registry, take the following steps:

a. Copy the .ibm-pak directory to a machine with access to the internal registry, then continue to the next step on that machine.

b. Push the images to the private repository:

```
pushd $WORKDIR ; while read MAPPING; do DEST="docker://$REGISTRY_HOST:$REGISTRY_PORT/`echo $MAPPING | cut -d '=' -f2 | sed "s/^.*\///"; echo "Copying $SOURCE -> $DEST" ; skopeo copy $SOURCE $DEST --remove-signatures --src-tls-verify=false --dest-tls-verify=false --dest-creds "$REGISTRY_USERNAME:$REGISTRY_PASSWORD" ; done < $WORKDIR/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt ; popd
```

What's next

After you create the container and store it in the registry, you need to configure the global pull secret, as described in [Configuring the cluster to pull images](#).

Configuring the cluster to pull images

If you are using a private registry, you need to update your cluster configuration to ensure that your cluster can pull External S-TAP software images. If you are using IBM Cloud® Container Registry, you can skip this step.

Permissions you need for this task

You must be a cluster administrator.

When you need to complete this task

You must complete this task the first time you install an External S-TAP.

Note: **Best practice:** You can run the commands in this task exactly as written if you set up environment variables that are described in step 2 of [Deploying External S-TAP with an operator](#). Run the environment variable script before you run the commands in this task.

Procedure

You only need to configure a global pull-secret and update the image source content policy only if your cluster pulls images from a private container registry.

The global image pull-secret must contain the credentials of an account that can *pull* images from the registry.

Important: When you change the global image pull-secret, each node in the cluster is *automatically* restarted so that the Machine Config Operator can apply the changes. This restart process happens one node at a time. The cluster will wait for a node to restart before starting the process on the next node. In some situations, it takes more than 30 minutes for all of the nodes to be restarted. During this process, you might notice that resources are temporarily unavailable.

If your deployment is on cloud, you must *manually* reload the worker nodes in your cluster for the changes to take effect.

1. Configure the global image pull-secret:

a. Confirm that the following installation variables are set based on the private container registry that OpenShift is going to pull from:

```
echo $REGISTRY_HOST
echo $REGISTRY_PORT
echo $REGISTRY_USERNAME
echo $REGISTRY_PASSWORD
```

b. Create an environment variable that points to a temporary directory on your workstation. For example:

```
export WORK_ROOT=$HOME/temp/work
```

c. Download the pull-secret for the cluster:

```
oc get secret/pull-secret
-n openshift-config
--template='{{index .data ".dockerconfigjson" | base64decode}}' > $WORKDIR/global_pull_secret.cfg
```

d. Store the registry credentials to the pull-secret config file:

```
oc registry login --registry="$REGISTRY_HOST:$REGISTRY_PORT" --auth-basic="$REGISTRY_USERNAME:$REGISTRY_PASSWORD" --
to=$WORKDIR/global_pull_secret.cfg
```

e. Update the global pull-secret with the new data:

```
oc set data secret/pull-secret
-n openshift-config
--from-file==$WORKDIR/global_pull_secret.cfg
```

f. Watch the machine config pool (MCP) status to see when all worker nodes have been updated to use the new pull-secret data:

```
watch oc get mcp
```

2. Edit the image content source policy:

a. Configure the cluster to pull from the mirror registry. Use the following command to open the source policy:

```
oc edit imagecontentsourcepolicy
```

Make changes to imagecontentsourcepolicy as needed for your system:

```
apiVersion: v1
kind: List
items:
- apiVersion: operator.openshift.io/v1alpha1
  kind: ImageContentSourcePolicy
  metadata:
    name: cloud-pak-for-data-cpfs-mirror
  spec:
    repositoryDigestMirrors:
      - mirrors:
          - $REGISTRY_HOST:$REGISTRY_PORT/cpopen
            source: icr.io/cpopen
      - mirrors:
          - $REGISTRY_HOST:$REGISTRY_PORT/guardium-insights
            source: icr.io/guardium-insights
```

b. Run the imagecontentsourcepolicy policy and wait until all of the nodes are updated. You can use the following command to track the progress:

```
watch oc get mcp
```

What's next

After you update the global pull-secret and push the images to the private repository, you can create your catalog sources as described in [Creating catalog sources](#).

Creating catalog sources

If you are using a private container registry, you must create the catalog source for each service that you plan to install.

Permissions you need for this task

You must be a cluster administrator.

When you need to complete this task

You must create the catalog sources for any of the software that you plan to install.

Note: **Best practice:** You can run the commands in this task exactly as written if you set up environment variables that are described in step 2 of [Deploying External S-TAP with an operator](#). Run the environment variable script before you run the commands in this task.

Run the following commands to install the catalog source:

1. Install the catalog source:

```
pushd $WORKDIR; oc ibm-pak launch $CASE_NAME --version $CASE_VERSION
--action install-catalog --inventory ibmEtapSetup --namespace openshift-marketplace
--args "--inputDir $WORKDIR/.ibm-pak/data/cases/$CASE_NAME/$CASE_VERSION"; popd
```

2. Verify the installation with the following command:

```
oc get catalogsource -n openshift-marketplace ibm-estap-catalog
-o jsonpath='{.status.connectionState.lastObservedState} {"\n"}'
```

Verify that the system returns **READY**. If it returns **CONNECTING**, wait until **READY** is returned.

Now that you've created the required catalog sources for your environment, you are ready to complete [Creating operator subscriptions](#).

Creating operator subscriptions

An operator subscription tells the cluster where to install a given operator and gives information about the operator to Operator Lifecycle Manager (OLM).

Before you begin

Note: You can run the commands in this task exactly as written if you set up environment variables for your installation. Run the environment variable script before you run the commands in this task.

Creating an operator subscription for External S-TAP

First, use the following commands to install the operator subscription:

```
pushd $WORKDIR; oc ibm-pak launch $CASE_NAME
--version $CASE_VERSION --action install-operator --inventory ibmEtapSetup --namespace
$CPD_NAMESPACE --args "--inputDir $WORKDIR/.ibm-pak/data/cases/$CASE_NAME/$CASE_VERSION"; popd
```

Then, take the following steps to verify that the operator is created:

1. Verify that the CSV for your CASE version is installed. For example:

```
ibm-estap-v1.1.1
```

```
oc get sub -n $CPD_NAMESPACE ibm-estap-catalog-subscription -o jsonpath='{.status.installedCSV} {"\n"}'
```

Note: Make sure that you check the correct CASE version. For more information about finding the correct CASE version, see [Before you begin](#).

- Verify that the CSV install strategy completed with no errors:

```
oc get csv -n $CPD_NAMESPACE $CASE_NAME.v$CASE_VERSION -o jsonpath='{ .status.phase } : { .status.message } {"\n"}'
```

- Verify that the deployment is ready by ensuring that one or more replicas are available:

```
oc get deployments -n $CPD_NAMESPACE -l olm.owner="$CASE_NAME.v$CASE_VERSION" -o jsonpath=".items[0].status.availableReplicas {'\n'}"
```

Important: If you create the Guardium External S-TAP operator with the manual install plan (installPlanApproval: Manual), a cluster administrator must approve the update request for ibm-estap-operator.

After you create and test the operator subscriptions, you can deploy the External S-TAP container as described in [Enabling the External S-TAP provisioning UI](#).

Enabling the External S-TAP provisioning UI

After all of the prerequisites are met, a project administrator can enable provisioning UI for the External S-TAP container.

Before you begin

Ensure that the cluster meets the minimum requirements for installing External S-TAP. For details, see [External S-TAP requirements](#). Specifically, verify that a cluster administrator completed the following tasks:

- The project where you plan to install External S-TAP exists.
- You have completed the tasks in [Deploying External S-TAP with an operator](#).

If these tasks are not complete, the External S-TAP deployment will fail.

About this task

You must be an administrator of the OpenShift® project (Kubernetes namespace) where you will deploy External S-TAP.

External S-TAP uses the following storage classes. If you don't use these storage classes on your cluster, ensure that you have a storage class with an equivalent definition:

- OpenShift Container Storage: ocs-storagecluster-cephfs
- NFS: managed-nfs-storage
- Portworx: portworx-shared-gp3

Procedure

- Log in to Red Hat® OpenShift Container Platform as a user with sufficient permissions to complete the task:

```
oc login OpenShift_URL:port
```

- Create the EstapServiceCPDAddOn custom resource to install External S-TAP. Follow the appropriate guidance for your environment.

```
cat | oc apply -f - << EOF
apiVersion: estap.ibm.com/v1
kind: EstapServiceCPDAddOn
metadata:
  labels:
    app.kubernetes.io/instance: ibm-estap
    app.kubernetes.io/managed-by: ibm-estap
    app.kubernetes.io/name: ibm-estap
  name: enable-ui
  namespace: $CPD_NAMESPACE
spec:
  cloudpakfordata: true
  description: External S-TAP CPD AddOn
  global:
    docker_registry_prefix: icr.io/guardium-insights
  license:
    accept: true
  version: $CASE_VERSION
EOF
```

- Run the following command to verify that the status of the EstapServiceCPDAddOn custom resource is **Completed**:

```
oc get -n $CPD_NAMESPACE EstapServiceCPDAddOn/enable-ui -o jsonpath='{.status.estapStatus} {"\n"}'
```

If it returns **InProgress**, wait until the system returns **Completed**.

What to do next

After you create the custom resource, you can provision the External S-TAP, as described in [Provisioning an instance of External S-TAP](#).

Provisioning an instance of External S-TAP

Before you can use the External S-TAP service, you must provision an instance service. Each provisioned instance corresponds to a certain cloud database that you want to proxy through Guardium® Data Protection.

Before you begin

Ensure that the External S-TAP service meets all of the prerequisites, as described in [Deploying External S-TAP with an operator](#).

About this task

Any IBM Cloud Pak® for Data user with Create service instances permission can provision an instance of the External S-TAP service. Each provisioned instance corresponds to a certain cloud database that you want to proxy through Guardium.

Procedure

1. Open the New service instance for External S-TAP page.
 - a. From the IBM Cloud Pak for Data home page, browse to Services > Services catalog. Then find and select Guardium External S-TAP under Data sources.
 - b. Select the Guardium External S-TAP text or logo to open the description page, and then click Provision instance to open the New service instance for the External S-TAP service.

The New service instance page contains a number of tabs. For each instance of an External S-TAP you want to provision, enter the information for each page, and then click Next to continue.

 2. From the Instance details tab, provide the following information and then click Next.
 - Name - Required. A name for this External S-TAP instance.
 - Namespace - Required. Select the Kubernetes namespace for this instance.
 - Description
 3. From the Storage tab, enter the following details for persistent storage.
 - Use existing storage - If a persistent volume claim (PVC) is available, then select this option and specify the PVC Claim name to use for storage
 - Create new storage - To create new storage, select the Storage class from the list and use the Size in GB slider to specify the size. The default is 1 GB.
 4. Under the General tab, enter information about the deployment and image.
 - Worker threads - Specify the number of threads for each External S-TAP container. You can specify up the number of cores available on the Kubernetes worker nodes.
 - Scaling type - Determine whether you want to use a default scaling type or customize the scaling. If you select predefined, you can select the following options:
 - Deployment size - Select a deployment size or use the default. Changing the deployment size determines the number of pods.
 - Pod memory size - The initial size of the pod's memory limit. Use the default, unless your deployment experiences *out of memory* issues. In that case, change the Pod memory size to *large*.
 - If you select custom, specify the following information:
 - Replicas - Use the slider to select the number of replicas of this instance to create. The default is 2.
 - CPU request - Default = 500m
 - Memory request - Default = 512Mi
 - CPU limit - Default = 500m
 - Memory limit - Default = 512Mi
 - For more information, see [Scaling services](#).
 - NodePort - Specify either random (the default) or specific. For specific, use the slider to select a port number on which to create the NodePort. When you deploy External S-TAP, the deployment creates a load balancer that uses the specified NodePort.
Note: If you select a port that is already in use, the deployment fails. Use kubectl to determine available ports.
 - Service account name - A service account provides an identity for processes that run in a Kubernetes pod. Specify the service account name that your site uses to create Kubernetes pods. If you don't have service account name, use *default*.
 - Registry path - Required. Specify the registry path that is accessible from the namespace that contains the External S-TAP image.
 - Image selection method - Specify the method to select the External S-TAP. Enter the following information:
 - Image label - Required. Specify the label of the External S-TAP image in the registry.
 - Hash or Tag - Depending on the selection method that you choose, specify either the image tag or the hash of the image name. Use Hash to specify a specific External S-TAP container image.
 - Use Tag to specify a class of External S-TAP images that you can use. For example, specify *v11.4.0* to pull the latest *v11.4* image. Make sure that the image tag you specify is intended to be deployed with the installed assembly version.
 - Image pull policy - Defaults to *IfNotPresent*.
5. From the Database and proxy tab, provide the following information.
 - Enter information for the back-end database service parameters:
 - Database host - Required. Specify the hostname or IP of the database instance for which the External S-TAP will monitor client connections.
 - Database port - Required. Use the slider to select a port for which the specified database is listening for client connections.
 - Database type - Required. Specify the type of database to monitor. The string must be one of the documented allowable database type strings for IBM Guardium External S-TAP. For information about supported data sources, see [IBM Guardium System Requirements and Supported Platforms](#) and select the System Requirements document for your Guardium version.
 - Debug - Enables debug logging for troubleshooting. Leave debug set to *0 (off)* except when debugging and troubleshooting. When debug is on, decrypted traffic might be stored in the logs and the additional logging might impact the performance of the External S-TAP.
 - Enter information for the general proxy parameters:
 - Proxy secret token - Specify the key for the token that is retrieved from the Guardium collector that is stored as the Kubernetes secret (from the General page). The proxy secret token is required only if you are retrieving or signing certificates from a Guardium collector. For more information, see [Managing certificates](#).

- Proxy group UUID - Specify a unique identifier to group replicas together in the Guardium appliance. If you do not specify the UUID, a UUID is randomly generated.
- Proxy protocol expected - When enabled, Proxy protocol expected tells the External S-TAP to expect a proxy protocol v1 packet at the beginning of each client connection. If the packet is not present, then the connection fails. External S-TAP removes the proxy protocol packet from the data stream before it relays the connection to the back-end service.
- Disconnect on invalid certificate - When enabled, disconnect the External S-TAP from the client or server if the certificate is invalid.
- Notify on invalid certificate - When enabled, send an alert that a client or server with an invalid certificate has attempted to contact the External S-TAP.
- Internal container listen port - Select the port on which the External S-TAP listens inside the container.
Note: This port is exposed by the load-balancing service and its associated NodePort. Note that port 8080 is exposed for an HTTP health check, but is not exposed by a service.
- Enter information for the proxy certificate signing request (CSR) parameters. This information is required only if you are retrieving or signing certificates from a Guardium collector. For more information, see [Managing certificates](#).
 - CSR Common Name - The common name for the CSR.
 - CSR Country - The country or region for the CSR.
 - CSR Province - The state or province for the CSR.
 - CSR City - The city or locality for the CSR.
 - CSR Organization - The organization or business name for the CSR.
 - Key length - Specify the key length for the CSR key.

6. From the Collector tab, provide information about the primary Guardium collector and up to nine secondary collectors.

For the primary collector, provide the following information:

- Primary Guardium collector host - Specify the hostname or IP of the Guardium appliance to which the External S-TAPs will connect.
- Primary Guardium collector port - Select the base port on which this Guardium appliance accepts UNIX protocol traffic.
- Primary Guardium collector connection pool size - Specify the number of auxiliary threads that the External S-TAP creates to send data to the Guardium appliance.
- Primary Guardium collector number of main threads - Specify the number of main threads created by External S-TAP to communicate with the Guardium appliance.
Main threads are used to participate in load balancing with options 1 and 4. When multiple main threads are available, the Guardium S-TAP connects multiple times to the same collector when threading the S-TAPs intercepted traffic read end. This is a shortcut for specifying the same collector multiple times as secondary collectors.
Note: Set the number of main threads to greater than 1 only when the collector has the capacity for the extra connections.
- Participate in load balancing with Guardium collectors - Select one of the following load-balancing options for External S-TAP.
 - 0 - No load balancing (default). Traffic is sent to one alive server. The primary server has highest priority.
 - 1 - Split sessions between collectors. Traffic is split between servers.
 - 2 - Duplicate traffic to all collectors. Traffic is sent to all servers.
 - 3 - Hardware load balancing with a load balancer such as F5. S-TAP sends traffic to the load balancer, which forwards it to one of the collectors in the pool.
 - 4 - Split sessions between collectors (multi-threading). Traffic is managed (and split) by multiple S-TAP threads.

Each External S-TAP instance can support up to nine additional collectors. If you start to add information for a secondary collector, the framework for the next collector displays. Leave the Secondary Guardium collector host field blank to ignore the collector.

Select All can control to allow all appliances to change the S-TAP configuration. If not selected, only the primary collector can make changes.

- Secondary Guardium collector host - A secondary hostname or IP of a Guardium appliance to which the External S-TAPs can connect. If you leave this field blank, the secondary collector is ignored.
- Secondary Guardium collector port - Select the base port on which this Guardium appliance accepts UNIX protocol traffic.
- Secondary Guardium collector connection pool size - Specify the number of auxiliary threads that the External S-TAP creates to send data to the Guardium appliance.
- Secondary Guardium collector number of main threads - Specify the number of main threads created by External S-TAP to communicate with the Guardium appliance.

7. Use the Probes and Limits tab to configure liveness and readiness probes along with some other options. In general, you do not need to change any of these options.

- Liveness probe options:
 - Probe command - The name of the script that determines whether the container is considered *live*.
 - Initial delay - Enter the time (in seconds) to wait before running the probe. The minimum is 1 and the maximum is 60.
 - Period - Select the time (in seconds) between probe runs (default = 10). The minimum is 1 and the maximum is 600.
 - Failure threshold - Number of failed attempts before stopping (default = 4). The minimum is 1 and the maximum is 10.
- Readiness probe options:
 - Probe command - The name of the script that determines whether the container is considered *ready*.
 - Initial delay - Enter the time (in seconds) to wait before running the probe. The minimum is 1 and the maximum is 60.
 - Period - Select the time (in seconds) between probe runs (default = 5). The minimum is 1 and the maximum is 600.
 - Failure threshold - Number of failed attempts before stopping (default = 5). The minimum is 1 and the maximum is 10.
- Advanced External S-TAP feature options:
 - Override server IP - If you enter a hostname or server IP, override the server IP that is recorded for intercepted traffic in the Guardium appliance with this value.
 - SQLGuard Certificate Common Name - If you provide a common name (CN), the External S-TAP checks the specified CN against the certificate for the Guardium appliance before the External S-TAP connects. If the CN does not match, the External S-TAP cannot communicate with the Guardium appliance.
 - Guardium certificate authority path - Enter the path to the CA certificate that the External S-TAP uses to verify the connection to the Guardium appliance.
 - Number of packets within which to be required to have detected SSL - Specify whether to look for SSL within a session, as follows:
 - -1 - Detect SSL at any point during a session.
 - 0 - Do not attempt to detect SSL.
 - Any integer greater than 0 - Attempt to detect SSL within the specified number of packets per session.

8. From the Summary page, review all of your settings, and then click Create to create this External S-TAP instance.

Results

From the IBM Cloud Pak for Data console, you can now configure and use External S-TAPs to monitor your data with Guardium.

What to do next

After you provision an External S-TAP instance, add a connection from your database to the External S-TAPs. You can connect to any target database supported by Guardium External S-TAP. For more information about connecting to data sources, see [Connecting to data sources](#). For information about supported data sources, see [IBM Guardium System Requirements and Supported Platforms](#) and select the System Requirements document for your Guardium version.

Deploying External S-TAP with Helm

Use Kubernetes with Helm to automate your External S-TAPs deployment.

Before you begin

Before you use Helm, take the following steps:

- Make sure that Git and Kubernetes are installed in your environment.
- Download and unpack Helm. For more information, see [Installing Helm](#) from the [Helm Docs](#) website.
- Gather the following information to use during installation:
 - DB host endpoint IP/address - The database hostname or IP address.
 - DB host endpoint port - The database host port number.
 - DB host endpoint type - The database type. For more information about supported data sources, see [System requirements](#).
 - Guardium appliance IP/address - The Guardium® collector hostname or IP address.

Procedure

1. Install Helm. On Linux®, run the following commands:

```
curl -fsSL -o get_helm.sh https://raw.githubusercontent.com/helm/helm/master/scripts/get-helm-3
chmod 700 get_helm.sh
./get_helm.sh
```

2. In Git, clone the External S-TAP Helm charts:

```
git clone https://github.com/IBM/Guardium_External_S-TAP
cd Guardium_External_S-TAP/charts
```

3. From the /charts directory, open the overrides_example.yaml file.

4. Search for required parameters in overrides_example.yaml and enter the appropriate values for your site. Parameters are described in the overrides_example.yaml file.

5. Based on your environment, determine how to install the certificate for your site. Uncomment the lines for the method that you select, as follows:

- To install External S-TAP with a default certificate, uncomment the following lines:

```
#secret: "estap-secret"
#secretWriterServiceAccountName: "estap-secret-writer"
```

- To install External S-TAP with a certificate that is stored in the collector, uncomment the following line:

```
#secret: estap-token
```

- To install External S-TAP with a certificate stored in a Kubernetes secret, uncomment the following line:

```
#secret: "estap-secret"
```

Tip: To use a certificate stored in a Kubernetes secret, create the Kubernetes secret by using one of the following methods:

- `kubectl create secret generic <secret-name> --from-literal=estap-token=<TOKEN>`
 - Or
- ```
kubectl create secret tls <secret-name> --key="your-certificate.key" --cert="your-certificate.crt"
```

If needed, use the following command to import the ca.pem file from the secret to the production environment, as follows:

```
kubectl get secret/estap-secret template- {{ 'print (index .data "ca.pem")' | base64 -d}}
```

Make sure that all the parameters are correct for your environment. For example, make sure that the Container image tag references your current Guardium version.

When you are done, save the overrides\_example.yaml file.

6. Run one of the following commands to either install or upgrade the Helm chart:

- To install the Helm chart:

```
helm install -f overrides_example.yaml my-estap-deployment estap
```

- To upgrade an existing Helm chart:

```
helm upgrade -f overrides_example.yaml my-estap-deployment estap
```

where,

- *my-estap-deployment* is the name for this deployment. Specify the name in the Estap Settings section of the yaml file.
- *estap* is the name of the External S-TAP Helm chart.

## What to do next

---

The External S-TAP is now available for use. View and manage the External S-TAP from Guardium. For more information, see [Edit External S-TAP group tab](#). You can now delete the Helm installation files by using the **helm delete** command to make sure that all the necessary files are properly removed. For example,

```
helm delete my-estap-deployment
```

where *my-estap-deployment* is the name of the deployment to delete.

## Deploying External S-TAP from the Guardium UI

If your site uses Kubernetes, you can deploy an External S-TAP directly from Guardium®.

### About this task

Before you can deploy an External S-TAP from Kubernetes, you need to:

1. Create a Kubernetes admin user.
2. Retrieve the Kubernetes cluster access token.
3. Retrieve the Kubernetes control plane URL.
4. Create the registry key for your cluster.
5. Ensure that any SSL-enabled collectors have valid SSL certificates.

Save the cluster access token, the Master URL, and the registry key. You need to enter them into the Kubernetes or Docker tabs of the Deploy External S-TAP window. For more information, see [Deploy External S-TAP window](#).

Note: For **Google Cloud deployments only**: If you plan to deploy the External S-TAP from the Guardium GUI, make sure that the IAM user has the following permissions: `container.clusterRoleBindings.create` and `container.clusterRoles.bind`.

These permissions allow the IAM user to add the cluster user and create tokens for GUI deployment.

Without these permissions, the IAM user can still deploy with Kubernetes by using the templates. For more information about generating and using the templates, see [Deploy External S-TAP window](#).

## Procedure

1. Create a Kubernetes admin user from kubectl (the Kubernetes command-line interface):
  - a. Create a yaml file that contains the following information. For this example, the yaml file is named `admin-service-account.yaml` where `admin-name` is the name of your administrative user:

```
apiVersion: v1
kind: ServiceAccount
metadata:
 name: <admin-name>
 namespace: kube-system

apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
 name: <admin-name>
roleRef:
 apiGroup: rbac.authorization.k8s.io
 kind: ClusterRole
 name: cluster-admin
subjects:
- kind: ServiceAccount
 name: <admin-name>
 namespace: kube-system
```

- b. Run the following command from kubectl to create the admin user:

```
$kubectl apply -f admin-service-account.yaml
```

2. Retrieve the Kubernetes cluster access token (also called the secret):

```
$kubectl -n kube-system describe secret $(kubectl -n kube-system get secret | grep <admin-name> | awk '{print $1}')
```

Enter the returned token in the Token field of the Kubernetes tab.

3. Retrieve the Kubernetes control plane URL.

Run **kubectl cluster-info** to find the name of the Kubernetes control plane URL. For example:

```
$kubectl cluster-info
Kubernetes control plane is running at https://azureaks01-dns-e1234567e.hcp.centralus.azmk8s.io:443
. . .
```

Enter the returned URL in the Kubernetes control plane URL field of the Kubernetes tab.

4. Create the registry key, which is called the secret in Kubernetes.

Run the following command to create the registry key, where the `<regcred>` is the secret for your registry:

```
$kubectl create secret docker-registry <regcred> \
--docker-server=$DOCKER_REGISTRY_SERVER \
--docker-username=$DOCKER_USER \
--docker-password=$DOCKER_PASSWORD \
--docker-email=$DOCKER_EMAIL
```

Enter the returned secret in the Registry key field of the Docker tab.

5. Make sure that each SSL-enabled collector on which you deploy an External S-TAP has a valid SSL certificate, as described in [SSL certificates for External S-TAP](#).

## What to do next

---

After you complete these tasks, you can deploy a new External S-TAP directly from Guardium. Kubernetes automatically manages the Docker container and balancing the load.

For more information, see [The External S-TAP user interface](#) and the [Deploy External S-TAP window](#)

## Deploying External S-TAP manually

Deploy an External S-TAP with Docker and the External S-TAP scripts.

After you have the signed SSL certificates, you can deploy the External S-TAP. To deploy an External S-TAP without Kubernetes, take the following steps:

- Download the Docker container as described in [Download the Docker container](#).
- Prepare the deployment script (and load balancer script, if you are using it) as described in [External S-TAP deployment scripts](#).
- After you deploy the External S-TAP, you can view and manage it from the External S-TAP instances page as described in [The External S-TAP user interface](#).

- [Download the Docker container](#)

To deploy a Guardium External S-TAP monitor, you first need to download the IBM Guardium External S-TAP container from the IBM Cloud Container Registry (icr.io). Deploy the container onto the machine (real, virtual, or cloud) that serves as the External S-TAP host.

- [External S-TAP deployment scripts](#)

Before you can run a Guardium External S-TAP container on your system, you need to prepare and run one or two deployment scripts.

## Related concepts

---

- [SSL certificates for External S-TAP](#)

## Download the Docker container

To deploy a Guardium® External S-TAP monitor, you first need to download the IBM® Guardium External S-TAP container from the IBM Cloud Container Registry (icr.io). Deploy the container onto the machine (real, virtual, or cloud) that serves as the External S-TAP host.

## Before you begin

---

1. Make sure that a Linux® environment is available for External S-TAP host. For the External S-TAP, Docker must be installed and running under Linux.
2. For SSL-enabled sites, make sure that you have with the appropriate security certificates as described in [SSL certificates for External S-TAP](#). If your environment is not SSL-enabled, you can skip this step.

## Procedure

---

1. If your site does not provide Docker, install Docker on the External S-TAP host. For more information, see [Get Docker](#).

2. Use `skopeo` to list the available docker tags for Guardium External S-TAP in the IBM Cloud Container Registry ([icr.io](#)). For example:

```
~$ skopeo
list-tags docker://icr.io/guardium-insights/guardium_external_s-tap
```

3. The `skopeo` command returns a list of all available tags for External S-TAP. Find and copy the appropriate docker pull command. For example:

```
myname:~$ skopeo list-tags docker://icr.io/guardium-insights/guardium_external_s-tap
{
 "Repository": "icr.io/guardium-insights/guardium_external_s-tap",
 "Tags": [
 "cpd-3.5-deploy-11.2.1-34",
 ...
 "v11.2.0-deploy-3.5-16",
 ...
 "v11.4.0",
 "v11.4.1",
 ...
 "v11.5.0",
 "v11.5.1"
 "v11.5"
]
}
myname:~$
```

Note: The container for the latest version of each Guardium release is available from the `vX.X` tag for that release. For example, for Guardium 11.5, copy docker pull from the `v11.5` tag.

4. Use the `docker pull` command to download the Docker container into your environment. For example, to pull the latest External S-TAP image,

```
docker pull
icr.io/guardium-insights/guardium_external_s-tap:v11.5
```

For more information about accessing [icr.io](#) and using the `skopeo` command, see <https://www.ibm.com/support/pages/node/6618197>.

To deploy to an internal repository: If your Docker host machine does not have access to the internet, create an internal repository on which to store the Docker containers. One method to create an internal repository is to use multiple steps, for example:

- a. Configure a host to run a local (private) docker registry. For more information, see [Deploy a registry server](#).

- b. Take the following steps on a host that where Docker is installed and that can contact both the local Docker registry and [icr.io](#):

- i. Pull the External S-TAP Docker image from icr.io.

- ii. Push the External S-TAP Docker image to the local Docker registry.
- c. After the image is in the local registry, you can deploy the External S-TAP containers on a host that has access to that registry.

## What to do next

---

After you download the External S-TAP Docker container, you can either deploy the container onto the Docker host machine or, if needed, create the security certificates to help ensure that your system remains secure. For more information, see [External S-TAP deployment scripts](#) or [SSL certificates for External S-TAP](#).

## Related concepts

---

- [SSL certificates for External S-TAP](#)
- [External S-TAP deployment scripts](#)

## External S-TAP deployment scripts

---

Before you can run a Guardium® External S-TAP container on your system, you need to prepare and run one or two deployment scripts.

## Preparing to deploy an External S-TAP

---

At this point, you have an External S-TAP container that is ready to deploy and each collector that is SSL-enabled has a valid SSL certificate. The next steps are to prepare and run the deployment scripts. You can run the scripts from the External S-TAP host or another machine that has access to the External S-TAP host and is running Linux.

1. If you plan to use the load balancing script to create a load balancing solution, you need to prepare the load balancer script. The first step that the deployment script takes is to call the load balancing script. For more information about the load balancer script, see [Load balancer scripts](#).  
Note: Using the load balancing script is recommended, but not required. If your site chooses not to use the load balancing script, make sure that you have another load balancing strategy in place.
2. Run the External S-TAP deployment script, `container_mgmt.sh`, in interactive mode to set the correct options for your site in an iterative fashion.  
Note: If you use persistent storage (see `--persist`), you need to initialize it before running the script. Initializing the persistent storage allows the Docker container to access data. For example,

```
docker run --rm -v my-vol:/persistent busybox /bin/sh -c 'touch /persistent/.initialized && chown -R 1000:1000 /persistent'
```

Note: The deployment and load balancing scripts are available on GitHub at [https://github.com/IBM/Guardium\\_External\\_S-TAP](https://github.com/IBM/Guardium_External_S-TAP). Before you run or modify the scripts, be sure to read the CONTRIBUTOR.md and README.md files.

## External S-TAP deployment example

---

The following example walks through the script that creates the External S-TAP containers in interactive mode:

1. From your Linux® command line, `cd` to the directory where the `container_mgmt.sh` and `lb_interface_nginx.sh` scripts are located.
  2. From the command line, call the `container_mgmt.sh` script, along with the `--state-file` and `--lb-script` parameters, as discussed in [Table 1](#). For example,
- ```
> container_mgmt.sh --state-file sample_state --lb-script lb_interface_nginx.sh
```
- Note: The `--state-file` parameter is always required. The `--lb-script` parameter is required if you are using the load balancing script (recommended). If you do not include `--lb-script`, a warning message displays.
3. At the prompt, specify the action that you want to take, as described in [Table 2](#). Depending on the action you select, the deployment script asks for the information it needs.
 4. For this example, at the `would you like` to prompt, select C and then press Enter to create External S-TAP containers.
Tip: If you are installing External S-TAP on a cloud host, select P to print the list of environment variables that are required to configure your cloud instance for the External S-TAP container.
 5. At the next prompt, `What host do you want to use to host the service containers?` [localhost]
`Non-interactive parameter: --svc-host localhost`
 6. The script echoes the actual parameter name and argument, as shown:

```
What host do you want to use to host the service containers? [localhost]
Non-interactive parameter: --svc-host localhost
```

Tip: Copy each parameter and argument into Notepad or another editor to build up the command line as you determine the required parameters. You can then copy and paste the completed command line into your Linux shell.

7. Continue responding to each prompt.
 - For parameters where you accept the default, press **Enter**.
 - For parameters for which you want to change the default (or which has no default), enter the new value and then press **Enter**.
8. After you successfully run the script, the host computer will `ssh` to the Guardium host and run commands to set up the External S-TAP containers and the load balancer.

When you run the deployment script in an on-premises environment, it creates a cluster of External S-TAP containers. External S-TAPs monitor all transactions, perform TLS decryption and reencryption (if the database is SSL-enabled), and forwards the traffic to the Guardium system. It also (optionally) configures a load balancer that clients can connect to. The load balancer then forwards these connections to one of the External S-TAP containers.

Use [Table 3](#) to determine which parameters you need. The parameters are shown in the order that they are called when you create a new cluster (that is, when you select the `--c` option).

Note: You can rename or edit any of the scripts as required for your installation. Make sure that any changes to one script (such as changing the name of the load balancing script) are propagated to any other scripts that call them. Do not change parameter names.

Required command line parameters

The parameters in [Table 1](#) must be available on the command line. If you do not include **--lb-script** on the command line, you must provide your own load balancing solution. For more information, see [Load balancer scripts](#)

Table 1. Required command line parameters

| Parameter | Meaning |
|---------------------------------|---|
| --state-file
<i>filename</i> | Required. The name of the file in which the state is recorded. For example:

--state-file /ext_stap_state

Note: You must specify the state file in the command line. |
| --lb-script
<i>filename</i> | The name of the load balancer deployment script. If you do not include the name of the load balancer script, you must configure the load balancer separately. For your convenience, two default scripts are available: <ul style="list-style-type: none">• lb_interface_echo.sh - An example script for a generic load balancer (does not work as is).• lb_interface_nginx.sh - An example script to create an NGINX-based load balancer. Note: To use the load balancer script, you must specify the parameter and script name in the command line. |

Selecting the action

Use the parameters in [Table 2](#) to specify the action you want to take each time you run the deployment script. In general, you use this script to create (--c) a cluster of External S-TAP containers. However, you can also use the same script to delete clusters, print the Docker container environment variables, and take other actions, as described in [Table 2](#).

Table 2. External S-TAP action parameters

| Parameter | Meaning |
|-----------|--|
| --ni | Run this script in non-interactive mode. Use interactive mode to set parameters as needed. After the script is set up for your environment, you can run the script in non-interactive mode. |
| --c | Create a cluster. |
| --d | Delete an existing cluster. |
| --e | Enable interception, that is restart intercepting database traffic. Requires the load balancer integration script. This command is generally only used for support and testing purposes. |
| --p | Do not create a cluster, but print the Docker container environment variables. The output is saved in the state file. For hosting in the cloud, use the --p parameter to print the environment variables you need to configure your cloud instance for the External S-TAP container. |
| --r | Remove interception, that is, stop intercepting database traffic. Requires the load balancer integration script. This command is generally only used for support and testing purposes. |
| --u | Upgrade an existing cluster. |
| --z | Clean up zombie instances, that is, stop and delete old containers that are still running on the host. |

Deployment script parameters

The remaining deployment script parameters specify important information for your deployment, such as host names, repository names, and the number of containers to deploy. When you run the script in interactive mode, you are prompted for the value of each parameter. For optional parameters, or to accept default values for required parameters, you can press Enter to continue without entering any information.

Note: The parameters that display depend on the action you select when you call the External S-TAP deployment script.

Table 3. External S-TAP deployment script parameters

| Parameter | Script Question/meaning |
|---------------------------------|--|
| --svc-host <i>host/ip</i> | What host do you want to use to host the service containers?
The host name or IP address of the host or hosts on which to create the containers. Separate multiple host names with a comma.

The default is \$SVC_HOST. |
| --svc-port-range <i>m-n</i> | What is the port range for the exported service port?
The exported port number for the Docker container. You can specify a range of available ports between <i>m-n</i> (inclusive). In this case, the host dynamically determines the port number for each Docker container. For example:

--svc-port-range 6100-6500

The default is 0, which uses the values from:

/proc/sys/net/ipv4/ip_local_port_range |
| --svc-host-user <i>username</i> | What user will be logging in to the host to start the service containers?
The user name of the user who creates containers on the Docker host machine.

The default is the current user, \$SVC_HOST_USER |
| --svc-image <i>image</i> | Enter the hash or tag for the service container image:
The name or hash of the External S-TAP image from Docker. For example:

--svc-image store/ibmcorp/guardium_external_s-tap:v10.6.0 |
| --repo-user <i>username</i> | What is the username to be used if login is required to pull the service container image?
The user name of the user who logs in to the repository from which the External S-TAP Docker image is pulled. |
| --repo-pass <i>password</i> | What is the password for user?
The password for the repo-user user name.

Tip: Before running the deployment script, log in to Docker (on the Docker host machine) with docker login to save your login information to <code>~/.docker/config.json</code> . After you are logged in, you do not need to enter the --repo-user and --repo-pass parameters. |

| Parameter | Script Question/Meaning |
|---------------------------------|--|
| --svc-container-num num | How many service containers would you like to create?
The number of External S-TAP Docker containers to create for this database inspection cluster.

The default is 1. |
| --uuid UUID | Please enter a UUID for this group:
The UUID of the External S-TAP cluster. The default is a random UUID generated from <code>uuidgen</code> . |
| --proxy-num-workers n | Enter the number of workers for each service container of Guardium External S-TAP:
The number of worker threads for the External S-TAP to use. You can set the number of worker threads from the Guardium collector Edit External S-TAP group page after the cluster is created.

The default is 1. |
| --db-host host/ip | Enter the hostname or IP to which the DB the Guardium External S-TAP group will be relaying traffic:
The host name or IP address to the computer where the External S-TAP will forward connections. |
| --db-type string | Enter the type of database for the DB host:
The database type for External S-TAP traffic. You can set the database type from the Guardium collector Edit External S-TAP group page after the cluster is created. Supported databases are listed on the Database tab of the Deploy External S-TAP page. |
| --db-port port | Enter the port for the DB to which the Guardium External S-TAP group will be relaying traffic:
The port number needed to access this cluster. You can set the port number from the Guardium collector Edit X-TAP group page after the cluster is created. |
| override_server_ip/ P address | Enter an IP to override and force the server IP to be reported as (optional and uncommon, leave blank if not needed) |
| --proxy-protocol n | If proxy protocol version 1 is enabled for the DB traffic, enter 1, otherwise enter 0:
Specifies whether the proxy protocol is enabled for the database traffic. For more information, see https://www.haproxy.org/download/1.8/doc/proxy-protocol.txt .

<ul style="list-style-type: none"> • 0 - Not enabled (default). • 1 - Protocol version 1.
If your load balancer supports proxy protocol, the protocol inserts data at the beginning of the connection to share the client's IP address with External S-TAP. With proxy protocol, connections are reported as being from the client to the DB host.

You can change this setting from the Guardium collector Edit External S-TAP group page after the cluster is created. |
| --invalid-cert-disconnect | Do you wish to disconnect the clients if the DB server certificate cannot be verified? (y/n)
If the database server certificate cannot be verified, terminate the client connection. |
| --invalid-cert-notify | Do you wish to log an error message if the DB server certificate cannot be verified? (y/n)
If the database server certificate cannot be verified, continue running and log a warning. |
| --proxy-secret string | Depending on how External S-TAP is configured on your system, you might see one of the following prompts:
If traffic is encrypted and you are generating CSRs on the collector and signing them separately, enter the secret token which will be used to retrieve the key and signed certificate from the Guardium Collector:

. The shared secret string, or token, needed to retrieve keys from the collector for External S-TAP. Run <code>show certificate External S-TAP</code> from the CLI on the Guardium collector to view the token you need to enter for proxy-secret.

Or:

If traffic is encrypted and you have a signing certificate stored on the collector to automatically sign CSRs generated by External S-TAP, enter the Name field for the CSR's CN:

In this case, use the shared secret string to generate a CSR container that is signed by the collector. In this case, the --proxy-csr-name is required.

In either case, --proxy-secret is required if you want to use encrypted External S-TAP traffic. |
| --proxy-csr-name string | If traffic is encrypted and you have a signing certificate stored on the collector to automatically sign CSRs generated by External S-TAP, enter the Name field for the CSR's CN:
Required if you have a signing certificate stored on the collector. Enter a name for the CSR's common name, or CN. |
| --proxy-csr-country string | Enter the Country field for the CSR's CN: |
| --proxy-csr-province string | Enter the Province field for the CSR's CN:
Enter the state or province for the CSR's CN. |
| --proxy-csr-city string | Enter the City field for the CSR's CN: |
| --proxy-csr-organization string | Enter the Organization field for the CSR's CN: |
| --proxy-csr-keylength integer | Enter the length for the CSRs private key:
The length of the CSR private key must be between 2048 and 8192. |
| --sqlguard-ip host/IP address | Enter the hostname or IP of the Guardium Collector:
Required. The collector host name or IP address for External S-TAP to relay decrypted traffic. |
| --sqlguard-cert-cn cn | CN to match when verifying collector certificates. Requires a derived container image with a CA populated at \${GUARDIUM_CA_PATH}
If your site chooses to verify collector certificates, enter the CN (common name) of the collector's certificate. Leave this entry blank to disable verification. For more information, see Verify collector certificates (optional) . |

| Parameter | Script Question/Meaning |
|--------------------------------------|--|
| --participate-in-load-balancing char | <p><code>Participate in load balancing or failover? 0: failover/no_lb, 1) split, 2)</code>
 <code>redundancy, 3) not allowed, 4) threaded:</code>
 <code>. Specify the type of load balancing solution to use.</code></p> <p>You can change this setting from the Guardium collector Edit External S-TAP group page later.</p> |
| --kill-after n | <p><code>Enter the number of seconds to wait before forcefully stopping the old containers (0 is wait 30s, but don't forcefully stop):</code>
 When stopping a container, if the container does not shut down within n seconds, forcefully remove it. The default is to wait 30 seconds but don't force removal.
 Note: This parameter does not display when creating containers.</p> |
| --state-file filename | <p><code>Name of the file in which the state is recorded.</code>
 Required. The name of the state file, for example <code>\". ./cluster_state\"</code>.</p> |
| --envvar environment setting | For support purposes only. |
| --persistent Docker volume | <p><code>Persistent storage source</code>
 The name of a Docker persistent volume. The volume must be accessible and shared between all of the nodes at the same path.
 If needed, change the owner on the host machine directory to the same UID as the UID of the External S-TAP. For example,
 <code>chown -R 1000:1000 <path_to_External_S-TAP_volume></code>
 Note: Be sure to initialize the persistent storage before you run the script.</p> |

- [Load balancer scripts](#)

Guardium External S-TAP requires integration with a load balancer to help provide redundancy to eliminate a single point of failure.

Related concepts

- [Load balancer scripts](#)

Load balancer scripts

Guardium® External S-TAP requires integration with a load balancer to help provide redundancy to eliminate a single point of failure.

Guardium provides two sample load balancer integration scripts that you can use as a base for your own script. The scripts provide a set of functions that are called by the Guardium External S-TAP deployment script to create and manage the load balancer configuration for your environment. In coordination with the load balancer integration script, the load balancer allows you to upgrade External S-TAP instances without impacting traffic between the client and server.

Important: If your site chooses not to use the load balancing script, make sure that you have another load balancing solution in place.

Note: Within the scripts, ignore any line that contains the phrase STATE=. Those lines are for internal use only.

You can use one of the sample scripts as a base, but actual implementation details will vary according to your needs. Both of the sample scripts include the required load balancer functions, which are described in [Table 1](#). Changes will be required to either script to meet your site's needs.

- The lb_interface_nginx.sh sample script provides a sample NGINX-based implementation.
- The lb_interface_echo.sh sample script provides information about a generic implementation and echoes back information about elements in the script.

Important: Do not run the load balancing script directly. Always call the script from the External S-TAP deployment script, with the script name as the first argument , for example, `--lb-script filename` (where `filename` is the name of your load balancing script).

The load balancer is activated when the External S-TAP is deployed.

The functions described in [Table 1](#) are required, and must use the exact function names provided. Change each function as needed to meet your site's requirements.

Table 1. Load balancing script functions

| Function name | Meaning |
|---------------------------------|--|
| lb_import_state() | <p>Takes a state file that is created by the deployment script and builds up the load balancer configuration. The file format is as follows:</p> <pre>Container 1 information Container 2 information ... Container n information</pre> <p>Where each line contains the following information as a comma-separated list:</p> <ul style="list-style-type: none"> • <code>host where container is running</code> • <code>external port on host for container</code> • <code>internal container listen port</code> • <code>listen port on database</code> • <code>container name</code> <p>The lb_import_state function prepares the configuration from the state provided. The state is passed to lb_import_state, which is called once each time the deployment script runs, and always before any other function.</p> |
| lb_redirect_around_containers() | Changes the configuration that is created by lb_import_state to temporarily direct traffic around (rather than through) the Docker containers. Receives two parameters that describe the <code>host</code> and <code>port</code> of the target server. Used to temporarily remove interception by External S-TAP instances for debugging and testing. |
| lb_add_one() | Takes two parameters, the <code>host</code> and <code>port</code> of the External S-TAP Docker container to add. The lb_add_one function uses the configuration that is prepared in lb_import_state to add a container to the configuration. |
| lb_remove_one() | Takes two parameters, the <code>host</code> and <code>port</code> of the External S-TAP Docker container to remove. The lb_remove_one function uses the configuration that is prepared in lb_import_state to remove the container from the configuration. |

| Function name | Meaning |
|----------------------|--|
| lb_apply_config() | Takes no parameters. Applies the current state of the configuration to the load balancer. Can be called multiple times per run of the deployment script. |
| lb_teardown_config() | Takes no parameters. Deactivates the load-balancer. Call this function to remove the External S-TAP containers as part of an uninstall process. |
| lb_cleanup() | Takes no parameters. Performs any cleanup necessary to remove temporary files. Call this function once, and only when you will not call load balancer integration again. |

The External S-TAP user interface

Use the External S-TAP instances page to create, monitor, start, stop, and configure Guardium® External S-TAPs.

Use the External S-TAP instances page to deploy an External S-TAP, check on the status of any currently running External S-TAPs, and to modify certain parameters.

To open the page, browse to `Manage > Activity Monitoring > External S-TAP Control`.

The External S-TAP instances page

The External S-TAP instances page displays all of the currently available External S-TAPs on the current Docker host machine, and provides some tools to help manage them.

From the External S-TAP instances page, you can select the following tools:

- New: Click to deploy a new External S-TAP. For more information, see [Deploy External S-TAP window](#).
- Edit: Select an External S-TAP and click to open the Edit External S-TAP group page. For more information, see [Edit External S-TAP group tab](#).
- Delete: Select one or more stopped External S-TAPs and click to delete them from the Guardium database. You cannot delete a running External S-TAP. If your site uses Kubernetes, deleting the External S-TAP from the UI does not remove it from the Kubernetes cluster. To remove the External S-TAP and all of its underlying structures, delete the External S-TAP deployment and service from the Kubernetes dashboard or by using the `kubectl` command-line interface. For more information, see the Kubernetes documentation.
- Refresh: Click to update your view of the External S-TAP instances page.
- Comment: Select an External S-TAP from the list and then click to display the Comments window. Add a comment for the selected External S-TAP and then click Close to save and close the window. Other users can reply to comments or add their own.
- Actions: Select an External S-TAP on which to perform one of the actions in the list. For more information, see [Actions menu](#).
- Export: From the Export menu, select one of the following options to save current information about the available External S-TAPs:
 - Download as CSV: Save information in an Excel file.
 - Download as PDF: Save information in a PDF file.
- Filter: Enter any string into the Filter text box to exclude External S-TAPs that do not contain the specified string. For example, enter 65 to show only those External S-TAPs that have the number 65 in the host IP address or the Group uuid.

For each External S-TAP, the following information displays:

- External S-TAP group: The name of the External S-TAP cluster. The name is created from the database type and the IP address of the Docker host machine.
- Group uuid: The uid for this cluster. The uid can either be a generated uid or a string that was entered as the uid during deployment.
- Host: The IP address of the Docker host machine.
- Database type: The type of database for this External S-TAP.
- Total members: The total number of containers in this cluster. Each cluster contains both a load balancer and one or more External S-TAP containers.
- Overall status: The status of this External S-TAP cluster.
 - If all of the External S-TAPs are down, the status is red.
 - If at least one External S-TAP is running, the status is green.
- Healthy members: The number of healthy members in this cluster. For a cluster with multiple External S-TAPs, if Total members is different than Healthy members, you know that some of the External S-TAPs are down.
- Collector: The name of the Guardium collector that this External S-TAP is using.

Actions menu

After you select an External S-TAP, you can select any of the following options from the Actions menu:

- Restart: Restarts the S-TAP that runs with this External S-TAP.
- S-TAP logging: From the S-TAP logging window, specify an External S-TAP group, a debug level, as described in [Table 1](#), and a time period for which to monitor S-TAP interaction and save the data to the S-TAP log file.
- Run diagnostics: From the Run diagnostics window, specify an External S-TAP group, a debug level, as described in [Table 1](#), and a time period for which to run the S-TAP diagnostics script. The diagnostics run with the specified debug level and are uploaded to the Guardium collector.
- Revoke ignore: If your installation has the IGNORE STAP SESSION (REVOCABLE) rule set, click Revoke ignore to open the Revoke ignore window. Click Apply for the selected External S-TAP group for the S-TAP to start transmitting data for any sessions that were in an ignore state.
- View details: View and manage details for one or more members of a selected External S-TAP group. If you view the details of an External S-TAP group that contains multiple members, all of the members display.

From the External S-TAP details window, you can take the following actions:

- View details and version information for each member of the selected External S-TAP group.
- Delete one or more inactive containers in the group. Select the containers that you want to delete and click . A confirmation message displays. Click Yes to delete the selected containers.

Note: You can delete only inactive containers.

- View events: View the events for the selected External S-TAP group. For each event, the report identifies the Event type, Event description, Timestamp, and Container (Group uuid). You can filter on any string in the report. For example, to see error messages, enter *ERR* to display only events with an event type of LOG-ERR.
- View deployment: View selected details about this External S-TAP deployment.

The External S-TAP page includes the following tabs.

- [Deploy External S-TAP window](#)

If your site uses Kubernetes to manage clusters, you can install and configure an External S-TAP from the Deploy External S-TAP window.

- [Edit External S-TAP group tab](#)

Use the Edit External S-TAP group tab, to view or change the information about an existing Guardium External S-TAP.

Deploy External S-TAP window

If your site uses Kubernetes to manage clusters, you can install and configure an External S-TAP from the Deploy External S-TAP window.

Deploy External S-TAP window

In the Deploy External S-TAP window, enter the required information in the tabs to deploy a new External S-TAP.

Note: For more information about creating the Master URL, Token, and Registry key, see [Deploying External S-TAP from the Guardium UI](#).

When you are done, click Apply to save your changes or Create templates to generate yaml templates that you can use to manage External S-TAPs from Kubernetes.

When you select Create templates, Guardium generates two files, **service.yaml** and **deployment.yaml**. When you call these files from the Kubernetes command line, Kubernetes can manage persistent storage, load balancing, and other External S-TAP requirements.

Note: To use persistent storage with Kubernetes, make the following changes to Kubernetes and to the **deployment.yaml** file:

1. In Kubernetes, create a persistent volume and a persistent volume claim. For PersistentVolumeClaim, make sure that accessModes is set to *ReadWriteMany* to allow the volume to access all of the parallel containers in the deployment.
2. In the **deployment.yaml** file, add the following information under spec:
 - *containers* includes volumeMounts and the following *mountPath*:

```
  containers:
    volumeMounts:
      - mountPath: "/persistent"
        name: mypd
```

- *volumes* includes the name of the persistent volume and persistent volume claim. For example:

```
  volumes:
    - name: mypd
      persistentVolumeClaim:
        claimName: myclaim
```

3. When you are done, apply the changes from kubectl:

```
kubectl apply -f deployment.yaml
```

4. Finally, make sure that persistent storage is deployed:

```
kubectl get deployment
```

For more information, see the Kubernetes documentation.

The Deploy External S-TAP window displays the following tabs:

- [Kubernetes tab](#)

Enter information required to run External S-TAP from Kubernetes.

- [Volume tab](#)

Specify whether to use an existing Kubernetes persistent volume or create a new persistent volume. After you have created the persistent volume, you can choose to use the volume for other External S-TAPs.

- [Docker tab](#)

Enter the registry key and Docker container location for External S-TAP.

- [Database tab](#)

Enter information about the External S-TAP database.

- [Guardium tab](#)

Enter load balancing and collector options.

- [Certificate tab](#)

Enter information to allow the External S-TAP to manage certificates and certificate signing requests (CSRs).

- [Advanced tab](#)

Enter information about certain External S-TAP advanced parameters.

Kubernetes tab

Enter information required to run External S-TAP from Kubernetes.

Table 1. Kubernetes tab parameters

| Parameter | Default | Meaning |
|-----------|---------|---------|
|-----------|---------|---------|

| Parameter | Default | Meaning |
|------------------------------|--------------|--|
| Cloud provider | | To install a cloud-based External S-TAP with Amazon (AWS), IBM (IBM Cloud), or Microsoft (Azure), select a cloud provider. To use an External S-TAP with an on-premises database, leave Cloud provider blank. For more information about deploying to IBM Cloud, see Step deploy_kubernetes.html#deploy_extap_kubernetes_ibm_cloud_deploy of Deploying External S-TAP from the Guardium UI . |
| Use internal load balancer | Not selected | If selected, adds an annotation to the service to set an internal load balancer for the selected cloud provider. |
| Kubernetes control plane URL | | Required. Established when you provision the Kubernetes cluster.
Note: If the Kubernetes control plane URL does not point to a cloud provider, you need to ensure that a load-balancing solution is available. |
| Authentication token | | Required. The Kubernetes cluster access token. |
| Deployment name | | Required. A user-defined name. The name can contain only lowercase alphanumeric characters and a dash (-). The name must start and end with an alphanumeric character (for example 'my-name', or 'philly-58'). |
| Namespace | default | Required. Kubernetes provides a default namespace. Specify <i>default</i> unless you created a namespace for your Kubernetes cluster. For OpenShift, namespace is the same as the project name. |

Volume tab

Specify whether to use an existing Kubernetes persistent volume or create a new persistent volume. After you have created the persistent volume, you can choose to use the volume for other External S-TAPs.

Table 1. Volume tab parameters

| Parameter | Default | Meaning |
|--------------------------------------|---------------|--|
| Use existing persistent volume claim | | If you already created a Kubernetes persistent volume, you can specify the persistent volume claim. |
| Create persistent volume claim | | Create a new Kubernetes persistent volume. If you select this option, then specify the storage and access mode for the volume that you create. |
| Claim name | | The name of the persistent volume claim. |
| Storage | | The amount of storage for this volume. Specify at least 500 mebibytes (MiB). |
| Access mode | ReadWriteMany | The access mode for this persistent volume. The access mode must be <i>ReadWriteMany</i> . |

Docker tab

Enter the registry key and Docker container location for External S-TAP.

Table 1. Docker tab parameters

| Parameter | Default | Meaning |
|------------------------|---------------------------------------|--|
| Registry key | | Required. The registry key, which is also called the Kubernetes cluster <i>Secret</i> . After you create it, you can find the Registry key (the <i>Secret</i>) with the command:
<code>kubectl get secret</code> |
| External S-TAP version | | The version of the External S-TAP you are using. Select whether your External S-TAP is from 11.3 or earlier or 11.4 or later. |
| Location | store/ibmcorp/guardium_external_s-tap | Required. The download location of your Docker image. |
| Tag | | Required. The Docker image tag used for the download. |

Database tab

Enter information about the External S-TAP database.

Table 1. Database tab parameters

| Parameter | Default | Meaning |
|---------------|---------|---|
| Database type | | The database for this External S-TAP. Select a database from the list or leave this field blank. If you leave the field blank, you can specify the database later in the Database type field on the Edit External S-TAP group Inspection engine tab . |
| Database port | | The port on the database host on which the External S-TAP is listening. |
| Database host | | The name or IP address of the database host that is being monitored by this External S-TAP cluster. You can change the name to monitor a different database. |

Guardium tab

Enter load balancing and collector options.

Table 1. Guardium tab parameters

| Parameter | Default | Meaning |
|-------------------|---------|---|
| Collector IP | | The IP address of the Guardium® collector. The collector IP is read-only. |
| Load balancing | 0 | Select an option: <ul style="list-style-type: none"> 0: No load balancing (default). Traffic is sent to one alive server. The primary server has highest priority. 1: Split sessions between collectors. Traffic is split between servers. 2: Duplicate traffic to all collectors. Traffic is sent to all servers. 3: Grid mode. The S-TAP communicates to the collector through a load balancer. |
| Add new collector | | If you select a load-balancing option greater than 0, the  icon becomes available. Click  to add up to 10 Guardium collectors. Change the collector information from the Edit External S-TAP group Collector tab . |

Certificate tab

Enter information to allow the External S-TAP to manage certificates and certificate signing requests (CSRs).

If you select Use CSR to generate certificate, then External S-TAP can automatically generate certificates as needed.

Table 1. Certificate tab parameters

| Parameter | Default | Meaning |
|---------------------------------|--------------|--|
| Certificate storage secret | estap-secret | The Kubernetes secret that contains the token that is used to deploy the External S-TAP. |
| Service account token secret | | The name of the token secret in the namespace where you deploy the External S-TAP. |
| Collector certificate token | | Required for SSL-encrypted traffic. The token, or secret, from the certificate alias. |
| Use CSR to generate certificate | | Select to have the CSR generate on demand External S-TAP certificates. |
| Common Name | | Required. The common name for the CSR. |
| Country/Region | | The country or region for the CSR. |
| State/Province | | The state or region for the CSR. |
| City/Locality | | The city or locality for the CSR. |
| Organization | | The organization or business name for the CSR. |
| Key Length | 2048 | Select the key length for the CSR key. |

Related tasks

- [Configure on-demand certificate generation](#)
- [Manually create a certificate signing request](#)

Advanced tab

Enter information about certain External S-TAP advanced parameters.

The pod security context parameters allow you to use External S-TAP when Kubernetes Pod Security Policies are enabled. The parameters help ensure that the pod user has access to files and mounted volumes. For more information, see the Kubernetes Pod Security Policies documentation.

Table 1. Advanced tab parameters

| Parameter | Default | Meaning |
|------------------------------|---------|--|
| Member count | | The number of External S-TAP Docker containers to create for this database inspection cluster. In general, you don't need more than four containers per cluster. |
| Worker threads | 1 | The number of threads used by each External S-TAP in the cluster. |
| Verify collector certificate | | Select to have any S-TAPs verify the collector's certificate before the collector connects to the S-TAP. Use this feature, along with block lists and allow lists, to strictly control access between the Guardium® collector and the External S-TAP. |
| Collector CN | | If you select Verify collector certificate, enter the common name (CN) of the collector to use in Collector CN, or enter a regular expression to specify a set of allowable collectors.
For more information about Regular Expressions, see Regular Expressions . |
| Override server IP | | Enter a default server IP address to use for all recorded traffic. |
| runAsUser | 1000 | The UID for the processes within the pod containers. If the user is not 1000, then GID 0 must be a valid group for the user. |
| fsGroup | 1000 | The file system group. Enter the GID for filesystem mounts in the containers of the Pod. The fsGroup is added to the pod's supplementalGroups parameter.
The default is 1000, but make sure that you specify a number that works with your policy. |

Edit External S-TAP group tab

Use the Edit External S-TAP group tab, to view or change the information about an existing Guardium® External S-TAP.

The Edit External S-TAP group tab

From the Edit External S-TAP group tab, you can view or change information about existing External S-TAPs. When you select an External S-TAP to edit, the name of the External S-TAP group displays at the top of the tab. You can change the name of the External S-TAP group from External S-TAP group name.

The Edit External S-TAP group tab includes tabs that you can use to change or view properties for the selected External S-TAP group.

External S-TAP tab

The External S-TAP tab allows you to view or change the information that is described in [Table 1](#).

Table 1. External S-TAP tab

| Parameter | Default | Meaning |
|------------------------|---------|---|
| Group uuid | | The uid for this cluster. A read-only parameter. |
| Member count | | The number of External S-TAPs in this cluster. A read-only parameter. |
| Database host | | The name of the database host that is being monitored by this External S-TAP cluster. You can change the name to monitor a different database. |
| Listen port | | The port on the database host on which the External S-TAP is listening. |
| Debug | 0 | Set the debugging level for this External S-TAP. The debug levels are as follows: <ul style="list-style-type: none"> • 0: No debug (the default) • 1: Configuration debug. Creates logs related to configuration and statistics. • 2: Packet digest. Read and write some actions for each packet. • 3: Extended packet digest. Includes information such as connection lifecycle, open, close, or TLS handshake logs, and some per connection logs. • 4: Full verbose debug. Includes all logs and a partial payload dump. |
| Worker threads | 1 | The number of threads used by each External S-TAP in the cluster. |
| Proxy protocol | 0 | Provide support for the load balancer proxy protocol, if it is enabled. For example, for an NGNIX load balancing solution, add proxy_protocol on to the /etc/nginx/nginx.conf configuration file and then enable Proxy protocol in this tab. |
| On invalid certificate | | Specify actions to take if the SSL certificate is not valid. You can choose to disconnect the External S-TAP from the server, notify the user that a server with an invalid certificate has attempted to contact the External S-TAP, or both.. |

Edit External S-TAP group also includes the following tabs:

- [TAP tab](#)

External S-TAPs are designed to use S-TAPs. From the TAP tab, you can set a number of S-TAP-related parameters.

- [Inspection engine tab](#)

From the Inspection engine tab, you can view or change the parameters related to the Guardium inspection engine.

- [Collector tab](#)

From the Collector tab, you can add, edit, or remove a Guardium collector.

- [Firewall tab](#)

From the Firewall tab, you can configure the Guardium firewall for an External S-TAP. Using the Guardium firewall can slow performance and might cause other issues. Guardium suggests that you use the firewall feature only when necessary.

TAP tab

External S-TAPs are designed to use S-TAPs. From the TAP tab, you can set a number of S-TAP-related parameters.

From the TAP tab, you can set a number of S-TAP-related parameters.

For the query rewrite (QRW) parameters,

- Make sure that QRW force watch and QRW force unwatch are not configured with the same IP ranges.
- In addition, these options are valid only when QRW installed is selected and QRW default state is set to 1.

The following caveats apply for QRW:

- QRW with External S-TAP works with the following databases:
 - Db2 (Linux and UNIX)
 - Microsoft SQL
 - Oracle
- You cannot deploy External S-TAP with QRW enabled. Deploy the External S-TAP first, and then enable QRW from the GUI.

For more information about the query rewrite parameters, see [Linux-UNIX: Query rewrite parameters](#).

Table 1. TAP tab

| Parameter | Default | Meaning |
|-----------------|-------------|---|
| All can control | Not checked | For configurations with multiple collectors, specifies whether all collectors can change the configuration or only the primary collector can make changes. The default allows only the primary collector to make changes. |
| Messages | Not checked | Turn remote and syslog messages on or off: <ul style="list-style-type: none"> • Remote: When selected, sends messages to the active Guardium® host. • Syslog: When selected, records system messages in the syslog. |

| Parameter | Default | Meaning |
|-----------------------------|---------|--|
| Load balancing | | Select a load balancing option: <ul style="list-style-type: none"> 0: No load balancing (default). Traffic is sent to one alive server. The primary server has highest priority. 1: Split sessions between collectors. Traffic is split between servers. 2: Duplicate traffic to all collectors. Traffic is sent to all servers. 4: Split sessions between collectors (multi-threading). Traffic is managed (and split) by multiple S-TAP threads. |
| Managed units | 1 | The number of managed units (MUs) to request from the load balancer |
| Compression level | 1 | Select the level of data compression between the S-TAP and the collector. Choose a compression level between 1 (none) to 9 (highest). |
| QRW force unwatch | | Client IPs addresses and masks (for example, 192.168.0.0/192.168.0.10) to exclude from watching.
Click  to add additional IP addresses and masks. |
| QRW force watch | | Client IP addresses and masks (for example, 192.168.0.0/32) to automatically watch .
Click  to add additional IP addresses and masks. |
| QRW default state | | Sets the query rewrite activation trigger. Must be 0 if Firewall default state (on the Firewall tab) is set to 1. Valid values: <ul style="list-style-type: none"> 0: QRW is activated per session when triggered by a rule in the installed policy. 1: QRW is activated for every session regardless of the installed policy. |
| QRW installed | | Enables or disables the Dynamic Data Masking for Databases feature. When set to 0, all other QRW parameters are ignored. |
| Load balancer node affinity | | For enterprise load balancing, specifies whether the S-TAP connects to more than one managed unit.
For more information, see Load balancer node affinity . |

Inspection engine tab

From the Inspection engine tab, you can view or change the parameters related to the Guardium inspection engine.

From the Inspection engine tab, you can view or change the parameters that are described in [Table 1](#).

Table 1. Inspection engine tab

| Parameter | Default | Meaning |
|------------------|---------|---|
| Database type | | The type of database for this External S-TAP. If you did not select a database when you deployed the External S-TAP, you can specify it here. If you selected a database earlier, the field displays the selected database type and is read-only. |
| Database port | | The port on which the database is listening. |
| Networks | Blank | Identify specific clients to monitor by IP address. Specify a begin and end range of IP addresses to monitor. If blank, all clients are monitored.
Note: You can specify either Networks or Exclude networks, but not both. |
| Exclude networks | Blank | Identify specific clients to exclude from monitoring. Specify a begin and end range of IP addresses to exclude. If blank, all clients are monitored. |
| Priority count | 20 | Specify the number of packets of a session to set as high priority. The first <i>number of packets</i> are sent to the high priority queue in the sniffer. The range is from 0 (off) to 50. |

Collector tab

From the Collector tab, you can add, edit, or remove a Guardium® collector.

- To add a collector, click the  icon to display the Add new collector window. In this window, enter the information described in [Table 1](#) and then click Save to save the new collector.

Table 1. Collector tab

| Parameter | Default | Meaning |
|----------------|---------|--|
| Guardium host | | The name of the Guardium collector you want to add. |
| Main threads | 1 | When you select load balancing methods 1 or 4 to split load balancing, the number of open main connections between the S-TAP and a server. For more information, see TAP tab . |
| Pool size | 1 | The number of open data connections between an S-TAP and a sniffer process on a server. |
| Set as primary | | If you have multiple collectors, select a collector to serve as the primary collector. |
| Filter | | Enter any string into the Filter text box to exclude collectors that do not contain the specified string. |

- To edit an existing collector, select the collector and then click  icon to display the Edit collector window. From this window, you can view the collector name and change the Main threads and Pool size, as described in [Table 1](#).

Make any changes that you want, and click Save to save your changes or Cancel to exit without saving.

- To delete an existing collector, select the collector and click the  icon. The collector is deleted.

Note: If you accidentally delete a collector, click Cancel to close the Edit External S-TAP group window without saving your changes.

Firewall tab

From the Firewall tab, you can configure the Guardium® firewall for an External S-TAP. Using the Guardium firewall can slow performance and might cause other issues. Guardium suggests that you use the firewall feature only when necessary.

The Firewall tab parameters are based on the Linux-UNIX firewall parameters for S-TAPs. For more information, see [Linux-UNIX: Firewall parameters](#). For more information about Guardium policies and the firewall, see [Blocking rule actions](#).

Table 1. Firewall tab

| Parameter | Default | Meaning |
|------------------------|--------------|--|
| Firewall installed | 0 | Enables or disables the firewall feature. Valid values: <ul style="list-style-type: none"> • 0: Disables the firewall. • 1: Enables the firewall. |
| Firewall timeout | 10 (seconds) | Time, in seconds, to wait for a verdict from the Guardium system. If the firewall times out, the Firewall fail close value determines whether to block or allow the connection. The value can be any integer value. |
| Firewall default state | 0 | Sets the default state for the firewall. Valid values: <ul style="list-style-type: none"> • 0: The firewall is activated per session when triggered by a rule in the installed policy. • 1: Watch all traffic for firewall policy violations. • 2: Watch all traffic for firewall policy violations for the initial priority_count packets. The External S-TAP watches the initial part of every new session to your database. Setting the default state to 2 is useful when you have session-based policies, firewall rules based on the user, or some other information that is passed early in the session. It limits the impact of firewall on the performance. Instead of watching every bit of the session (Firewall default state=1) and waiting for an UNWATCH verdict, the External S-TAP unwatches automatically if no WATCH or DROP is sent. |
| Firewall fail close | 0 | The action to take when the verdict cannot be set by the policy rules, for example, if Firewall timeout expires. <ul style="list-style-type: none"> • If the check box is selected, the connection is blocked. • If not selected, the connection goes through. |
| Firewall force watch | | A comma-separated list of IP/mask values.
If Firewall default state is set to 0 (off), then Firewall force watch specifies the network address or mask of the IP addresses that you want the firewall to watch, overriding the default. |
| Firewall force unwatch | | A comma-separated list of IP/mask values.
If Firewall default state is set to 1 (on), then Firewall force unwatch specifies the network address or mask of the IP addresses that you want the firewall to ignore, overriding the default. |

Best practices for using External S-TAPs with on-premises databases

To use External S-TAPs with on-premises databases, you need to take a few steps to prepare both your database and the External S-TAP. Examples are shown using PostgreSQL.

To use an External S-TAP solution with an on-premises database, make sure that:

- All remote traffic can be directed through the External S-TAPs by using TCP/IP.
- Determine whether to use mutual authentication for the on-premises databases. If you do use mutual authentication, local traffic to the database is allowed only through an unencrypted named pipe protocol, which is monitored by an S-TAP. For more information, see [Manage certificates for mutual authentication](#).
- Your site uses TCP/IP to configure the firewall to block both local and remote traffic except from the External S-TAP host. For more information, see [Set up a firewall on Linux](#).

Prepare the deployment

Gather the following information about your database:

- The database IP address or host name and ports.
- Determine whether your database is SSL-enabled (encrypted).
- Determine whether your database is using mutual authentication.

Set up the solution to monitor databases

To monitor databases with an External S-TAP, you need both an S-TAP and an External S-TAP. The S-TAP is required to monitor local traffic, and the External S-TAP monitors remote traffic.

To prepare the solution, take the following steps:

1. Install an S-TAP on the database host and add (or modify) an inspection engine to accept local traffic to monitor the local connection to the database. Use an unencrypted named pipe (npipe) for the S-TAP.
Note: When you install an S-TAP to use with an External S-TAP, set the intercept type to `npipe` for each database you want to monitor, as follows:
 - From the GUI, under Inspection Engine, set Intercept Types to `npipe`.
 - From the interactive installer, set intercept_types=`npipe` in the `guard_tap.ini` file.
 For more information about installing an S-TAP, see [Linux-UNIX: Install S-TAP agents installation flow](#).
2. Deploy the External S-TAP to monitor remote connections by using TCP/IP protocol. For more information, see [Inspection engine tab](#) or [External S-TAP deployment scripts](#), depending on your deployment method. Optionally, to use mutual authentication, the root certificates that are used by the External S-TAPs must be the

same as the root certificates for the database.

- Secure your database by setting up the firewall. Make sure that all remote traffic goes through the External S-TAPs.

Manage certificates for mutual authentication

To use the mutual authentication option with External S-TAPs, the External S-TAP certificate must be signed by the same certificate authority (CA) as the host database certificate.

When you create the External S-TAP certificate, the CN (Common Name) parameter is required. For mutual authentication, make sure that the CN of the certificate that is used by the External S-TAP is the same as the External S-TAP host name. In addition, if you use a load balancer, use the same certificate CN as the end point of the load balancer.

Set up a firewall on Linux

Use the following example to configure iptables to prevent direct access to your on-premises database. For the following example:

- The PostgreSQL database listen port is 5432.
- External S-TAPs are installed on 172.17.0.3 and 172.17.0.4.

The following code example configures the iptables to prevent direct access to PostgreSQL:

```
# Reject access to MongoDB container
iptables -I INPUT -p tcp --dport 5432 -j REJECT
# Allow access to MongoDB container from External S-TAP (IP needs to match)
iptables -I INPUT -p tcp --src 172.17.0.3 --dport 5432 -j ACCEPT
iptables -I INPUT -p tcp --src 172.17.0.4 --dport 5432 -j ACCEPT
iptables -I DOCKER-USER -p tcp --src 172.17.0.3 --dport 5432 -j ACCEPT
iptables -I DOCKER-USER -p tcp --src 172.17.0.4 --dport 5432 -j ACCEPT
```

Additional notes about certificates for External S-TAPs

The host parameter of certificate for External S-TAP must match the CN of the certificate that the database client gets in the TLS handshake, that is:

- If the client connects to the server directly, the host parameter must match the CN of the certificate on the PostgreSQL or MySQL server.
- If the client connects to the server via an External S-TAP, set the host parameter to the host of the External S-TAP. Make sure that the CN of the External S-TAP certificate matches the host parameter in the command.
- If the External S-TAP uses a TCP-IP load balancer, set the host parameter to the host or domain name of the load balancer. Make sure that the CN of the External S-TAP certificate matches the host parameter.

PostgreSQL notes

To use PostgreSQL with mutual authentication, make sure that the host parameter that is used by client matches the CN of the certificate of the External S-TAP.

Note: You can use a wildcard to match the certificate CN.

For PostgreSQL, the METHOD field in the pg_hba.conf file controls the client authentication method. External S-TAP supports the following methods:

- trust, trust clientcert=1
- md5, md5 clientcert=1
- password, password clientcert=1

Configuring AWS HA for External S-TAPs

Include External S-TAPs in your existing Amazon AWS high availability (HA), or failover, configuration.

If your site uses Amazon AWS that is configured for high availability (HA), or failover, Guardium® recommends that you include External S-TAPs in your existing HA configuration. Include External S-TAPs in your existing failover scenario by integrating with either Elastic Load Balancer, Route 53, or both. To integrate External S-TAPs in your failover scenario, you can:

- Add multiple External S-TAP instances behind your load balancer for active-active failover.
- Use your DNS server to deploy active-passive failover for External S-TAP instances.

Note: Guardium assumes that your site is already using HA configuration with Amazon AWS. For more information about using an HA configuration with Amazon, see the [Amazon Route 53 Developer Guide](#) (and other Amazon and AWS documentation). Because your configuration is based on your specific requirements, Guardium can provide only general guidance for how to configure HA and failover for your site.

Prerequisites

To use External S-TAPs in an HA environment, the following applications must be deployed inside your AWS service, along with any web services:

- Amazon EC2 and Relational Database Service (RDS).
- AWS Identity and Access Management (IAM): Assign appropriate roles to run Lambda functions.
- Amazon Route 53: Provides domain registration, DNS routing, and health checking.
- Amazon CloudWatch: Monitors services and provides actionable insights and alerts.
- Health Check (AWS ELB): Monitors registered instances to ensure that the load balancer sends requests only to healthy instances.
- Amazon Simple Notification Service (SNS): Provides messaging services between CloudWatch Alarm and Lambda functions.
- Amazon Lambda: A serverless platform that the failover mechanism uses to provide a trigger point to maintain firewall rules.
- AWS Elastic Load Balancing (ELB): Automatically distributes traffic between multiple External S-TAP instances for load balancing and active-active failover. ELB also acts as the entry for the External S-TAP micro service.

Configuring failover for External S-TAP

The following instructions assume that you are familiar with Amazon AWS for HA and failover for other applications.

1. In Route 53, register for a domain name and create health check rules as needed, including checks to monitor CloudWatch alarms.
 - Health check constantly monitors traffic through the External S-TAP.
 - If the failure rate for a health check rule exceeds the configured threshold, health check triggers an alarm or events.
2. Configure SNS and CloudWatch as needed. When an alarm is triggered, CloudWatch alarms and SNS notifications update the DNS record and the access control list rules. In addition, you can set SNS to notify IT or other personnel. In Route53, you can configure CloudWatch to monitor the health checks.
3. In the EC2 Management Console, create and configure a Security Group specifically for the External S-TAP. To provide flexibility in managing firewall rules, Guardium recommends that you also create security groups for the load balancer, PostgreSQL client, and PostgreSQL server domains.
4. Route 53 reroutes the DNS servers when a server fails. The DNS server updates the record according to the status of the alarm. Configure Route 53 to:
 - Create a policy record to route the entry domain to a different domain based on the status of the CloudWatch alarm.
 - In your DNS, find or create the following domains:
 - A domain for the load balancer. For failover, specify this domain as the primary domain. The endpoint for this domain is available from AWS > Amazon RDS > Databases > <your_dbname>.
 - An entry domain of the policy record. Specify this domain as the secondary domain. The DNS name can be found from Amazon EC2 Management Console > Load Balancing > Load Balancers.
 - The DNS of the service endpoint in RDS. The domain name depends on your configuration. For instance, the name might be found in the Amazon Route 53 dashboard under Hosted Zones > Policy Records as the Policy Record DNS Name for the External S-TAP traffic policy.
5. In AWS Lambda, create functions to update the access control list rules. Make sure that your Lambda functions have an IAM rule that has sufficient permissions.

After you add an External S-TAP to your HA configuration, CloudWatch monitors the External S-TAP along with your other applications.

Configuring Google BigQuery for External S-TAPs

Include External S-TAPs in your Google BigQuery configuration for Guardium®.

You can use External S-TAPs to intercept Google BigQuery traffic in three different ways:

- The BigQuery client libraries
- BigQuery JDBC driver from CData Software
- Google Cloud Console

You can deploy External S-TAP for Google BigQuery either with Kubernetes as described in [Deploying External S-TAP from the Guardium UI](#) or with Docker, as described in [Deploying External S-TAP manually](#).

If you use Kubernetes, set the following Kubernetes environment variables for External S-TAP:

- STAP_CONFIG_PROXY_DB_HOST=*bigrquery.googleapis.com*
- STAP_CONFIG_DB_0_REAL_DB_PORT=443
- STAP_CONFIG_DB_0_DB_TYPE=bigrquery

If you use Docker, set the following variables in the deployment script:

- db_host: *bigrquery.googleapis.com*
- db_type: *bigrquery*
- db_port: 443

How you configure Google BigQuery depends on which method you want to use to intercept traffic. Follow the directions for the method you want to use.

Configure the certificate for BigQuery client libraries or CData BigQuery JDBC driver

For either the BigQuery client libraries or the CData BigQuery JDBC driver, you need to take the following steps:

1. Generate a replacement certificate and private key for External S-TAP that meet the following requirements:
 - The key type is RSA.
 - Common Name (CN) - *bigrquery.googleapis.com*
 - Subject Alternative Names (SAN) - *DNS:*.cloud.google.com, DNS:clients6.google.com, DNS:*.clients6.google.com, DNS:bigrquery.googleapis.com*
 - The certificate is signed by a CA key pair.
2. Deploy the certificate and private key. Combine the certificate and private key into a single file and put them into a Docker volume or Kubernetes secret.
 - If you use a Kubernetes cluster, set the External S-TAP `STAP_CONFIG_PROXY_PEM_PATH` environment variable to the path of the file that contains the combined certificate and key inside the container.
 - If you use Docker on a virtual machine, store the certificate and private key by using the “store certificate external_stap_signing” cli command which creates a certificate token for the External S-TAP. For more information, see [Certificate CLI Commands](#).
3. Configure DNS so that the clients you want to monitor get the IP address of the External S-TAP for the following domain names:
 - *bigrquery.googleapis.com*
 - *console.cloud.google.com*
 - *cloudconsole-pa.clients6.google.com*
 - *clients6.google.com*

Note: To test on a local machine, you can use an entry into `/etc/hosts`. For production, Guardium suggests that you use a DNS system (such as BIND 9).

Configure the BigQuery API Client Libraries

To use the Google BigQuery API Client Libraries with External S-TAP, you first need to install the client libraries, as described in the Google Cloud BigQuery documentation. Then, configure the client library to trust the new External S-TAP certificate as well as the certificates that make up the signing chain.

To use the `bq cli` tool, you must append the External S-TAP certificate and signing chain to the `cacerts.txt` file, which you can find in one of the following locations (depending on your python version).

- `/google-cloud-sdk/platform/bq/third_party/httplib2/python3/cacerts.txt`
- `/google-cloud-sdk/platform/bq/third_party/httplib2/python2/cacerts.txt`

Configure the CData BigQuery JDBC driver

If you plan to use the CData BigQuery JDBC driver to connect through External S-TAP, you first need to install and configure the CData BigQuery JDBC driver. For more information, see the CData JDBC Driver for Google BigQuery documentation.

After you configure the CData BigQuery JDBC driver for your project, data set, and OAuth, set the following properties:

- `ProxyAuthScheme=NONE`
- `ProxyPort=443`
- `ProxySSLType=ALWAYS`
- `ProxyServer=` The IP address of your External S-TAP. If not set correctly, the Google BigQuery servers reject the connection with a "handshake failure."
- `SSLServerCert=` The path to the file that contains the External S-TAP certificate and signing chain.

Configuring Google Cloud Console (BigQuery web UI)

To use an External S-TAP to intercept data from the Google Cloud Console, create or select a Google Cloud project.

Note: BigQuery is automatically enabled in Cloud Console projects.

1. Generate a replacement certificate and private key for External S-TAP that meet the following requirements:

- The key type is `ECDSA` with `secp256r1 (prime256v1)`
 - Common Name (CN) - `bigrquery.googleapis.com`.
 - Subject Alternative Names (SAN) - `DNS:*.cloud.google.com, DNS:clients6.google.com, DNS:*.clients6.google.com, DNS:bigrquery.googleapis.com`.
 - The certificate is signed by a CA key pair.
2. Deploy the certificate and private key. Combine the certificate and private key into a single file and put them into a Docker volume or Kubernetes secret.
 - If you use a Kubernetes cluster, set the `External S-TAP_CONFIG_PROXY_PEM_PATH` environment variable to the path of the file that contains the combined certificate and key inside the container.
 - If you use Docker on a virtual machine, store the certificate and private key by using the `store certificate external_stap_signing` cli command which creates a certificate token for the External S-TAP. For more information, see [Certificate CLI Commands](#).
 3. Configure DNS so that the clients you want to monitor get the IP address of the External S-TAP for the following domain names:
 - `bigrquery.googleapis.com`
 - `console.cloud.google.com`
 - `cloudconsole-pa.clients6.google.com`
 - `clients6.google.com`

Note: To test on a local machine, you can use an entry into `/etc/hosts`. For production, Guardium suggests that you use a DNS system (such as BIND 9).

4. Configure the web browser. Make the following changes to the client web browser:

Tip: This example uses the Firefox web browser. For other browsers, the parameters might be slightly different. From Firefox, change the settings from the preference page. Enter `about:config` in the Firefox address bar, and click through the warnings to open the preference page.

- a. When available, the Google BigQuery Cloud Console uses HTTP 2. Since Sniffer does not support HTTP 2, you need to disable HTTP 2 support in the browser to force it to use HTTP 1.1.
 - `network.http.spdy.enabled = false`
 - `network.http.spdy.enabled.http2 = false`

- b. The client web browser needs to trust the External S-TAP certificate and signing chain.
 - `security.osclientcerts.autoload = true`
 - `security.enterprise_roots.enabled = true`

- c. Add the External S-TAP certificate (along with the other certificates in the signing chain) to your browser's trusted certificates.

On Linux, copy the External S-TAP certificate and the rest of the certificates in its signing chain to the following location:

```
/etc/pki/ca-trust/source/anchors/
```

In Windows, take the following steps:

- Break all of the certificates into separate certificate files with a `.crt` file extension.
- Import the certificates into a Windows trusted CA by clicking each certificate file to display an import dialog.
- If the certificate is the root CA, select Trusted root Certificate Authorities. For intermediate certificates, select Intermediate Certificate Authorities.

- d. After the certificates are in place, you need to update the certificate truststores. Run the following command as root:

```
update-ca-trust
```

If your browser is open, you need to close and reopen it.

Troubleshooting External S-TAP issues

Check for solutions if something goes wrong with your External S-TAPs.

The database connection closes unexpectedly

When External S-TAPs are running, you might encounter an infrequent situation in which the database connection closes unexpectedly. In this case, you need to delete the certificate that is associated with the External S-TAP and restart the External S-TAP, as follows:

1. Call `delete_certificate_external_stap` from the Guardium CLI to delete the certificate. This command lists all the available certificates that are associated with External S-TAPs. Select the number that corresponds to the certificate for the associated External S-TAP.
2. Restart the External S-TAP from the UI.

Even without the External S-TAP certificate, the External S-TAP continues to forward traffic to the database.

Database is blocked due to too many connection errors

If your site is using Amazon elastic Kubernetes service (EKS) with Aurora MySQL, you might experience connection errors. In this case, in the Amazon Relational Database Service (RDS) console, set the values for the following instance-level parameters by applying the Parameter Groups to your database instance.

- max_connect_errors=10000
- max_connections = 200

Client IP is not correctly recorded for session

Load balancers and proxies can obscure the IP of the client. This behavior is not unique to External S-TAP and multiple methods are available to address this issue. One straight-forward method is to use a load balancer that can inject a proxy protocol.

Note: Most databases do not accept proxy protocol themselves and if proxy protocol is enabled, External S-TAP cannot accept sessions without proxy protocol. If a proxy protocol packet is expected, the packet must exist. Conversely, if a proxy protocol is not expected, the existence of a packet causes the connection to fail.

External S-TAP consumes and removes the proxy protocol packet from the database stream before it sends the session to the backend service.

In AWS, proxy protocol support is available with the classic load balancer. For more information, see the AWS online help on configuring proxy protocol support for the classic load balancer.

Many standard load-balancing applications, such as HAProxy, NGINX, or F5 (requires iRules) support proxy protocol. Set the proxy protocol for External S-TAP as follows:

- From the External S-TAP UI , set Proxy Protocol to 1 - Enabled in the External S-TAP group tab.
- From the `container_mgmt.sh` script, specify `--proxy-protocol 1`.
- If you deploy External S-TAP with helm, set `estap.proxy.proxy_protocol` to 1 in the overrides yaml file.
- If you deploy External S-TAP by using Cloud Pak for Data 3.x, set Proxy protocol expected to 1 in the Database and Proxy tab.

Connection to GIM Server fails

External S-TAP does not use GIM. You can ignore all error messages that are related to GIM.

Adding users for PostgreSQL 14 and later

Channel binding is enabled by default for PostgreSQL 14 and later. If your site records passwords with Salted Challenge Response Authentication Mechanism (SCRAM), then the server also supports channel binding. To use External S-TAP when channel binding is enabled, set password encryption when you add new users, as follows:

```
set password_encryption = 'md5'; alter user "username" with password 'newPassword';
```

Connections resetting with AWS Elastic Load Balancer

In general, you can use AWS network load balancing with External S-TAP (as recommended by AWS). However, if you have issues with resetting the connections, then use the classic elastic load balancer (ELB) that allows you to change the idle session timeout.

For AWS ELB, set the idle session timeout to 4000 seconds.

AWS ELB health check generates misleading connections

By default, the AWS ELB health check uses an available traffic port to connect to the database. These connections can be misinterpreted as suspicious activities. To prevent AWS ELB health check from connecting to the database, set the AWS ELB health check port to 22.

Deploying External S-TAP with AWS fails

To deploy External S-TAP with AWS, IAM user must have installed the following AWS EKS policies:

- AmazonEKSClusterPolicy
- AmzonEKSWorkerNodePolicy
- AdministratorAccess
- AmzonEKSServicePolicy
- AmzonEKS_CNI_Policy

Using External S-TAP with a single host

If you use External S-TAP on a Kubernetes cluster that has a single node (which can be the database), then you do not need a load balancing service. Instead of a load balancer, create a **NodePort** service and set the database connection to use the node hostname and **NodePort** for monitoring.

12.1 and later External S-TAP does not support sending early session resumption data

Certain databases such as Elasticsearch and CockroachDB can send session resumption data early during the Transport Layer Security (TLS) handshake instead of sending it after the TLS handshake is complete. External S-TAP currently does not support sending session resumption data early in the process so it cannot forward the session resumption data to the client. Due to this limitation, the UI displays an error and the session gets disconnected.

Guardium Installation Manager

You can use the Guardium® Installation manager (GIM) to install and maintain Guardium components on managed servers.

The GIM component includes a GIM server, which is installed as part of the Guardium system, and a GIM client, which must be installed on servers that host databases or file systems that you want to monitor. The GIM client is a set of Perl scripts that run on each managed server. After you install the GIM client, it works with the GIM server to perform these tasks:

- Check for updates to installed software
- Transfer and install new software
- Uninstall software
- Update software parameters
- Monitor and stop processes that run on the database server

For example, you can use GIM to install your S-TAP modules and keep them up-to-date.

The GIM client uses port 8444 to communicate with the GIM server.

You can use the GIM server through the Guardium user interface or through the command-line interface (CLI).

The software modules that you can deploy by using GIM are packaged as GIM bundles. A *bundle* is a file of type `gim` that contains software that can be deployed by using GIM.

If your environment includes a Guardium system that is configured as a central manager, you must decide which Guardium systems you want to use as GIM servers. You can either manage all of your GIM clients, up to 4000, from a single Guardium system, such as the central manager, or you can manage them in groups from the different Guardium systems. If you manage all of your GIM clients from a single Guardium system, then you can view the status of all the GIM clients and perform related tasks from that one UI. If you choose to manage your GIM clients in groups from separate Guardium systems, then you can use each UI to work with the GIM clients that it manages; no overall view is available. You can view each GIM client only from the Guardium system that functions as its GIM server.

To manage large numbers of GIM installations, you can create groups of GIM clients. Then, you can use the groups to install, update, and manage software bundles.

The GIM client monitors the processes that you install by using GIM. It checks the heartbeat of each process once each minute, and passes status changes for the processes to the GIM server. The status of each process is displayed on the Process Monitoring panel. Changes are reflected within three minutes. Changes to the status of the GIM client itself are reflected according to the interval at which the client polls the server and delivers its "alive message".

Note: When performing a system backup and restore from one server, which has GIM defined, to another server, then the user must configure a GIM failover to the restore server. This GIM configuration applies to a Backup Central Manager or a System backup and restore.

Creating and managing custom GIM certificates

You can replace the default Guardium®, privately signed, certificates with trusted CA certificates, without interrupting the GIM server to GIM client communication.

Before you begin

- All GIM clients must be running v11.0 or higher.

CAUTION:

Failure to upgrade the clients before you start this procedure complicates the certificate distribution process and can require substantial efforts to recover the GIM clients running earlier versions.

- Make sure that a GIM client is registered to the Guardium appliance.
- In adherence to the mutual Transport Layer Security (mTLS) mandate for Guardium Installation Manager (GIM) client-server communication, custom certificates must comply with the following best practices:
 - To ensure streamlined verification processes, certificates must not contain Subject Alternative Name (SAN) entries.
 - If Extended Key Usage (EKU) is used within the certificates, it is essential that they possess both serverAuth and clientAuth properties. This ensures comprehensive authentication capabilities for both server and client endpoints.

About this task

The GIM server-GIM client communication is secured by an encrypted channel and authentication. When you install GIM, it uses default Guardium certificates that are privately signed. Best practice is to install your own certificates from a trusted CA. In both cases, certificates are stored on the GIM server, and distributed to the GIM clients.

When you enable this feature, each GIM client downloads its new certificate, but continues to communicate with the GIM server by using its current certificate. After the new certificates are downloaded to all of the GIM clients, you then install a new certificate on the GIM server, and each GIM client starts by using the new certificate. The clients and their server do not lose any communication.

You can activate GIM listeners after the GIM certificates on the appliance has been changed. See [What to do next](#).

You can observe progress in the GIM Distributed Certificates report, and view GIM events in the GIM Events List report.

The pre-V11.0 method of deploying certificates is fully compatibility with this new method. If you want to deploy certificates by using your own applications, you can configure GIM to use these certificates by using the common GIM update parameters mechanism.

For authentication to succeed, all certificates must be signed by the same CA certificates (root, and intermediate if applicable), whether they are trusted or private.

Certificates expire at some point. Use the command **show certificate warn_expired** to view all expired certificates or certificates that expire within the next six months. When your certificates expire, perform this procedure again with the new certificates.

Procedure

1. Enable the GIM certificate distribution feature. On the central manager, in the GIM Global Parameter page, enter the GIM command:
gim_auto_certificate_distribution=1.
2. Open the Guardium GUI, and in your Dashboard, add the GIM Distributed Certificates Report so you can view progress.
3. Create GIM client certificates. If the Root CA did not change, you do not need to create a server certificate at all. If you are changing the Root CA, you need to create a server certificate, in steps [3.g](#), and [3.h](#).
 - a. Log in to Guardium CLI as CLI user.
 - b. Run **create csr gim client** to create a new CSR with the alias gim. Complete the details:
 - Common Name
 - Organizational Unit
 - Organization
 - City or Locality
 - State or Province
 - Two-letter country code
 - Encryption algorithm (Default: RSA)
 - Keysize (Default: 2048)
 - Subject Alternative Name (Optional)
 - c. Get the CSR signed by either a private CA or trusted CA. The Certificate needs to be in PEM format so that it can be imported into the Guardium appliance. Intermediate and root certificates must be appended.
 - d. Run **store certificate gim client <type>** to store the GIM client certificate into its own keystore, where <type> represents the mode of import:
 - **console**: Paste the Certificate to the console
 - **external**: Import the Certificate from an external location
 - e. If you entered **console** in [3.d](#), paste the end-entity and trusted CA certificates to the console, forming a trusted chain, then press Ctrl+D
 - f. If you entered **external** in [3.d](#), you are prompted to provide the location of where the certificate is stored, and possibly a password.
4. Check the GIM client status by one of:
 - a. Run the CLI command: **show certificate gim client console**. Verify that all intermediate (if applicable) and root certificates are concatenated.
 - b. Look at the GIM client states in the GIM Distributed Certificates report. They should change from Pending to Processing to one of:
 - If the root CA changed: Deployed. New certificates were downloaded but not actively used. The GIM client still uses its original certificates.
 - If the root CA was not changed: Deployed, then Active. New certificates were downloaded and are in use.
- If you're using a new CA for the new certificates, the GIM clients should be in the state Deployed. If you're using a new CA, continue with [5.e](#).
- If you're not using a new CA for the new certificates, the GIM clients should be in the state Active. If you're not using a new CA, continue with [5.f](#).
- If a GIM client remains in the state Processing (or N_A) after the alive cycle passes, the GIM client is either inactive or it cannot process its certificate. Contact Customer support.
5. If you're using a new CA for the new certificates, verify in the GIM Distributed Certificates report that all the client certificates are in the Deployed state.
6. If you're using a new CA for the new certificates, on the primary central manager, create and load the new GIM server certificate.
 - a. Run **create csr gim server** to create a new csr with the alias gim for the gim server certificate.
 - b. Get the GIM server CSR signed by the same CA certificate as used in step [3.c](#).
 - c. Run **store certificate keystore trusted console** to import the trusted CA certificates into the keystore.
 - d. Run **store certificate gim server console** to store the gim server certificate into the keystore. (You can also use the command **store certificate gim server external**. See step [3.f](#).
- Do not change the GIM server certification on the backup central manager.
7. Verify that the GIM Distributed Certificates report that all clients have the state 'ACTIVE' (meaning the clients are connected to the server by using new certificates). It can take up to one complete alive cycle before all clients are in their updated states.
8. If you're using a new CA for the new certificates, update the backup central manager with the new GIM server certificate.
 - a. Log in to the backup central manager.
 - b. Run **store certificate keystore trusted console** to trust and store the CA certificate that was used to sign the gim server certificate.

- c. Run **store certificate gim server console** to store the gim server certificate into the keystore. The root and intermediary certificates (if applicable) also need to be concatenated.
9. Verify in the GIM Distributed Certificates report that all the clients are in the Active state, whether you're using a new CA for the new certificates, or the original CA.

What to do next

You can add GIM clients after you replace the default GIM server certificate. The new GIM clients automatically retrieve the custom certificates in listener mode. Install the GIM client without specifying a collector's IP address (sqlguardip) to ensure it is in listener mode. Then activate the GIM clients. For more information, see [GIM remote activation](#). The certificates are streamed during activation. You can also check that the activated GIM client is listed in the GIM Clients report.

Replacing default GIM certificate with SHA1 or SHA256 certificate

You can replace the default SHA2 GIM certificates with SHA1 or SHA256 without interrupting the GIM server to GIM client communication.

About this task

The GIM server-GIM client communication is secured by an encrypted channel and authentication. When you install GIM, it uses default Guardium certificates that are privately signed. If the GIM client communication fails with the certificate that is installed by default, then you can replace GIM certificates with SHA1 or SHA256. The clients and the server do not lose any communication.

The following conditions must be met for the replace certificate command to work as expected:

- GIM uses default certificates that are privately signed.
- You are using the latest GIM bundle.
- You updated GIM and GIM CA certificates in Tomcat keystore to SHA1 or SHA256.

Procedure

1. To check the currently installed certificate, run the following command on the Guardium CLI.

show certificate gim server

You can see the details of the currently installed certificate.

2. To update the certificate to SHA1 or SHA256, run the following command and enter **y**.

replace certificate gim algorithm

USAGE:**replace certificate gim algorithm < default | default_sha1 >**, where 'default' represents SHA256 and 'default_sha1' represents SHA1 signature algorithm.

3. Restart the Guardium GUI after replacing the default certificate by using the following command.

restart gui

GIM server failover

You can define a backup GIM server. If a GIM client fails to connect to its GIM server after five consecutive attempts, the GIM client automatically connects to the failover server if it is specified.

When you install the GIM client, you specify the collector that GIM reports by using the GIM parameter GIM_URL. You can specify another collector for GIM client to fail over to in case primary collector goes down, with the GIM parameter GIM_FAILOVER_URL.

The GIM client reverts to its original GIM server when that server becomes available.

You can add the failover GIM server at any time by using the GIM parameter GIM_FAILOVER_URL.

The GIM server failover has no relationship to the central manager redundancy. The GIM parameter GIM_FAILOVER_URL is not copied or maintained in the backup central manager, so upon central manager switchover there is no defined GIM server.

Running GIM diagnostics

You can run diagnostics on GIM clients to verify that the GIM server has accurate data about each client.

About this task

If you experience trouble with a GIM client, your first step should be to verify that the GIM server has accurate data about that client. Running GIM diagnostics verifies that the modules listed for that client on the GIM server match the modules installed on that client, and that the parameters stored on the GIM client match those stored on the GIM server.

You can run GIM diagnostics either from the Guardium user interface or from the command line. To run from the command line, use this command:

```
grdapi gim_set_diagnostics clientIP=xx.xx.xx.xx
```

The value of clientIP can be either an IP address or a hostname. You must run the command on the Guardium® system that is the GIM server for this client. To run GIM diagnostics from the GUI, use this procedure:

Procedure

1. Use the check boxes next to each client to choose the clients for which you want to run GIM diagnostics.
2. Click Run diagnostics.

The next time that each client polls the GIM server for updates, it will receive the diagnostic command and run it immediately.

Results

You can review the results in the GIM_EVENTS report.

Enable/disable the GIM server log

You can enable the GIM server log to assist with troubleshooting.

Procedure

1. Log in to the CLI of the Guardium® system that the GIM clients point to.
2. Enable debug with the CLI command: **support store debug on GIM**
3. When you have gathered enough details, disable debug with the CLI command: **support store debug off GIM**

Results

The GIM server log is located on the appliance in: /opt/IBM/Guardium/log/gimserver.log

GIM server allocation

Remotely connect to a preinstalled and inactive (not connected to any collector) GIM agent and make it connect to some collector without the need to access the database server.

Overview

Use the following process (also called GIM auto-discovery) to remotely connect to a preinstalled and inactive GIM agent and make it connect to a collector without accessing the database server.

1. An inactive GIM client runs in listener mode and waits for a connection from any collector.
2. From the collector's graphic user interface (GUI) or the GuardAPI, you can send the IP address of any collector to the inactive GIM client.
3. The inactive GIM client accepts the collector's IP address and connects to it.

If GIM is installed without specifying a collector's IP address (--sqlguardip), it runs in listener mode. When the GIM agent is running in server mode, it accepts messages only from verified collectors over SSL that have certificate authentication and shared secret verification. After 30 (or more) consecutive authentication failures, the GIM agent stops listening for requests and runs in server mode. This action prevents denial of service (DoS) attacks.

You can define your own certificates, shared secret, and port number. To use other certificates, specify the certificate/key full path name in the installation parameters: --key_file and --cert_file. See also [Creating and managing custom GIM certificates](#).

To set a shared secret other than the default one, use the GuardAPI command **grdapi gim_set_global_param paramName=gim_listener_default_shared_secret paramValue=<password>**. The shared secret must be identical on the database server and collector.

Note: Do not specify the unencrypted shared secret in the command line.

To use a port other than the default one, specify the port in the installation parameter --listener_port. Set the GIM global parameter **gim_listener_default_port** with the new port in the GIM Global Parameters.

Note: The default or user-defined port must be enabled in the firewall.

Parameters

The following list describes the GIM installation parameters:

- `--sqlguardip` - Sets the collector IP address/hostname that the GIM client is connecting to. If it is not specified, the GIM client runs in "Listener mode".
- `--ca_file` - Full file name path to the certificate authority PEM file.
- `--key_file` - Full file name path to the private key PEM file.
- `--cert_file` - Full file name path to the certificate PEM file.
- `--shared_secret` - specify a shared secret to verify collectors.
- `--listener_port` - specify a port number that is different than the default.
- `--no_listener` - disables GIM from running in "Listener mode" even if `--sqlguardip` is not specified.

Taking any of the following actions causes the GIM agent to exit server mode and process the request.

- Update parameters
- Install modules
- Uninstall GIM directly on the database server

If the GIM client cannot connect to the designated collector, it returns to server mode. After the GIM agent is assigned to a valid collector's IP address or hostname, you cannot set the GIM server to run in server mode again. All new GIM agent server mode parameters appear as READ-ONLY.

Note: The following parameters must exist in the file system or the installation fails:

- `ca_file`
- `key_file`
- `cert_file`

Additional command-line parameter

GIM and Consolidated Installers for GIM have an additional command-line parameter:

`--allow_ip_hostname_combo <0|1>`

This command-line parameter sets the `GIM_ALLOW_IP_HOST_COMBO` GIM parameter. Enter `0` (the default) to disable, and `1` to enable.

When `--allow_ip_hostname_combo <0|1>` is enabled,

- If `GIM_CLIENT_IP` is different than the db server's hostname, `GIM_CLIENTS.GIM_CLIENT_NAME` is set to `hostname_<GIM_CLIENT_IP>`
- If `GIM_CLIENT_IP` is an IP address, the GIM hostname is set to `<hostname>_<GIM_CLIENT_IP>` This naming convention allows GIM clients to be unique across database servers with a common hostname.
- Restriction: You cannot set `GIM_CLIENT_IP` with a common hostname. Using a common hostname is considered as an attempt to register with a duplicate identifier.

Setting GIM in server mode global parameters

You can set up the server mode GIM parameters by using the following GuardAPI command:

```
grdapi gim_set_global_param  
paramName=gim_listener_default_shared_secret  
paramValue=<password>
```

This value is encrypted and stored in the database. The value must be identical to the unencrypted value as the shared secret if you install the GIM agent on the database server.

To set up a new default server mode GIM port, use the following GuardAPI command:

```
grdapi gim_set_global_param paramName=gim_listener_default_port paramValue=<port number>
```

This value must be identical to the unencrypted value of the shared secret if you install the GIM agent on the database server.

Note: If you use a different port or shared secret, you must specify the shared secret or port every time you connect the collector IP/hostname to the server mode GIM agent.

GIM remote activation

Use GIM remote activation to remotely connect to a preinstalled GIM agent and connect it to a collector without accessing the database server. To use GIM remote activation, browse to `Manage > Module Installation > GIM Remote Activation`.

Enter the following information:

1. Host name or IP address or Server group - You can either:
 - Enter the database IP address or host name where GIM is running in listener mode.
 - To activate a group of GIM clients in listener mode, select a server group from the list.Note: If the collector can use either IPv4 or IPv6 addresses, but this appliance supports IPv6 only, enter the IPv6 IP address to prevent errors.
2. GIM Listener Port - Enter the port number if it is different than the GIM Global setting. The default is `8445`.
3. GIM Listener Password - Enter the shared secret if it is different than the GIM Global setting.
4. Guardium hostname or IP address - Specify the hostname or IP address of the Guardium appliance where you want the GIM client to connect. If you leave this field blank, the GIM client connects to the Guardium appliance from which it was activated.
5. Click Submit to save your changes or Reset to exit without saving.

Note: You must either enter an IP address or hostname or select a server group, but the GIM listener port and GIM listener password (shared secret) are optional. When you install the GIM client in listener mode, you cannot change the settings of the shared secret and certificates unless you reinstall the GIM client.

Creating a GIM auto-discovery process

Create a GIM auto-discovery process to identify and associate GIM clients that are installed in listener mode. You can also activate GIM clients that are installed in listener mode by using [Deploy monitoring agents](#).

1. Navigate to Discover > Database Discovery > GIM Auto-discovery Configuration.
 2. Create a GIM auto-discovery process by clicking the  icon.
 3. In Process name, provide a name for the process and then click Apply.
 4. Define hosts to scan for GIM clients that were installed in listener mode using the Add hosts and ports to process section.
 - a. Identify a host or subnet to scan in Host(s). Wildcard characters are allowed. For example, to select all addresses that begin with 192.168.2, use **192.168.2.***.
 - b. To add the host or subnet to the GIM auto-discovery process, click Add scan.
 - c. Repeat the previous steps to define multiple hosts or subnets to include in the GIM auto-discovery process.
- Note:
- If you have a dual stack configuration, define scans for both the IPV4 and the IPV6 addresses.
 - Modify existing host or subnet scans by typing over the existing value and clicking Apply to save the changes.
 - Remove scans by clicking the  icon. If a task has scan results dependent upon it, the scan cannot be deleted.
5. Run the GIM auto-discovery process by clicking Run Once Now or define a schedule for running the process by clicking Modify Schedule. For more information, see [Scheduling](#).
 6. After the process has completed, click View Results to see a list of discovered GIM clients and associate those clients with Guardium systems.
 - a. Select the GIM clients to associate.
 - b. Click Associate to assign the clients to the current Guardium system or click Assign Collector to assign the clients to another Guardium system in your environment.
 - c. Use the Results dialog to review the status of client association. After you associate the GIM clients, the clients are no longer in listener mode and are not shown in the GIM Auto-Discovery Results Viewer window.
 - d. Click Close to close the results window.

GIM global parameters

Define your own shared secret or GIM listener port through the user interface.

1. To open the GIM Global Parameters, click Manage > Module Installation > GIM Global Parameters.
2. Select `gim_listener_default_shared_secret` to set the shared secret or `gim_listener_default_port` to set the port.
3. Click the  icon to edit the selected parameter.
4. Change the value and click Save to change the parameter or Close to return to the page.

Install, upgrade, and uninstall GIM clients on Linux-UNIX servers

Follow best practices when installing or upgrading GIM clients:

- Upgrade to the latest GIM client after upgrading the Guardium system.
- Replace the default GIM certificates with more secure custom certificates. For more information, see [Creating and managing custom GIM certificates](#).

Attention: Read the following information before installing Guardium 12.0 or later: [Updating Guardium Data Protection GIM clients with SHA256 certificates](#)

- [Installing the GIM client on a UNIX server](#)
Learn how to install the GIM client on Unix database servers.
- [Upgrading the GIM client](#)
You can use GIM to upgrade the GIM client to a newer version.
- [Uninstalling GIM and its modules on a UNIX database](#)
You can uninstall GIM and its modules either from the GUI, or on the database server itself.
- [Installing GIM and other packages on Linux servers by using the consolidated installer](#)
Use the consolidated installer to install the GIM client and other agents, such as the S-TAP, CAS, and FAM, on the database server, in a one-step process.
- [Managing GIM clients during a major upgrade of the database server operating system](#)
When you upgrade the operating system on your database server, use the GIM client to automatically upgrade itself and the GIM bundles (for example, GIM, S-TAP, CAS) installed on the Linux-UNIX database. However, most operating systems do not support a major upgrade, for example from RHEL7 to RHEL8.

Installing the GIM client on a UNIX server

Learn how to install the GIM client on Unix database servers.

Before you begin

Disk Space requirements

- Perl 5.8 (and up)
- 1GB of space to accommodate all GIM modules (including maintaining a copy of the previous and current installed versions). Without FAM, 300MB.

Port requirements

- **8445:** GIM client listener, both directions. Any GIM server on either the central manager or the collector can communicate with the GIM client.
- **8443:** (discovery) on the DB server to allow communication from the DB server to the Guardium appliance, and for uploading features.
- **8446:** Used between the GIM client and the GIM server (on the central manager or collector) for authenticated TLS, both directions, custom kernel upload, MustGather loggers upload. If `GIM_USE_SSL` is enabled (default), then the GIM client attempts to communicate its certificate by using port 8446. If port 8446 is not open, then it defaults to 8444, but no certificate is passed (for example, TLS without verification).

- 8081:** Used between the GIM client and the GIM server (on the central manager or collector) for non-TLS (but with message signing verification), both directions, custom kernel upload, MustGather loggers upload. In this scenario, the parameter GIM_USE_SSL must be disabled (=0).

About this task

You can install and use the GIM client in a Solaris slave zone or an AIX workload partition (WPAR). This enables you to use the GIM client to install an S-TAP in a slave zone or WPAR. When you install an S-TAP in a slave zone or WPAR, the K-TAP is disabled, regardless of the setting of the ktap_enabled parameter. You can also use the GIM client to install the Configuration Auditing System (CAS) agent in a slave zone or WPAR. You cannot install the discovery bundle in a slave zone or WPAR; the discovery agent running on the global zone can collect information from other zones. The process for installing the GIM client in a Solaris slave zone or an AIX workload partition is the same as the process for installing in the master zone. The installation can take a few seconds longer than installing in the master zone. If you install the GIM client on a Solaris system with master and slave zones, you must install the client in the same location on the master and slave zones. This location cannot be a shared directory. On Solaris, the GIM client and supervisor in each slave zone are controlled by the GIM supervisor process that runs in the master zone. If the supervisor process on the master zone is shut down, all GIM processes on the slave zones are shut down as well.

Table 1. Installation parameters

| Parameter | Description |
|--------------------------|---|
| dir | Target directory of the GIM client installation. |
| tapip | The IP address or FQDN of the database server or node on which the GIM client is being installed. |
| sqlguardip | The collector IP address/hostname that the GIM client connects to. If it is not specified, the GIM client installs in "Listener mode". |
| no_ssl | Use SSL to encrypt traffic between the GIM client and the Guardium appliance. <ul style="list-style-type: none"> 0: no 1: Use SSL to encrypt traffic between the agent and the Guardium system. This adds ~15% of CPU usage to the GIM client. Guardium® recommends encrypting network traffic between the GIM client and the collector whenever possible: only in cases where the performance is a higher priority than security should this be disabled. |
| perl | Path to perl script, for example: /usr/bin/ |
| ca_file | Full file name path to the Certificate Authority PEM file. |
| key_file | Full file name path to the private key PEM file. |
| cert_file | Full file name path to the certificate PEM file. |
| listener_port | Listener port for registration with appliance. Default = 8445. |
| shared_secret | Set the shared secret to verify collectors. |
| no_listener | Disables "Listener mode" even if sqlguardip is not specified. |
| install_customed_bundles | Allow GIM clients to install custom bundles. <ul style="list-style-type: none"> 0: no 1: yes |
| failover_sqlguardip | The IP address/hostname of the secondary collector with which this GIM client communicates. |
| allow_ip_hostname_combo | Enables GIM client uniqueness across database servers with "common" hostname. <ul style="list-style-type: none"> 0: no 1: yes <ul style="list-style-type: none"> If GIM_CLIENT_IP is an IP address, the GIM client hostname is a combination of the <hostname>_<GIM_CLIENT_IP>. If GIM_CLIENT_IP is set with an IP address and the GIM_ALLOW_IP_HOST_COMBO is enabled, GIM's hostname is a combination of the <hostname>_<GIM_CLIENT_IP>. This allows GIM clients uniqueness across database servers with "common" hostname. You can NOT set GIM_CLIENT_IP with a "common" hostname. This is considered as an attempt to register with a duplicate identifier. |
| auto_set_gim_tapip | When value set to 1, a local IP is automatically assigned. Do not specify both auto_set_gim_tapip and tapip when installing the GIM client. <ul style="list-style-type: none"> 0: no 1: yes Default value is 0. |

Note: Install the GIM client first on the master zone, then on the local.

Procedure

- Place the GIM client installer on the database server in any folder.
- Run the installer: `./installer_name` [-- --dir <install_dir> <--sqlguardip> <g-machine ip> --tapip <db server ip address> --perl <perl dir> -q]

The installer name has the syntax: guard-bundle-GIM-<release build>-<DB>-<OS>_<bit>.gim.sh, for example:

```
guard-bundle-GIM-10.5.0_r103224_v10_5_1-rhel-6-linux-x86_64.gim.sh
```

Attention:

- Omit the --sqlguardip parameter to install the client in GIM listener mode. Listener mode makes the GIM client available for remote registration from a Guardium system. For more information, see [GIM remote activation](#) and [Creating a GIM auto-discovery process](#).
- When cloning database servers and establishing large deployments, use --auto_set_gim_tapip to allocate a random IP address from one of the valid IP addresses of a database server. Do not specify both auto_set_gim_tapip and tapip when installing the GIM client. Update the GIM_AUTO_SET_CLIENT_IP parameter after GIM client installation by using [Manage Module Installation](#). Set up by Client.

- On Red Hat Linux, version 6 or later, run these commands to verify that the files have been added:

```
ls -la /etc/init/gim*
ls -la /etc/gsvr*
```

On Solaris, version 10 or later, run this command:

```
ls /lib/svc/method/guard_g*
```

On all other platforms, run these commands to verify that the following new entries were added to /etc/inittab:

```
gim:2345:respawn:<perl dir>/perl <modules install dir>/GIM/<ver>/gim_client.pl  
gsvr:2345:respawn:<modules install dir>/perl <modules install dir>/SUPERVISOR/<ver>/guard_supervisor
```

Where modules install dir is the directory where all GIM modules are installed, for example, /usr/local/guardium/modules.

4. Enter this command to verify that the GIM client, SUPERVISOR process, and modules are running:

```
ps -afe | grep modules
```

5. Log in to the Guardium system and check the Process Monitoring status.

Upgrading the GIM client

You can use GIM to upgrade the GIM client to a newer version.

Procedure

1. Upload the latest available BUNDLE-GIM.gim file to the Guardium® system.
2. Use the GIM GUI to schedule the installation of the new BUNDLE-GIM.gim file.
3. Monitor the installation process. Click the icon and then click Refresh. When the installation successfully completes the status displays as INSTALLED.

Uninstalling GIM and its modules on a UNIX database

You can uninstall GIM and its modules either from the GUI, or on the database server itself.

Procedure

1. To uninstall using the Guardium GUI.
 - a. Schedule an uninstall of the S-TAP bundle (Setup by Client).
 - b. Schedule an uninstall of the GIM bundle (Setup by Client).
 - c. Reboot the database server to remove K-TAP from the drivers.
2. Alternatively, uninstall on the DB server itself:
 - a. Uninstall both the GIM bundle and the S-TAP bundle by executing as root: **/full/path/modules/GIM/current/uninstall.pl**
 - b. Reboot the database server to remove K-TAP from the drivers.

Installing GIM and other packages on Linux servers by using the consolidated installer

Use the consolidated installer to install the GIM client and other agents, such as the S-TAP, CAS, and FAM, on the database server, in a one-step process.

Before you begin

Download both the GIM and S-TAP installation packages from [Fix Central](#), and optionally CAS and FAM bundles.

About this task

The consolidated installer is supported on:

- AIX, Solaris, Linux (Red Hat, Linux for System z)
- Guardium central managers
- Guardium stand-alone systems

Procedure

1. Use root access and create a directory on the database server.
2. Copy the shell installers for GIM bundles (for example, BUNDLE_GIM, BUNDLE_STAP, BUNDLE_CAS, BUNDLE_FAM) to the new directory.
3. Copy the script consolidated_installer.sh to the same directory and make sure that this script has the execute permission. (If not, then change it.)
4. Run the script.

```
./consolidated_installer.sh --installdir <install dir> --tapip <ip or hostname> --gim_sqlguardip <ip or hostname> --perl <perl dir> [--no_ssl] [--install_customed_bundles] [--failover_sqlguardip <ip or hostname>] [--allow_ip_hostname_combo <0|1>] [-auto_set_gim_tapip]
```
5. To also install BUNDLE_STAP, add the following parameters: --stap_sqlguardip <ip or hostname> [--load-balancer-ip <load_balancer_ip> --lb-app-group <app_group> --lb-mu-group <mu_group> --lb-num-mus <number_of_mus> --ktap_allow_module_combos --use_discovery <0|1> --privatetapip <tapip>]
6. To also install BUNDLE_CAS, add the following parameters: [--cas_sqlguardip <ip or hostname>] --javadir <java directory, excluding the /bin/java from the path>
7. To also install BUNDLE_FAM, add the following parameters: [--icm_url <icm url>] [--fam_port <fam port>] --fam_source_directories <comma delimited directories.no spaces allowed>
8. After the installation is complete with a successful message, check that the modules are installed on the database server, and that they are running. For example,

- ps -eaf | grep gim: to check the GIM module
 - ps -eaf | grep modules: to check the all modules
9. Verify that the modules are running. Go to Reports > Guardium Operational Reports > GIM Installed Modules, and verify that the modules are installed.
10. Go to Reports > Real-Time Guardium Operational Reports > GIM Events List, and verify status for each GIM bundle installation.

Results

First GIM is installed. GIM looks in the deploy folder for the files, and then installs the other packages, all in the /deploy directory. The S-TAP with all of its components is installed under the guardium installation directory along with the GIM.

Managing GIM clients during a major upgrade of the database server operating system

When you upgrade the operating system on your database server, use the GIM client to automatically upgrade itself and the GIM bundles (for example, GIM, S-TAP, CAS) installed on the Linux-UNIX database. However, most operating systems do not support a major upgrade, for example from RHEL7 to RHEL8.

Before you begin

The target upgrade GIM bundles must be available on the GIM server. The build number of each bundle must be the same or greater than the bundle that is installed. Download from [Fix Central](#).

About this task

This procedure is only relevant for databases whose operating system can be upgraded. If you cannot upgrade the operating system, you must uninstall the S-TAP, install the new operating system, and install the S-TAP bundle that is compatible with the newly installed operating system.

GIM bundles are OSType/OsVersion/Processor specific. When the OS version changes (for example, from RHEL7 to RHEL8), all the bundles need to be upgraded.

The GIM parameter auto_install_on_db_server_os_upgrade controls GIM's ability to auto-upgrade all bundles. If enabled, when the database server boots up after an operating system upgrade, GIM automatically downloads and install these bundles. This parameter is disabled by default, to prevent unintentional bundle upgrades.

If the parameter is disabled when you upgrade the database operating system, the GIM client detects that the operating system changed, and it changes the _x suffix of the version to _0. You can see the version in the Set up by Client, for example, 10.6.1.4_r123456_0. To resolve the mismatch between the GIM client and the database operating system, do one of:

- Enable the GIM global parameter auto_install_on_db_server_os_upgrade, which automatically upgrades all the GIM clients with the latest bundle of the operating system they support.
- Do not enable auto_install_on_db_server_os_upgrade, and upgrade the GIM clients manually.

It is best to update all your GIM-installed modules as soon as possible after the upgrade, whether manually or automatically. K-TAP is not loaded after an operating system upgrade.

Procedure

1. Log in to the CLI of the Guardium system that is the GIM server
2. Enable auto_install_on_db_server_os_upgrade by entering:

```
grdapic gim_set_global_param paramName="auto_install_on_db_server_os_upgrade" paramValue="1"
```

3. Upgrade the operating system on your database server.

Results

At first boot after OS upgrade, the GIM client recognizes that the operating system was upgraded and:

1. Changes the configuration files for all GIM-installed modules to support the new operating system attributes.
2. Registers all the modules to the GIM server with the updated attributes. This change triggers the GIM server to look for a bundle that has the same build number as the previously installed bundle, but is compatible with the upgraded operating system. If it does not find such a bundle, it looks for the latest bundles that

support the new operating system attributes. When the server finds appropriate bundles, it schedules them for upgrade and runs the upgrade process immediately. If the server cannot find appropriate bundles, it issues an error message.

3. Records an alert in the GIM_EVENTS report, that an operating system upgrade occurred and lists the actions that should be taken.

What to do next

Review the messages in the GIM_EVENTS report. If the GIM server reports that the modules were upgraded successfully, verify the proper operation of the modules as you would do after any update.

If error messages were written to the GIM_EVENTS report, indicating that the upgrade was not successful, review the error messages for guidance.

When the operating system upgrade is complete, disable the automatic update option on the GIM server to prevent a GIM client from erroneously starting an update process.

```
grdapi gim_set_global_param paramName="auto_install_on_db_server_os_upgrade" paramValue="0"
```

Install, upgrade, and uninstall GIM clients on Windows servers

Follow best practices when installing or upgrading GIM clients:

- Upgrade to the latest GIM client after upgrading the Guardium system.
- Replace the default GIM certificates with more secure custom certificates. For more information, see [Creating and managing custom GIM certificates](#).

Installing the GIM client on a Windows server

Learn how to install the GIM client for Windows by using either an interactive installer or a silent installation. Instructions are also provided for uninstalling the GIM client.

About this task

The Windows GIM client installer changed to a .NET based installer in v10.1. The installer for the GIM client is based on your GIM client version. Build numbers start from 10.2.30.5.

Port requirements

- **8445:** GIM client listener, both directions. Any GIM server on either the central manager or the collector can communicate with the GIM client.
- **8443:** (discovery) on the DB server to allow communication from the DB server to the Guardium appliance, and for uploading features.
- **8446:** Used between the GIM client and the GIM server (on the central manager or collector) for authenticated TLS, both directions, custom kernel upload, MustGather loggers upload. If GIM_USE_SSL is enabled (default), then the GIM client attempts to communicate its certificate by using port 8446. If port 8446 is not open, then it defaults to 8444, but no certificate is passed (for example, TLS without verification).
- **8081:** Used between the GIM client and the GIM server (on the central manager or collector) for non-TLS (but with message signing verification), both directions, custom kernel upload, MustGather loggers upload. In this scenario, the parameter GIM_USE_SSL must be disabled (=0).

Installing the GIM client with an interactive installer

A wizard is provided to help you install the GIM client on each database server.

About this task

You can specify a custom key, certificate, and CA file when you install the GIM client in both standard mode and in listener mode. For more information, see [Creating and managing custom GIM certificates](#).

Procedure

1. Place the GIM client installer on the database server, in any folder.
2. Run the setup.exe file to start the wizard that installs the GIM client.
The setup.exe file is located in the GIM-Installer-<version> folder.
3. Follow and answer the questions in the installation wizard.

What to do next

You can view the results of the installation in the log file at C:\IBM Windows GIM.ctl.

Installing the GIM client with silent installation

If you prefer, you can install the GIM client from the command prompt instead of the wizard.

Procedure

1. Place the GIM client installer on the database server, in any folder.
2. Open a command prompt and navigate to the GIM_Installer* folder under the folder where you placed the installer.
3. Enter the following command, with no line break:

```
setup.exe -UNATTENDED -INSTALLPATH "c:\Program Files(x86)\Guardium Installation Manager" -LOCALIP <GIM CLIENT IP> -  
APPLIANCE <Appliance IP>
```

Attention:

- The UNATTENDED and LOCALIP parameters are required. APPLIANCE is optional and if not supplied, triggers Listener Mode.
- Do not specify both AUTO_ASSIGN_IP parameter and LOCALIP.
- Omit the APPLIANCE parameter to install the client in GIM listener mode. Listener mode makes the GIM client available for remote registration from a Guardium system. Example of how to install as listener:
`setup.exe -UNATTENDED -INSTALLPATH "c:\Program Files(x86)\Guardium Installation Manager" -LOCALIP <GIM CLIENT IP>`
For more information, see [GIM Remote Activation](#) and [Create a GIM Auto-discovery Process](#).
- When cloning database servers and establishing large deployments, use auto_assign_ip 1 to allocate a random IP address from one of the valid IP addresses of a database server. Do not specify both auto_assign_ip and localip when you install the GIM client. When you update the GIM_AUTO_SET_CLIENT_IP parameter by using `ManageModuleInstallation`. Set up by Client, you must restart the GIM client service for the new setting to take effect.

Table 1. Parameters applicable to all .NET installers

| GIM parameter | Description |
|------------------|---|
| -UNATTENDED | Install silently. A value is not required. |
| -UNINSTALL | Uninstall. A value is not required. |
| -INSTALLPATH | The installation directory. The default installation path is "C:\Program Files (x86)\Guardium\Guardium Installation Manager". |
| -CUSTOMER | Change customer name. |
| -COMPANY | Change company name. |
| -SERVICEUSER | Specify a user to run the service under. |
| -SERVICEPASSWORD | The password for the user. |

Table 2. Parameters specific to GIM .NET installers

| GIM parameter | Description |
|-------------------|---|
| -APPLIANCE | To set the appliance address that GIM connects to. If not specified, GIM installs in Listener Mode. |
| -AUTO_ASSIGN_IP | When the value is set to 1, a local IP is automatically assigned. In this case, do not specify the local IP with -LOCALIP. Default value is 0 (do not auto-assign the IP address). |
| -CA_FILE | Set the CA file to non-default file. |
| -CERT_FILE | Set the certificate file to non-default file. |
| -INSTALLERLOGPATH | Specifies the location for storing the S-TAP installer log files. Use this parameter if you don't want to use the default location (C:). |
| -KEY_FILE | Set the key file to non-default file. |
| -LISTENER_PORT | If you do not use the -APPLIANCE parameter, then set the -LISTENER_PORT for registration with appliance. Default value is 8445. |
| -LOCALIP | The IP of the server where you are installing GIM. |
| -NO_SSL | Use SSL to encrypt traffic between the GIM client and the Guardium appliance. <ul style="list-style-type: none">• 0: Do not use SSL.• 1: Use SSL to encrypt traffic between the agent and the Guardium system. Using SSL adds ~15% of CPU usage to the GIM client. Guardium recommends that you encrypt network traffic between the GIM client and the collector whenever possible. Disable this parameter only when performance is a higher priority than security. |
| -SHARED_SECRET | Set a shared secret for registration with appliance if not specified by using -APPLIANCE parameter. |

What to do next

You can view the results of the installation in the log file at C:\IBM Windows GIM.ctl.

Uninstalling the GIM client

Procedure

1. Open a command prompt and navigate to the GIM_Installer* folder under the folder where you installed the client.
2. Enter the following command:

```
setup.exe -UNINSTALL
```

Installing GIM and other packages on Windows servers by using the consolidated installer

Use the consolidated installer to install the GIM client and other agents, such as the S-TAP, on the database server, in a one-step process.

Before you begin

Download both the GIM and S-TAP installation packages from [Fix Central](#).

About this task

Each agent installer package (WINSTAP, CAS, GAM) has a folder called Gim-Kits that contains a conf.reload.* and a signed file. The conf.reload files have the agent configuration parameters, which are the same as the parameters in the other installation packages. The conf.reload.* files need editing for your specific environment. The signed files do not need editing.

Procedure

1. Copy the GIM installer to the database server.
2. Create a folder called `deploy` in the GIM installer directory.
3. Examine the conf.reload.* files and make any configuration changes for the S-TAPs in your environment. For example, the sqlguard IP setting or the enterprise load balancing settings.
4. Customize the conf.reload.* files for all other packages you are going to install.
5. Copy all of the edited conf.reload files, and the SIGNED files, into the `deploy` folder that you created in step 2.
6. Install the GIM with the CLI, or the wizard on a Windows server. For example:
`setup.exe -UNATTENDED -AUTO_ASSIGN_IP 1 -APPLIANCE <IP>`
where APPLIANCE <IP> is the GIM Server.

Results

First GIM is installed. GIM looks in the `deploy` folder for the files, and then installs the other packages, all in the `/deploy` directory. The S-TAP is installed with all of its components, located under the `guardium` installation directory along with the GIM.

Starting and stopping the GIM client on a Windows server

Learn to start and stop the GIM client on a Windows server.

Procedure

1. Log on to the database server system using a system administrator account.
2. From the Services control panel, start or stop the IBM Security Guardium Installation Manager.

Managing GIM clients

Learn how to configure the GIM global parameters, how to simplify some GIM tasks by using groups of GIM clients, and learn about GIM dynamic updating.

- [GIM global parameters](#)
Define global parameters for GIM clients using the GIM Global Parameters page or the `gim_set_global_param` API.
- [Using groups with GIM](#)
You can use groups of GIM clients to simplify some GIM tasks.
- [GIM dynamic updating](#)
GIM clients check for updates from the GIM server at regular intervals. The GIM server can calculate the best polling interval to use based on system conditions.

GIM global parameters

Define global parameters for GIM clients using the GIM Global Parameters page or the `gim_set_global_param` API.

Define parameters using the GIM Global Parameters page

1. From the Guardium UI, open `Manage > Module Installation > GIM Global Parameters`.

2. Select a parameter and click the  icon.
3. Use the Global Parameter dialog to edit the selected parameter.
4. Click Save.

Define parameters using the `gim_set_global_param` API

1. From the Guardium CLI, run the API command:

```
grdapi gim_set_global_param paramName=<parameter name> paramValue=<parameter value>
```

Where `<parameter name>` and `<parameter value>` are replaced with parameter name and value being defined.

GIM global parameters

| Parameter name | Value type | Description |
|--|------------|--|
| <code>auto_install_on_db_server_os_upgrade</code> | Boolean | If enabled, automatically upgrade modules when the client operating system vendor version changes. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
For more information, see Linux®-UNIX: Managing GIM clients when upgrading your database server operating system , and Windows: Managing S-TAP when upgrading your database operating system . |
| <code>dynamic_alive_enabled</code> | Boolean | Controls the dynamic alive feature. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
For more information, see GIM dynamic updating . |
| <code>enable_secure_unauthenticated_communication</code> | Boolean | If enabled, allow unauthenticated GIM communication over a secure port: communication between the GIM client and server are encrypted with SSL on port 8444, but the communication is handled without using certificates for peer authentication. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
The <code>enable_secure_unauthenticated_communication</code> allows distributing new GIM client certificates when it is time to replace certificates. |
| <code>gim_auto_certificate_distribution</code> | Boolean | Controls automatic distribution of certificates to GIM clients. Valid values: <ul style="list-style-type: none"> • 0: disabled • 1: enabled Default = 0
For more information, see Create and manage GIM certificates . |
| <code>gim_file_upload_token</code> | string | Define the GIM file upload exchange token. |
| <code>gim_listener_default_port</code> | string | Define the GIM listener default port.
Default = 88445
For more information, see Gim server allocation . |
| <code>gim_listener_default_shared_secret</code> | string | Define the GIM listener encrypted shared secret.
For more information, see Gim server allocation . |
| <code>gim_quick_start_enabled</code> | Boolean | Controls the GIM quick start feature. Valid values: <ul style="list-style-type: none"> • 0: disabled • 1: enabled Default = 0 |

Using groups with GIM

You can use groups of GIM clients to simplify some GIM tasks.

About this task

You can create groups of GIM clients and use them to roll out updates to those managed servers.

Procedure

1. Open the group builder by navigating to Setup > Tools and Views > Group Builder.
2. Click  to open the Create new group dialog.
3. Define the group:
 - Enter a group description.
 - Application type: Public.
 - Group type: Client Hostname.Click Save.
4. To add members by filtering for GIM clients:
 - a. In the Members Tab, click Import and select From query.
 - b. In the Import by query tab, select a report name that begins with GIM, for example, GIM Client Status. The Client hostname drop-down appears.
 - c. In each Enter ... (Like) field, enter a value to be matched, or % to ignore this field when matching clients.
5. To add members individually, in the Members Tab, click , and enter clients by IP or hostname.
6. Click Save.

Results

You can use the group in the Manage > Module Installation > Set up by Client screen to work with this set of clients as a group rather than individually.

GIM dynamic updating

GIM clients check for updates from the GIM server at regular intervals. The GIM server can calculate the best polling interval to use based on system conditions.

Each GIM client sends an "alive" message to its GIM server regularly, to check whether any updates are ready to be processed. This polling interval is calculated and updated based on conditions at the GIM server. The interval is calculated regularly, and the new value is passed to the GIM client in response to its "alive" message. This feature is enabled by default, but you can turn it off if you prefer a fixed interval.

Dynamic updating is controlled by the Guardium API command **gim_set_global_param**, with these parameters.

dynamic_alive_enabled
Dynamic alive feature control. 1 – enabled, 0 – disabled. Default =1
dynamic_alive_check_interval
The interval, in minutes, at which the polling interval is recalculated. Default = 5

For example:

```
grdapic gim_set_global_param dynamic_alive_enabled=0
```

When each GIM client sends its alive message to the server, the server responds with the new polling interval as well as any other updates that have been scheduled for that client.

These parameters were valid in 10.0, and removed from 10.1 and higher:

- **dynamic_alive_default_load_factor**
- **dynamic_alive_cpu_level1_threshold**
- **dynamic_alive_cpu_level2_threshold**
- **dynamic_alive_db_conn_level1_threshold**
- **dynamic_alive_db_conn_level2_threshold**
- **dynamic_alive_cpu_load_sample_time**

Managing software with GIM

- **[Deploy monitoring agents](#)**
Use the Deploy Monitoring Agents tool to automatically activate GIM clients, install S-TAPs, and begin monitoring database traffic.
- **[Set up by Client](#)**
Quickly deploy S-TAPs and other software packages by using the GIM Set up by Client tool.
- **[Uploading and importing GIM modules](#)**
Use the Upload Modules page to upload, import, view, and delete GIM bundles and modules.
- **[Centralized module view](#)**
The Centralized module view is available from any GIM server and lists all bundles and modules present in a Guardium environment.
- **[Managing bundles by using the configurator.sh script](#)**
Use the configurator.sh script to list the installed modules and bundles that are managed by GIM, and to display and change any parameter for the bundles.
- **[GIM CLI commands](#)**
You can use the CLI to install and upgrade modules on the database server.
- **[GIM user interfaces](#)**
The purpose of GIM is to provide automatic installation capability for modules, taking advantage of a GIM client residing on each database server and a GIM server on the Guardium system.
- **[Distributing GIM bundles to managed units](#)**
You can distribute GIM bundles to managed units in order to deploy them on the GIM clients managed by those managed units.
- **[Removing unused GIM bundles](#)**
You can remove GIM bundles from your GIM server if they are no longer used on any database server.

Deploy monitoring agents

Use the Deploy Monitoring Agents tool to automatically activate GIM clients, install S-TAPs, and begin monitoring database traffic.

The deploy monitoring agents tool simplifies the process of establishing a Guardium deployment. Building on existing Guardium installation manager (GIM) infrastructure, the deploy monitoring agents tools helps you quickly find database servers, install monitoring agents (S-TAPs), and configure inspection engines for your databases. In addition, the tool provides a centralized view for tracking and reviewing deployment status.

Prerequisites

Review prerequisites and restrictions before you begin deploying monitoring agents.

Before using the deploy monitoring agents tool to install S-TAPs and configure inspection engines on your database servers, verify the following prerequisites.

The target S-TAP installation directory must be empty or not exist.

You cannot install an S-TAP into a directory that already contains any files.

Review S-TAP prerequisites

[Windows: Prerequisites: Installing S-TAP](#)

[Linux-UNIX: S-TAP installation prerequisites](#)

Install GIM clients in listener mode

Install GIM clients in listener mode on one or more database servers in your environment. To install the GIM client in listener mode on Windows systems, omit the `-host` parameter. To install the GIM client in listener mode on systems such as AIX and Linux, omit the `--sqlguardip` parameter. For more information about GIM listener mode, see [GIM server allocation](#).

Important: You may need to open a port between the GIM client on the database server and the Guardium system where you will run the deploy monitoring agents tool. The default port 8445 is used unless you specify a different port when installing the GIM client.

Upload GIM S-TAP modules to the Guardium system

Run the deploy monitoring agents tool as an administrative user from any Guardium system that is not configured as an aggregator. Before you begin, use the following procedure to upload GIM S-TAP modules to the Guardium system.

1. Navigate to Manage > Module Installation > Upload Modules.
2. Click Choose file and select the module you want to install.
3. Click Upload to upload the module to the Guardium system. After uploading, the module will be listed in the Import uploaded modules table.
4. In the Import uploaded modules table, click the check box next to the module you want to install. The module will be imported and made available for installation. After the module is imported, the Upload Modules page will reload and the module will no longer appear in the Import uploaded modules table.

For information about S-TAP offerings and supported platforms, see [System requirements and supported platforms for IBM Security Guardium](#).

Verify that all discoverable database servers are running

Inspection engines can be automatically configured for some databases, including the following:

- DB2 for Linux, UNIX, and Windows
- Informix
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL
- Sybase
- Teradata

To allow the auto-configuration of inspection engines, verify that databases servers are running before deploying monitoring agents.

For more information about automatically discovering database instances, see [Discover database instances: Windows: Discover database instances](#).

Deploying agents

Learn how to quickly deploy S-TAPs and configure inspection engines for monitoring database traffic.

Before you begin

Run the deploy monitoring agents tool as an administrative user from any Guardium system that is not configured as an aggregator. Verify the following before you begin:

- GIM clients are installed in listener mode.
- GIM S-TAP modules are imported to the Guardium system.
- Discoverable database servers are running.

For more information, see [Prerequisites](#).

Procedure

1. Open the deploy monitoring agents tool by navigating to Setup > Smart Assistant > Deploy Monitoring Agents.

2. In the Identify database servers section, use the IP addresses field to specify a range of IP address to search for GIM clients in listener mode.

Use the  icon to specify additional IP addresses. Include wildcard (*) or range (-) characters to expand the search. For example, 10.0.0-5.*. Use commas to separate complete IP addresses or ranges. For example, 9.70.145.165, 9.70.145-148.165, 9.70.145.*.

Important: Scanning a large number of IP addresses is time intensive and may time-out before the scan completes. Use the IP addresses fields to define a narrow range of IP addresses where you expect to find GIM clients in listener mode.

3. Click Discover to begin scanning for GIM clients in listener mode.

Tip: By default, the discovery of GIM clients and the deployment of monitoring agents (S-TAPs) is completed in two separate steps: discovery, then deployment.

This allows you to manually select the database servers where you want to install S-TAPs, as described in the following steps.

However, it is possible to streamline the process by automatically installing S-TAPs on all compatible GIM clients that are discovered while scanning IP addresses.

To enable the automated mode, click  to open the Customize settings dialog and select Automatically deploy agents on discovered database servers. When using the automated mode, after specifying the IP addresses to scan, simply click the Discover and Deploy button.

- In the Database server status section, select the database servers where you would like to deploy monitoring agents and click Deploy Agents to open the Configure monitoring agents dialog.
- From the Configure monitoring agents dialog, review and adjust the installation parameters. Click Deploy to begin installing monitoring agents. The default parameters should work well for most new deployments. However, you may want to adjust the following settings for your specific environment.

Windows installation directory

Specify an installation directory for S-TAPs deployed on Windows database servers. The parameter is ignored and default installation paths are used when deploying on other platforms. For more information about S-TAP installation parameters, see [S-TAP command line and GIM installation parameters](#) and [S-TAP install script parameters](#).

Assign a Guardium collector

Select Use enterprise load balancing to automatically assign S-TAPs based on the relative load or availability of Guardium collectors in a centrally-managed environment. For more information, see [Enterprise load balancing](#).

Select Specify collector to assign S-TAPs to a specific Guardium collector.

- In the Database server status section, use the S-TAP installation status column to monitor the progress of module installation. A status of **Installed** indicates successful and complete installation.

What to do next

If the S-TAP installation status of a database server is marked **Failed**, click the  icon to learn more about the problem. If a database server disappears from the Database server status after attempting to deploy monitoring agents, click Error log (if a log is available) to learn more about the problem.

Tip: The Error log captures issues related to the Deploy monitoring agents tool. For example, if Deploy monitoring agents cannot find a module required for installation, a message is added to the Error log. Other errors are recorded in component-specific logs and made available for investigation by clicking the  icon in the S-TAP installation status column.

After successfully deploying monitoring agents, you are ready to monitor traffic on your database servers and begin meeting security compliance requirements. To configure compliance monitoring, navigate to [Setup > Smart Assistant > Compliance monitoring](#) and see [Compliance monitoring](#) for more information.

Set up by Client

Quickly deploy S-TAPs and other software packages by using the GIM Set up by Client tool.

Before you begin

Before you use the Set up by Client tool, verify the following items:

- GIM clients are installed on database servers and connected to the Guardium system.
- Compatible GIM bundles are uploaded and imported to the Guardium system.

About this task

The Set up by Client page includes a column named Installed Version. If the version ends with _0, it means that the operating system on the database changed (as part of a system reboot). In this scenario, the GIM client also needs upgrading. In this situation, upload the GIM client bundle that supports the new OS to the Guardium system. Then do one of:

- Enable the GIM Global parameter auto_install_on_db_server_os_upgrade on the Guardium system that is the GIM client, which automatically upgrades all of the GIM clients with the latest bundle of the OS they support.
- Keep auto_install_on_db_server_os_upgrade disabled and do the upgrade yourself,

Procedure

- Go to [Manage > Module Installation > Set up by Client](#).
- In the Choose clients section, select the database servers where you want to install or update software using GIM. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients.

Attention:

- To create a client group, click  to open the Create client group dialog. Click Add Clients to open the Existing Clients window, select the clients, and click OK.
- To import clients from a CSV file. Click Import from CSV, and selecting your CSV file. Modify the field delimiter if relevant. Click Load to create a group of type Client Hostname, with Application type of Public. This group can be accessed and managed from the Group Builder.
- After you modify the client list, click  to update the display.
- Use Reset Connection to remove GIM client information from the Guardium system before reregistering the client. After clicking Reset Connection, it might take a few minutes before the status of the GIM client process is reflected.
- Select a client and click View Installed Modules. The View Installed Modules window shows all the modules that are installed on this client (including S-TAP), their versions, and if any module is in pending state for all the selected clients. (The module COMMON, if it appears, can be ignored.)
- When you create or update a group and edit the Client Name of GIM clients, the host name and address must reflect a valid value for a GIM client that is connected to the Guardium system. If an invalid host name is specified, the edited client does not appear as a member of the group. Adding clients by IP address is not supported.

Click Next to continue.

- In the Choose bundle section, use the Select a bundle menu to identify the software you want to install or update. Click Next to continue. After selecting a software bundle, the Selected bundle action column indicates the action that will be performed for each client:

Install

The selected bundle will be installed on the client. This action indicates a first-time installation of the software on the client.

Upgrade

The bundle will be upgraded on the client. This action indicates that an earlier version of the software is currently installed on the client.

Update parameters

The bundle parameters will be updated on the client. This action indicates that the selected software and the currently-installed software are the same version.

None (bundle not found)

No actions will be performed, indicating that there are no compatible actions on the client for the selected bundle.

None (newer version installed)

No actions will be performed because the selected bundle is older than the version that is currently installed on the client. To install an older version of software, first uninstall the current version.

The Available column indicates whether the selected software is available for installation from the GIM server. If the software is not available, click Import Bundles to upload and import the bundle or module.

Tip:

- You can filter the clients, for example, by name, module, Selected bundle actions, and client OS. The resulting selection is persistent; **the action is applied only to the filtered list of clients**. You can see that the number of clients in the Choose Clients section is greater than the number in Configure Clients section.
- Clear the Show only latest versions checkbox to view and work with earlier versions of a bundle.
- Clear the Show only bundles checkbox to identify individual modules within a bundle.
- Select the Show only compatible clients checkbox to hide clients that are not compatible with the selected bundle.

Attention:

- By default, the Select a bundle menu shows only the latest uploaded bundle version regardless of platform or compatibility with selected clients. To install a different bundle version for a specific platform or client, clear the Show only latest versions checkbox and select the required bundle.
- If you upload and import new bundles while working in the Set up by Client tool, refresh the browser to see the new bundles.
- If you have a bundle that is already scheduled for installation, installing a new bundle removes the existing schedule.

4. In the Choose parameters section, specify values for the required and optional parameters. Use the or icons to add or remove optional parameters. Use the icon to search for parameters by name or description. Click Next to continue.

Important: Unless identified as a client-specific parameter, values that are provided in the Choose parameters section are applied to all clients where the software will be installed, upgraded, or updated. For client-specific parameters, the value field is unavailable and values are defined per-client in the Configure clients section.

5. In the Configure clients section, use the table to review, and edit parameter values for each client.

Editable parameters show a icon next to the parameter value. Click the icon to edit the value. The Selected bundle action column shows the action that will be performed on each client.

6. Click Install to begin the software installation. Use the icon to schedule the installation, then click OK to continue.

7. To create the Guardium API syntax for the current configuration in the Setup by Client, click Generate GuardAPI. If enough information is available, it generates API commands for multiple clients in the GuardAPI commands dialog. If there isn't enough information, it shows a default template.

What to do next

In the Success dialog, click Show Status to open the Status window to monitor the software install/upgrade. Click to refresh the results. If an install/upgrade has a failed status, click Uninstall if you see the button, otherwise, click Reset connection.

If you see a Failed installation status for a bundle or module, open the Choose bundle section, select the client, click Uninstall, and use the icon to monitor the installation status. If the Uninstall button is not available, open the Choose clients pane, select the affected client, and click Reset connection. Use the icon to monitor the client list as the connection is reset.

Uploading and importing GIM modules

Use the Upload Modules page to upload, import, view, and delete GIM bundles and modules.

About this task

The Upload module page opens the list of all modules and bundles on the Guardium system, their status (imported or uploaded), their OS and version, and the date they were imported. You can modify the view by:

- Use the free text filter.
- Hide earlier versions of a bundle or module by checking Show only latest version in the table header.
- View the modules included in a bundle. Click next to a bundle name.
- Expand all bundles. Click Expand all modules in the table header.

Procedure

1. Go to Manage > Module Installation > Upload Modules.

2. To upload a module:

- a. Click to open the Upload module dialog.
- b. Click Browse and select a GIM bundle or module to upload.
- c. Click Upload.
- d. In the Confirmation dialog, select one of:
 - Import now: Imports the bundle or module and makes it available for deployment to GIM clients. The resulting status is *Imported*.
 - Import later: Does not import the bundle or module. The resulting status is *Uploaded*.

3. To import one or more bundles or modules, select each one and click Import

4. To delete a bundle or module, select it and click and click Yes to confirm.

Only bundles and modules that are not being used by a GIM client can be deleted. Deleting a bundle or module removes it both from the Upload Module table and from the file system.

Centralized module view

The Centralized module view is available from any GIM server and lists all bundles and modules present in a Guardium environment.

Open the view at Manage > Module Installation > Centralized Module View

Note: Only bundles and modules present on V11.2 and later systems are displayed.

The Centralized module view table supports the following actions:

- The GIM server column shows the total number of servers that have the bundle or module available locally.
- Use the  icon next to a bundle or module to show the specific servers that have it available locally.
- Use the Expand all modules button to expand and view all modules in all bundles.
- Select a bundle and click View modules in bundle to view the modules in the bundle and the servers where they are available.

Managing bundles by using the configurator.sh script

Use the configurator.sh script to list the installed modules and bundles that are managed by GIM, and to display and change any parameter for the bundles.

The configurator.sh script is installed with the GIM bundle on the database server, and is located in the UTILS folder.

The GIM and S-TAP clients do not need restarting after running this script.

The syntax is:

```
<GIM installation directory>/UTILS/current/files/bin/configurator.sh [--set <param name> <param value>| --get <module name> | -list | --delayed_bundle_deployment <enable|disable>
```

| Parameter | Description |
|------------------------------|--|
| delayed_bundle_deployment | <ul style="list-style-type: none">• <i>enable</i>: suspends any scheduled installations• <i>disable</i>: scheduled installations take place
Default = <i>disable</i> |
| get <module name> | Returns the value of all the parameters that are specified for the module. Modules are returned by the parameter list. |
| list | Lists all the GIM modules and their status. |
| set <parameter name> <value> | Set the module's parameter to the specified value. |

Examples:

- To list the GIM-managed modules and bundles, and their status:

```
/usr/local/IBM/modules/UTILS/current/files/bin/configurator.sh --list
[Wed Jan 20 08:58:56 2021] STAP-UTILS      11.1.0.11_r109779_1  INSTALLED

```

- To change the value of the GIM_URL parameter:
`/usr/local/IBM/modules/UTILS/current/files/bin/configurator.sh --set GIM_URL nn.nn.nn.nn`
- To disable any GIM upgrades from deploying:
`/usr/local/IBM/modules/UTILS/current/files/bin/configurator.sh --delayed_bundle_deployment enable`

GIM CLI commands

You can use the CLI to install and upgrade modules on the database server.

The following examples are presented only to cover some of the more common scenarios. For more information and a complete list of all supported CLI commands, see [Guardium Installation Manager \(GIM\) APIs](#).

- Loading module packages
- Upgrade or Scratch install by using bundles
- Uninstall a module or bundle
- Installation Status
- Querying modules state

Loading module packages

Before modules can be installed on DB server, they must be loaded onto the Central Manager GIM database. If a Central Manager is not part of the architecture, packages must be loaded onto each Guardium® system. Use the Load package option in the GIM UI to get the packages loaded to the database.

Upgrade or Scratch install by using bundles

Note: Scratch installation refers also to a case where old (pre-GIM) S-TAP is installed on the database server.

A bundle is a list of modules that are grouped for ease of installation. Always use bundles to install or upgrade modules.

1. Get the list of registered clients (database servers installed with GIM client that have registered with the GIM server):

```

grdapic gim_list_registered_clients
ID=0
##### ENTRY 0 #####
CLIENT_ID: 1
IP: 192.168.2.204
OS: HP-UX
OS_RELEASE: B.11.00
OS_VENDOR: hp
OS_VENDOR_VERSION: B.11.00
OS_BITS: 64
PROCESSOR: 9000
##### ENTRY 1 #####
CLIENT_ID: 2
IP: 192.168.2.210
OS: Linux
OS_RELEASE: 2.6.16.54-0.2.5-smp
OS_VENDOR: suse
OS_VENDOR_VERSION: 10.1
OS_BITS: 64
PROCESSOR: x86_64

```

2. Assign (prepare to install; NOT a request to install it on the client) the latest bundle available for a specific client:

```
grdapic gim_assign_latest_bundle_or_module_to_client clientIP=198.168.2.210 moduleName=BUNDLE-STAP
```

Note: To assign a specific bundle or module to a client, use this sequence:

```
gim_get_available_modules clientIP="client ip"
gim_assign_bundle_or_module_to_client_by_version clientIP="client ip" moduleName="Bundle/Module name"
moduleVersion="Bundle/Module version"
```

3. Schedule the installation.

```
grdapic gim_schedule_install clientIP=192.168.2.210 date=now
```

Note: For multiple client installation repeat steps 2-3.

Note: For flexible GIM scheduling, use now + [1-9][0-9]* minute | hour | day | week | month. Example: now + 1 day, now + 3 minutes

GIM scheduling

All time is relative to Guardium system time. Now means right now as specified by the Guardium system. Now +30 minutes is the current Guardium system time + 30 minutes. If the time on the database server has passed the time on the Guardium system that is specified for installation, then the installation begins.

Example one, set up three clients (a) set for Guardium system time - 1 hour, (b) set for Guardium system time, and (c) set for Guardium system time + 1 hour.

Set up an S-TAP installation by using GIM for "now +30 minutes".

Guardium system (a), which is already 30 minutes ahead of the time set for installation, installs immediately.

Guardium system (b) installs in 30 minutes.

Guardium system (c) takes another hour after (b) to install.

Example two - Same setup as example one but this time specify "now".

Installation status changes to IP immediately on all clients.

Uninstalling a module or bundle

```
grdapapi gim_uninstall_module clientIP=192.168.2.210 module=BUNDLE-STAP date=now
```

You can specify `date=now` or use the format of `YYYY-MM-DD HH:mm`. The uninstallation will take place the next time GIM client checks for updates (GIM_INTERVAL).

Installation Status

Additional information about the latest status the client sent can be retrieved by running the following command. (The status message appears as an entry in GIM_EVENTS table from which a report can be generated):

The general status message can be obtained by running the following CLI command:

```
grdapapi gim_get_client_last_event clientIP="client ip"
grdapapi gim_get_client_last_event clientIP=winx64
grdapapi gim_get_client_last_event clientIP=9.70.144.73
```

Sample output from this command:

```
ID=0
OK
BUNDLE-STAP-8.0_r2609_1 INSTALLED
STAP-UTILS-8.0_r2609_1 INSTALLED
COMPONENTS-8.0_r2609_1 INSTALLED
KTAP-8.0_r2609_1 INSTALLED
STAP-8.0_r2609_1 INSTALLED
TEE-8.0_r2609_1 INSTALLED
ATAP-8.0_r2609_1 INSTALLED
```

Querying modules state

To query the installed module's state per client, enter the following CLI command:

```
grdapapi gim_list_client_modules clientIP="client ip"
```

The following states are possible:

INSTALLED
Module is installed.

PENDING-INSTALL
Module is pending to be scheduled for installation.

PENDING-UNINSTALL
Module is pending to be scheduled for uninstallation.

PENDING-UPDATE
Module is pending to be scheduled for update.

IP
Module installation is in progress.

FAILED
Module's last operation failed.

IP-PR
Module requires client reboot to complete the installation process. Before rebooting, deactivate all A-TAP instances. Rebooting the database server is different per OS (Any other way of rebooting the system keeps the pending modules in a pending state).

- AIX: reboot
- Linux® shutdown -r
- SuSe: reboot
- HP-UX: shutdown -r
- Solaris: shutdown -i [6|0] (Note: '0' can be used only if shutdown is done from the terminal server)

Output example:

```
ID=0
##### ENTRY 0 #####
MODULE_ID: 11
NAME: INIT
INSTALLED_VERSION 8.0_r3852_1
SCHEDULED_VERSION 8.0_r3852_1
STATE: INSTALLED
IS_SCHEDULED: N
#####
ENTRY 1 #####
MODULE_ID: -1
NAME: COMMON
INSTALLED_VERSION 8.0_r0_1
SCHEDULED_VERSION 8.0_r0_1
```

```

STATE:           INSTALLED
IS_SCHEDULED:   N
##### ENTRY 2 #####
MODULE_ID:      12
NAME:            UTILS
INSTALLED_VERSION 8.0_r3852_1
SCHEDULED_VERSION 8.0_r3852_1
STATE:           INSTALLED
IS_SCHEDULED:   N
##### ENTRY 3 #####
MODULE_ID:      13
NAME:            SUPERVISOR
INSTALLED_VERSION 8.0_r3852_1
SCHEDULED_VERSION 8.0_r3852_1
STATE:           INSTALLED
IS_SCHEDULED:   N
##### ENTRY 4 #####
MODULE_ID:      14
NAME:            GIM
INSTALLED_VERSION 8.0_r3852_1
SCHEDULED_VERSION 8.0_r3852_1
STATE:           INSTALLED
IS_SCHEDULED:   N
##### ENTRY 5 #####
MODULE_ID:      15
NAME:            BUNDLE-GIM
INSTALLED_VERSION 8.0_r3852_1
SCHEDULED_VERSION 8.0_r3852_1
STATE:           INSTALLED
IS_SCHEDULED:   N

```

GIM user interfaces

The purpose of GIM is to provide automatic installation capability for modules, taking advantage of a GIM client residing on each database server and a GIM server on the Guardium® system.

Users may also interact with GIM through the CLI. See [GIM CLI commands](#) for information on installing and upgrading modules with GIM using CLI.

You can use the GUI of the Guardium Installation Manager (GIM) for these tasks:

- Process Monitoring
- Upload Module Package
- Configure, Install, or Update Modules
- Rollback Mechanism

Note: If A-TAP is being used, A-TAP must first be disabled on the database server before performing a GIM-based S-TAP upgrade or uninstall.

Note: GIM does not support the installation of native S-TAP installers (rpm, dept, bff, etc.)

Note: Installation of modules on a specific client for the FIRST TIME using the GIM utility must be in the form of a BUNDLE. Future upgrades of specific modules which are part of the installed bundle can be either as single modules or bundles.

GIM Processes

- Supervisor: The GIM Supervisor is a process with the main purpose of supervising and monitoring Guardium processes. Specifically, it is responsible for starting, stopping, and making sure all of Guardium processes are running at all times, and restarting them if they fail.
- GIM: The GIM process is the GIM client process, which is responsible for such duties as registering to the GIM server, initiate a request to check for software updates, installing the new software, updating module parameters, and uninstalling modules.

Commands for starting and stopping services are listed in [Linux-UNIX: Start and stop S-TAP and GIM processes for various OS types/versions](#).

GIM Processes Monitor page

This page displays the status of GIM processes on servers. You can filter for: up, down, unknown; or use the free text filter.

Configure, Install, or Update Modules

For information about the latest GIM software management tool, see [Set up by Client](#).

Windows S-TAP Parameters in GIM

During S-TAP installation, or to update the S-TAP configuration, you can use the WINSTAP_CMD_LINE field in the Setup by Client page.

You can input any parameter in the Setup by Client page, in the Choose parameters row, using the command WINSTAP_CMD_LINE with the syntax **parameter=value** for [TAP] parameters, or CLI parameters ([Windows: S-TAP command line installation parameters](#)) with the syntax **-param value**, and it is added or updated in the guard_tap.ini.

CAUTION:

There is no validation of input to this field.

For example, the following command line options skip the installation of CAS and Named Pipes support.

```
CAS=0 NamedPipes=0
```

If you are installing an S-TAP and you do not want it to automatically discover MSSQL databases, type **START=0** in the **WINSTAP_CMD_LINE** column to prevent the S-TAP from starting when it is installed. You can also specify this parameter for a single database server by using the GIM API:

```
grdapic Gim_update_client_params clientIP=xx.xx.xx.xx paramName=WINSTAP_CMD_LINE paramValue="START=0"
```

Additional guard_tap.ini parameters may also be set at installation. An example is **paramValue="START=1 !client_timeout_sec=120&use_tls=1!"**

Note: When using GuardAPI commands, the **WINSTAP_CMD_LINE** **paramValue** should be quoted and each parameter separated by spaces, such as **paramValue="START=1 CAS=0"** as in the prior example. A lack of spaces can cause the subsequent installation to not complete as anticipated.

Rollback Mechanism

GIM's rollback mechanism purpose is to handle errors during installation and recover modules to their prior state. The Rollback mechanism supports the following recovery scenarios:

1. Live Upgrade Recovery

For Bundles

- When bundles are installed, recovery will rollback the modules that have an install failure within the bundle.
- Modules that are marked as **NO_ROLLBACK** (in the form of a read-only parameter <MODULE>_NO_ROLLBACK=1) will not be rolled back in the event of a failure. S-TAP/KTAP are two such modules that once successfully installed will not be rolled back in the event of a failure of another module.

For non-Bundles

- Rollback entails the removal of the standalone module in the case of a scratch install or reverting back to the previous version in case of an upgrade.

2. Boot Time Installation Recovery

If installation failure occurs during a system reboot, a second system reboot will be needed in order to complete the recovery. Users will still see the status IP-PR after reboot, and a GIM_EVENT entry that indicates a second reboot is needed to complete the recovery process. The module/bundle state will then indicate a "FAILED" status after the second reboot.

Note: When the status is 'IP-PR' booting the DB-server is different per OS (Any other way of rebooting the system will keep the pending modules in a pending state):

```
Linux   : shutdown -r
SuSe   : reboot
HP     : shutdown -r
Solaris : shutdown -i [6|0]  (Note : '0' can be used only if shutdown is done from the terminal server)
AIX    : reboot
Tru64  : reboot
```

Note: In addition, prior to reboot, A-TAP instances must be disabled/deactivated.

Distributing GIM bundles to managed units

You can distribute GIM bundles to managed units in order to deploy them on the GIM clients managed by those managed units.

About this task

If you manage all your GIM clients from your Central Manager, you can deploy bundles to all your GIM clients directly from the Central Manager. If you manage groups of clients from several managed units, you can distribute GIM bundles from your central manager to those managed units.

The time required for distribution depends on the size of the bundles and network conditions. In a network with substantial latency, transfers can take several hours.

Procedure

1. Copy the bundles that you want to distribute into the **/var/gim/dist_packages** directory on your Central Manager. All files in this directory will be distributed; you cannot select which bundles you want to distribute.
2. Choose the managed units to which you want to distribute the bundles.
3. Click Distribute GIM bundles.

The bundles are copied to the selected managed units.

Results

You can install the bundles from each managed unit to the GIM clients that it manages.

Removing unused GIM bundles

You can remove GIM bundles from your GIM server if they are no longer used on any database server.

About this task

This function enables you to maintain your inventory of GIM bundles and prevent it from using disk space unnecessarily.

You can use two new Guardium API commands to identify and remove unused GIM bundles. Perform this procedure on each Guardium system that acts as a GIM server.

Procedure

1. Run the **gim_list_unused_bundles** command to identify unused bundles for FAM install. Use the **includeLatest** parameter to indicate whether you want the list that is returned by the command to include the latest version of each GIM bundle. You might have some bundles that you have not yet distributed, or you might want to

keep one older version so that you can reinstall it if needed. Set includeLatest to 0 to exclude the latest unused version of each bundle from the command results. Set it to 1 to include all unused versions. This parameter is required and no default value is provided. For example:

```
gim_list_unused_bundles includeLatest=0
```

The command returns a list of GIM bundles that are found on the GIM server but are not installed on any database server whose GIM client works with this GIM server.

2. If step 1 identifies some unused bundles, use the **gim_remove_bundle** command to remove each unwanted bundle. This command takes a single parameter, bundlePackageName, which identifies the bundle to be removed. This parameter is required and no default value is provided. Use names that are returned by the **gim_list_unused_bundles** command.

The named bundle is removed only if:

- The name specified in bundlePackageName matches the name of one and only one specific GIM bundle.
- There is no GIM bundle whose name matches bundlePackageName installed on any database server whose GIM client works with this GIM server.

For example:

```
gim_remove_bundle bundlePackageName=name
```

where name is a bundle name that was returned by the **gim_list_unused_bundles** command.

Results

GIM bundles that are not needed are removed from your GIM server.

Starting and restarting GIM services and components

- [Restarting the supervisor for Solaris with SMF support](#)

Use a set of CLI commands to restart the supervisor on Solaris servers with SMF support.

Restarting the supervisor for Solaris with SMF support

Use a set of CLI commands to restart the supervisor on Solaris servers with SMF support.

About this task

To restart the supervisor, complete the following procedure. Only use this procedure on Solaris servers with SMF support.

Procedure

1. Stop the supervisor by running the command **svcadm -v disable guard_gsvr**.
2. Run the command **svccfg delete -f guard_gsvr**.
3. Restart the supervisor with the command **svccfg import <gim install dir>/SUPervisor/current/guard_gsvr.xml** where **<gim install dir>** is the file path to the GIM installation directory.

Results

The supervisor is restarted for Solaris with SMF support.

Installing your Guardium Data Protection system

This document details the steps necessary to install and configure your IBM® Guardium system.

This document also provides information on how to customize the partitioning on the appliance and how to install on a remote drive (SAN).

The steps are:

1. Assemble configuration information and the hardware required before you begin.
2. Set up the physical appliance or the virtual appliance.
3. Install the Guardium image.
4. Set up initial and basic configurations.
5. Verify successful installation.

The IBM Guardium solution is available as:

- Hardware offering – a fully configured software solution delivered on physical appliances provided by IBM.
- Software offering – the solution delivered as software images to be deployed by the customers on their own hardware either directly or as virtual appliances.

The requirements listed in this document apply to the installation of both the physical appliance and the virtual appliance unless specified otherwise.

- [Operating modes](#)

You can deploy a Guardium system in any of several operating modes.

- [License keys](#)

Establishing a functional Guardium system requires both a base license and one or more append licenses.

- [Hardware Requirements](#)
Detailed hardware requirements and sizing recommendations are available on the IBM Support Portal.
- [Guardium port requirements](#)
Each Guardium system must have ports available for several types of communication. This section lists these connections and the default port numbers that are assigned to them.
- [Step 1. Assemble the following before you begin](#)
To prepare for the deployment of the Guardium system, the network administrator needs to supply the following information.
- [Step 2. Set up the physical or virtual appliance](#)
The setup instructions in this section are different when installing to a physical appliance or a virtual appliance.
- [Step 3. Install the Guardium image](#)
This section explains how to install the image and partition the disk.
- [Step 4. Set up initial and basic configuration](#)
The initial step should be the network configuration, which must be done locally through the Command Line Interface (CLI) accessible through the serial port or the system console.
- [Step 5. What to do next](#)
This section details the steps of verifying the installation, installing license keys, and installing any available maintenance patches.
- [Creating the Virtual Image](#)
Use this section to install the virtual image.
- [Custom Partitioning](#)
If you customize the partitioning of the hard drive, you must make several choices.
- [How to partition with an encrypted LVM](#)
If you use an encrypted disk, create an encrypted LVM volume that contains the / and /var logical volumes.
- [Create an LVM disk with four disks](#)
- [Example of SAN Configuration](#)
This appendix details the steps involved in moving to a command prompt in order to pre-partition a hard drive (as is needed for SAN installation).

Operating modes

You can deploy a Guardium® system in any of several operating modes.

As you plan your Guardium environment, you might deploy systems in any or all of these operating modes:

Collector

A collector receives data about database activities or file activities from agents that are deployed on database servers and file servers. The collector processes this data and responds according to policies that are installed on the collector. A collector can export data to an aggregator.

Aggregator

An aggregator collects data from several collectors, to provide an aggregated view of the data. The aggregator is not connected directly to database servers and file servers. You can allocate collectors to aggregators according to location or function. For example, you might want to connect the collectors that monitor your human resources database servers to a single aggregator, so that you can view data that is related to all those servers in one location. If you want, you can implement a second tier of aggregation by deploying an aggregator that collects data from all your other aggregators, rather than from collectors.

Note: If you plan to use the appliance as a central manager you MUST select Aggregator option.

Central manager

There is only one central manager in a Guardium environment, although you can designate another Guardium system as a backup central manager. You can use the central manager to define policies and distribute them to all collectors, to perform other configuration tasks that affect all your Guardium systems, and to perform various other administrative tasks from a single console. Your central manager can also function as an aggregator, collecting data from collectors or from other aggregators. This model provides an enterprise-wide view of activities and enables you to view reports that are based on data that is aggregated from all your Guardium systems.

The number of monitored database servers and file servers that you assign to a collector depends on the amount of data that flows from the servers to the collector. For information about how many collectors and aggregators your environment requires, and how to locate your Guardium systems for best results, refer to the [Deployment Guide for IBM® Guardium](#).

If you are using the Guardium Vulnerability Assessment component, you must decide where to run assessment tests. Some customers dedicate a separate Guardium system for this function. You can also run tests from any Guardium system that is deployed as a collector, an aggregator, or a central manager.

License keys

Establishing a functional Guardium® system requires both a base license and one or more append licenses.

Base and append licenses are described as follows:

- Base license keys (also known as reset keys) reflect the machine type of the system. For example, establishing collector system requires a collector base license.
- Append license keys enable specific sets of features. For example, typical data activity monitoring features require a DAM Standard append license. Multiple append licenses can be installed in combination to enable expanded Guardium functionality.

When applying a base license, the machine type is checked to verify compatibility. There are two types of base licenses:

Table 1. Base license types

| Base License Type | License Description |
|-------------------|---|
| Collector | Collector base licenses are valid for establishing a standalone system or a collector. |
| Aggregator | Aggregator base licenses are valid when establishing an aggregator or a central manager system. |

The features available on your Guardium system depend on the append license(s) you have installed. The following append licenses are available and can be used in combination:

Table 2. Append license types

| Append License Type | License Description |
|---------------------|---------------------|
|---------------------|---------------------|

| Append License Type | License Description |
|---------------------|---|
| DAM Standard | Core functionality for data activity monitoring. |
| DAM Advanced | DAM Standard functionality plus fine-grained access control, masking, quarantine, and blocking (activity terminate). |
| FAM Standard | Core functionality for file activity monitoring. |
| FAM Advanced | FAM Standard functionality plus blocking. |
| VA Standard | Vulnerability assessment plus database protection service (DPS), change audit system (CAS), and database entitlement reporting. |

For information about installing Guardium licenses, see [Install license keys](#).

Related tasks

- [Install license keys](#)

Hardware Requirements

Detailed hardware requirements and sizing recommendations are available on the IBM Support Portal.

For detailed hardware specifications and sizing recommendations, refer to [Hardware requirements](#).

Guardium port requirements

Each Guardium® system must have ports available for several types of communication. This section lists these connections and the default port numbers that are assigned to them.

Open ports

Ports that are used in or by the Guardium system.

DB Server – Collector

- TCP 8443 - open from DB server to collector
- TCP 16016 – UNIX STAP, both directions, registration, heartbeat, and data (including IBM i S-TAP running in PASE)
- TCP 16017 – Windows/Unix CAS, both directions, templates and data
- TCP 16018 – UNIX S-TAP (TLS) and External S-TAP, both directions, registration, heartbeat, and data
- TCP 16019 – Windows/Unix CAS (TLS), both directions, templates and data
- TCP 16020 - From S-TAP agent Clear UNIX S-TAP connection pooling
- TLS 16021 - From S-TAP agent Encrypted UNIX S-TAP connection pooling
- TCP 8081 – Guardium Installation Manager, both directions, database server to collector/Central Manager
- TCP 9800 – Windows S-TAP using protocol 8, both directions, DB Server to Collector, S-TAP registration and data
- TCP 9801 – Encrypted (TLS) Windows S-TAP using protocol 8, both directions, DB Server to Collector, S-TAP registration and data

Collector – Aggregator (Secure Shell – SSL)

- TCP 22 – collector to aggregator, SCP data exports, both directions

Central Manager – Managed Devices

- TCP 22 – SSH/SCP data transfers, both directions
- TCP 8443 – SSL, both directions
- TCP 8444 – SSL, STAP to GIM file upload
- TCP 3306 – MySQL, opened to specific sources (for instance, the Central Manager is open to all managed units; a managed unit is open to the Central Manager)
- TLS 8447 - Used for remote messaging service infrastructure (and profile distribution infrastructure) for communication between Guardium systems in the federated environment / centrally-managed environment. Configuration profiles allow the definition of configuration and scheduling settings from a Central Manager and conveniently distribute those settings to managed unit groups without altering the configuration of the Central Manager itself.
- TCP 8983 –Apache Solr Index. Used for establishing communication between the Central Manager and every Managed Unit, as well as between each Managed Unit and the Central Manager that is required in default mode. Communication between all the Managed Units is required only in the 'all machines' mode.
- TCP 9983 –Apache Solr Index. Establish communication in between Managed Units and Central Manager. Both directions.

File Activity Monitoring (FAM), on the unit where it is installed. (Bidirectional means data can be sent or received in both directions once connection is established.)

- TCP/TLS 16022/16023: Universal Feed. 16022 (FAM monitoring, unencrypted) and 16023 (FAM monitoring, encrypted) both need to be open bidirectionally.
- 16016 to 16023: These ports must be open bidirectionally for the sniffer. The connection is made from the S-TAP to the sniffer (sniffer does not initiate the connection); listening ports are on the sniffer side only.
- 18087: Listener port for FAM on IBM Content Classification (ICM) server located on the same machine where FAM is installed.
(serverSettings.icmURL=http://localhost:18087) Open bidirectionally.

Guardium Installation Manager (GIM)

- 8445 - GIM client listener, both directions. The GIM client is doing the listening. Any GIM server on either the Central Manager or the collector can reach out to it the GIM client.
- 8446 - GIM authenticated TLS, both directions. Use between the GIM client and the GIM server (on the Central Manager or collector). If GIM_USE_SSL is NOT disabled, then the gim_client will attempt to communicate its certificate via port 8446. IF port 8446 is NOT open, then it defaults to 8444, BUT no certificate is passed (for example, TLS without verification).
- 8081 - TLS - To use 8081 for the GIM client to connect to the GIM server, there is a need to disable the GIM_USE_SSL parameter - it is ON by default. This parameter is part of the GIM common parameters in the GUI. If GIM_USE_SSL is NOT disabled, then the gim_client will attempt to communicate its certificate via port 8446. IF port 8446 is NOT open, then it defaults to 8444, BUT no certificate is passed (for example, TLS without verification).

Enterprise load balancer

- TLS 8443 - S-TAP load balancer - This is needed for UNIX/Linux S-TAPs to communicate instances to the collector. However this port is also used for the Central Manager load balancer. The S-TAP initiates a request to central manager (load balancer) on 8443 sending HTTPS message, if installation indicates to use Enterprise load balancer. Between the database server and central manager, there will be the capability to use a proxy server, if customer doesn't want an open port directly from database to central manager.

User Interface - Guardium System (standalone, aggregator, central manager)

- TCP 22 - user to system, CLI connectivity, both directions
- TCP 8443 - user to system, GUI connectivity (configurable), both directions, sending discovered instances to the UI
- 8445 - TLS. Bidirectional port to connect to a file server.

System – SMTP server

- TCP 25 – system to SMTP server, email alerts

System – SNMP server

- UDP 161 - SNMP client to system – SNMP Polling
- UDP 162 - system to SNMP server, SNMP traps

System – SYSLOG server

- UDP/TCP 514 – remote syslog message from/to other systems, typically SIEM
Note: The local port is 514, but the remote port must be entered into the configuration. If encryption is used, the protocol must be TCP, not UDP.

System – NTP server

- UDP 323 – system to Network Time Protocol Server

System – DNS server

- TCP/UDP 53 – system to Domain Name Server

System – EMC Centera (backups)

- TCP 3218 – system to EMC Centera

System – Tivoli LDAP

- UDP 389 – system to/from Tivoli LDAP

System – Mainframe

- TCP 16022 – connects S-TAP to DB2 z/OS, S-TAP IMS, S-TAP VSAM (S-TAP Data Set)
- TCP 16023 - TLS connections, specifically IBM's Application Transparent Transport Layer Security (AT-TLS)

Outbound ports to monitor Azure streaming

The following ports must be open to support IPv4 connections to Azure services.

| Port | Protocol | Purpose |
|------------|----------|-----------------|
| 443 | SSL | Azure Namespace |
| 5671, 5672 | AMQP | Azure Namespace |
| 443 | SSL | Azure Storage |

Outbound ports to monitor AWS streaming

The following ports must be open to support IPv4 connections to AWS.

| Port | Protocol | Purpose |
|------|----------|--|
| 443 | SSL | AWS Kinesis, AWS DynamoDB, AWS CloudWatch, and AWS KMS |

Ports for connections to Windows database servers

| Port | Protocol | Purpose |
|-------|----------|--|
| 9500 | TCP | Clear Windows S-TAP |
| 9501 | TLS | Encrypted Windows S-TAP (optional) |
| 16017 | TCP | Clear Windows CAS |
| 16019 | TLS | Encrypted Windows CAS (optional) |
| 9800 | TCP | Windows S-TAP using protocol 8, both directions, DB Server to Collector, S-TAP registration and data |
| 9801 | TLS | Encrypted (TLS) Windows S-TAP using protocol 8, both directions, DB Server to Collector, S-TAP registration and data |

Default ports used for Guardium Application Access

| Port | Protocol | Purpose |
|------|----------|---------|
| | | |

| Port | Protocol | Purpose |
|------|----------|--|
| 8443 | TCP | <p>The port is used for:</p> <ul style="list-style-type: none"> • Web browser access (https) to the Guardium user interface. • Registering a managed unit to a central manager. • Checking connectivity between aggregators or central managers and collectors. <p>Note: Change this port using the HTTPS Port setting available at Setup > Tools and Views > Portal.</p> |
| 22 | TCP | SSH access from clients to manage the Guardium appliance |
| 3306 | TCP | Communication between central manager and managed units |

Ports for connections to z/OS database servers

| Port | Protocol | Purpose |
|-------|----------|---|
| 16022 | TCP | Connects to S-TAP for DB2 z/OS, S-TAP for IMS, S-TAP for Data Sets |
| 16023 | TCP | TLS connections, specifically IBM's Application Transport Layer Security (AT-TLS) |
| 41500 | TCP | Default starting port for internal message logging communications – LOG_PORT_SCAN_START |
| 39987 | TCP | Default agent-specific communications port between the agent and the agent secondary address spaces – ADS_LISTENER_PORT |

Default ports used for other features

| Port | Protocol | Purpose |
|--------------|----------|---|
| 20, 21 | TCP | FTP Server for backups/archiving (optional) |
| 22 | TCP | SCP for backups/archiving, patch distributions, and file-transfers |
| 25 | TCP | SMTP (email server) for alerts and other notification |
| 53 | TCP | DNS Servers |
| 123 | TCP, UDP | NTP (Time Server) for time synchronization |
| 161 | TCP, UDP | SNMP Polling (optional) |
| 162 | TCP, UDP | SNMP Traps (optional) |
| 389 | TCP | LDAP, for example, Active Directory or Sun One Directory |
| 443 | TCP | Default outbound port from External S-TAP® GUI to Kubernetes API |
| 514 | TCP | Syslog Server (optional) |
| 636 | TCP | LDAP, for example, Active Directory or Sun One Directory over SSL (optional) |
| 1500 | TCP | Tivoli Storage Manager backup hosts (optional) |
| 3218 | TCP, UDP | EMC Centera backup hosts (optional) |
| user-defined | TCP | Database Server listener ports, for example, 1521 for Oracle or 1433 for MS-SQL, for Guardium datasource access (optional). Use this port for S-TAP verification and Discovery. |
| 16022/16023 | TCP/TLS | Universal Feed - File Activity Monitoring (FAM0) |
| 18027 | | FAM using IBM Content Classification locally (serverSettings.icmURL=http://localhost:18087) |
| 8445 | | GIM client listener, both directions

The GIM client is doing the listening. Any GIM server on either the central manager or the collector can reach out to it (the GIM client). |
| 8446 | TLS | GIM authenticated TLS, both directions

Use between the GIM client and the GIM server (on the central manager or collector).

If GIM_USE_SSL is NOT disabled, then the gim_client will attempt to communicate its certificate via port 8446. If port 8446 is NOT open, then it defaults to 8444 BUT no certificate is passed (for example, TLS without verification). |
| 8447 | TLS | Used for remote messaging service infrastructure (and profile distribution infrastructure) for communication between Guardium systems in the federated environment / centrally-managed environment. Configuration profiles allow the definition of configuration and scheduling settings from a central manager and conveniently distribute those settings to managed unit groups without altering the configuration of the central manager itself. |
| 8443 | TLS | Enterprise load balancer

This is needed for UNIX/Linux S-TAPs to communicate instances to the collector.

However, this port is also used for the central manager load balancer. If the installation wants to use Enterprise load balancer, then the S-TAP initiates a request to the central manager on port 8443 by sending an HTTPS message.

So, between database server and central manager, there will be the capability to use a proxy server, if customer doesn't want an open port directly from database to central manager. |
| 8081 | TLS | To use 8081 for the GIM client to connect to the GIM server - need to disable the GIM_USE_SSL parameter - it is ON by default. This parameter is part of the GIM common parameters in the GUI. If GIM_USE_SSL is NOT disabled, then the gim_client will attempt to communicate its certificate via port 8446. If port 8446 is NOT open, then it defaults to 8444 BUT no certificate is passed (for example, TLS without verification). |
| 8983 | TCP | Used for establishing communication between the Central Manager and every Managed Unit, as well as between each Managed Unit and the Central Manager that is required in default mode.

Communication between all Managed Units is required only in 'all machines' mode. |
| 9983 | TCP | Used for establishing communication from the Managed Unit to the Central Manager. |

Step 1. Assemble the following before you begin

To prepare for the deployment of the Guardium® system, the network administrator needs to supply the following information.

- IP address for the interface card (the primary interface)
- Subnet mask for primary IP address
- Default router IP address.
- Hostname and domain name to assign to system
- DNS server IP addresses (up to three addresses), and add the new Guardium system to your DNS domain
- (optional) IP address for secondary management interface
- (optional) Mask for secondary IP management interface
- (optional) Gateway for secondary IP management interface
- (optional) NTP server hostname
- (optional) SMTP configuration information (for email alerts): IP address, port, and if authentication is used, an SMTP user name and password
- (optional) SNMP configuration information (for SNMP alerts) the IP address of the SNMP server and the trap community name to use.
- **[SAN storage devices](#)**
If the installation is to be deployed on a Storage Area Network (SAN), all configuration information needed by the SAN, must be prepared before deployment. Also, there are additional installation steps required to partition the SAN storage device and install the Guardium OS.

SAN storage devices

If the installation is to be deployed on a Storage Area Network (SAN), all configuration information needed by the SAN, must be prepared before deployment. Also, there are additional installation steps required to partition the SAN storage device and install the Guardium® OS.

Note: Installation on a SAN is supported, installation on a NAS is not supported.

Step 2. Set up the physical or virtual appliance

The setup instructions in this section are different when installing to a physical appliance or a virtual appliance.

- **[Physical Appliance](#)**
After the appliance has been loaded into the customer's rack, connect the appliance to the network in the following manner:
- **[Identify network ports](#)**
Use the following CLI commands to map the network ports.
- **[Default passwords for physical appliances](#)**
Default passwords are supplied for predefined users.
- **[Virtual appliance](#)**
The IBM Guardium Virtual Machine (VM) is a software-only solution licensed and installed on a guest virtual machine such as VMware ESX Server.

Physical Appliance

After the appliance has been loaded into the customer's rack, connect the appliance to the network in the following manner:

1. Find the power connections. Plug the appropriate power cord(s) into these connections.
2. Connect the network cable to the primary interface network port. Connect any optional secondary network cables.
3. Connect a Keyboard, Video and Mouse directly or through a KVM connection (either serial or through the USB port) to the system.
4. Power up the system.

-  [Changes in eth0 management port](#)

Identify network ports

Use the following CLI commands to map the network ports.

show network interface inventory

Use this CLI command to display the port names and MAC addresses of all installed network interfaces.

```
show network interface inventory
Current network card configuration:
Device          | Mac Address           | Member of
ens4f1np1      | 84:16:0C:AA:36:ED    | br3
ens4f2np2      | 84:16:0C:AA:36:EE    | br4
```

```

ens4f3np3      | 84:16:0C:AA:36:EF      | br5
ens2f1         | B4:96:91:F7:D1:6D.     | br1
ens4f0np0      | 84:16:0C:AA:36:EC.      |
ens2f0         | B4:96:91:F7:D1:6C       | br0
ok

```

show network interface role

Use this CLI command to display the network port that is assigned as the primary port.

```

show network interface role
Device:          Role:
ens2f0           bridgemember
ens2f1           bridgemember
ens4f0np0        primary
ens4f1np1        bridgemember
ens4f2np2        bridgemember
ens4f3np3        bridgemember
br3              -
br4              -
br5              -
br1              -
br0              -
ok

```

The port ens4f0np0 is assigned as the primary port.

show network interface port

This command flashes the light 20 times on the physical port. Use this CLI command to locate a physical connector on the back of the appliance.

```
show network interface port ens4f0np0
```

The light on port ens4f0np0 flashes 20 times.

Install the software directly on a dedicated computer

When you install the Guardium software directly to disk on a dedicated computer, use the Physical appliance instructions.

Default passwords for physical appliances

Default passwords are supplied for predefined users.

When you receive a physical appliance from IBM, use these passwords for your initial configuration.

Note: Be sure to change all default passwords when you complete the installation.

Table 1. Default passwords for predefined users

| User | Default password |
|-----------|------------------|
| accessmgr | guard1accessmgr |
| admin | guard1admin |
| cli | guard1cli |

Virtual appliance

The IBM® Guardium® Virtual Machine (VM) is a software-only solution licensed and installed on a guest virtual machine such as VMware ESX Server.

To install the Guardium VM, follow the steps in Creating the Virtual Image. The steps are:

- Verify system compatibility
- Install VMware ESX Server
- Connect network cables
- Configure the VM Management Portal
- Create a new Virtual Machine
- Install the IBM Guardium virtual appliance

After installing the VM, return to Step 4, Setup Initial and Basic Configuration, for further instructions on how to configure your Guardium system.

Step 3. Install the Guardium image

This section explains how to install the image and partition the disk.

1. Make sure your UEFI/BIOS “boot sequence” settings are set to attempt startup from the removable media (the CD/DVD drive) before using the hard drive.
Note: Installation can take place from DVD. If needed, get the UEFI/BIOS password from Technical Support.
2. Load the Guardium® image from the installation DVD.

3. The following two options appear:

Standard Installation: this is the default. Use this choice in most cases when partitioning the disk.

Custom Partition Installation: allows more customization of all partitions (locally or on a SAN disk). See Custom partitioning for further information on how to implement this option.

Note:

- The Standard Installation wipes the disk, repartitions and reformats the disk, and installs a new operating system.
- On the first boot after installation, the user is asked to accept a Licensing Agreement. They can use PgDn to read through the agreement or Q to skip to the end. To accept the terms of the agreement, enter q to exit and then type yes. The user must enter yes to the agreement or the machine will not boot up.

4. The system boots up from DVD. It takes about 12 minutes for this installation.

(d) The installation process will now ask you to choose a collector or aggregator (will be set to "Collector" automatically after 10 seconds if no input is provided). See the Product Overview for an explanation of Collector and Aggregator. If you wanted to choose aggregator and you did not choose it within 10 seconds, you must reinstall in order to get back to this point where you have a choice of aggregator.

Note: If you plan to use the appliance as a central manager you MUST select Aggregator option.

5. The system automatically reboots at this point to complete the installation. The first login after a reboot requires a changing of passwords.

Step 4. Set up initial and basic configuration

The initial step should be the network configuration, which must be done locally through the Command Line Interface (CLI) accessible through the serial port or the system console.

In the following steps, you will supply various network parameters to integrate the Guardium® system into your environment, using CLI commands.

In the CLI syntax, variables are indicated by angled brackets, for example: <ip_address>

Replace each variable with the appropriate value for your network and installation. Do not include the brackets.

- **[Set the primary and secondary system IP addresses](#)**

Define the primary and secondary interfaces. Use these commands to specify the primary interface:

- **[Set the Default Router IP Address](#)**

Use the following CLI command:

- **[Set DNS Server IP Address](#)**

Set the IP address of one or more DNS servers to be used by the appliance to resolve host names and IP addresses. The first resolver is required, the others are optional.

- **[SMTP Server](#)**

An SMTP server is required to send system alerts. Enter the following commands to set your SMTP server IP address, set a return address for messages, and enable SMTP alerts on startup.

- **[Set Host and Domain Names](#)**

Configure the hostname and domain name of the appliance. This name should match the hostname registered for the appliance in the DNS server.

- **[Set the Time Zone, Date and Time](#)**

There are options for setting the date and time for the appliance.

- **[Set the Initial Unit Type](#)**

An appliance can be a standalone unit, a manager or a managed unit; In addition, an appliance can be set to capture database activity via network inspection or S-TAP or both. The standard configuration would be for a standalone appliance (for all appliances), and the most common setting would use S-TAP capturing (only for collectors).

- **[Resetting the root password](#)**

To reset your root password on the appliance, use your own private passkey and run the `support reset-password root` CLI command.

- **[Validate All Settings](#)**

Before logging out of CLI and progressing to the next configuration step, review and validate the configured settings using the following commands:

- **[Reboot the System](#)**

If the system is not in its final location, now is a good time to shut down the system, place it in its final network location, and start it up again.

Set the primary and secondary system IP addresses

Define the primary and secondary interfaces. Use these commands to specify the primary interface:

```
store network interface ip <ip_address>
store network interface mask <subnet_mask>
```

The default network interface mask is 255.255.255.0. If this value is the correct mask for your network, you can skip the second command.

To assign a secondary IP address, use the CLI command, **store network interface secondary** [on <interface> <ip> <mask> <gw> | off], that can be used to enable/disable the secondary interface. The secondary IP can not be in the same subnet as the primary interface IP. Assigning a secondary IP address can only be done using the CLI (and not the GUI).

Next, you must restart the network by using the CLI command, **restart network**.

The remaining network interface cards on the appliance can be used to monitor database traffic, and do not have assigned IP addresses.

Set the Default Router IP Address

Use the following CLI command:

```
store network routes defaultroute <default_router_ip>
```

Set DNS Server IP Address

Set the IP address of one or more DNS servers to be used by the appliance to resolve host names and IP addresses. The first resolver is required, the others are optional.

```
store network resolvers <IP address of resolver 1 [IP address of resolver 2] [IP address of resolver 3 ]>
```

For more information, see [Store network resolvers](#).

SMTP Server

An SMTP server is required to send system alerts. Enter the following commands to set your SMTP server IP address, set a return address for messages, and enable SMTP alerts on startup.

```
store alerter smtp relay <smtp_server_ip>
store alerter smtp returnaddr <first.last@company.com>
store alerter state startup on
```

Note: You can also configure the SMTP server by using the user interface. Click [Setup > Alerter](#).

Set Host and Domain Names

Configure the hostname and domain name of the appliance. This name should match the hostname registered for the appliance in the DNS server.

```
store system hostname <host_name>
store system domain <domain_name>
```

Set the Time Zone, Date and Time

There are options for setting the date and time for the appliance.

Timezone, date, time and Network

1. Set timezone
2. Set date and time
 - Option 1 - Set the Network Time Protocol (NTP) time server.
 - Option 2 - Store the system clock datetime.

Date/Time Option 1: Network Time Protocol

Provide the details for one or more accessible time servers (NTP) and then start the time server. As of Guardium 12.0, Guardium uses the chrony daemon to manage NTP servers.

```
store system time_server hostnames
store system time_server state on
```

Date/Time Option 2: Set the time zone, date and time

Use the following command to display a list of valid time zones:

```
store system clock timezone list
```

Choose the appropriate time zone from the list and use the same command to set it.

```
store system clock timezone <selected time zone>
```

Note: Setting up a new timezone restarts internal services. Data monitoring is disabled for a few minutes during this restart.

Store the date and time, in the format: YYYY-mm-dd hh:mm:ss

```
store system clock datetime <date_time>
```

Note: Do not change the hostname and the time zone in the same CLI session.

Set the Initial Unit Type

An appliance can be a standalone unit, a manager or a managed unit; In addition, an appliance can be set to capture database activity via network inspection or S-TAP or both. The standard configuration would be for a standalone appliance (for all appliances), and the most common setting would use S-TAP capturing (only for collectors).

store unit type standalone - use this command for all appliances.

store unit type stap - use this command for collectors.

Unit type standalone and unit type stap are set by default. Unit type manager (if needed) must be specified.

Note: Unit type settings can be done at a later stage, when the appliance is fully operational.

Resetting the root password

To reset your root password on the appliance, use your own private passkey and run the **support reset-password root** CLI command.

Note: The **support reset-password root** command requires the access key *t0Tach*.

Save the passkey used in your documentation to allow future Technical Support root accessibility. To see the current pass key, use the following CLI command:

```
support show passkey root
```

Questions - How secure is the Guardium system root password? Who has access to it?

For Guardium appliances, end users can use limited access operating system accounts, such as *cli* and *guardcli1* to *guardcli9*.

The GUI user accounts (such as admin and accessmgr) are not defined by the Guardium system's operating system, but are application IDs defined and managed from the accessmgr application interface.

Being a secured server, root access is not readily available to anyone. Root access is often required by Guardium support to gain access to the Guardium appliances to troubleshoot and resolve issues. Guardium support does not use sudo, or any other user ID other than root, to gain access to Guardium appliances.

The root password is secured by using a "joint password" mechanism. Your site holds the keys to the appliance in the form of an encoded numeric passkey. IBM holds the passkey decoder. For either you or IBM to access the appliance as root, both the passkey and passkey decoder are required.

You can manage the passkey from the CLI interface. You can change the passkey at any time, without notifying IBM, by using the following CLI command:

```
support reset-password root
```

Anyone with CLI access can retrieve the passkey for root by using the following CLI command:

```
support show passkey root
```

If you need to work with Guardium support on a remote desktop sharing session, the support analyst requests the root passkey for the Guardium appliance in question. After the passkey is decoded, Guardium support uses the root password to gain access to the appliance as root. After the remote desktop session ends, be sure to change the passkey (by using **support reset-password root**) to ensure that IBM no longer has the root password for this appliance.

All encoded passwords are hardened. They do not contain any common passwords or dictionary words, their length varies and they might contain national, special, and alphanumeric characters.

Access to the passkey decoder is restricted to a select few IBM Guardium employees, such as Guardium R&D, Guardium QA, and Guardium support staff members. It is not available to IBM staff.

The CLI user IDs (*cli*, *guardcli1* to *guardcli9*) do not use the passkey mechanism. Their passwords are entirely governed by your organization and IBM does not have access to their passwords. IBM recommends that you keep the root passkey in a password vault. This action ensures that you can access the appliance even if users at your site leave or misplace the CLI account passwords.

Validate All Settings

Before logging out of CLI and progressing to the next configuration step, review and validate the configured settings using the following commands:

```
show network interface all  
show network routes defaultroute  
show network resolver all  
show system hostname  
show system domain  
show system clock timezone  
show system clock datetime  
show system time_server all  
show unit type
```

Reboot the System

If the system is not in its final location, now is a good time to shut down the system, place it in its final network location, and start it up again.

Remove the installation DVD before you reboot the system.

To stop the system, enter the following command in the CLI:

```
stop system
```

The system shuts down. Move the system to its final location, re-cable the system, and power the system back on. After the system is powered on, it is accessible (using the CLI and GUI) through the network, using the provided IP address or host name.

Step 5. What to do next

This section details the steps of verifying the installation, installing license keys, and installing any available maintenance patches.

- **[Verify Successful Installation](#)**
Verify the installation by following the following steps:
- **[Set Unit Type](#)**
To set up a federated environment, configure one of the appliances as the central manager and set all the other appliances to be managed by the central manager.
- **[Install license keys](#)**
This topic guides you through the procedure of installing and accepting Guardium license keys.
- **[Install maintenance patches \(if available\)](#)**
You can install patches by using the CLI or through the GUI.
- **[Additional Steps \(optional\)](#)**
The following sections discuss changing the baseline English to another language, installing S-TAP® agents, defining Inspection Engines and installing CAS agents.

Verify Successful Installation

Verify the installation by following the following steps:

1. Login to CLI - ssh cli@<ip of appliance>
2. Login to GUI - https://<hostname of appliance>.<full domain>:8443 (use admin userid)

The first login after a reboot will require a changing of passwords.

Login to the Guardium web-based interface and go to the embedded online help for more information on any of the following tasks.

Set Unit Type

To set up a federated environment, configure one of the appliances as the central manager and set all the other appliances to be managed by the central manager.

Use the CLI command **store unit type** to set the type of each Guardium system.

Install license keys

This topic guides you through the procedure of installing and accepting Guardium® license keys.

Before you begin

- Download your license keys from Passport Advantage
- Install or upgrade your Guardium system
- Verify that the machine type is correctly set for your system

About this task

Installing a Guardium license key is a two-step process: you need to install the license key and then read and accept the terms of the license agreement. After installing a Guardium license key, the user interface will reload to reflect the functionality enabled by the new license.

Establishing a functional Guardium system requires installing both a base and at least one append licenses. The base license must be installed and accepted before installing and accepting any append licenses.

For more information about Guardium license keys, see [License keys](#).

Attention:

When upgrading a Guardium system, you will not need to apply licenses. License keys will be automatically generated based on your preexisting installation, but you will need to review and accept the license agreements before you can begin using your Guardium system. To review and accept licenses on an upgraded system, navigate to Setup > Tools and Views > License and click the Read and accept license link.

Procedure

1. Log in to your Guardium system as the `admin` user.
 2. Verify that the Machine Type displayed in the Guardium banner is correct for the system you are licensing.
The machine type will be one of the following:
 - Standalone
 - Central Manager
 - Aggregator
- Attention: If you are setting up a central manager and the Machine Type indicates an aggregator, convert the system from an aggregator to a central manager using the following CLI command: **store unit type manager**.
3. Install a base license.
 - a. Navigate to Setup > Tools and Views > License.
 - b. On the License page, enter the base key for your system in the License key field and click Apply to continue.
Attention: Depending on the system you are setting up, you will need to apply either a base collector key or a base aggregator key. A base aggregator key is required when setting up a central manager system.
 - c. From the License Agreement dialog, review the license agreement associated with the base key and click Accept when you are ready to accept the terms.
The Guardium interface will automatically refresh after accepting the agreement, but there will be no change in available functionality after installing a base license key.

4. Install one or more append licenses.

Repeat the following steps for each append licence you have purchased and want to install.

- a. Navigate to **Setup > Tools and Views > License**.
- b. On the License page, enter an append key in the License key field and click **Apply** to continue.
- c. From the License Agreement dialog, review the license agreement associated with the append key and click **Accept** when you are ready to accept the terms. The Guardium interface will automatically refresh after accepting the agreement, and any new functionality associated with the append license will become available.
- d. Repeat the steps in this section for each append license you want to install.

What to do next

In an environment with a central manager, you can distribute the new licenses by navigating to the **Manage > Central Management > Central Management** page and clicking the  icon to distribute licenses from the central manager to managed units.

In an environment with a central manager, the central manager and its managed units must use the same shared secret. Set the shared secret from the **Setup > Tools and Views > System** page or by using the CLI command **store system shared secret**.

License text is also available for download by starting the Guardium **fileserver** and navigating to `opt-ibm-guardium-log/install/[LICR number]`, where [LICR number] identifies the license you want to download.

- [fileserver CLI command](#)

Install maintenance patches (if available)

You can install patches by using the CLI or through the GUI.

Note: In federated environments, maintenance patches can be applied to all of the appliances from the Central Manager.

There may not be any maintenance patches included with the installation materials. If any are included, follow these steps to apply them:

1. Log in to the Guardium® console, as the cli user, using the temporary cli password you defined in the previous installation procedure. You can do this by using an ssh client.

2. Do one of the following:

- If installing from a network location, enter the following command (selecting either ftp or scp):

```
store system patch install [ftp | scp]
```

And respond to the following prompts (be sure to supply the full path name to the patch file):

Host to import patch from:

User on <hostname>

Full path to patch, including name:

Password:

- If installing using the fileserver function, enter the following command:

```
store system install patch sys
```

You will be prompted to select the patch to apply. Use wildcards in the pathname to get multiple patches. Also separate patch names by commas.

3. To install additional patches, repeat step 2.

4. To see if patches have been installed successfully, use the CLI command:

```
show system patch installed
```

Patches are installed by a background process that may take a few minutes to complete.

Additional Steps (optional)

The following sections discuss changing the baseline English to another language, installing S-TAP® agents, defining Inspection Engines and installing CAS agents.

Change the language

Initial installation of Guardium® is always in English. Use the **store language** CLI command after installation to convert the database from English to the desired language. Setting the desired language is considered part of the initial system set up: changing the language on an established system will impact the information already captured, stored, customized, archived or exported on that system.

Important:

- After switching from English to a desired language, it is not possible to revert back to English using this CLI command. The Guardium system must be reinstalled in English.
- To prevent the system from displaying a mixture of languages, set a central manager and all its managed units to the same language.

Syntax

store language

Example

```
store language
The following languages are available on this appliance:
  1. French
  2. German
  3. Italian
  4. Japanese
  5. Korean
  6. Polish
  7. Pseudo
  8. Simplified Chinese
  9. Spanish
  10. Traditional Chinese
Please enter the number of the language you want or 0 to quit:
```

Install S-TAP agents

Install S-TAP agents on the database servers and define their inspection engines. S-TAP is a lightweight software agent installed on the database server, which monitors local and network database traffic and sends the relevant information to a Guardium system (the collector) for further analysis, reporting and alerting. To install an S-TAP, refer to the S-TAP section of this information center. To verify that the S-TAP have been installed and are connected to the Guardium system:

1. Log in to the administrator portal.
2. Do one of the following:

Navigate to the Manage > System View, and click S-TAP Status Monitor from the menu. All active S-TAPs display with a green background. A red background indicates that the S-TAP is not active.

Navigate to Manage > Activity Monitoring > S-TAP Control, and confirm that there is a green status light for this S-TAP.

Define Inspection Engines

Define Inspection Engines for network-based activity monitoring.

Install CAS agents

Install Configuration Auditing System (CAS) agents on the database server.

Creating the Virtual Image

Use this section to install the virtual image.

- [**VMware Infrastructure Overview**](#)
While you can install a Guardium VM on any VMware product, the VMware ESX server is the recommended platform for a virtual solution and is presented here.
- [**VM Installation Overview**](#)
To install the IBM Guardium VM, follow the steps that are described here. After you install the VM, return to earlier Step 3, Install the IBM Guardium image, and earlier Step 4, Initial Setup and Basic Configuration.
- [**Creating a Hyper-V Virtual Machine**](#)
- [**Red Hat Virtualization**](#)
Install Guardium in a Red Hat Virtualization environment.
- [**vMotion Installation**](#)
Guardium can be deployed in various virtualized environments, including a VMware virtual environment. In a vSphere deployment, this virtual environment includes the vMotion feature, which allows live migration of a virtual machine.

VMware Infrastructure Overview

While you can install a Guardium® VM on any VMware product, the VMware ESX server is the recommended platform for a virtual solution and is presented here.

The VMware ESX Server on which you can install the Guardium VM is one component of the VMware infrastructure. Although not all VMware Infrastructure components are required to support the Guardium VM, you should be familiar with all components that are in use at your installation.

ESX Server: This component is used to configure and control VMware virtual machines on a physical host referred to as the ESX Server host. To install an Guardium VM, you first define a virtual machine on an ESX Server host, and then install and configure the Guardium VM image on that virtual machine. You can create multiple Guardium VMs on a single ESX Server.

VI Client (Virtual Infrastructure Client): This component is used to connect to a standalone ESX Server, or to a VirtualCenter Server. In the latter case, you can administer multiple virtual machines created over multiple ESX Server hosts.

Web Browser: Use a Web browser to download and use the VI Client software from an ESX Server host or the VirtualCenter server.

VirtualCenter Management Server (Optional): This component runs on a remote Windows machine, and can be used to manage multiple virtual machines on multiple ESX Server hosts. It offers a single point of control over all the ESX Server hosts.

Database (Optional): The VirtualCenter Server uses a database to store configuration information for the infrastructure. The database is not needed if the VirtualCenter Server is not used.

License Server (Optional): Stores and manages the licenses needed to maintain a VMware Infrastructure.

For more information, go to www.vmware.com and search for “ESX Quick Start”

VM Installation Overview

To install the IBM® Guardium® VM, follow the steps that are described here. After you install the VM, return to earlier Step 3, Install the IBM Guardium image, and earlier Step 4, Initial Setup and Basic Configuration.

If you are installing multiple Guardium VM systems in a VMware VirtualCenter Management Server environment, you can create a template system from the first Guardium VM that you create, and then clone that template as necessary. Then, all you need to do is set the IP address on each cloned system. For more information, see the note following Step 7.

Step 1: Verify system compatibility

1. Verify that the host is compatible with VMware's ESX Server (ESX 4.0 Update 4 and higher is the bare minimum to run a Guardium system). See the VMware document entitled Systems Compatibility Guide for ESX Server, which is available online in PDF format.
2. Verify that a virtual machine installed on the host will be able to provide the minimum recommended resources for a Guardium system, whether you plan to use it as a collector, central manager, or aggregator. See the Minimum/Recommended Resources in the Hardware Requirements section of this document.
3. When you create a 64-bit VM for the first time or upgrade a 32-bit VM to 64-bit, ensure that the virtual hardware is correctly configured for 64-bit operation. In some cases, you might need to perform an Upgrade Virtual Hardware operation. For information, refer to your VMware documentation.

Step 2: Install VMware ESX Server

If it is not already installed, install VMware ESX Server. VMware provides installation instructions on their website to help with installing and configuring the VMware Infrastructure and ESX server.

Note: The ESX server is only supported on a specific set of hardware devices. For more information, see the VMware Virtual Infrastructure documentation.

Step 3: Connect network cables

Before you define any virtual switches that will be used for the Guardium VM, you must connect the appropriate NICs to the network. You cannot assign NICs to virtual networks or switches until the NICs are physically connected.

The following table describes how the Guardium VM uses network interfaces. Refer to this table to make the appropriate connections before you configure the virtual switches for use by the Guardium VM.

Table 1. IBM Guardium VM Network Interface Use

| Interface | Description |
|--|--|
| Proxy interface (the primary interface) | This interface is the main gateway to the appliance, and is used for these purposes: <ul style="list-style-type: none">• Graphical web-based User Interface (GUI) to manage, configure, and use the solution• Command Line Interface (CLI) for initial setup and basic configuration• Connections with external systems such backup systems, database servers, and LDAP server• Communication with other Guardium components such as other appliances (aggregator, central manager) and agents that are installed on database or file servers such as S-TAP® or CAS clients |
| Application server interface (the secondary interface) | This interface is required if you configure your Guardium system as a transparent proxy. It connects to the application servers whose content your Guardium system is configured to mask. |

Step 4: Configure the Guardium VM management portal

The default configuration for a new VMware ESX Server installation creates a single port group for use by the VMware service console and all virtual machines. For the Guardium VM, we strongly recommend that you do not share ports with the VMware console or any other virtual machine. Follow these instructions to create one or more virtual switches to be used by a Guardium VM.

1. Open the VMware VI Client, and log on to either a VirtualCenter Server, or the ESX Server host on which you want to create a new virtual machine.
2. If you are logged in to a VirtualCenter Server, click Inventory in the navigation bar, and expand the inventory as needed to display the managed host or cluster on which you plan to install a Guardium VM.
3. In the inventory display, click the host or cluster on which you plan to install a Guardium VM.
4. Click Configuration tab, click Networking in the Hardware box, and then click Add Networking.

This opens the Add Network Wizard, which is used for various purposes.

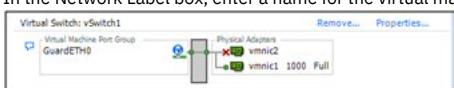

Use the Add Network Wizard to define a new virtual switch for the Guardium VM network interface. This is the connection over which you will access the Guardium VM management console, and over which the Guardium VM will communicate with other Guardium components (S-TAPs, for example, which are software agents that you will install later on one or more database servers).

5. In the Connection Types box, click Virtual Machine and click Next.
6. In the Network Access panel, click Create a virtual switch, and mark the unclaimed network adapter that you will use for the Guardium VM network interface.

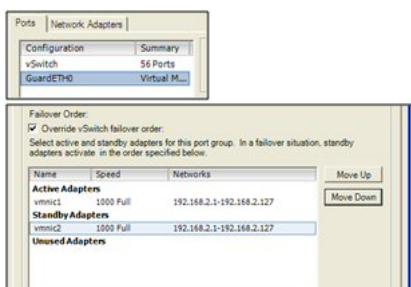

Note: The recommended network adapter type is VMXNET3. Avoid using the Flexible network adapter.

7. Optionally mark a second unclaimed network adapter if want to use the VMware IP teaming capability to provide a secondary (failover) network interface. Later, you will designate this second adapter as a Standby Adapter (and of course, you must cable both NICs appropriately).
8. Click Next to continue to the Connection Settings page of the Add Network Wizard.
9. In the Network Label box, enter a name for the virtual machine port group, for example: GuardETH0, and click Next.

10. In the Summary page, click Finish. The new virtual switch is displayed in the Configuration tab.
11. Optional. If you have defined a second adapter for failover purposes: (a) Click Properties link for the virtual switch just created to open the virtual switch Properties panel. (b) Click Ports tab and select the virtual port group just created (GuardETH0 in the example), and click Edit. (c) In the virtual port group Properties panel, click NIC Teaming tab, mark the Override vSwitch Failover box, and then move the second adapter to the Standby Adapters list. (d) Click OK to close the virtual port group Properties box, and click Close to close the virtual switch Properties box.

Step 5: Create a new virtual machine

If you have not already done so, create a new virtual machine on which to install a Guardium VM.

Perform this task by using the VMware VI Client.

1. Open the VMware VI Client, and log on to either a VirtualCenter Server, or the ESX Server host on which you want to create a new virtual machine.
2. If you are logged in to a VirtualCenter Server, click Inventory in the navigation bar, expand the inventory as needed, and select the managed host or cluster to which you want to add the new virtual machine.
3. From the File menu, click New – Virtual Machine to open the configuration Type panel of the New Virtual Machine wizard.
4. Click Typical as the configuration type, and click Next to continue with the Name and Folder panel.
5. On the Name and Folder panel:

Enter a name for the new virtual machine in the Virtual Machine Name field. This name appears in the VI Client inventory and is also used as the name of the virtual machines files.

To set the inventory location for the new virtual machine, select a folder or the root location of a datacenter from the list under Virtual Machine Inventory Location.

Click Next.

6. If your host or cluster contains resource pools, the Resource Pool panel is displayed, and you must select the resource (host, cluster, or resource pool) in which you want to run the virtual machine. Click Next.
7. On the Datastore panel, optionally select a datastore in which to store the new virtual machine files, and click Next.
8. In the Choose the Guest Operating System panel, choose the operating system that corresponds to the Guardium image that you are installing. Click Linux > RedHat Enterprise Linux 9, 64-bit from the Version box, and click Next.

The operating system is not installed now, but the OS type is needed to set appropriate default values for the virtual machine.

For VM minimum resources, refer to the Hardware Requirements in the Before you begin section.

9. On the Virtual CPUs panel, select the number of CPUs recommended for the type of Guardium VM being installed, and click Next.
10. On the Memory panel, select the amount of memory recommended for the type of Guardium VM being installed, and click Next. Important: the initial value must be at least 16 GB. If customers want to work outside the required range, consult with Technical Support.
11. On the Network panel, click 1 as the number of ports that are required, and click Next.

12. For the selected port, use the Network pull-down menu to choose a port group configured for virtual network use. (You should have defined this port group in the previous procedure.)
13. For the selected port group, mark the Connect at Power On check box (it should be marked by default), and click Next.
14. On the Virtual Disk Capacity panel, enter the amount of disk space to reserve for the new virtual machine in the Disk Size field.
15. On the Ready to Complete panel, verify your settings and click Finish.

This completes the definition of the new virtual machine. The operating system has not yet been installed, so if you attempt to start the virtual machine, that activity will fail.

Step 6: Install the Guardium system

Perform this task using the VMware Virtual Infrastructure Client.

1. Open the VMware VI Client, and log on to either a VirtualCenter Server, or the ESX Server host on which you want to create a new virtual machine.
2. If logged into a VirtualCenter Server, click Inventory in the navigation bar, expand the inventory as needed, and select the virtual machine on which you want to install the Guardium VM.
3. On the Summary tab, click Edit Settings.
4. Click CD/DVD Drive 1.
5. Select one of the following options to determine from where the virtual DVD device will read the Guardium Installation program. **We strongly recommend the first option:**

Datastore ISO File – Connect to the Guardium Installation ISO file on a datastore. If you have not already done so, copy the Guardium ISO files to a datastore accessible from the ESX Server host on which the virtual machine is installed. Click Browse to select the file.

Caution: For the remaining options, you will place the Guardium Installation DVD in a DVD drive. If you reboot any system with an Guardium Installation DVD in its DVD drive, you will install Guardium on that system, wiping out the host operating system and files.

Client Device – Connect to a DVD device on the system on which you are running the VI Client. If you select this option, insert the Guardium DVD in the DVD drive of the system on which the VI Client is running.

Host Device – Connect to a DVD device on the ESX Server host machine on which the virtual machine is installed. If you select this option, choose the device from a drop-down menu, and insert the Guardium DVD in the DVD drive of the ESX Server host machine.

6. Click OK.
7. Click Power On to start the virtual machine.
8. If you selected Client Device as your DVD Drive option, click Virtual CD-ROM (ide0:0) in the toolbar, and select the local DVD device to connect to.
9. Click Console tab to display the virtual machine console.
10. When asked if building a collector or aggregator, choose the appropriate type.

Caution: If a DVD drive was used, the DVD ejects when the installation completes. Be sure to remove the installation DVD from that drive. If the ISO file was used, be sure to remove the ISO CD ROM by changing the virtual CD/DVD back to a Client or Host Device. Otherwise, the next time it is rebooted, you will install Guardium on the host machine, wiping out the host machine operating system and all files.

The machine will reboot automatically, and you will be prompted to log in as the CLI user.

11. At this point, return to Step 4, Set up Initial and Basic Configurations for complete instructions on configuration of the Guardium system.

Step 7: Install Multiple VMs

(Optional) To install multiple GuardiumVMs, you can repeat the procedures for each appliance, or you can minimize your work by cloning the first Guardium VM that you created, and following these steps:

1. Use the VMware virtual infrastructure server product to clone the first Guardium VM that you configured to a template.
2. From the template, create a clone for each additional Guardium VM to be configured.
3. For each clone, log in to the Guardium VM console as the cli user by using the temporary cli password and reset any of the IP configuration parameters that you set in the previous procedure. Mandatory tasks: reset the IP address, reset the GLOBAL_ID (GID), and reset the host name. The UNIQUE_ID (UID) is set automatically and does not require manual configuration. Be sure to review all of the IP configuration settings entered in the previous procedure.

```
store network interface ip <ip_address>
store network interface mask <subnet_mask>
store product gid <n>
store system hostname <host_name>
```

When you are done, enter the **restart network** command.

```
restart network
```

Note: The unique ID (UID) of the appliance is recalculated every time the hostname changes in order to avoid having multiple appliances with the same unique ID.
Note: The global ID (GID) can be any number so long as it is unique and less than 9223372036854775808. During the cloning process this unique number is necessary. Please obtain the global IDs from your other appliances and use a number that is unique for this clone.

Creating a Hyper-V Virtual Machine

Before you begin

- Hyper-V is a virtualization solution from Microsoft. It is assumed that the Guardium user using Hyper-V has prior experience with Hyper-V.
- Verify system requirements for the version of Guardium® being installed.

Procedure

1. Start the Hyper-V Manager and connect to your Hyper-V server.

2. In the Actions pane, select **New > Virtual Machine** to begin the New Virtual Machine wizard. Click **Next**.
3. Specify names and location:
 - a. Name: This is the name of the virtual machine containing the Guardium system.
 - b. You may select Store the virtual machine in a different location and provide the path to your data store, if appropriate.
 - c. Click **Next** when done.
4. Specify Generation of the virtual machine: Select Generation 1 and click **Next**.
5. Assign memory: Verify that the allocated RAM meets the minimum system requirements. Leave the option **Use Dynamic Memory** for this virtual machine unchecked and click **Next**.
6. Configure Networking: Select your virtual switch and click **Next**. Note that hardware may differ and there may be multiple choices.
7. Connect Virtual Hard Disk: Select **Create a virtual hard disk**.
 - a. Specify the path to the virtual disk.
 - b. Verify that the size of the virtual hard disk meets the minimum system requirements.
 - c. Click **Next**.
8. Installation Options: The operating system can be installed through a physical CD/DVD drive or through an Image file (.ISO).
 - a. **DVD Installation:** select Physical CD/DVD drive and choose the correct drive letter.
 - b. **.ISO Installation:** select Image File (.ISO) and browse to your image file.
 - c. Click **Next**.
9. Complete installation: Verify all selected options in the Description box. Click **Finish** to create the virtual machine and close the wizard.
10. Open Console: Select your new virtual machine from the virtual machines pane and click **Connect**.
11. Click on **File > Settings**.
12. On the Hardware pane:
 - a. Select BIOS. Move IDE to the top of the Startup order.
 - b. Select the Processor section. Allocate the minimum number of virtual processors needed based on your system requirements.
 - c. Expand the Processor section. Select NUMA in the subsection and change the Maximum amount of memory (MB) to the assigned memory entered in the step 5.
 - d. Select the SCSI Controller section and click on the Remove button.
13. Optionally, in the Management pane below the Hardware pane, you may set up your preferences for Automatic Start up and Stop Actions.
14. Click **Apply** and if there are no warnings, click **OK**.
15. Click the green Start button to start your virtual machine.
16. Install your Guardium system. For more information see [Installing your Guardium Data Protection system](#). Power down after installation.
17. On the Hyper-v virtual machine console, open **File > Settings**.
18. On the Hardware pane, expand the Network Adapter section and select the Advanced Features subsection.
19. Configure the MAC address by selecting the Static radio button. Click **Apply** and **OK**.
20. Power on your virtual Guardium system.
21. 12.0 and later The installer automatically adds the necessary RPMs for Hyper-V.

Red Hat Virtualization

Install Guardium in a Red Hat Virtualization environment.

Before you begin

Red Hat Virtualization is a virtual machine platform based on Red Hat Enterprise Linux. This procedure assumes familiarity with the Red Hat Virtualization platform. For more information, see the Red Hat Virtualization documentation.

Procedure

1. Upload the Guardium ISO image on the system running the Red Hat Virtualization software using the following command:

```
engine-iso-uploader -i ISO
upload <Guardium ISO image
file name>.iso
```
2. Install the Virtual Viewer for your environment.

Access viewers at the following URL, then select and install the correct version for your environment: <https://<Red Hat Virtualization server host name>/ovirt-engine/rhv/client-resources>. For example, a 64-bit Windows users would select Virt Viewer for 64-bit Windows then Right-click > Install the virt-viewer-x64.msi file.
3. Log in to the Red Hat Virtualization server web interface: https://<Red Hat Virtualization server host name>/ovirt-engine/webadmin/?locale=en_US#dashboard-main
4. Open Compute > Virtual Machines and click **New** next to the Vms field to create a new virtual machine.
5. Configure the virtual machine as follows:
 - a. On the General page, define the following settings:
 - Operating System: Linux
 - Optimized for: High Performance
 - Name: provide a name for the virtual machine, for example gkvm04.
 - Description: provide a description for the virtual machine, for example Guardium 11.2.
 - nic1: 3148/3148
 - b. On the System page, define the following settings:
 - Maximum memory: 24576 MB
 - Total Virtual CPUs: 4
 - Configure the Hardware Clock Time Offset for your location.
 - c. On the Console page, clear the Headless Mode check box.
 - d. On the Boot Options page, define the following settings:
 - Second Device: CD-ROM
 - Check the Attach CD check box and select the Guardium ISO image.
 - Check the Enable menu to select boot device check box.
 - e. Click **OK** to save the settings.
6. From the Compute > Virtual Machines page, double-click the virtual machine created in the previous steps, select Disks and click **New** to create a new virtual disk.
7. From the New Virtual Disk page, select the Image page, define Size (GiB): 300, and click **OK**.

8. From the Compute > Virtual Machines page, click Run, and then click Console to open the remote console.
 9. From the console, press the **ESC** key to access the boot menu and select DVD/CD to boot the Guardium ISO image.
 10. From the Guardium Installer menu, select an installation type and install the Guardium system on the virtual machine.
-

vMotion Installation

Guardium can be deployed in various virtualized environments, including a VMware virtual environment. In a vSphere deployment, this virtual environment includes the vMotion feature, which allows live migration of a virtual machine.

vMotion is of two types, host and storage. Host vMotion is the live migration of the OS, and network transactions, from one hypervisor to another. Storage vMotion is the live migration of a running virtual machine's file system from one storage system to another. Both types of vMotion are supported by Guardium. For more information, see <https://www.vmware.com/products/vsphere/vmotion.html>.

Best Practices

- Configure your environment to support vMotion by using VMware documentation found here: <https://www.vmware.com/>. Contact VMware Support for configuration assistance.
- Guardium is a high performance, and high transaction system. Data is transferred between hypervisors in a host vMotion, and between storage systems in a storage vMotion. So, vMotion must be used when the Guardium appliance is shut down or at a low level of activity.
- The vMotion process is transparent to the virtual guest and does not affect the guest system. However, as part of a robust disaster recovery plan, verify that your backup and restore procedures are up to date.
- Guardium 11.4 and later includes **open-vm-tools**. If **open-vm-tools** is already installed, it is not necessary to install VMWare tools on the Guardium appliance.

VMWare Tools Installation

Install VMWare tools on the Guardium appliance by using these methods.

Method 1:

1. Open the VM client/console and select the VM instance that contains the InfoSphere Guardium appliance. Right-click the instance, select Guest > Install/upgrade VMware tools from the menu. Your instance is enabled to access the VMWare tools via a mount point.
2. To install VM tools, run the CLI command **setup vmware_tools install** from the VM client or console. For more information, see [setup vmware_tools install](#).

Method 2:

1. Open the VMware VI Client, and log on to either a VirtualCenter Server, or the ESX Server host on which you want to upgrade the VMware Tools.
2. If you are logged in to a VirtualCenter Server, click inventory in the navigation bar, expand the inventory as needed, and select the virtual machine on which you want to upgrade VMWare Tools.
3. On the Summary tab, click Edit Settings and select CD/DVD Drive 1.
4. The virtual CD-ROM/DVD device reads the VMware Tools program from the datastore ISO File. To enable this device, click Browse and select the VMware Tools ISO file on a datastore. If you have not already done so, copy the VMware Tools ISO file to a datastore accessible from the ESX Server host on which the virtual machine is installed.

Note: The file name for the VMware Tools package must not be modified when the ISO image is created.

5. To create the ISO, run the appropriate command. This command can differ based on the OS running on your system.

Example of a LINUX command:

```
mkisofs -r -J -L -l -allow-lowercase -allow-multidot -N -v -d -o vmware_tools3.iso vmware_tools/
```

Check the Mkisofs documentation for more information.

6. Under Device status check the Connected checkbox. Click OK.
7. From the VM Console screen, log in using CLI.
8. Run the CLI command **setup vmware_tools install** and press the Enter key on your keyboard. For more information, see [setup vmware_tools install](#)
9. When the installation is complete, you are brought back to the CLI prompt. Disconnect the CD/DVD drive from the ISO on the datastore.

open-vm-tools updates

For Guardium 12.0 and later, **open-vm-tools** is up to date with the latest 9.X Extended Update Support (EUS) stream.

Custom Partitioning

If you customize the partitioning of the hard drive, you must make several choices.

1. Choose Custom Partitioning Installation from the boot screen.

Choose Create custom layout and use the recommended partitioning scheme listed here.

Note: The boot loader, a special program that loads the operating system into memory, is part of any custom partitioning installation.

2. Create custom layout. In this case, there are existing partitions on the disk. Do not delete any partitions. Choose the custom layout selection to add whatever partitions you want to what is already on the disk. The following table specifies recommended values for custom layout.

Table 1. Recommended values for custom layout

| Partitions | Values |
|--------------|------------------|
| / | 25 GB |
| Swap portion | half of RAM size |
| /boot | 5 GB |
| /var | All the rest |

All the available drives are also displayed on this screen. Choose the drive for the partitioning and then installation.

After the partitioning is finished, the Guardium® system software is installed automatically.

If values are created that exceed the space available on the disk, an error message appears.

Click OK to reboot the system and return to the beginning of Custom Partitioning.

See the Red Hat Enterprise Linux documentation for more information about how the Red Hat distribution handles partitioning.

Note: Non-default partitioned systems - Custom partitioned systems cannot be upgraded using an upgrade patch. Instead, you must use the backup, rebuild, and restore method. If there is uncertainty regarding the partitioning of systems, download and install Health Check p9997. The resulting patch log contains information regarding system partitioning.

How to partition with an encrypted LVM

If you use an encrypted disk, create an encrypted LVM volume that contains the / and /var logical volumes.

About this task

The following procedure requires either physical or remote console access to the Guardium system.

Procedure

1. Insert the IBM® Guardium® DVD and boot the machine.
2. Choose Custom Partition Installation from the boot screen.
3. Press Enter.
4. In the Installation Summary, select Installation Destination. Under Other Storage Options, select I will configure partitioning and check Encrypt my data.
5. Select Click here to create them automatically and change the Mount Point and Name from home to var. Click Done.
6. When prompted, enter a Disk encryption passphrase and safeguard it. Click Save Passphrase and Accept Changes.
Tip: The encryption passphrase is required to unlock the LVM volume when you restart the system. This key cannot be replaced if lost.
7. Optional: You can set up a tang server to automatically enter the encryption key and unlock each volume of your encrypted disks when you restart your system. If a tang server is down when rebooting, the message dracut-initqueue: Error communicating with server appears. You must then unlock the encrypted machine by manually entering the passphrase.
Tip: Set up the tang server by using the CLI command **store tang server** or by using the API command **grdapiclevis_bind** on your central manager to bind all your managed units to a tang server. For more information on the commands, see [store tang server](#), [reset luks keys](#), and [grdapiclevis_bind](#).

Create an LVM disk with four disks

About this task

Use the following instructions to create an IBM Guardium VM with 4 Hard disks, LSI Logic Parallel SCSI controller, and E1000 network adapter.

Procedure

1. Click on Edit Settings of the Guardium VM appliance.
2. Mount a Guardium V10.6 ISO image. Make sure the following items are selected:
 - Connected
 - Connect at Power On
3. Click VM Options > Boot Options. Select the During the boot, force entry into the BIOS setup screen check box, and click OK.
4. Power on the Guardium VM.

5. In the setup screen, select Boot from the menu, and click CD-ROM Drive, and move it to the top.
 6. From the menu, select Exit . Click Exit Saving Changes and press the Enter key.
 7. Select Yes to save configuration changes, and exit. This will start the installation.
 8. In the IBM InfoSphere Guardium Installer, select Custom Partition installation (Graphical Mode).
 9. In the Storage Device Warning dialog, click on Yes, discard any data.
 10. To configure the installation type, select the Use All Space radio button. Then, select the Review and modify partitioning layout check box, and click Next.
 11. Under Data Storage Devices, select all four VMware virtual disks, and then click the right arrow.
 12. Under Install Target Devices, select the first disk for Boot loader, and click Next.
 13. Under LVM Volume groups, select lv_home and click Edit.
 14. In the Edit Logical Volume dialog, click the drop down for Mount Point, and select /var. In the Logical Volume Name text box, enter lv_var. Click ok.
 15. In the Format warnings dialog, click Format.
 16. To start installation, select Install boot loader on /dev/sda and click Next.
- Note: The Guardium VM will reboot when the installation complete.
-

Example of SAN Configuration

This appendix details the steps involved in moving to a command prompt in order to pre-partition a hard drive (as is needed for SAN installation).

First partition space on the SAN storage device, and then install the IBM® Guardium® OS. Choose one hard disk for this installation.

Note: Depending on what SAN hardware is used, specific instructions may be different. Installation on a SAN is supported; installation on a NAS is not supported.

Summary of steps

1. Enter system setup (press F1 on IBM servers during initial boot) and modify the Start Options to select the appropriate PCI slot to boot from (where the QLogic Card is).
2. Modify the BIOS for the QLogic card by pressing Ctrl-Q, when the QLogic BIOS is loading, to enable it to be a boot device. Then select the LUN (logical unit number) of the boot device.
3. Boot from the RedHat 5.8 DVD and enter Rescue mode in order to run fdisk and create partitions on the SAN device using the specifications listed here:

Table 1. Partitions on SAN device

| Partitions | Space |
|------------|--------------------------------|
| 1 | 500 MB for /boot |
| 2 | Amount of system memory + 4 GB |
| 3 | 25 GB for / |
| 4 | All remaining space for /var |

Note: While the RedHat installation process would allow you to create the partitions and load the OS, the system does not boot properly after the installation unless the partitions are pre-created with **fdisk**.

4. Proceed with the OS installation utilizing the previously defined partitions (use only the /dev/sda device).
5. Reboot and finish the remaining installation steps (hostname, IP configuration, and so on).

Note:

In the SAN environment, the single LUN is presented to RedHat 5.8 as multiple devices due to redundant paths within the network switch(es) on the SAN. (The SDD storage was eight devices.)

This is a function of the SAN storage brand/type and how it is configured at each site.

It is very important to only edit the existing partitions that the IBM Guardium installation sees by adding the mount point and setting the file system (ext4 or swap,) and not changing other settings (such as size) and to unselect all devices other than /dev/sda when selecting which device to load the OS on.

Instructions for running fdisk

Follow these instructions for running **fdisk** to pre-partition the SAN storage from RedHat rescue mode:

1. Assuming SAN is the only storage attached to the server, type **fdisk /dev/sda**. Type **y** if a warning appears regarding working on the whole device.
2. Type **n** for a new partition.
3. Type **p** for a primary partition.
4. Type **1** for partition #1.
5. Press Enter to accept the default start location.
6. Type **+512M** to make partition 1 500MB in size (this will be the /boot partition).
7. Type **n** for a new partition.
8. Type **p** for a primary partition.
9. Type **2** for partition #2.
10. Press Enter to accept the default start location.
11. Type **+12288M** to make partition 2 12GB in size (this assumes 8GB of physical RAM). The recommended size is physical RAM + 4GB (this will be the swap partition).
12. Type **n** for a new partition.
13. Type **p** for a primary partition.
14. Type **3** for partition #3.
15. Press Enter to accept the default start location.
16. Type **+10240M** to make partition 3 10 GB in size (this will be the / partition).
17. Type **n** for a new partition.
18. Type **p** for a primary partition (will default to partition #4).
19. Press Enter to accept the default start location.
20. Press Enter to fill to maximum size (this will be the /var partition).
21. Type **w** to write the partition table to the SAN.
22. Type **exit** to exit rescue mode and reboot to begin the Custom Partition Installation (Step 3, Install the IBM Guardium image).

Examples of screenshots for QLogic setup

The Q-Logic screens used here are representative of the steps needed. Other Fiber Channel cards can be used.

1. Modify the BIOS for the QLogic card by pressing CTRL-D. This is the first screen presented after pressing Ctrl-Q when prompted to enter the Configuration Setup Utility. This is a two-port card; select the appropriate port and press Enter.

2. Press Enter to change Configuration Settings.

3. Press Enter to change Adapter Settings.

4. Use your arrow keys to select Host Adapter BIOS and press Enter to toggle to Enabled.

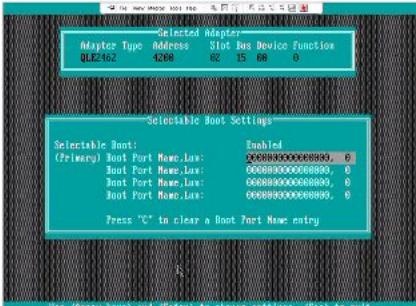

5. Press Esc to back up to the previous screen and use the down-arrow to select Selectable Boot Settings and press Enter.

6. Press Enter to change Selectable Boot to Enabled.

7. Select the first Boot Port Name, LUN and press Enter to display a list of LUNs. If you are configuring the proper card/port, the LUN number(s) appear here. Select the first one in the list.

8. Press Esc until you have backed out to the screen that says Reboot and select it to reboot the system. You are now ready to proceed with the IBM Guardium installation.

Upgrading your Guardium system

Upgrade your IBM® Guardium® system to the latest offering.

- [Planning an upgrade](#)
Review upgrade scenarios and identify the correct upgrade path for your Guardium systems.

Upgrade your stand-alone system to the next major version.

Planning an upgrade

Review upgrade scenarios and identify the correct upgrade path for your Guardium® systems.

- [Identifying the correct upgrade path](#)
The best approach for upgrading IBM Guardium depends on the version you are upgrading from, the hardware of your system, and any special partitioning requirements you might have.
- [Mixed-version environments during an upgrade](#)
During an upgrade, your Guardium environment enters a mixed-version state with restricted functionality.
- [Upgrading with central managers and aggregators](#)
Minimize disruptions to your Guardium environment by following a top-down upgrade approach.

Identifying the correct upgrade path

The best approach for upgrading IBM Guardium® depends on the version you are upgrading from, the hardware of your system, and any special partitioning requirements you might have.

Before you begin

Before you upgrade to Guardium 12.x, take the following actions:

- Disable TLS 1.0 and TLS 1.1 in your environment. Guardium 12.0 requires TLS 1.2 or later, and any managed units or S-TAPs that do not support at least TLS 1.2 are disconnected after upgrade. From a central manager, use an API command `grdap1 disable_deprecated_protocols all=true` to identify any connected components that do not support at least TLS 1.2. Upgrade those components to TLS 1.2 or later so they remain connected after the upgrade. For more information, see [Managing the TLS version](#).
- Configure a system backup with secure file copy (SCP) or secure file transfer protocol (SFTP) on all Guardium systems to upgrade, even if a system backup was never configured for those systems. The upgrade patch creates and sends an upgrade backup file to a remote server by using the current appliance system backup configuration to determine the destination for that file.

About this task

Determine the current Guardium version and patch level by clicking the Help icon in the product and selecting About Guardium. The following table describes how to upgrade to the latest Guardium version.

| Current Guardium version | Upgrade path |
|--------------------------|--|
| Version 11.5 | 1. Archive and purge system data.
2. Backup your system. Include both your data and configuration files.
3. Apply health check patch 11.0p9998.
4. Apply the latest version 12 upgrade patch.
5. 12.1 and later Apply health check patch 12.0p9997.
6. 12.1 and later Apply the latest version 12 GPU and maintenance patches, if available. |
| Versions 11.0 to 11.4 | 1. Apply health check patch 11.0p9997.
2. Archive and purge system data.
3. Backup your system. Include both your data and configuration files.
4. Apply the version 11.5 GPU and maintenance patches.
5. Follow the version 11.5 upgrade path that is described in the Procedure . |
| Version 10.6 | 1. Apply health check patch 10.0p9998.
2. Archive and purge system data.
3. Backup your system. Include both your data and configuration files.
4. Apply the latest version 11 upgrade patch.
5. Apply health check patch 11.0p9997.
6. Apply the latest version 11 GPU and maintenance patches (to get to version 11.5).
7. Follow the version 11.5 upgrade path that is described in the Procedure . |

The version 12 upgrade patch is incompatible with the following configurations:

- Guardium systems with custom partitions.
- Encrypted Logical Volume Management (LVM) disks.
- Guardium systems that are deployed in cloud environments.

If your upgrade scenario satisfies the following conditions, use the procedure that is described in the following technote to upgrade your environment:
<https://www.ibm.com/support/pages/node/7032147>.

1. You are upgrading an environment with a central manager.
2. You are upgrading from versions 10.6, 11.0, or 11.1 to versions 11.5, 12.0 or later.

Procedure

1. Apply the latest health check patch that is relevant to your version.
 - For version 12.0 and later, apply health check patch 12.0p9997.
 - For version 11.5 or earlier, apply health check patch 11.0p9998.
 - For version 10.6, apply health check patch 10.0p9998.
2. Archive and purge system data.
3. Backup your system including your data and configuration files.
4. Rebuild the appliance by using the latest version 12 ISO.
5. Apply the latest version 12 GPU.
6. Apply the relevant maintenance bundle, sniffer, and security patches.
Important: If you applied the maintenance patches a few weeks earlier, apply the version 12 health check patch (12.0p9997) to confirm that the system is ready before you continue to the next step.
7. Restore the system backup. Include both your data and configuration files.

What to do next

After you upgrade to Guardium 12.x, take the following actions:

- To restore backups that are taken before the upgrade to 12.0, disable FIPS mode, restore the backups, and then re-enable FIPS mode.
Important: To run configuration auditing system (CAS) with FIPS mode enabled, the CAS server requires TLS 1.2 to be enabled and the CAS client requires IBM Java 8 SR7 or later.
- After you upgrade to 12.0 or later, custom SHA256 GIM certificates are required before you can deploy new SHA256-signed GIM bundles. For more information, see [Updating Guardium Data Protection GIM clients with SHA256 certificates](#).
- If you use S-TAP for z/OS with TLS 1.3, verify that the z/OS version is 2.04 or later.
- 12.0 After you upgrade from 11.x to 12.0, you can log in to the CLI only after you change the password.

Mixed-version environments during an upgrade

During an upgrade, your Guardium® environment enters a mixed-version state with restricted functionality.

Guardium upgrades cannot be completed on all systems (central managers, aggregators, and collectors) and all S-TAPs simultaneously. As a result, your environment enters a mixed-version state during the upgrade process. For example, after upgrading a central manager to the latest version, managed units continue operating at the previous version level until they are also upgraded.

Although mixed-version environments are supported, several limitations exist. For example, while data collection, data assessment, and policies (with some restrictions) continue working in a mixed-version environment, some new or enhanced functionality is not available until all systems are upgraded.

Important: Upgrade your entire environment to the latest release and patch level as soon as possible.
Be aware of the following restrictions while operating in a mixed-version environment:

- Complete functionality is not available until the entire environment has been upgraded to the latest release and patch level.
- Do not make configuration changes while operating in a mixed-version environment.
- Disable TLS 1.0 and TLS 1.1 in your environment. Guardium 12.0 requires TLS 1.2 or later, and any managed units or S-TAPs that do not support at least TLS 1.2 are disconnected after upgrade. From a central manager, use an API command `grdapi disable_deprecated_protocols all=true` to identify any connected components that do not support at least TLS 1.2. Upgrade those components to TLS 1.2 or later so they remain connected after the upgrade. For more information, see [Managing the TLS version](#).
- After you upgrade to 12.0 or later, custom SHA256 GIM certificates are required before you can deploy new SHA256-signed GIM bundles. For more information, see [Updating Guardium Data Protection GIM clients with SHA256 certificates](#).
- Central managers on version 11.5 do not support registration of new managed units that are lower than version 11.5.

Upgrading with central managers and aggregators

Minimize disruptions to your Guardium® environment by following a top-down upgrade approach.

This means first upgrading one high-level system and then upgrading the systems or agents that report to it, then upgrading the next high-level system and the systems or agents that report to it, and so on. This approach minimizes the impact of operating a mixed-version Guardium environment.

A top-down approach is necessary because an upgraded aggregator can aggregate data from older releases, but an older aggregator cannot aggregate data from collectors on newer releases. Similarly, an upgraded central manager can manage units running older releases, but the managed units are not fully functional until they are upgraded to match the central manager.

To avoid these issues, upgrade a central manager before upgrading any of its managed units. If you have multiple central managers, first upgrade one central manager and then upgrade its managed units before going on to upgrade the next central manager and its managed units.

Similarly, upgrade an aggregator before upgrading any units that export data to it. If you have several aggregators, first upgrade one aggregator and then upgrade the collectors that report to it before going on to upgrade the next aggregator and its collectors.

Finally, upgrade a collector before upgrading the S-TAPs registered to it. Upgrade one collector and all the S-TAPs registered to it before going on to upgrade the next collector and its S-TAPs.

Use failover collectors to ensure that the data collection from S-TAPs is not interrupted during the upgrade process.

This is the most efficient approach for establishing compatible systems in each branch of your environment.

Upgrading an environment with a central manager

Upgrade your central manager environment to the next major version.

1. [Preparing for upgrade in a managed environment](#)

The upgrade patch promotes your Guardium system to the next major version. In an environment with a central manager, you must first upgrade your central manager and then the managed units. Use the following workflow to prepare your central manager and managed units for upgrade.

2. [Upgrading the central manager](#)

Upgrade your central manager to the next major version.

3. [Upgrading the managed unit](#)

Upgrade your managed units after upgrading your central manager.

4. [Upgrading S-TAP agents in a managed environment](#)

After you upgrade your central manager and managed units, upgrade your S-TAP agent.

Preparing for upgrade in a managed environment

The upgrade patch promotes your Guardium® system to the next major version. In an environment with a central manager, you must first upgrade your central manager and then the managed units. Use the following workflow to prepare your central manager and managed units for upgrade.

Procedure

1. Ensure that you meet the minimum system requirements. For more information, see [Hardware requirements](#).
2. Plan your upgrade strategy. For more information, see [Planning an upgrade](#).
3. Identify your upgrade path and download the relevant patches from the IBM Fix Central website. For more information, see [Identifying the correct upgrade path](#).
 - The latest applicable health check patch.
 - The latest upgrade patch or GPU.
 - All applicable maintenance patches, such as the latest bundle, security fix, and sniffer patch. To view the list of available patches, access the home page of the Guardium UI and click the bell icon.
 - Base and append licenses.
4. Upgrade your firmware to the most recent version provided by your vendor. If you use a Guardium appliance, check the Fix Central website for the latest firmware.
5. If you want to use an external storage system for your archive and backup, ensure that you have the configuration details ready. For more information, see [Configuring external storage](#).
6. Unmount all media such as DVDs or USB disks that are mounted either directly or virtually on the physical appliance. Mounted media might cause the upgrade to fail.
7. Schedule the installation during a quiet time on your Guardium system to avoid conflicts with other long-running processes such as heavy reports, audit processes, backups, and imports.

8. Set the time to the local time zone and synchronize time across all your Guardium systems and agents by using a Network Time Protocol (NTP) server.

Upgrading the central manager

Upgrade your central manager to the next major version.

1. Applying the health check patch on central managers

The health check patch performs preliminary checks on your Guardium system to prevent potential issues during the upgrade. This patch must be successfully installed on your central manager in the last seven days before you install the Guardium upgrade patch.

2. Archiving data from central managers

You can archive the audit data that is captured by your Guardium system to another location. These archived files can be restored later for forensic purposes without replacing the audit data that is already available in your Guardium system. Use the following procedure to archive data on your central manager.

3. Purging system data from central managers

Purging unnecessary data from the Guardium system can significantly speed up the upgrade process. For best performance and to minimize risks that are associated with upgrading large amounts of data, try to achieve less than 20% internal database utilization by purging unnecessary system data. Use the following procedure to purge data from your central manager.

4. Backing up a central manager

System backups store all the necessary data and configuration values to restore your Guardium system. Use the following procedure to back up your central manager.

5. Applying the upgrade patch on central managers

To upgrade your central manager, you must install the upgrade patch. You can install the patch from your local system, from a network location, from a file server, or by using media such as a CD or DVD.

6. Installing maintenance patches on central managers

After you upgrade your central manager, apply the relevant maintenance patches.

Previous topic: [Preparing for upgrade in a managed environment](#)

Archiving data from central managers

You can archive the audit data that is captured by your Guardium® system to another location. These archived files can be restored later for forensic purposes without replacing the audit data that is already available in your Guardium system. Use the following procedure to archive data on your central manager.

Procedure

1. Go to Manage > Data Management > Data Archive.
2. Select the Archive checkbox.
3. In the Archive data older than field, enter a value and select a unit of time from the menu.
For example, to archive data from yesterday, enter the value 1, and select Day(s) from the menu.
Tip: If you archive data on a schedule, check your archive log by accessing Manage > Reports > Data Management > Aggregation/Archive Log to ensure that there are no data gaps in your archive.
4. In the Ignore data older than field, enter the time interval to archive.
For example, to archive one day's data, enter 2. Any value that is specified here must be greater than the Archive data older than value. If you leave this field blank, you archive data for **all days** older than the value specified in Archive data older than.

5. Select the Archive Values checkbox to include values from SQL strings in the archived data. If this option is not selected, the values are replaced with question mark characters and are not available after the restore operation.
6. Select the Protocol that you want to use to store your archive and enter the configuration details.
7. Click Test connection The system verifies the configuration by sending a test data file to the configured location. If the operation fails, an error message is displayed.
8. Click Save to save the configuration changes. If the operation fails, an error message is displayed and the configuration is not saved.
9. Click Run Once Now to run the operation now.

What to do next

Go to [Manage > Reports > Data Management > Aggregation/Archive Log](#) to verify that the archive operation is successful. Each archive operation shows multiple activities. Ensure that the status of each activity is Succeeded.

Purging system data from central managers

Purging unnecessary data from the Guardium® system can significantly speed up the upgrade process. For best performance and to minimize risks that are associated with upgrading large amounts of data, try to achieve less than 20% internal database utilization by purging unnecessary system data. Use the following procedure to purge data from your central manager.

Procedure

1. Open [Manage > Data Management > Data Archive](#).
2. Click the Purge checkbox to define a purge operation.
Important: Changes made to the Data Archive purge configuration is also applied to the Data Export purge configuration.
3. Define a Purge data older than time period.
All data older than the specified period of days, weeks, or months are purged from the system.
4. Click the Allow purge without archiving or exporting checkbox.
5. Click Save to save the configuration changes.
6. Click Run Once Now to run the purge operation and purge old system data.

What to do next

Open [Manage > Reports > Activity Monitoring > Scheduled Jobs](#) to monitor the status of the data archive job.

Previous topic: [Archiving data from central managers](#)

Next topic: [Backing up a central manager](#)

Backing up a central manager

System backups store all the necessary data and configuration values to restore your Guardium® system. Use the following procedure to back up your central manager.

Before you begin

Determine whether you have sufficient disk space available for backup.

Tip:

For a successful backup, ensure that the DB utilization size < available disk space for backup.

You can use the following formula to calculate the disk space available for backup:

Available disk space for backup = free space available in your /var partition - 10% of the total size of your /var partition.

To find the disk size of your /var partition, navigate to [Manage > System View > System Monitor](#). On the Hard Disk Usage tile, click Tabular View to list the values for the total disk size, free disk space, and used disk space for your partitions.

Procedure

1. Go to [Manage > Data Management > System Backup](#).
2. Select the Protocol that you want to use for your backup and enter the configuration details.
3. Select one or both of the backup options:
 - Select Configuration to back up important definitions.

- Select Data to back up all data.
- Backing up both configuration and data is recommended for most deployments. In deployments where the data is not needed, for example if the data collected by Guardium is sent to another system for processing, backing up only the configuration and excluding the data is faster and produces a smaller backup file.
- Warning: If data is not backed up, it cannot be restored later.
4. Click Save to verify and save the configuration changes. The system verifies the configuration by sending a test data file to your chosen location for backup. If the operation fails, the configuration is not saved and an error message is displayed.
 5. Click Run Once Now to run the operation once.

What to do next

Go to Manage > Reports > Data Management > Aggregation/Archive Log. Verify that the operation has Succeeded.

Applying the upgrade patch on central managers

To upgrade your central manager, you must install the upgrade patch. You can install the patch from your local system, from a network location, from a file server, or by using media such as a CD or DVD.

About this task

The installation time depends on the amount of data that is involved, your system's specifications, and configurations. After the patch installation completes, the upgrade process begins automatically and the system restarts. Do not restart the system manually.

After restart, the system begins the following processes:

- Network configuration, database data migration, database startup.
- License upgrade and language setting.
- Database restart, certificate and key migration, password migration, and file clean-up.

Procedure

1. Install the patch by using the CLI command **store system patch install**. For more information, see [store system patch install](#).
2. When prompted, select the upgrade patch from the list of available patches.
3. Monitor the installation by using the CLI command **show system patch installed**. After installation is complete, the system restarts automatically.

Procedure

1. Open Manage > Data Management > Data Archive.
2. Click the Purge checkbox to define a purge operation.
Important: Changes made to the Data Archive purge configuration is also applied to the Data Export purge configuration.
3. Define a Purge data older than time period.
All data older than the specified period of days, weeks, or months are purged from the system.
4. Click the Allow purge without archiving or exporting checkbox.
5. Click Save to save the configuration changes.
6. Click Run Once Now to run the purge operation and purge old system data.

What to do next

- Open Manage > Reports > Activity Monitoring > Scheduled Jobs to monitor the status of the data archive job.

Previous topic: [Archiving data from managed units](#)

Next topic: [Backing up a managed unit](#)

Backing up a managed unit

System backups store all the necessary data and configuration values to restore your Guardium® system. Use the following procedure to back up a managed unit in your centrally managed environment.

Before you begin

Determine whether you have sufficient disk space available for backup.

Tip:

For a successful backup, ensure that the DB utilization size < available disk space for backup.

You can use the following formula to calculate the disk space available for backup:

Available disk space for backup = free space available in your /var partition - 10% of the total size of your /var partition.

To find the disk size of your /var partition, navigate to Manage > System View > System Monitor. On the Hard Disk Usage tile, click Tabular View to list the values for the total disk size, free disk space, and used disk space for your partitions.

Procedure

1. Go to Manage > Data Management > System Backup.
 2. Select the Protocol that you want to use for your backup and enter the configuration details.
 3. Select one or both of the backup options:
 - Select Configuration to back up important definitions.
 - Select Data to back up all data.
- Backing up both configuration and data is recommended for most deployments. In deployments where the data is not needed, for example if the data collected by Guardium is sent to another system for processing, backing up only the configuration and excluding the data is faster and produces a smaller backup file.
- Warning: If data is not backed up, it cannot be restored later.
4. Click Save to verify and save the configuration changes. The system verifies the configuration by sending a test data file to your chosen location for backup. If the operation fails, the configuration is not saved and an error message is displayed.
 5. Click Run Once Now to run the operation once.

What to do next

Go to Manage > Reports > Data Management > Aggregation/Archive Log. Verify that the operation has Succeeded.

Previous topic: [Purging system data from managed units](#)

Next topic: [Applying the upgrade patch on managed units](#)

Applying the upgrade patch on managed units

Upgrade your managed unit by distributing the upgrade patch from the central manager. Upgrade the aggregators first before you upgrade collectors.

Before you begin

Ensure that the upgrade patch is installed on your central manager.

Procedure

1. On your central manager, go to Manage > Central Management > Central Management
2. Select your managed units and click Patch Distribution.
3. Select the patch to distribute and click Install Patch Now to install the patch immediately. To schedule the installation later, click Schedule Patch.

Previous topic: [Backing up a managed unit](#)

Next topic: [Installing maintenance patches on managed units](#)

Installing maintenance patches on managed units

Distribute the maintenance patches to your managed units by using the Central Management page on the central manager.

Before you begin

Ensure that all relevant maintenance patches such as the latest bundle, security fix, and sniffer patch are installed on your central manager.

Procedure

1. On your central manager, go to Manage > Central Management > Central Management
2. Select your managed units and click Patch Distribution.
3. Select the patch to distribute and click Install Patch Now to install the patch immediately.

Previous topic: [Applying the upgrade patch on managed units](#)

Upgrading S-TAP agents in a managed environment

After you upgrade your central manager and managed units, upgrade your S-TAP agent.

Procedure

For information on upgrading UNIX S-TAPs, see:

- [Upgrading an S-TAP agent with GIM Setup by Client](#)
- [Upgrading S-TAP using RPM](#)
- [Upgrading the S-TAP agent using the shell installer](#)

For information on upgrading Windows S-TAPs, see:

- [Upgrading S-TAP agent with GIM Setup by Client](#)
- [Upgrading the S-TAP agent using the interactive installer](#)
- [Upgrading S-TAP using the command line](#)

Previous topic: [Upgrading the managed unit](#)

Upgrading a stand-alone system

Upgrade your stand-alone system to the next major version.

1. [Preparing for upgrade in a stand-alone environment](#)

The upgrade patch promotes your Guardium system to the next major version. Use the following workflow to prepare your stand-alone system for upgrade.

2. [Applying the health check patch on stand-alone systems](#)

The health check patch performs preliminary checks on your Guardium system to prevent potential issues during the upgrade. This patch must be successfully installed on your stand-alone system in the last seven days before you install the Guardium upgrade patch.

3. [Archiving data from stand-alone systems](#)

You can archive the audit data that is captured by your Guardium system to another location. These archived files can be restored later for forensic purposes without replacing the audit data that is already available in your Guardium system. Use the following procedure to archive data on your stand-alone system.

4. [Purging system data from stand-alone systems](#)

Purging unnecessary data from your stand-alone system can significantly speed up the upgrade process. For best performance and to minimize risks that are associated with upgrading large amounts of data, try to achieve less than 20% internal database utilization by purging unnecessary system data.

5. [Backing up a stand-alone system](#)

System backups store all the necessary data and configuration values to restore your Guardium system. Use this procedure to back up your stand-alone system.

6. [Applying the upgrade patch on stand-alone systems](#)

To upgrade your stand-alone Guardium system, you must install the upgrade patch. You can install the patch from your local system, from a network location, from a file server, or by using media such as a CD or DVD.

7. [Installing maintenance patches on stand-alone systems](#)

After you upgrade your Guardium system, apply the relevant maintenance patches.

8. [Upgrading S-TAP agents in a stand-alone environment](#)

After you upgrade your stand-alone system, upgrade your S-TAP agent.

Preparing for upgrade in a stand-alone environment

The upgrade patch promotes your Guardium® system to the next major version. Use the following workflow to prepare your stand-alone system for upgrade.

Procedure

1. Ensure that you meet the minimum system requirements. For more information, see [Hardware requirements](#).
2. Plan your upgrade strategy. For more information, see [Planning an upgrade](#).
3. Identify your upgrade path and download the relevant patches from the IBM Fix Central website. For more information, see [Identifying the correct upgrade path](#).
 - The latest applicable health check patch.
 - The latest upgrade patch or GPU.
 - All applicable maintenance patches, such as the latest bundle, security fix, and sniffer patch. To view the list of available patches, access the home page of the Guardium UI and click the bell icon.
 - Base and append licenses.
4. Upgrade your firmware to the most recent version provided by your vendor. If you use a Guardium appliance, check the Fix Central website for the latest firmware.
5. If you want to use an external storage system for your archive and backup, ensure that you have the configuration details ready. For more information, see [Configuring external storage](#).
6. Unmount all media such as DVDs or USB disks that are mounted either directly or virtually on the physical appliance. Mounted media might cause the upgrade to fail.
7. Schedule the installation during a quiet time on your Guardium system to avoid conflicts with other long-running processes such as heavy reports, audit processes, backups, and imports.
8. Set the time to the local time zone and synchronize time across all your Guardium systems and agents by using a Network Time Protocol (NTP) server.

Next topic: [Applying the health check patch on stand-alone systems](#)

Related information

-  [Understanding Guardium patch types and patch names](#)

Applying the health check patch on stand-alone systems

The health check patch performs preliminary checks on your Guardium® system to prevent potential issues during the upgrade. This patch must be successfully installed on your stand-alone system in the last seven days before you install the Guardium upgrade patch.

Procedure

1. Install the patch by using the CLI command **store system patch install**. For more information, see [store system patch install](#).
2. When prompted, select the health check patch from the list of available patches.
3. Monitor the installation by using the CLI command **show system patch installed**.

If the health check patch is an incorrect version, the installation fails with the error message Patch Installation Failed - Latest patch *patch_version_number* required.

Archiving data from stand-alone systems

You can archive the audit data that is captured by your Guardium® system to another location. These archived files can be restored later for forensic purposes without replacing the audit data that is already available in your Guardium system. Use the following procedure to archive data on your stand-alone system.

Procedure

1. Go to Manage > Data Management > Data Archive.
2. Select the Archive checkbox.
3. In the Archive data older than field, enter a value and select a unit of time from the menu.
For example, to archive data from yesterday, enter the value 1, and select Day(s) from the menu.
Tip: If you archive data on a schedule, check your archive log by accessing Manage > Reports > Data Management > Aggregation/Archive Log to ensure that there are no data gaps in your archive.
4. In the Ignore data older than field, enter the time interval to archive.
For example, to archive one day's data, enter 2. Any value that is specified here must be greater than the Archive data older than value. If you leave this field blank, you archive data for **all days** older than the value specified in Archive data older than.
5. Select the Archive Values checkbox to include values from SQL strings in the archived data. If this option is not selected, the values are replaced with question mark characters and are not available after the restore operation.
6. Select the Protocol that you want to use to store your archive and enter the configuration details.

7. Click Test connection The system verifies the configuration by sending a test data file to the configured location. If the operation fails, an error message is displayed.
8. Click Save to save the configuration changes. If the operation fails, an error message is displayed and the configuration is not saved.
9. Click Run Once Now to run the operation now.

What to do next

Go to [Manage > Reports > Data Management > Aggregation/Archive Log](#) to verify that the archive operation is successful. Each archive operation shows multiple activities. Ensure that the status of each activity is Succeeded.

Applying the upgrade patch on stand-alone systems

To upgrade your stand-alone Guardium system, you must install the upgrade patch. You can install the patch from your local system, from a network location, from a file server, or by using media such as a CD or DVD.

About this task

The installation time depends on the amount of data that is involved, your system's specifications, and configurations. After the patch installation completes, the upgrade process begins automatically and the system restarts. Do not restart the system manually.

After restart, the system begins the following processes:

- Network configuration, database data migration, database startup.
- License upgrade and language setting.
- Database restart, certificate and key migration, password migration, and file clean-up.

Procedure

1. Install the patch by using the CLI command **store system patch install**. For more information, see [store system patch install](#).
2. When prompted, select the upgrade patch from the list of available patches.
3. Monitor the installation by using the CLI command **show system patch installed**. After installation is complete, the system restarts automatically.

Deploying Guardium on a cloud service

IBM® Guardium® offers data activity monitoring, vulnerability assessment capabilities and more on several cloud platforms.

For a list of supported cloud platforms, see [System requirements](#).

For more information about deploying a Guardium instance on a specific cloud platform, see the deployment guide for that platform in [Deploying Guardium in the cloud](#).

In addition to the Guardium instance, you might need to download updates for S-TAPs or other components from Fix Central. For more information, see [IBM Support Fix Central](#).

Important: Upgrading multi-cloud images directly from Guardium v10.x to v11.0 or later is supported only for AWS. If your site uses Guardium v10.x with another cloud platform, you cannot directly upgrade the Guardium images to v11.

If you try to upgrade, the instance becomes inaccessible and irretrievable. To upgrade images on these platforms to v11.0 or later:

1. Start a new v11 image.
 2. Back up and restore from your Guardium system as described in [System Backup](#).
-

CLI Commands

The Guardium® command line interface (CLI) is an administrative tool that allows you to configure, troubleshoot, and manage your Guardium system.

- [**Using the CLI**](#)
Learn how to access the CLI, and understand the command syntax, and the types of commands.
- [**Aggregator CLI Commands**](#)
This section lists Aggregator CLI commands.
- [**Alerter CLI Commands**](#)
This section describes the Alerter CLI commands.
- [**Certificate CLI Commands**](#)
Use the certificate commands to create a certificate signing request (CSR), and to install server certificates, CA (certificate authority) certificates, or trusted path certificates on the Guardium system.
- [**Configuration and control CLI commands**](#)
Use the following CLI commands for configuration and control.
- [**diag CLI command**](#)
Use the **diag** CLI command to access troubleshooting and maintenance utilities through the SQLGuard Diagnostics interface.
- [**File handling CLI Commands**](#)
Use these commands to backup and restore system information. Many of these tasks can be performed from Guardium user interface.
- [**Inspection Engine CLI Commands**](#)
Use these CLI commands to configure the inspection engines.
- [**Investigation Dashboard CLI Commands**](#)
Use these CLI commands to configure the Investigation Dashboard.
- [**Network Configuration CLI Commands**](#)
Use the network configuration CLI commands to set IP addresses, handle bonding and failover, handle secondary functionality, and reset networking.
- [**Support CLI Commands**](#)
Use the following CLI commands only under the direction of Technical Support.
- [**System CLI Commands**](#)
Use these CLI commands to view and configure system settings.
- [**User account, password, and authentication CLI Commands**](#)
Use these CLI commands to configure user accounts, passwords, and authentication.

Using the CLI

Learn how to access the CLI, and understand the command syntax, and the types of commands.

Documentation Conventions

All CLI command examples are written in courier text (for example, `show system clock`).

To illustrate syntax rules, some command descriptions use dependency delimiters. Such delimiters indicate which command arguments are mandatory, and in what context. Each syntax description shows the dependencies between the command arguments by using special characters:

- Angle brackets (< >) denote a required argument.
- Square brackets ([]) denote an optional argument.
- A vertical bar (|) separates alternatives when only one can be selected. For example:

```
store full-bypass <ON | OFF>
```

CLI Command Usage

- Commands and keywords can be abbreviated by entering enough characters so the commands are not ambiguous. For example, show can be abbreviated sho.
- Most Guardium® CLI commands consist of a command word followed by one or more arguments. The argument can be a keyword or a keyword followed by a variable value (for example an IP address, subnet mask, or date).
- Commands and keywords are not case-sensitive, but element names are.
- To display command syntax and usage options, enter a question mark (?) as an argument that follows the command word.
- Use quotation marks around words or phrases to precisely define search terms.

Accessing the CLI

An administrator can access the CLI through either:

- A network connection that uses an SSH client.
- A physically connected PC console or serial terminal.

Network SSH Access

Remote access to the CLI is available on the management IP address or domain name, by using an SSH client. SSH clients are freely or commercially available for most desktop and server platforms. A UNIX SSH connect command to log in as the cli user might look like this:

```
ssh -l cli 192.168.2.16
```

The SSH client might display a request to accept the cryptographic fingerprint of the Guardium appliance. Accept the fingerprint to proceed to the password prompt.

Note: If you are asked again for a fingerprint after the first connection, someone might be trying to induce you to log in to the wrong machine.

Physical Console Access

Interactive access to the Guardium appliance is through the serial port or the system console.

- PC keyboard and monitor: A PC video monitor can be attached to either the front panel video connector or the video connector on the back of the appliance.
- A PC keyboard with a USB keyboard can be connected to the USB connectors at the front or back of the appliance.
- Serial port access: Use a NULL modem cable to connect a terminal or another computer to the 9-pin serial port at the back of the appliance. Set the terminal or a terminal emulator on the attached computer to communicate as 19200-N-1 (19200 baud, no parity, 1 stop bit).

A login prompt displays after the terminal is connected to the serial port, or the keyboard and monitor are connected to the console. Enter `cli` as the user name, and continue with CLI Login.

CLI Login

Access the CLI through the admin CLI account `cli` or one of the special `guardcli` accounts (`guardcli1`, ..., `guardcli9`). The `guardcli` accounts are available to help you separate administrative duties.

Access to the GuardAPI requires that the access manager create a user (GUI username/`guiuser`) with either the admin or CLI role. To log into the CLI to use GuardAPI commands, the user must first log in with one of the CLI accounts (`guardcli1`, ..., `guardcli9`) and then log in with their own user name to the `guiuser` by issuing the `set guiuser` command. For more information, see [Using GuardAPI commands](#) or [Authenticating GuardAPI commands with set guiuser command](#).

In addition, if multi-factor authentication is set up for your site, an additional message displays after you log in.

Password Hardening

To meet various auditing and compliance requirements, the following password rules are in place for CLI accounts:

- For the account `cli` either use the CLI password that is supplied or be sure to set a strong password to protect this account. If you rebuild the system, the Guardium `cli` user has a default password of `guardium`. Change the password immediately.
- Passwords expire for the CLI and `guardcli` accounts every 90 days by default. Passwords for your site might be different, depending on the values of the [store password_expiration](#) CLI command. After a password expires, you must change the password when you next log in.
- Passwords must be a minimum of 8 characters long. Depending on the value of the [enable_strong_cli_password](#) API command, the password minimum for the `cli` user might be 15 characters.
- Passwords must contain at least one character from three of the following four categories:
 - Any uppercase letter
 - Any lowercase letter
 - Any number (0,1,2,...)
 - A non-alphanumeric (special) character as described in [Special characters for Guardium passwords](#)

- After access is granted by using a separate GUI username (guiuser), the CLI audit trail shows the CLI_USER+GUI_USER pair that was used to log in.

Limited CLI commands during maintenance of internal database

CLI has three sets of commands - general commands, specialized support commands, and recovery commands. Technical support uses the support commands to analyze the system. Recovery commands help recover the system when the database is down.

The initial CLI login is:

```
Welcome to CLI - your last login was <date>
```

The welcome message will add further information if the internal database is down due to maintenance or during an upgrade.

In this case, the number of CLI commands available are limited.

```
The internal database on the appliance is currently down and CLI will be working  
in "recovery mode"; only a limited set of commands will be available.
```

The following CLI commands are available for use during recovery mode:

```
support reset-password root  
restart mysql  
restart stopped_services  
restart system  
restore backup  
restore pre-patch-backup
```

Aggregator CLI Commands

This section lists Aggregator CLI commands.

aggregator backup keys file

Use this command to back up the shared secret keys file to the specified location.

Syntax

```
aggregator backup keys file <user@host:/path/filename>
```

Parameters

`user@host:/path/filename` For the file transfer operation, specifies a user, host, and full path name for the backup keys file. The user you specify must have the authority to write to the specified directory.

Note: For more information about the shared secret use, see System Shared Secret.

aggregator clean shared-secret

Sets the system shared secret value to null. All files archived or exported from a unit with a null shared secret can be restored or imported only on systems where the shared secret is null.

Syntax

```
aggregator clean shared-secret
```

Note: For more information about the shared secret use, see System Shared Secret.

aggregator debug

Starts or stops writing debugging information relating to aggregation activities. Use these commands only when directed to do so by Guardium® Support, and be sure to issue the stop command after you have gathered enough information.

Note: Debug mode will automatically expire after 7 days.

Syntax

```
aggregator debug <start | stop>
```

aggregator list failed imports

When an import operation fails because of a shared secret mismatch, the offending file is moved from the /var/importdir directory to the /var/dump directory, and it is renamed using the original file name plus the suffix .decrypt_failed. Use this command to list all such files.

Syntax

```
aggregator list failed imports
```

aggregator recover failed import

Use this command to move and rename failed import files, prior to re-attempting an import or restore operation. Failed import files are stored in the /var/dump directory, with the suffix .decrypt_failed. Before re-attempting an import or restore operation, those files must be renamed (by removing the .decrypt_failed suffix) and moved to the

/var/importdir directory.

Syntax

```
aggregator recover failed import <all | filename>
```

Parameters

Use the all option to move all files from the /var/dump directory ending with the suffix .decrypt_failed, or use the filename option to identify a single file to be moved.

Note: After moving the failed files, but before a restore or import operation runs, be sure that the system shared secret matches the shared secret used to encrypt the exported or archived file.

[**aggregator restore keys file**](#)

Use this command to restore the shared secret keys file from the specified location.

Syntax

```
aggregator restore keys file <user@host:/path/filename>
```

Parameters

user@host:/path/filename For the file transfer operation, specifies a user, host, and full path name for the backup keys file.

Note: For more information about the shared secret use, see System Shared Secret.

[**store aggregator drop_ad_hoc_audit_db**](#)

Audit Process reports on Aggregator – creates ad-hoc databases for each of its tasks that will include only the relevant days for that task. These ad-hoc databases can be kept for 14 days (for analysis) or deleted immediately after use. The CLI command defines the ad-hoc databases purging policy. Choices are 0 or 1(0 - keep for 14-days or 1 - delete after use).

Syntax

```
store aggregator drop_ad_hoc_audit_db [1|0]
```

Drop ad-hoc merge databases? 0

```
show aggregator drop_ad_hoc_audit_db
```

[**store aggregator orphan_cleanup_flag**](#)

Use this CLI command to regularly run static orphans cleanup on an aggregator.

Use this CLI command to clean orphans on aggregators that will be scheduled to run on data older than 3 days and will run at the end of a purge.

This process will be started by the user with this CLI command, so in case of large database, the user will be aware of the time length of the process.

It will cover the whole data on the aggregator, but will run it all on a separate temporary database.

Note: On a collector, orphans cleanup is not changed - it runs with the small cleanup tactics and is invoked before export/archive.
show aggregator orphan_cleanup_flag Displays small, large or analyze.

```
store aggregator orphan_cleanup_flag
```

```
store aggregator orphan_cleanup_flag <flag>, where flag is one of the words < small large analyze >
```

These commands are applicable on aggregator only.

If set to one of small, large or analyze - orphans cleanup script is invoked after each run of merge process.

The orphans cleanup on an aggregator does not remove orphan records of the last 3 days - it does remove all orphans older than 3 days.

If small is specified, the process does not interfere with audit processes that can start after the merge is completed.

If large is specified, the process would run faster where there is a large number of orphans but it's run might interfere with audit processes - if large is specified, audit processes will not start until orphans cleanup is complete.

If analyze is specified, the process first evaluates the number of orphans and uses the large tactics if there are more than 20% orphans - if analyze is specified, audit processes will not start until orphans cleanup is complete.

Syntax

```
store aggregator orphan_cleanup_flag [ small | large | analyze]
```

Show command

```
show aggregator orphan_cleanup_flag
```

[**store archive_static_table**](#)

Use this CLI command to turn off/ turn on the archive static table

USAGE: store archive_static_table <state>,

where state is on/off.

Show command

```
show archive_static_table
```

store next_export_static

The aggregation software makes a distinction between two types of tables:

- static tables - grow slowly over time, data in these tables is not time dependent (GDM_OBJECT, GDM_FIELD, GDM_SENTENCE, GDM_CONSTRUCT, etc.).
- dynamic tables- grow quickly with time, data is time dependent (GDM_CONSTRUCT_INSTANCE, GDM_SESSION, GDM_CONSTRUCT_TEXT etc.).

As stated previously, the data of static tables is not time dependant. The data of dynamic tables that is time dependant is linked to static data. As static tables can grow to be very large, the export/archive process does not archive the full static data every day - it archives the full static data the first time it runs, and then at the first day of each month, on any day besides the first of the month, it only archives static data that changed during that day. For this reason when restoring data of any day, it is also required that the first of the month be restored - this ensures that full static data is present and references are not broken.

Use the CLI command, store next_export_static, to set a flag so that the next export contains the full static data.

Syntax

```
store next_export_static [ON | OFF]
```

Show command

```
show next_export_static
```

store last_used

Use this CLI command during purging and aggregation.

Syntax

```
store last_used [size | interval | logging]
```

Show command

```
show last_used [size | interval | logging]
```

LAST_USED SIZE - Integer, Default is 50

LAST_USED INTERVAL - Integer, default is 60 (minutes)

LAST_USED LOGGING - Integer

All Tables - 1

Only GDM_Object - 2

None - 0 (Default)

store aggregator static_data

```
store aggregator static_data [TIMESTAMP | LAST_USED_FOR_OBJECT_ONLY | LAST_USED ]
```

Note: Set the CLI command, last_used logging, prior to using this command.

When the LAST_USED column is updated by the Sniffer in Static tables, this column can be referenced when purging data from these tables or when archiving and exporting data from these tables.

The value of this column can also be updated when importing data to an aggregator.

There are three options:

1. By default, the system behaves like it did in previous versions - the LAST_USED column is not considered in purge, archive and export and is not updated on import, archive and export are done by TIMESTAMP.
2. LAST_USED_FOR_OBJECT_ONLY is considered only for GDM_OBJECT table.
3. LAST_USED is considered for GDM_CONSTRUCT, GDM_SENTENCE, GDM_OBJECT, GDM_FIELD, GDM_JOIN, GDM_JOIN_OBJECT

Note: Options 2 and 3 are only enabled when the sniffer is configured to collect and update this data.

Note: Validations performed only on a collector - If ADMINCONSOLE_PARAMETER.LAST_USED_LOGGING=0, then only TIMESTAMP is allowed. If ADMINCONSOLE_PARAMETER.LAST_USED_LOGGING=1 then all parameters are allowed. If ADMINCONSOLE_PARAMETER.LAST_USED_LOGGING=2, then TIMESTAMP and LAST_USED_FOR_OBJECT_ONLY are allowed. On an aggregator, all parameters are allowed.

Syntax

```
store aggregator static_data <type>
```

where <type> is <TIMESTAMP | LAST_USED | LAST_USED_FOR_OBJECT_ONLY> depends on the last_used logging flag.

Use show/store last_used logging commands.

Show command

```
show aggregator static_data
```

store archive_table_by_date

Use the CLI command, store archive_table_by_date, only on Aggregators. Use this CLI command to archive all static tables on a daily basis or archive static tables data at the first time of running and every first day of the month. In default, archive data on an aggregator will run with full static tables on a daily basis. If this CLI command is set to ENABLE, static tables will be archived only on the first day of month or the first time archive data is running.

store run_cleanup_orphans_daily

Use this CLI command to clean all the old construct records that are no longer in use. This CLI command is relevant for collectors and aggregators and by default is enabled.

store run_cleanup_orphans_daily

USAGE: store run_cleanup_orphans_daily [on|off]

Show command

show run_cleanup_orphans_daily

store max_number_collector

Set the maximum number of collectors managed by aggregator. Default is 10.

Show command

show max_number_collector

store purge_age_period

Set the period of purge age.

Show command

show purge_age_period

Alerter CLI Commands

This section describes the Alerter CLI commands.

The Alerter subsystem transmits messages that are queued by other components, for example, correlation alerts that are queued by the Anomaly Detection subsystem, or run-time alerts that are generated by security policies. You can configure the Alerter subsystem to send messages to both SMTP and SNMP servers. You can also send alerts syslog or custom alerting classes, but no special configuration is required for those two options, beyond starting the Alerter. Alerter commands fall into the following categories:

- Alerter Start-up and Polling Commands
- SMTP Configuration Commands
- SNMP Configuration Commands

Note: In addition to these Alerter commands, there are configuration Alerter commands. For more information, see [Configuration and control CLI commands](#).

restart alerter

Restarts the Alerter. You can perform the same function using the store alerter state operational command to stop and then start the alerter:

store alerter state operational off

store alerter state operational on

12.0 Syntax

restart alerter

12.1 and later Syntax

restart alerter [--yes]

Where --yes causes the command to run automatically.

stop alerter

Stops the Alerter.

You can perform the same function using the store alerter state operational command:

store alerter state operational off

Syntax

stop alerter

store alerter delay

Sets the number of seconds to delay real-time alerts. The default is 300 (5 minutes), the maximum is 3600. Some real-time alert values, such as Records Affected, require that snif receive and process all response data for the alerting request. This value sets the time that the Alerter waits before processing alerts that rely on this response data.

Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter delay <n>
```

Show Command

```
show alerter delay
```

store alerter email append_name_subject

Appends the appliance name in email subject.

Syntax

```
store alerter email append_name_subject <on | off>
```

Show command

```
show alerter email append_name_subject
```

store alerter email append_subject_body

Appends the email subject in the beginning of the email body.

Syntax

```
store alerter email append_subject_body <on | off>
```

Show command

```
show alerter email append_subject_body
```

store alerter poll

Sets the number of seconds, n, that the Alerter waits before checking its outgoing message queue to send SNMP traps or transmit email using SMTP. The default is 30. Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter poll <n>
```

Show Command

```
show alerter poll
```

store alerter smtp authentication password

Sets the alerter SMTP authentication password to the specified value. There is no corresponding show command. Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter smtp authentication <value>
```

store alerter state operational

Starts or stops the Alerter. The default state at installation time is off. You can also use the **restart alerter** or **stop alerter** commands to restart or stop the Alerter subsystem.

Syntax

```
store alerter state operational <on | off>
```

Show Command

```
show alerter state operational
```

store alerter state startup

Enables or disables the automatic start-up of the Alerter on system start-up. The default state at installation time is off.

Syntax

```
store alerter state startup <on | off>
```

Show Command

```
show alerter state startup
```

store anomaly-detection poll

Sets the Anomaly Detection polling interval, in minutes (n). This controls the frequency with which Guardium® checks log data for anomalies.

Syntax

```
store anomaly-detection poll <n>
```

Show Command

```
show anomaly-detection poll
```

store alerter smtp authentication type

Sets the authentication type required by the SMTP server to the one of the following values:

- none: Send without authentication.
- auth: Username/password authentication. Set the user account and password using the following commands:
 - store alerter smtp authentication username
 - store alerter smtp authentication password

Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter smtp authentication type <none | auth>
```

Show Command

```
show alerter smtp authentication type
```

store alerter smtp authentication username

Sets the alerter SMTP email authentication username to the specified name.

Syntax

```
store alerter smtp authentication username <name>
```

Show Command

```
show alerter smtp authentication username
```

store alerter smtp port

Sets the port number on which the SMTP server listens, to the value specified by n. The default is 25 (the standard SMTP port). Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter smtp port <n>
```

Show Command

```
show alerter smtp port
```

store alerter smtp relay

Sets the IP address of the SMTP server to be used by the Guardium appliance. Restart the Alerter for configuration changes to take effect.

Syntax

```
store alerter smtp relay <ip address>
```

Show Command

```
show alerter smtp relay
```

store alerter smtp returnaddr

Sets the return email address for email alerts. Any bounced messages or email failures will be returned to this address.

Syntax

```
store alerter smtp returnaddr <email address>
```

Show Command

```
show alerter smtp returnaddr
```

store alerter smtp starttls

Sets encryption for the email server.
Note: For SMTP, TLS works over port 587.
Syntax

```
store alerter smtp starttls < TLS | SSL | none >
• none: No encryption is required.
• SSL: Sets TLS data encryption.
• TLS: Sets TLS data encryption.
```

Show command

```
show alerter smtp starttls
```

store alerter snmp community

Sets the SNMP trap community used by the Alerter, to the name specified. There is no corresponding show command.

Syntax

```
store alerter snmp community <name>
```

store alerter snmp secondary_community

Sets a secondary SNMP trap community used by the Alerter, to the name specified. There is no corresponding show command.

Syntax

```
store alerter snmp secondary_community <string>
```

Where string is the text community string.

store alerter snmp traphost

Sets the Alerter SNMP trap server to receive alerts, to the specified IP address or DNS host name.

Syntax

```
store alerter snmp traphost <snmp host>
```

Show Command

```
show alerter snmp traphost
```

store alerter snmp secondary_traphost

Sets a secondary Alerter SNMP trap server to receive alerts to the specified IP address.

Syntax

```
store alerter snmp secondary_traphost <arg>
```

Where <arg> is the IP address of the secondary SNMP server or the word "null" to reset value.

Show Command

```
show alerter snmp secondary_traphost
```

store anomaly-detection state

Enables or disables the Anomaly Detection subsystem, which executes all active statistical alerts, checks the logs for anomalies, and queues alerts as necessary for the Alerter subsystem.

Syntax

```
store anomaly-detection state <on | off>
```

Show Command

```
show anomaly-detection state
```

Certificate CLI Commands

Use the certificate commands to create a certificate signing request (CSR), and to install server certificates, CA (certificate authority) certificates, or trusted path certificates on the Guardium® system.

Note: Guardium does not provide certificate authority (CA) services and does not deliver systems with different certificates than the one installed by default. If you want your site to have its own certificate, you must contact a third-party CA (such as VeriSign or Entrust).

Certification Expiration

Expired certificates result in a loss of function. Run the **show certificate warn_expire** command periodically to check for expired certificates. The command displays certificates that expire within six months and already-expired certificates. The user interface also informs you of certificates that are due to expire. To see a summary of all certificates, run the command **show certificate summary**.

New Certificates

To obtain a new certificate, generate a certificate signed request (CSR) and contact a third-party certificate authority (CA) such as VeriSign or Entrust. Guardium does not provide CA services and does not ship systems with different certificates than the ones that are installed by default. The certificate format must be in PEM and include BEGIN and END delimiters. You can either paste the certificate from the console or import it through one of the standard import protocols.

Note: Do not create the CSR until after the system network configuration parameters are set.

create csr

Creates a certificate signing request (CSR) for the Guardium system. Do not create the CSR until after the system network configuration parameters are set. Within the generated CSR, the common name (CN) is created automatically from the host and domain names assigned.

Note: Where indicated, specify the rfc7468 parameter to generate a CSR that conforms to RFC 7468 formatting. Some CAs, such as the Amazon Web Services (AWS) CA, require RFC 7468 format. Check with your CA to determine whether RFC7468 formatting is accepted or required.

Note: The following CLI commands support the subject alternative name (SAN): **create csr alias**, **create csr external_stap**, **create csr gim**, and **create csr gui**. There are 100 SAN slots for each CSR generation command. 99 of the SANs are optional and can be added in FQDN (Fully Qualified Domain Name) format. The first SAN slot is reserved for the common name.

Parameters

`create csr alias [rfc7468]`

Creates a certificate signing request CSR for a supplied alias.

`create csr external_stap [rfc7468]`

Creates a CSR for a Guardium External S-TAP® Docker container. After a certificate is signed and stored, you can deploy the External S-TAP to monitor traffic from databases in the cloud or in other situations in which you cannot use a local agent.

Note: As of Guardium V11.0, the `create csr gim` client and `create csr gim server` CLI commands replace `create csr gim`.
`create csr gim client [rfc7468]`

Creates a CSR with the alias gim in the GIM client keystore. Used for centralized GIM certificate distribution. See [Manage GIM certificate distribution](#).

`create csr gim server [rfc7468]`

Creates a CSR with alias gim for the GIM server certificate. Used for centralized GIM certificate distribution. See [Manage GIM certificate distribution](#).

`create csr gui`

Creates a CSR for the GUI.

`create csr gui [custom-dn | rfc7468]`

Where:

- `custom-dn` - Creates a CSR for the GUI with a custom distinguished name (DN). The DN is a name that uniquely identifies an entry and includes a slash-separated (/) string of identifiers. For example:

`/C=US/OU=Guardium Appliances/OU=Example/CN=mycompany.com`

The DN must be ASCII-encoded and end with a CN (common name) entry.

- `rfc7468` - Creates a CSR for the GUI with RFC7468 formatting.

`create csr insights`

Creates a CSR for IBM® Guardium Insights.

`create csr mysql`

Creates a CSR for a MySQL certificate.

`create csr saml`

Creates a CSR for SAML certificates.

`create csr sniffer`

Creates a CSR for sniffer.

`create csr sniffer custom-dn`

Creates a CSR for sniffer with a custom distinguished name (DN). The DN is a name that uniquely identifies an entry and includes a slash-separated (/) string of identifiers. For example,

`/C=US/OU=Guardium Appliances/OU=Example/CN=mycompany.com`

The DN must be ASCII-encoded and end with a CN (common name) entry.

`create csr wildcard [rfc7468]`

Generates a wildcard CSR certificate. For example, if your site has machines that are named nyc.yourdomain.com, la.yourdomain.com, and tokyo.yourdomain.com, use a wildcard certificate to specify the hostname with an asterisk (*) wildcard. The wildcard creates a certificate that is valid for all three machines. For example, *.yourdomain.com.

To generate a CSR (Certificate Signing Request) wildcard certificate:

1. On the central manager (in a managed environment), run the **create csr wildcard** command.
 2. Copy the CSR into a file and get it signed by a CA.
 3. Store the signed certificate by using the **store certificate gui** CLI command. The certificate must be in PEM format in order to import it into the Guardium appliance. Make sure that you have the root CA available.
 4. In a centrally managed environment, add the certificate to each managed unit,
 - a. Store the root CA by running the **store certificate keystore** CLI command on the managed unit that uses the same root CA as you used for the central manager.
 - b. Store both the certificate and the private key with the **store certificate privatekey gui** command with the same wildcard certificate that you used for the central manager.
- Note: Use the **show csr wildcard** CLI command to view the privatekey.

Note: The Common Name for wildcard certificates must always start with an asterisk.

Syntax

- **create csr alias [rfc7468]**
- **create csr external_stap [rfc7468]**
- **create csr gim [client | server] [rfc7468]**
- **create csr gui [custom-dn | rfc7468]**
- **create csr insights**
- **create csr mysql**
- **create csr saml**
- **create csr sniffer [custom-dn]**
- **create csr wildcard [rfc7468]**

Show command

show csr wildcard key

create self-signed gui

Use this command to manually create a self-signed certificate that uses the fully qualified domain name (FQDN) of the Guardium system. Before you use this command, set the hostname and domain name.

Syntax

create self-signed gui <force>

The parameter force creates a new self-signed certificate even if a certificate exists on the Guardium system. Nondefault certificates are removed.

delete certificate

Use this command to remove SSL certificates that are expired or revoked.

Note: Use caution when you delete certificates. If a GUI certificate is deleted in error, you cannot connect to the GUI until the certificate is restored. For more information about restoring certificates, see [restore certificate keystore](#).

Parameters

Syntax

delete certificate <external_stap | external_stap_signing | keystore>

Where:

- **external_stap** displays all of the available certificates for the External S-TAP.
- **external_stap_signing** displays aliases of all available intermediate certificates for External S-TAP and prompts you to select the certificate to delete.
- **keystore** displays all certificates in the certificate keystore.

When prompted, select the number of the certificate to delete. To delete more than one certificate, enter a comma-separated list of the certificate numbers.

distribute certificate showlog

Use this command to view the certificate distribution log.

Syntax

distribute certificate showlog <all | fail | success>

where:

- **all** displays all the lines in the distribution log.
- **fail** displays the lines with failures and warnings only.
- **success** displays the lines with success only.

replace certificate

12.1 and later Replaces the GIM certificates that is installed by default with SHA1 or SHA256. The GIM client and the server do not lose communication.

```
replace certificate gim algorithm
```

USAGE:**replace certificate gim algorithm < default | default_sha1 >**, where 'default' represents SHA256 and 'default_sha1' represents SHA1 signature algorithm.

restore certificate

Parameters

```
restore certificate insights <default | last>
```

Restores the Guardium Insights certificate to either the default certificate keystore or to the last saved certificate keystore.

```
restore certificate keystore <backup | default>
```

Restores the certificate keystore to the last certificate keystore on record or the default certificate keystore that was originally provided.

- restore certificate keystore backup

Restores the certificate keystore to the last saved certificate keystore.

- restore certificate keystore default

Restores the certificate keystore to the default value that was supplied with the system.

```
restore certificate mysql backup <client <ca|cert> | server <ca|cert>>
```

Restores the last saved MySQL certificate. Specify which certificate you want to restore; the client or server certificate and the certificate authority (CA) or client certificate.

- restore certificate mysql backup client ca

Restores the last saved client certificate authority (CA) certificate.

- restore certificate mysql backup client cert

Restores the last saved client certificate.

- restore certificate mysql backup server ca

Restores the last saved server certificate authority (CA) certificate.

- restore certificate mysql backup server cert

Restores the last saved server certificate.

```
restore certificate sniffer <backup | default>
```

Restores the certificate to either the last saved sniffer certificate (the backup) or the default certificate.

Syntax

- restore certificate insights < default | last >

- restore certificate keystore <backup | default>

- restore certificate mysql backup <client | server> <ca | cert>

- restore certificate sniffer <backup | default>

restore cert_key

```
restore cert_key mysql backup <client | server>
```

Restores the MySQL client or server certificate key to the last saved value.

```
restore cert_key sniffer <backup | default>
```

12.0 This command is deprecated in Guardium 12.1.

Restores the sniffer certificate key to the last saved certificate key (backup) or the default sniffer certificate key.

Syntax

```
restore cert_key mysql backup <client | server>
```

```
restore cert_key sniffer <backup | default>
```

show certificate

Displays the summary of all certificates, certificate information, alias list, certificates in the keystore, and expired or soon-to-expire certificates.

This certificate authenticity can be verified by a Guardium CA public key (contained in the CA certificate that is distributed with the client software). The certificate has either a customer company-unique CN (Common Name - for example, acme.com), or a machine-specific CN (for example x4.acme.com). This permits any client to establish that the Guardium system has a valid certification (it is a real Guardium system), but also that it is a specific Guardium system (or a set of Guardium systems) that the client is supposed to connect to.

Parameters

```
show certificate all
```

Displays all the certificates on the Guardium appliance.

```
show certificate external_stap
```

Displays a summary of External S-TAP certificates, including certificate information, alias, certificates in the keystore, and expired or soon-to-expire certificates.

```
show certificate external_stap_signing
```

Displays a summary of External S-TAP intermediate certificates, including certificate information, alias names, certificates in the keystore, and expiration information.

```
show certificate gim client
Displays the GIM client certificate or certificates.

show certificate gim server
Displays the GIM server certificate.

show certificate gui
Displays the GUI certificate.

show certificate insights
Displays all Guardium Insights certificates that are stored in the Guardium Insights keystore

show certificate keystore alias
Displays a list of certificates. Select a certificate from the list to display its alias.

show certificate keystore all
Displays all the certificates in the Guardium keystore.

show certificate mysql client
Displays the MySQL client certificate.

show certificate mysql server
Displays the MySQL server certificate.

show certificate saml
Displays the SAML certificate.

show certificate sniffer
Displays the sniffer certificate.

show certificate starttls
Displays an existing starttls certificate.

show certificate squid
show certificate summary
Displays a summary of all certificates on the Guardium appliance.

show certificate trusted
Displays all trusted certificate information.

show certificate warn_expired
Displays all expired certificates or certificates that expire in 6 months.

show certificate wkc
Displays the certificate that is required for IBM Knowledge Catalog integration.
```

Syntax

- show certificate all
- show certificate external_stap
- show certificate external_stap_signing
- show certificate gim <client | server>
- show certificate gui
- show certificate insights
- show certificate keystore <alias | all>
- show certificate mysql <client | server>
- store certificate saml
- show certificate sniffer
- show certificate starttls
- show certificate summary
- show certificate trusted
- show certificate warn_expired
- show certificate wkc

store certificate

Stores a certificate. Follow the directions to paste your certificate (in PEM format) and include the BEGIN and END lines.

All certificates except for GIM client and GIM server are merged into the main keystore during the store certificate operation.

Note: Where [console | external] is specified, use console to paste the content to the console; use external to import a certificate located externally. The default is console.

Parameters

```
store certificate allowlist_external_stap
For the External S-TAP, stores trusted certificates. For more information, see Client and server certificate verification.
store certificate blocklist_external_stap
For the External S-TAP, store certificates that you know cannot be trusted. For more information, see Client and server certificate verification.
store certificate cms
For managing GUI and GIM certificates by using the Venafi certificate management system. For more information, see Managing certificates by using Venafi.
store certificate custom_keystore_external_stap
Store certificates in the custom keystore to verify that the External S-TAP communicates only with trusted clients and servers. For more information, see Client and server certificate verification.
store certificate external_stap
Stores the signed External S-TAP certificate into the corresponding keystore. For more information, see External S-TAP.
store certificate external_stap_signing
Stores the signed intermediate External S-TAP certificate into the corresponding keystore. For more information, see External S-TAP.
store certificate gim client [auto-generate|console|external]
Stores the signed GIM client certificate into the corresponding keystore and prepares it for distribution. Used for centralized GIM certificate distribution. See Manage GIM certificate distribution. Unlike all other certificates, storing the GIM client certificate does not affect the main keystore. Instead, the GIM client keystore is saved in a custom keystore that can be distributed to registered GIM clients.
Use auto-generate to generate and distribute selected GIM client certificates. You can generate only SHA-1 certificates. You do not need to use this command to generate SHA-256 certificates.
store certificate gim server [console|external]
Stores the signed GIM server certificate into the keystore. Used for centralized GIM certificate distribution. See Manage GIM certificate distribution.
store certificate gui
Stores a GUI certificate in the keystore.
store certificate insights [console | external | trusted]
Stores a Guardium Insights certificate in the keystore, where:

- console - Paste the certificate to the console.
- external - Import an externally generated certificate.
- trusted - Paste a trusted CA certificate to the console.

store certificate keystore_external_stap
Stores root and intermediate trusted certificates, which are used to sign External S-TAP certificates.
store certificate keystore [alias | trusted | trusted-venafi] [console|external]
Store certificates on the keystore. You can store the certificate alias, a trusted certificate, or a trusted Venafi certificate. Specify trusted to store CA certificates for TLS validation.
store certificate mysql
Stores MySQL client and server certificates. For both client and server certificates, specify ca to store certificate authority (CA) certificates. Specify cert to store client or server default certificates.

- store certificate mysql client <ca|cert> [console|external]
      Stores MySQL client certificates.
- store certificate mysql server <ca|cert> [console|external]
      Stores MySQL server certificates.

Storing certificates with private key

The following commands overwrite self-signed GUI, GIM, and Insights certificates with private keys in the keystore.

Note:  
Certificates and private keys must be in PEM format.

Certificates start with "-----BEGIN CERTIFICATE-----" and end with "-----END CERTIFICATE-----"

Private keys start with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"

PEM certificates can also be imported by using the GUI. For more information, see Importing a PEM certificate.

store certificate privatekey gim [console | external]

Stores GIM self-signed certificate and private key in the keystore.

store certificate privatekey gui [console | external]

Stores GUI self-signed certificate and private key in the keystore.

```

Stores a Guardium Insights self-signed certificate and private key in the keystore.

Note: You must restart the Guardium Insights agent.

store certificate rsa_securid console

Stores a certificate for RSA SecurID multi-factor authentication. The certificate verifies the RSA SecurID Authentication Manager. Run this command on a central manager. SSH authentication is required for SSH logins with RSA SecurID. The certificate must be in PEM format.

After you store the certificate, use the **configure_mfa** API command to configure multi-factor authentication from the CLI.

Note: From **configure_mfa**, make sure that you set the `sslVerify` parameter to `true`. If `sslVerify` is not set to `true`, the GUI and `SET_GUIUSER` logins does not use the certificate, and for SSH logins, the **configure_mfa** API command fails.

For more information, see [Configuring multi-factor authentication with RSA SecurID](#).

store certificate saml

Stores SAML certificates.

store certificate scanner ca_bundle <agent>

Stores the certificate for the CVE scanner agent. For more information, see [Configuring vulnerability scanner agents](#).

store certificate sniffer

Stores sniffer certificates.

store certificate starttls [console | external]

Store a trusted certificate in the keystore to support an encrypted TLS connection.

store certificate wkc [console | external]

Required for the Guardium and IBM Knowledge Catalog integration. Use this command to store the IBM Cloud Pak® for Data root CA certificate, which is required to connect to your IBM Knowledge Catalog environment.

Important: The Cloud Pak for Data installation includes a self-signed certificate. Do not use the self-signed certificate in a production environment. Acquire and install a CA-signed certificate for production use.

For more information about obtaining and using a Cloud Pak for Data certificate, see [Using a custom TLS certificate for HTTPS connections to the platform](#) in the IBM Cloud Pak for Data documentation.

For more information about using the IBM Knowledge Catalog integration, see [Integrating with IBM Knowledge Catalog for federated data protection](#) and [store_wkc_configuration](#).

Note: This command is available only on managed units and stand-alone machines.

Syntax

- store certificate allowlist_external_stap
- store certificate blocklist_external_stap
- store certificate cms
- store certificate custom_keystore_external_stap
- store certificate external_stap
- store certificate external_stap_signing
- store certificate gim client [auto-generate|console|external]
- store certificate gim server [console|external]
- store certificate insights [console|external|trusted]
- store certificate keystore <alias | trusted> [console|external]
- store certificate keystore_external_stap
- store certificate mysql client <ca|cert> [console|external]
- store certificate mysql server <ca|cert> [console|external]
- store certificate privatekey <gim | gui > [console|external]
- store certificate rsa_securid console
- store certificate saml
- store certificate scanner ca_bundle
- store certificate sniffer
- store certificate starttls [console | external]
- store certificate wkc [console | external]

store cert_key mysql

Stores the certificate key of a MySQL client or server. Specify `console` to paste the key into the console. Specify to import the key file from an external source. Specify to import the key file from an external source.

Parameters

Use the following parameters to store the certificate key of a MySQL client:

store cert_key mysql client [console|external]

Use the following parameters to store the certificate key of a MySQL server:

store cert_key mysql server [console|external]

store cert_key sniffer

12.0 This command is deprecated in Guardium 12.1.

If the certificate signing request (CSR) is not generated in the Guardium appliance, the **store cert_key sniffer** command prompts you to enter the key to store the certificate.

Stores the system certificate key. This command enables a user to set the system certificate that is used by the Guardium system (in communication with S-TAP). The certificate can either be pasted from the console or imported through one of the standard import protocols. Use the PEM certificate format and include the BEGIN and END delimiters. This certificate needs to be signed by a CA whose self-signed certificate is available to S-TAP software through the `guardium_ca_path`.

Parameters

`store cert_key sniffer console`

Stores the sniffer certificate key by pasting the key into the console.

`store cert_key sniffer external`

Stores the sniffer certificate key by importing the key file from an external source.

Syntax

`store cert_key sniffer <console | external>`

Backup and Default Options

You can choose to restore certificates and certificate keys with the backup or default parameter. Use the backup parameter to restore a certificate to the last saved certificate. Use the default parameter to restore a certificate to the original certificate that Guardium supplied.

Certificate Expiration Dates and Summary Commands

Run the `show certificate warn_expire` command periodically. This command warns you of certificates that expire in six months and displays a list of expired certificates. For more information, see the **show certificate CLI** command. To show a summary of all certificates, run the CLI command `show certificate summary`. Run the commands periodically to review certificate expiration dates.

Configuration and control CLI commands

Use the following CLI commands for configuration and control.

? (question mark)

To find more information about a command, enter a question mark at any point to display the arguments.

Syntax

`<partial_command> ?`

Example

`CLI> show account strike ?`

`USAGE: show account strike <arg>, where arg is:
?, count, interval, max
ok
CLI>`

commands

Displays an alphabetical listing of all CLI commands.

Syntax

`commands`

debug

Enable or disable debug mode. Without an argument, it toggles the debug state. Optionally, you can include a state argument (`on` or `off`)

Syntax

`debug <on | off>`

clean load_balance_inactive_stap_queue

Use this command to manually clear an inactive S-TAP and its corresponding collector from the inactive S-TAPs queue in the load balancer.

Syntax

`clean load_balance_inactive_stap_queue <stapHost> <collectorName>`

delete scheduled-patch

To delete a patch installation request, use the **delete scheduled-patch** CLI command.

For more information about installing patches, see the **store system patch install** CLI command.

[delete ssl_gui_ciphers and restore ssl_gui_ciphers](#)

Use these commands to select and delete out-of-date GUI ciphers, and, if necessary, restore deleted ciphers.

Syntax

```
delete ssl_gui_ciphers
```

Guardium returns a list of ciphers. Specify the number of the cipher to delete. Use a comma to separate multiple cipher numbers.

Click q to quit without deleting any ciphers.

If you accidentally delete the wrong cipher, use restore ssl_gui_ciphers to restore it.

Restore command

```
restore ssl_gui_ciphers [ last | list ]
```

Where:

- last: Restores one or more last deleted ciphers.
- list: Restores all deleted ciphers.

Before you restore ciphers, Guardium warns that restoring the certificates can affect the connectivity of GUI and GIM-TLS. Make sure that when you restore deleted ciphers, the results that are returned are expected.

Show command

```
show ssl_gui_ciphers
```

For more information about supported ciphers, see [Cipher suites](#).

[delete unit type](#)

Use this command to clear one or more unit type attributes. Note that this command cannot clear all unit type attributes. For more information, see [store unit type](#).

Syntax

```
delete unit type [manager | standalone] [aggregated] [netinsp] [network routes static] [stap] [mainframe]
```

[eject](#)

This command dismounts and ejects the CD ROM, which is useful after you upgrade or reinstall the system, or after you install patches that were distributed on a CD ROM.

Syntax

```
eject
```

[export gim_bundle](#)

This command exports a selected S-TAP bundle that contains a custom K-TAP module from one GIM server to another.

Syntax

```
export gim_bundle <IP address or hostname>
```

IP address or hostname is the name of the machine to which you want to export the custom K-TAP module.

Note: You can run this command from any GIM appliance. Before you begin, make sure that the bundle you want to export is available on your current machine. When you run this command, a numbered list of all of the S-TAP bundles on your current machine that include a custom K-TAP module displays. To export an S-TAP bundle with a custom K-TAP module:

1. Run the **export gim_bundle** command.
2. Select the bundle that you want to export.
3. Guardium exports the bundle to the staging directory on the GIM appliance that you specified.
4. From the new GIM appliance, run the **grdapim_load_package** GuardAPI to upload the S-TAP bundle to your GIM appliance. For more information, see [gim_load_package](#).

[forward support email](#)

When the support-state option is enabled (which it is by default), this command sets the email address to receive system alerts.

Syntax

```
forward support_email to <email address>
```

Show command

```
show support-email
```

[import jproxy_files](#)

Use this command, along with **store jproxy_config ssh_key_file** to upload the GBDI SSH key file (in .pem format) and configure the SSH target host to communicate with GBDI. For more information, see [store jproxy_config ssh_key_file](#).

iptraf

IPTraf is a network statistics utility that is distributed with the underlying operating system. It gathers information such as TCP connection packet and byte counts, interface statistics and activity indicators, TCP/UDP traffic breakdowns, and LAN station packet and byte counts. For more information, see the IPTraf User Manual at the following location (it might also be available at other locations):

<http://iptraf.seul.org/2.7/manual.html>

Syntax

iptraf

license check

Indicates whether the installed license is valid. Use this command after you install a new product key.

Syntax

license check

license clear

Removes product licenses. After running this command, you will need to reapply base and append license keys and accept their terms and conditions. For more information about applying licenses, see [License keys](#) and [Install license keys](#).

Syntax

license clear

ping

Sends ICMP ping packets to a remote host. This command is useful for checking network connectivity. The value of host can be an IP address or host name.

Syntax

ping <host>

quit

Exits the command-line interface.

Syntax

quit

recover failed

Command to restore failed CSV/CEF/PDF transfer files, placing the files back into the export folder for another export attempt.

Syntax

recover failed [csv|cef|pdf]

register management

Registers the Guardium system for management by the specified central manager. The pre-registration configuration of this Guardium system is saved, and that configuration is restored later if the unit is unregistered.

Syntax

register management <manager ip> <port>

Parameters

manager ip is the IP address of the central manager.

port is the port number used by the central manager (usually 8443).

reset luks keys

Clears all stored tang keys in the Linux Unified Key Setup (LUKS) and removes all connections to the tang server.

Syntax:

reset luks keys

restart datastreams

Use this command to restart stopped AWS database activity-monitoring data streams. For more information, see [Cloud database service protection with data streams](#).

12.0 Syntax

restart datastreams

12.1 and later Syntax

```
restart datastreams [--yes]
```

Where --yes causes the command to run automatically.

restart gui

Restarts the IBM® Guardium Web interface. To optionally schedule a restart of the GUI once a day or once a week, use additional parameters. HH is hours 01-24. MM is minutes 01-60. W is the day of the week, 0-6, Sunday is 0. If HHMM is listed twice, only the last entry is used. The parameter clear deletes the scheduled time.

In order to restart the classifier and security assessments processes, run the **restart gui** command from the CLI (not from the GUI).

Running **restart GUI** from the GUI only restarts the web services. It is necessary to run the **restart GUI** command from the CLI to fully restart all processes, including Classifier and Security Assessments processes. It is necessary to run the **restart GUI** command from the CLI for each managed unit to restart the Classifier listener.

12.0 Syntax

```
restart gui [HHMM|HHMMW|clear]
```

12.1 and later Syntax

```
restart gui [HHMM|HHMMW|clear] [--yes]
```

Where --yes causes the command to run automatically.

restart rds_monitoring

Restart the AWS RDS monitor for Oracle. For more information, see [Cloud database service protection with native audit](#).

12.0 Syntax

```
restart rds_monitoring
```

12.1 and later Syntax

```
restart rds_monitoring [--yes]
```

Where --yes causes the command to run automatically.

restart sniffer_buffer_usage

Restarts the sniffer buffer.monitor.

12.0 Syntax

```
restart sniffer_buffer_usage
```

12.1 and later Syntax

```
restart sniffer_buffer_usage [--yes]
```

Where --yes causes the command to run automatically.

For more information about using **restart sniffer_buffer_usage**, see [Performance issue: buffer usage process not running](#).

restart stopped_services

Use this CLI command to restart services previously stopped with the **store auto_stop_services_when_full** CLI command.

12.0 Syntax

```
restart stopped_services
```

12.1 and later Syntax

```
restart stopped_services [--yes]
```

Where --yes causes the command to run automatically.

restart system

Reboots the Guardium system. The system will completely shut down and restart, which means that the cli session will be terminated.

12.0 Syntax

```
restart system
```

12.1 and later Syntax

```
restart system [--yes]
```

Where --yes causes the command to run automatically.

restart ticket_service

Restarts the external ticketing service. For more information, see [Configure an external ticketing system](#).

You can also stop and start the ticketing service from the CLI.

12.0 Syntax

```
restart ticket_service
```

12.1 and later Syntax

```
restart ticket_service --yes
```

Where --yes causes the command to run automatically.

restore rsyslog

Compares the current remotelog (rsyslog) on your system with an rsyslog that is restored from a CONFIG backup file, if one is available. You can then choose to override the existing rsyslog with the backed-up rsyslog.

Syntax

```
restore rsyslog
```

show buffer

This command displays a report of buffer use for the inspection engine process. If you are experiencing load problems, IBM Technical Support may ask you to run this command.

Syntax

```
show buffer <log | snif>
```

Examples

To display the buffer usage of the inspection engine process:

```
show buffer log
```

To display the buffer usage of the sniffer:

```
show buffer snif
```

show build

Displays build information for the installed software (build, release, snif version).

Syntax

```
show build
```

show load_balance_inactive_stap_queue

This command shows the list of inactive S-TAPs and corresponding collectors that have accumulated in the load balancer's inactive S-TAP queue.

Syntax

```
show load_balance_inactive_stap_queue
```

show network routes static

Permit the user to have only one IP address per appliance (through the primary interface) and direct traffic through different routers using static routing tables. List the current static routes, with IDs.

Syntax

```
show network routes static
```

Delete command

```
delete network routes static
```

show remotelog

Displays information about the rsyslog program that runs syslog. For information about adding and configuring remote logs, see the **store remotelog** commands, beginning with [store remotelog add](#).

Syntax

```
show remotelog <escape_control_characters_on_receive | host | max_message_size| status | test>
```

Where:

- **escape_control_characters_on_receive** - Displays the value of the rsyslog \$EscapeControlCharactersOnReceive directive.
- **host** - Displays the name of any remote hosts.
- **max_message_size** - Displays the value of the rsyslog \$MaxMessageSize directive.
- **status** - Displays the status of the rsyslog.
- **test** - Verifies the configuration of a configured rsyslog, as follows:
 - If the remote log is configured: The configuration displays. The test message sent to syslog targets the configured facility.priority. If the facility is ALL, then the message is sent using the **daemon** facility. If the priority is ALL, then the message is sent using **info**. You can verify that the messages are sent. To confirm, gather a tcpdump targeting the hosts, ports, and protocols and verify that rsyslog is transmitting the messages to the SIEM system. For more information, see [Facility and priority of syslog messages](#).
 - If a remote log is not configured, then a test message is sent to syslog without a specific facility or priority.

Syntax

```
show remotelog escape_control_characters_on_receive
show remotelog host
show remotelog max_message_size
show remotelog status
show remotelog test
```

Examples

```
show remotelog host
```

Sample output

```
Remote syslog is in non-encrypted mode.
Remote syslog format is default.
user.=warning    @@9.30.252.111
user.=alert      @@myhost.mycompany
user.=alert      @@myhost.mycompany
```

```
show remotelog status
```

```
show remotelog test
```

Sample output

```
show remotelog status test
The following receivers are configured
Messages will be written to syslog targeting these.
Please verify that the messages were received.
```

The tests could take several minutes

| Facility | Priority | Protocol | Host:port |
|----------|----------|----------|-------------------|
| daemon | info | TCP | 9.30.252.192:514 |
| user | info | UDP | 9.30.252.192:514 |
| user | alert | TCP | 9.30.252.192:5514 |

```
Sending message: daemon.info: Guardium test message
Sending message: user.info: Guardium test message
Sending message: user.alert: Guardium test message
```

```
Test message 'Guardium test message' successfully sent to syslog
```

```
Analyzing tcpdump. If a message is found in the tcpdump
output, but not in the syslog receiver, please consult your
administrator for the syslog receiver.
```

```
Message to 9.30.252.192:514 sent
Message to 9.30.252.192:514 sent
Message to 9.30.252.192:5514 sent
ok
```

show security policies

Displays the list of security policies.

Syntax

```
show security policies
```

show ticket update interval

View the interval for updating the status of records from external ticketing systems like Service Now. For more information, see [Configure an external ticketing system](#).

Set the value using **store ticket update interval <n>**.

Show command

```
show ticket update interval
```

show tls enabled

Show the versions of TLS that are enabled on the current machine. Both TLS 1.2 and TLS 1.3 can be enabled on the same machine.

For more information about TLS versions, see [Managing the TLS version](#).

start datastreams

Use this command to start existing AWS database activity-monitoring data streams. For more information, see [Cloud database service protection with data streams](#).

Syntax

```
start datastreams
```

start rds_monitoring

Start the AWS RDS monitor for Oracle. For more information, see [Cloud database service protection with native audit](#).

Syntax

```
start rds_monitoring
```

start ticket_service

Starts the external ticketing service. The ticketing service synchronizes external tickets (such as Service Now tickets) that are stored in local system. When the ticketing service is running, the synchronization runs once an hour. For more information, see [Configure an external ticketing system](#).

You can also stop or restart the ticketing service from the CLI.

Syntax

```
start ticket_service
```

stop datastreams

Use this command to stop running AWS database activity-monitoring data streams. For more information, see [Cloud database service protection with data streams](#).

Syntax

```
stop datastreams
```

stop gui

Stops the Web user interface.

Syntax

```
stop gui
```

stop rds_monitoring

Stop the AWS RDS monitor for Oracle. For more information, see [Cloud database service protection with native audit](#).

Syntax

```
stop rds_monitoring
```

stop system

Stops and powers down the appliance.

Syntax

```
stop system
```

stop ticket_service

Stops the external ticketing service. For more information, see [Configure an external ticketing system](#).

You can also start or restart the ticketing service from the CLI.

Syntax

```
start ticket_service
```

store aes_256_cbc_encryption

Use this command to set password encryption for the datasource to AES-256-CBC. You can run this command on a central manager or standalone machine to toggle the encryption cipher. If you run the command on a central manager, the encryption propagates to any managed units.

Note: The central manager and all managed units must be running Guardium 11.5 or later. If any managed units are running an earlier version, Guardium returns an error message.

Syntax

```
store aes_256_cbc_encryption [ on | off ]
```

Show command

```
show aes_256_cbc_encryption
```

store apply_user_hierarchy

Use this CLI command to apply user hierarchy to audit receiver.

If ON, the non-audit group receiver (the receiver other than the audit group receiver (normal or role) will only see audit results with a group IP beneath the receiver's hierarchy, including the receiver.

Syntax

```
store apply_user_hierarchy [ON | OFF]
```

Show command

```
show apply_user_hierarchy
```

store alert_timestamp_unit

Controls the timestamp unit for syslog alerts. Default is seconds.

Syntax

```
store alert_timestamp_unit [millisecond | second]
```

Show command

```
show alert_timestamp_unit
```

store alert_object_num_limit

Sets the maximum number of objects to show in the Alert log with the %%Object or %%objectType variables.

Syntax

```
store alert_object_num_limit <n>
```

Where *n* is a positive integer between 1 and 50. The default is 10.

Show command

```
show alert_object_num_limit
```

store alert_verb_num_limit

Sets the maximum number of SQL verbs to show in the Alert log. You can also set this parameter from the GuardAPI or REST API. For more information, see [modify_guard_param](#).

Syntax

```
store alert_verb_num_limit <n>
```

Where *n* is a positive integer between 1 and 50. The default is 10.

Show command

```
show alert_verb_num_limit
```

store allow_simulation

Enables (on) or disables (off) the ability to run the Policy Simulation on the appliance.

To run the simulation, the original traffic must be replayed through the rules engine (with the policy needing to be tested). This requires some of the original SQL on the appliance to be saved with their values. The enable or disable of allow_simulation instructs IBM Guardium to save or NOT save any SQL or values whatsoever.

Syntax

```
store allow_simulation [on|off]
```

Show command

```
show allow_simulation
```

store alp_throttle

Use this CLI to determine the amount of data logged by the Analyzer into the GDM_FLAT_LOG table.

The analyzer can lose packets in the analyzer circular queue for several different reasons, including the following:

- The incoming packet rate is too high.
- The parser is too slow for some complex or long SQL statements.

- The analyzer is too slow for some database packets.

Use `store alp_throttle` to choose how much data to log into the GDM_FLAT_LOG table.

Syntax

```
store alp_throttle <n>
```

Where *n* can be 0 or a positive integer.

- If *n* = 0 (the default), report without logging any SQL statements.
- If *n* is a positive integer, report and log every *n*th SQL statement in GDM_FLAT_LOG.

Examples

To report and log all SQL statements (100%):

```
store alp_throttle = 1
```

To report and log every 2nd SQL statement (50%):

```
store alp_throttle = 2
```

To report and log every 1000th SQL statement (0.1%):

```
store alp_throttle = 1000
```

store analyzer

This command sets the value of the timeout of the ignore session and sets the duration of the ignore session.

Ignore session: The current request and the remainder of the session will be ignored. This action does log a policy violation, but it stops the logging of constructs and will not test for policy violations of any type for the remainder of the session. This action might be useful if, for example, the database includes a test region, and there is no need to apply policy rules against that region of the database.

Syntax

```
store analyzer [ignore_sess_timeout | max_open_sess]
```

Show command

```
show analyzer
```

store auto_stop_services_when_full

When ON, stops internal services if the database exceeds the 90% full threshold.

Inspection Engine, Classification and other Collection-related services will stop. Also, Aggregation import/restore will not process any new files.

To remediate, use the various Support commands (support clean audit_task, support clean log_files, support clean DAM_data, support show large_files) to analyze and manually purge large tables.

Syntax

```
store auto_stop_services_when_full [ON | OFF]
```

Show command

```
show auto_stop_services_when_full
```

store connect oracle_parser

Use this command to connect and disconnect the Oracle parser from the DB2 parser. The default is OFF (disconnect).

Syntax

```
store connect oracle_parser [ON | OFF]
```

Show command

```
show connect oracle_parser
```

store csv_fetch_size

This command is used by the report REST service to control total number of records. Guardium reports can be downloaded in CSV file format.

`store csv_fetch_size` and `store csv_max_size` are GLOBAL_PROFILE parameters that can only be modified via CLI.

Note: `csv_max_size` requires a restart of the GUI for changes to take effect. `csv_fetch_size` does not require a restart.

Syntax

```
show csv_fetch_size <num>
```

Where *<num>* is a number greater than 0

Show command

```
store csv_fetch_size
```

store csv_max_size

This command controls the size of the CSV downloads that are retrieved when you click Download all records from the report export menu. The default value is 30,000.

Note: csv_max_size requires a restart of the GUI for changes to take effect.

Syntax

```
store csv_max_size <num>
```

Where <num> is a number greater than 0.

Show command

```
show csv_max_size
```

store cyberark config_failover

Use this command to configure standby CyberArk vault servers on your Guardium system.

Syntax

```
store cyberark config_failover
```

store cyberark install

Use this command to install CyberArk on your Guardium system.

Syntax

```
store cyberark install
```

You are prompted to enter the vault host name or IP address, vault user name and vault password.

Show command

Use the show command to verify if CyberArk is installed on your Guardium system.

```
show cyberark status
```

store cyberark service [start | stop]

Use this command to start or stop the CyberArk service on your Guardium system.

Syntax

```
store cyberark service start  
store cyberark service stop
```

store cyberark uninstall

Use this command to uninstall CyberArk from the Guardium system.

Before uninstalling, you must remove the reference to the Guardium system from the CyberArk vault server first. For more information, see [Uninstalling CyberArk](#).

Syntax

```
store cyberark uninstall
```

store cyberark upgrade_parameter

Before installing the CyberArk SDK upgrade patch on your Guardium system, run this command to enter the CyberArk upgrade parameters. The upgrade parameters are the CyberArk vault hostname or IP address, the vault username, and the vault password.

Syntax

```
store cyberark upgrade_parameter
```

Show command

```
show cyberark upgrade_parameter
```

store default_queue_size

Use this command to control the ADMINCONSOLE_PARAMETER.DEFAULT_QUEUE_SIZE configuration parameter. The default is 25. The range is 25-300.

The sniffer must be restarted after a change in value.

Syntax

```
store default_queue_size <N>, where N is the number in range of 25 to 300
```

Show command

```
show default_queue_size 25
```

store defrag

Use this command to restore defragmentation defaults, or to set the defragmentation size. After entering this command, you must issue the **restart inspection-core** command for the changes to take effect. The defrag is relevant only for network sniffing through SPAM or a TAP device.

Syntax

```
store defrag [default | size <s> interval <i> trigger <t> release <r>]
```

Where:

- default: Restore the default size.
- S: The packet size in bytes, up to a maximum of 217 (131072)
- I: The time interval
- T: The trigger level
- R: The release level specified as a number of seconds, up to a maximum of the 31st power of two (2147483648).

Show command

```
show defrag
```

Identify fragmented packets and attempt to reconstruct the packets before they get to the network sniffing process. Defrag is relevant only for network sniffing through SPAM or a TAP device.

store delayed_firewall_correlation

Use this CLI command to hold a user connection until the decryption correlation has taken place.

Syntax

```
store delayed_firewall_collection [on | off]
```

Show command

```
show delayed_firewall_correlation
```

store disk_space_reserved

Use this command to change the amount of disk space to reserve on a Guardium aggregator or collector. Reserving disk space allows you to customize the percentage of free space to preserve on the data partition.

12.0 Syntax

```
store disk_space_reserved [ custom <pct> | reset ]
```

12.1 and later Syntax

```
store disk_space_reserved [ custom <pct> | reset [-- yes ] ]
```

Where:

- **custom <pct>** - The percentage of available disk space to reserve, from 0 to 100.
- **reset** - Reset the amount of reserved disk space to the default.
- 12.1 and later --yes causes the command to reset automatically.

Note: The suggested (and default) reserved disk space is 25% for an aggregator and 50% for a collector. If you set the reserved disk space to less than the default, a warning message displays.

When you run **store disk_space_reserved reset** the reserved disk space is reset to the default percentage based on the type of the machine (25% for an aggregator, 50% for a collector).

Show command

```
show disk_space_reserved
```

store dump_data_for_forensics

This command dumps full SQL details into the local Kafka server for forensic and analysis purposes.

12.0 Syntax

```
store dump_data_for_forensics <ON | OFF>
```

12.1 and later Syntax

```
store dump_data_for_forensics <ON | OFF> [--yes]
```

Where --yes causes the command to run automatically.

Show command

```
show dump_data_for_forensics
```

Note: You can also set the dump SQL details behavior on or off from the GuardAPI [modify_guard_param](#) DUMP_DATA_FOR_FORENSICS parameter.

store encrypt_must_gather

Guardium collects certain data (must gather information) that IBM support uses if something goes wrong. This command determines whether must gather data is encrypted (on) or compressed, but not encrypted (off).

Syntax

```
store encrypt_must_gather <on | off>
```

Show command

```
show encrypt_must_gather
```

store full-bypass

This command is intended for emergency use only, when traffic is being unexpectedly blocked by the Guardium system. When on, all network traffic passes directly through the system, and is not seen by the Guardium system.

When using this command, you will be prompted for the admin user password.

Syntax

```
store full-bypass <on | off>
```

store gdm_analyzer_rule

Analyzer rules - Certain rules can be applied at the analyzer level. Examples of analyzer rules are: user-defined character sets, source program changes, and firewall watch or firewall unwatch modes. Rules applied at the analyzer level means decisions can be made at an earlier stage.

Note: When applying analyzer rules on source program changes, if the source program does not match the exact pattern, add .* at the end of the pattern to deal with the possibility that the source program has a trailing space (unseen by user).

Syntax

```
store gdm_analyzer_rule [active_flag | new ]
store gdm_analyzer_rule active_flag <id> <on|off>
```

Where <id> is the rule ID.

Show command

Use the CLI command, show gdm_analyzer_rule, to see a list of GDM analyzer rules.

```
show gdm_analyzer_rule
```

store gdm_analyzer_rule new

Use the Guardium CLI to add an analyzer rule for a direct regular expression to Mask UID Chain pattern.

Syntax

```
store gdm_analyzer_rule new
Enter rule description (optional):
Enter rule type (required):
```

Example

```
store gdm_analyzer_rule new
Please enter rule description: new rule 4
Rule type
 1. Change source program
 2. Set alternate character set
 3. Send verdict
 4. HADOOP exclude
 5. Define protocol and port
 6. Ignore session after packets
 7. Set empty Oracle DB user when login information is missed
 8. Force MS SQL login
 9. Transform string
Please select rule type (required): 9
Please enter pattern (required, regex string): (.*)(-ppassword)(.*)
Please enter format (required, regex string): \\\\1-p****\\\\3
Do you want to activate the rule now? (Yes/No)
Y
ok
```

store gdm_http_session_template

Use this CLI command to set the template for the HTTP session.

Usage

```
store gdm_http_session_template [activate] [add] [deactivate] [remove]
```

Show command

```
show gdm_http_session_template
```

Attempting to retrieve the template information. It may take time. Please wait.

Table 1. store gdm_http_session_template

| ID# | Active URL Regex | Session Regex | Username Regex | Login_Session Regex | Comment | Logout_Session_ID | Logout_URL_Regex |
|-----|------------------|---|--|--------------------------|---------------------------------|-------------------|------------------|
| 1 | 1 | Cookie.*PHPSESSID=([a-zA-Z0-9_-]{32}) | .*user_name=([a-zA-Z0-9_-]{1,16}) | Set-Cookie:.*PHPSESSID= | example of HTTP session deleted | | |
| 2 | 1 | Cookie.*PSJSESSIONID=([a-zA-Z0-9_-]{32}) | .*SignOnDefault=([a-zA-Z0-9_-]{1,16}) | | example of HTTP session | cmd=logout | |
| 3 | 1 | Cookie.*JSESSIONID=([a-zA-Z0-9_-]{32}) | .*username=([a-zA-Z0-9_-]{1,16}) | Set-Cookie:.*JSESSIONID= | example of HTTP session | | Logout.jsp |

store log external

Use this command to set file size, flush period, gdm error and state of the log external. This rule displays only if the following CLI command is executed:

```
store log external state on
```

Then log external shows up as a policy action.

CLI command to check the state:

```
show log external state
```

CLI command to enable and disable this action:

```
store log external state on/off
```

Usage

```
store log external [file_size] [flush_period] [gdm_error] [state]
```

Syntax

```
store log external gdm_error <state>
```

Where state is on or off. 'on' is to enable and 'off' is to disable.

```
store log external file_size <num>
```

Where <num> is the size of the file. Default is 4096 bytes.

```
store log external flush_period <num>
```

Where <num> is the flush period. Default is 60 seconds.

```
store log external state <state>
```

Where state is on or off. 'on' is to enable and 'off' is to disable.

Show command

```
show log external [file_size] [flush_period] [gdm_error] [state]
```

store monitor gdm_statistics

Use this CLI command to get information about the Unit Utilization. Default is 1 (run the script every hour).

Syntax

```
store monitor gdm_statistics
```

USAGE: store monitor gdm_statistics <hour>, where hour is a value from 0 to 24. Default value is 1, means to run the script every hour. Value 0, means not to run the script.

Show command

```
show monitor gdm_statistics
```

Disable command

```
Disable gdm_statistics monitor
```

store gui

Sets the TCP/IP port number on which the IBM Guardium appliance management interface accepts connections. The default is 8443.

n must be a value in the range of 1024 to 65535. Be sure to avoid the use of any port that is required or in use for another purpose.

Set session timeout: Sets the length of time (in seconds) with no activity before timeout. After the no-activity-timeout has been reached, it is necessary to log on again to Guardium. The default length is 900 seconds (15-minutes).

Enable or disable the Cross-site Request Forgery (CSRF) status. Trying to use certain web browser functions (for example, F5/CTRL-R/Refresh/Reload, Back/Forward) results in a 403 Permission Error message.

The new session timeout value will take effect only after the next GUI restart.

Syntax

```
store gui port <n>
store gui session_timeout <n>
store gui csrf_status [on | off]
```

Show command

Displays the GUI port number, state, session timeout (in seconds) and/or CSRF status.

```
show gui [port | state | all | session_timeout | csrf_status ]
```

store gui cache

Use this CLI command to turn web browser caching ON or OFF (Enable or Disable).

The response is:

```
The parameter has been changed.
Restarting gui
Changing to port 8443
Stopping.....
Safekeeping xregs
ok
```

The default setting for browser caching is enabled.

The act of changing the cache setting will automatically restart the Guardium web server.

For Firefox, you must clear the browser cache for the setting to take effect.

Syntax

```
store gui cache [ON | OFF]
```

Show command

```
show gui cache
```

store gui hsts_status

Use this CLI command to enable or disable the HSTS (HTTP Strict Transport Security Filter). This option is disabled by default on upgraded systems and is recommended to be turned on after valid certificates are installed. See the topic, How to install an appliance certificate to avoid a browser SSL certificate challenge, for further reference.

Syntax

```
store gui hsts_status [ on | off ]
```

Show command

```
show gui hsts_status
```

store gui xss_status

Use this CLI command to enable or disable the Cross-Site Scripting (XSS) status. This option is enabled by default on upgraded systems.

Syntax

```
store gui xss_status [ on | off ]
```

Show command

```
show gui xss_status
```

store installed security policy

Sets the security policy named **policy-name** as the installed security policy.

Syntax

```
store installed security policy <policy-name>
```

Show command

```
show installed security policy
```

store jproxy_config flush_at_size/store jproxy_config flush_timeout_sec

Use these commands to configure the streaming interval for transporting the JSON document data from Guardium to Guardium Big Data Intelligence (GBDI). Whenever Guardium hits either threshold, jProxy sends the data to GBDI. For more information, see [Big Data Intelligence with data streaming](#).

Syntax

```
store jproxy_config flush_at_size <bytes>
```

The default is 102400000.

```
store jproxy_config flush_timeout_sec <seconds>
```

The default is 60 seconds.

Show commands

```
show jproxy_config flush_at_size <bytes>
show jproxy_config flush_timeout_sec <seconds>
```

store jproxy_config ssh_key_file

Use this command, along with **import jproxy_files** to upload the GBDI SSH key file (in .pem format) and configure the SSH target host to communicate with GBDI. For more information, see [Big Data Intelligence with data streaming](#)

Syntax

```
import jproxy_files
store jproxy_config ssh_key_file <key_file_name>
```

- Use **import jproxy_files** to import the signed certificate (the SSH key file).
- Use **store jproxy_config ssh_key_file <key_file_name>** to store the SSH key file in the keystore.

store keep_psmls

Use this CLI command to retain the current layouts/profiles/portlets created by the users of the Guardium application. Set this CLI command to ON before an upgrade, and the psmls from the previous version will be retained.

Syntax

```
store keep_psmls [ON | OFF]
```

Show command

```
show keep_psmls
```

store ldap-mapping

Store LDAP-mapping parameters - allow a custom mapping for the LDAP server schema. This command permits customized mapping to the LDAP server schema for email, firstname and lastname attributes. The paging parameter is used to facilitate transfer between any LDAP server type (Active Directory, Novell Directory, Open LDAP, Sun One Directory, Tivoli® Directory). If the paging parameter is set to on, but paging is not supported by the server, the search is performed without paging.

Example for paging. If the CLI command, **ldap-mapping paging** is set to ON, then Microsoft Active Directory will download the maximum number users defined under the limit value on the LDAP Import configuration screen. If CLI command, **ldap-mapping paging** is set to OFF, then Active Directory will download up to only 1000 users no matter what the limit value is set to. All other LDAP server configurations must use the CLI command, **ldap-mapping paging off** in order to download users up to the set limit value.

Note: Each time you change the CLI ldap-mapping attributes you also need to select Override Existing Changes on the LDAP Import configuration screen in IBM Guardium GUI before updating. This action must occur each time you change the CLI ldap-mapping email, firstname or lastname attributes and import LDAP users.

Show commands

```
show ldap-mapping [email] [firstname][lastname] <name>
show ldap-mapping paging ON|OFF
```

A GUI restart of the CLI is required for new parameters to take effect.

Examples

```
store ldap-mapping firstname name
store ldap-mapping lastname sn
store ldap-mapping email mail
store ldap-mapping paging on
```

If the attributes are written as follows, the mapping process will use the first attribute it finds. If this is not what you want, use one of the examples to map to specific attributes.

- Values for firstname attribute: gn,givenName,name
- Values for lastname: attribute: sn,surname,name
- Values for email attribute: userPrincipalName,mail,email,emailAddress,pkcs9email,rfc822Mailbox
- Values for paging: on, off

store license

This command applies a new license key to the appliance.

A license key may be of one of two kinds: override type or append type; an override type replaces the currently installed license while the append type license will be appended to the currently installed license. Append-type licenses can only add functionality; new functions may be enabled and when relevant - updates expiration dates, the remaining number of scans, the number of datasources, or might replace certain numeric fields in the license, such as the number of managed units.

Syntax

```
store license
```

Example

When using the **store license** command, you are prompted to paste the new product key:

```
CLI> store license
Please paste the string received from customer services. Then press <ENTER> to continue.

Copy and paste the new product key at the cursor location, and then press Enter. The product key
contains no line breaks or white space characters, and it always ends with (and includes) a trailing
equal sign. A series of messages will display, ending with:
>We recommend that the machine be rebooted at the earliest opportunity in order to complete the
license updating process.
ok
CLI>
Run the restart gui command at this time.
```

Show command

```
show license
```

Shows details about the license for this appliance, as follows:

- License - A single license that includes the base license merged with information from any older licenses and append licenses. For central managers, this license key is sent to any associated managed units when the managed unit is registered or the system is refreshed.
- Number of Licenses - Specifies the number of managed units that can be associated with a central manager. This value cannot be changed after the license is installed.
- Metering - If this appliance has a metered license, then you can run only a certain number of vulnerability assessment scans. A value of -1 means there is no limit. For a metered license, Guardium checks this value each time you run a security assessment or classifier process. The process runs only if the number of datasources in the security assessment or classifier is less than or equal to the metering value. When a process runs, the metering value is updated by subtracting the number of datasources from the metering.
- Number of Datasources - The maximum number of datasources for which the appliance has license for. A value of -1 means there is no limit. This value cannot be changed after license installation. If your site has a limited license, the value is decremented each time you add or import a datasource. A datasource, for this purpose, is a database server that you add either from the Datasource Definition page of the Guardium UI, by using the **create_datasource** GRDAPI command.
- Valid until - The expiration date for this license.
- Licensed Applications - The Guardium applications that this appliance can access under this license.
- Licensed Product Types - The Guardium add-on products that this appliance can access under this license.

store log classifier level

Sets the debugging level for the classifier, to one of the values shown.

Syntax

```
store log classifier level TRACE|DEBUG|INFO|WARN|ERROR|FATAL
```

Show command

```
show log classifier level
```

store log exception sql

When **on**, logs the entire SQL command when logging exceptions.

Syntax

```
store log exception sql <on | off>
```

Show command

```
show log exception sql
```

store log_general_response_length

Use this CLI to enable or disable logging the response length. When enabled, controls whether the sniffer logs the response length for every SQL instance.

store log_general_response_length is disabled by default. Enabling response length logging can impact sniffer performance.

Syntax

```
store log_general_response_length [ enable | disable ]
```

Where:

- **enable** - Always log the response length. The responseLength value is logged for all entities.
- **disable** - Do not log the response length (default).

Show command

```
show log_general_response_length
```

store log object_join_info

Sets the logging of object_join.

A join table is a way of implementing many-to-many relationships. Use join entity to join tables in a SELECT SQL statement.

Syntax

```
store log object_join_info [ on | off]
```

Show command

```
show log object_join_info
```

store log object_join_info

Sets the logging of object_join.

A join table is a way of implementing many-to-many relationships. Use join entity to join tables in a SELECT SQL statement.

Syntax

```
store log object_join_info [ on | off]
```

Show command

```
show log object_join_info
```

store log session_info

This command enables or disables storing sniffer log session information.

Syntax

```
store log session_info [ on | off]
```

Show command

```
show log session_info
```

store log sql parser_errors

Sets the logging of syntactically wrong SQL commands.

Syntax

```
store log sql parser_errors [on|off]
```

Note: A restart of the inspection engine is required after the store command is issued to apply change.

Show command

```
show log sql parser_errors
```

store logger_data_destination_config

Use the following CLI commands to optionally configure information for Guardium Big Data Intelligence (GBDI) data streaming such as logger destination, Mongo client authentication (username, auth, database, and mechanism).

For more information, see [Big Data Intelligence with data streaming](#).

- `store logger_data_destination_config type <database type>`
 - `store logger_data_destination_config database_name <db name>`
 - `store logger_data_destination_config destination [hostname | port] <value>`
 - `store logger_data_destination_config [auth_username | auth_database_name | mechanism] <value>`
 - `store logger_data_destination_config data <collection type> [on|off]`
- Where the collection types are:
- session
 - instance
 - full_sql
 - policy_violations
 - exception

Show command

```
show logger_data_destination_config <parameter>
```

store logging granularity

Sets the logging granularity to the specified number of minutes. You must use one of the minute values shown in the syntax. The default is 60.

Syntax

```
store logging granularity <1, 2, 5, 10, 15, 30 or 60>
```

Show command

```
show logging granularity
```

store max_audit_reporting

Displays the audit report threshold in days. The default is 32. When defining reports in audit process, the number of days of the report (defined by the FROM-TO fields) should not exceed a certain threshold (one month by default). For more information, see [Audit processing notes](#).

Syntax

```
store max_audit_reporting <days>
```

Show command

```
show max_audit_reporting
```

store max_result_set_packet_size

Store the max_result_set_packet_size, default value is 32 (size is between 1 and 65535) and aids in tuning the inspection engine when observing returned data. This command sets the limitation for packet size in response. This parameter works for any type of database. If the value is beyond the defined threshold, the analyzer will not retrieve data to calculate records affected value.

Syntax

```
store max_result_set_packet_size <size>
```

Show command

```
show max_result_set_packet_size
```

store max_result_set_size

Store the max_result_set_size, default value is 100 (size is between 1 and 65535) and aids in tuning the inspection engine when observing returned data. This command sets the limitation for total result set size. This parameter works for any type of database. If the value is beyond the defined threshold, the analyzer will not retrieve data to calculate records affected value.

Syntax

```
store max_result_set_size <size>
```

Show command

```
show max_result_set_size
```

store max_tds_response_packets

Store the max_tds_response_packets, default value is 5 (size is between 1 and 65535) and aids in tuning the inspection engine when observing returned data. This command sets the limitation for number of packets in response. This parameter works for MS SQL only. If the value is beyond the defined threshold, the analyzer will not retrieve data to calculate records affected value.

Syntax

```
store max_tds_response_packets <size>
```

Note: max_tds_response_packets (Tabular Data Stream) is only applicable for MS SQL Server and Sybase.

Show command

```
show max_tds_response_packets
```

store maximum query duration

Sets the maximum number of seconds for a query to the value specified by **n**. The default is 180. We recommend that you **do not** set this value greater than the default, because doing so increases the chances of overloading the system with query processing. This value can also be set from the Running Status Monitor panel on the administrator portal.

Syntax

```
store maximum query duration <n>
```

Show command

```
show maximum query duration
```

store monitor

Use the store monitor buffer CLI command to

Syntax

```
store monitor [buffer | custom_db_usage [state <hour>] | gdm_statistics <hour> ]
```

Where:

- buffer - Set the interval of how often to run the script that retrieves the information shown in the Buffer Usage Monitor report of the IBM Guardium Monitor tab.
- custom_db_usage [state][hour] - Set the state and specify a time to run this job.
When state = *on*, specify the hour (0 - 23) to run.
- gdm_statistics <hour> - Get information about the Unit Utilization, where *hour* is a value from 0 to 24. Default = 1 (run the script every hour).

Show commands

```
show monitor buffer
show monitor custom_db_usage
show monitor gdm_statistics
```

store mysql_utf8mb4

Enable support for 4-byte UTF-8 encoding (utf8mb4).

This command modifies Guardium sniffer processes and internal databases to correctly capture and store 4-byte UTF-8 characters. Enabling utf8mb4 may be useful if datasources in your environment contain 4-byte characters, for example as used for Chinese, Japanese, and Korean ideographs.

Observe the following when using this command:

- The additional processing required to capture and store 4-byte characters will negatively impact the performance of your Guardium system. For this reason, do not enable utf8mb4 unless you require 4-byte character support in your environment.
- If support for 4-byte UTF-8 encoding is required in an aggregated or centrally managed environment, utf8mb4 should be enabled on all Guardium systems in the environment. Enabling utf8mb4 on only some systems in the environment may create problems, such as failed aggregation or incorrectly displayed reports.
- Data collected or aggregated before enabling utf8mb4 will still be available and function correctly after enabling utf8mb4.

CAUTION:

Once 4-byte UTF-8 support has been enabled using the **store mysql_utf8mb4** command, the change cannot be undone or reversed. After enabling utf8mb on a Guardium system, the only way to remove support for 4-byte UTF-8 characters is to completely rebuild the system.

Important: To ensure that multi-bytes are represented correctly on your Guardium system, you must restart sniffer as soon as you enable mysql_utf8mb4.

12.0 Syntax

```
store mysql_utf8mb4
```

Syntax12.1 and later Syntax

```
store mysql_utf8mb4 [--yes]
```

Where --yes causes the command to run automatically.

Show command

```
show mysql_utf8mb4
```

Examples

```
> show mysql_utf8mb4
```

mysql configuration NOT set with UTF8MB4.
ok

```
>store mysql_utf8mb4
```

Attempting to change the mysql config file. It may take time. Please wait.
Start to modify mysql config file
Restarting mysql
Mysql has been restarted. Please exit CLI and log back on.
The parameter IS_UTF8MB4 has been changed to 1.

```
> show mysql_utf8mb4
```

mysql configuration set with UTF8MB4.
ok

store packet max-size

Limit the maximum size of packets from the sniffer.

Syntax

```
store packet max-size 1536
```

Show command

```
show packet max-size
```

store pdf-config

Use this command to change the font size and orientation of the PDF image body content (excluding header/footer).

Size unit ranges from 1 (smallest) to 10 (largest) with default value of 6.

Orientation unit is 1 (for landscape orientation) or 2 (for portrait). The default value is 1.

The change takes effect immediately after typing the CLI command and pressing the Enter key.

Syntax

```
store pdf-config [ orientation | size ]
```

Show command

```
show pdf-config [ orientation | size ]
```

store pdf-config multilanguage_support

There are different static PDF generator config files for English (Used on English version) and language C/J (Used on Chinese/Japanese). Use this CLI command to define the fonts in the PDF generator. Default is English. Multilanguage is language C/J.

Syntax

```
CLI> store pdf-config multilanguage_support
```

Current setting is Default

```
1 Default  
2 Multi-language  
Please select the option (1,2, or q to quit)
```

Show command

```
show pdf-config multilanguage_support
```

store populate_from_query_maxrecs

Sets the maximum number of records that can be used to populate groups and aliases from a query.

Use caution when setting a maximum records value via this CLI command. Setting it too high may result in incomplete populate group from query processes. The maximum threshold is dynamic and dependent on the system load and memory utilization. The default value is 20,000 records. The maximum configurable value is 200,000 records.

Syntax

```
store populate_from_query_maxrecs 100000
```

Show command

```
show populate_from_query_maxrecs
```

store product gid

Sets the stored unique product <n> GID value.

Syntax

```
store product gid <n>
```

Show command

```
show product gid
```

store purge object

Sets the age (in days) at which non-essential objects will be purged. Use the **show purge objects age** command to display a table showing the index, object name, and age for each object type for which a purge age is maintained. Then use the appropriate index from that table in the command to set the purge age.

Note: The value of number of days will be set to the default (90 days) when the unit type changes between managed unit/Manager/standalone unit.

Syntax

```
store purge object age <index> <days>
```

Show command

```
show purge object age
```

Example

Assume you want to keep an Event Log for 30 days. First issue the **show purge objects age** command to determine the index (do not use the table; your list may be different). Then enter the **store purge object** command.

For example:

```
>show purge objects age
```

```
Index Name, Age  
... purge objects
```

```
>store purge object age 2 30
```

store quartz_thread_num

This CLI command is for use by Technical Support.

The Java™ Virtual Machine allows the application to have multiple threads. Thread is a piece of the program execution.

Use the **store quartz_thread_num** CLI command to set the number of threads that can run at the same time.

Use this command to ease conflict between too many threads running at the same time.

The **show quartz_thread_num** CLI command displays the number of Quartz scheduler threads that run at the same time.

12.0 Syntax

```
store quartz_thread_num <number>
```

12.1 and later Syntax

```
store quartz_thread_num [number [-yes]]
```

Where --yes causes the command to run automatically.
Where number is in range 3 to 15. Default value = 5.

Show command

```
show quartz_thread_num  
org.quartz.threadPool.threadCount= 5
```

store remotelog add

Controls the use of remote logging. In addition to system messages, statistical alerts and policy rule violation messages can be written to syslog. For each host and port combination, you can direct messages from the syslog to a remote host. This command works with any syslog implementation that supports TCP or UDP protocol.

If you enable remote logging, be sure that the receiving host can accept the log information.

Syntax

```
store remotelog add <encrypted | non_encrypted> <facility.priority> <host[:port]> <protocol> [format]
```

Where:

- **<encrypted | non_encrypted>** - Specify whether the connection to the remote host is encrypted. Guardium suggests that you encrypt all communications to a remote syslog server.

Note: To add an encrypted log, you must provide a signed certificate. For more information, see [Encrypting syslog](#).

- **facility** - Required. The service routed to the remote logger. To see the available facilities, enter **store remotelog add encrypted ?** in the CLI.
- **priority** - Required. The log priority, which can be:

- **alert** - Guardium severity code HIGH
- **all**
- **crit**
- **debug**
- **emerg**
- **err** - Guardium severity code MED
- **info** - Guardium severity code INFO
- **notice**
- **warning** - Guardium severity code LOW

Note: Both facility and priority are required, in the format **facility.priority**.

- **host** (required) and **port** - The remote host name or IP address and optional port to send syslog messages. The default port is 514.

- **protocol** - Required. The protocol to use to connect to the remote host. Protocol can be either:

- **tcp**
- **udp**

Note: Only TCP supports encrypted connections to the remote host.

- **format** - Some SIEM products process IETF RFC 5424 style syslog messages better than the default messages. This parameter changes the syslog format for this remote logger only to one of the following options:
 - **default** - rsyslog default format.
 - **rfc5424** - rsyslog RFC 5424 format.

Note: To use RFC 5425 format, the syslog receiver must be configured to accept RFC 5424 format. Otherwise, it receives the log in the default format.

Examples

```
cli> store remotelog add encrypted user.info 9.30.252.111 tcp  
  
cli> store remotelog add non_encrypted user.warning myhost.mycompany.com tcp  
tcp forwarder to myhost.mycompany.com added to rsyslog configuration:  
user.=warning @myhost.mycompany.com  
Restarting remote logger...  
Remote logger restarted successfully  
ok  
cli> store remotelog clear myhost.mycompany.com  
Remote logger configuration updated.  
Restarting remote logger...  
Remote logger restarted successfully
```

store remotelog clear

Use this command to clear the specified facility.priority combination from the list of messages to send to the specified host.

Syntax

```
store remotelog clear host
```

Example

```
cli> store remotelog clear myhost.mycompany.com  
Remote logger configuration updated.  
Restarting remote logger...  
Remote logger restarted successfully
```

store remotelog escape_control_characters_on_receive

Use this command to escape the control characters if your system mangles messages that include control characters. The default is on (escape control characters).

Syntax

```
store remotelog escape_control_characters_on_receive <on|off>
```

Run **restart remotelog** to apply the new configuration.

store remotelog format

Sets the default syslog format in the rsyslog configuration (in the global directive **\$Undoable-in-transactional**).

Some SIEM products process IETF RFC 5424 style syslog messages better than the default messages. In that case, change the format to **rfc5424**.

Note: The **store remotelog format** command permanently changes the default format.

- **default** - rsyslog default format.
- **rfc5424** - rsyslog RFC 5424 format.

Note: To use RFC 5425 format, the syslog receiver must be configured to accept RFC 5424 format. Otherwise, it receives the log in the default format.

Run **restart remotelog** to apply the new configuration.

store remotelog max_message_size

Use this command to set the maximum message size from 5k to 64k. Specify the maximum message size with a single number, as follows:

- 1 = 5k
- 2 = 10k
- 3 = 15k
- 4 = 20k
- 5 = 32k
- 6 = 64k

Syntax

```
store remotelog max_message_size <1|2|3|4|5|6>
```

Run **restart remotelog** to apply the new configuration.

Show command

Use this command to display the current value of the **\$MaxMessageSize** parameter.

Configuring remotelog receivers

To configure a receiving system to accept remote logging, edit **/etc/sysconfig/syslog** on the system to include the **-r** option. For example:

```
SYSLOGD_OPTIONS=-r -m 0
```

Then restart the syslog:

```
/etc/init.d/syslog restart
```

The standard syslog file in Linux® is named:

```
/var/log/messages
```

Notes:

- To send the encrypted remote log message to the server, the rsyslog configuration in the server needs to accept encrypted messages.
- TCP protocol is required to use the encrypted setting on client and server.
- If you change from one mode to another, you need to modify the configuration file to sync with the designated mode and restart the remote service.

Encrypting syslog

Alerts and other messages can be forwarded to a remote syslog receiver, such as a SIEM system. This message traffic can be encrypted from the collector or aggregator to the remote syslog receiver.

Note: Encryption only works in TCP mode. By default, syslog forwarding uses UDP, so if encryption is required, specify TCP.

You need the certificate used by the remote syslog receiver. Store that certificate on the Guardium system.

To add an encrypted remote log:

1. Have the public certificate available from a CA (Certificate Authority) such as Verisign, Thwate, or in-house.
2. Log into the CLI on the individual Guardium system from which to send the encrypted syslog. Before you execute the command, obtain the appropriate certificate (in PEM format) from the CA, and copy the certificate, including the Begin and End lines, to your clipboard.
3. Enter the following CLI command:

```
store remotelog add encrypted user.all <remote host IP address>:<remote host port number> tcp
```

4. The following instructions display:

```
Please paste your CA certificate, in PEM format. Include the BEGIN and END lines, and then press CTRL-D.
```

- Paste the PEM-format certificate to the command line, then press **CTRL-D**. Guardium stores the input as **/etc/pki/rsyslog/ca.pem**.
- Guardium returns a message informing you of the success or failure of the store operation.
- If successful, Guardium can send encrypted traffic to the remote system with the correct key.

5. Repeat the procedure for each collector and aggregator that is sending syslog traffic to the encrypted host.

store s2c

Sets several configurable parameters for ADMINCONSOLE. These parameters are used for throttling server-to-client (S2C) traffic.

Note: Use this CLI command only when directed by IBM Guardium Technical Services.

Minimum and maximum values:

- ANALYZER_S2C_IGNORE = {0,1,2,3}
- MAX_S2C_VELOCITY (K bytes/sec) - number >=0 and <= 2147483647
- MAX_S2C_INTERVAL (sec) - number >=1 and <= 2147483647

See also the CLI command Store Throttle.

Syntax

```
store s2c
```

USAGE: store s2c ignore I maxrate M maxinterval T where 0<=I<=3 (level), 0<=M<=2147483647 (K/sec), and 1<=T<=2147483647 (seconds) OR store throttle default.

For example:

```
>store s2c ignore 3 maxrate 300 maxinterval 5007
```

The new configuration will take effect after you run the **restart inspection-core**,CLI command.

Show command

```
show s2c
```

Throttle S2C parameters (defaults):

```
Ignore:    0  
Max rate: 999999  
Max interval: 30
```

ANALYZER_S2C_IGNORE (0,1,2,3) - Switch s2c throttling mechanisms on/off based on scenarios. This flag is based on bits. 0 = the s2c throttling mechanism is OFF. 1 = turns on the function described in scenario 1, 2 = turns on the function described by scenario 2. 3 = turns both on.

MAX_S2C_VELOCITY - maximal rate (K bytes/sec). If this rate is exceeded, then analyzer should send CLI commands, ignore session, or ignore session reply, request to S-TAP® or sniffer.

MAX_S2C_INTERVAL - time interval in seconds (default 30 sec.) between possible CLI commands, ignore session, or ignore session reply, requests.

Scenario 1

The sniffer starts to receive traffic from S-TAP or network in the middle of large query. Since all incoming packets are DB server responses, no new session will be created by the analyzer and therefore no information will be sent to logger and rules engine. This type of traffic is useless for the sniffer. From the other side, this type of traffic can create additional S-TAP and sniffer loads.

A throttling mechanism helps to decrease S-TAP and network sniffer load by sending an ignore session message from the analyzer, if the S2C velocity is greater than MAX_S2C_VELOCITY. If, for some reason, S-TAP or network sniffer were not affected, then the analyzer sends ignore session request again after MAX_S2C_INTERVAL seconds. In order to switch this throttling mechanism on, set ANALYZER_S2C_IGNORE flag to 1.

Scenario 2

If the incoming traffic has a high S2C rate (>MAX_S2C_VELOCITY), then a throttling mechanism sends a ignore session reply request to S-TAP for local database connections in the case when S2C velocity is greater than MAX_S2C_VELOCITY. If from some reason S-TAP was not affected, then analyzer will send the ignore session reply request again after MAX_S2C_INTERVAL seconds. In order to switch this throttling mechanism on, set ANALYZER_S2C_IGNORE flag to 2.

store save_result_max_size

This CLI command modifies the GLOBAL_PROFILE field SAVE_RESULT_MAX_SIZE to set the amount of data in reports that are generated from the GUI that reflect the maximum number of result records in the reports.

Syntax

```
store save_result_max_size <num>
```

Where <num> is a number greater than 0.

Show command

```
show save_result_max_size
```

store sender_encoding

Use this CLI command to encode outgoing messages (email and SNMP traps) in different encoding schemes, where previously everything is encoded in UTF8.

For example, a Guardium customer wanted to encode all of the outgoing SNMP messages in SJIS - an alternative Japanese encoding.

Note: If the conversion fails, for either reason (a) the encoding scheme specified is invalid, or (b) the characters to be encoded can not be represented in the requested encoding scheme, then the message will be sent using UTF8, which is the default encoding scheme.

Syntax

```
store sender_encoding <str>,
```

where str is the encoding with maximum length 16

Show command

```
show sender_encoding
```

store set_informix_driver_property

Use this command to set the connection property IFX_USE_STRENC=true on all Informix® datasources.

12.0 Syntax

```
store set_informix_driver_property
```

12.1 and later Syntax

```
store set_informix_driver_property [--yes]
```

Where --yes causes the command to run automatically.

store set_partitions_for_queries

Use this CLI command to enable or disable partition selection on queries.

Syntax

```
store set_partitions_for_queries <on|off>
```

store skip_extrusion_on_sql_access_rule_match

Use this CLI to control extrusion rule actions for data security policy extrusion rule actions when the SQL access rule matches.

For more information, see [Logging or ignoring rule actions](#)

Syntax

```
store skip_extrusion_on_sql_access_rule_match [n]
```

Where n is one of the following values:

- 0 - Default. Do not skip extrusion rule actions.
- 1 - Skip all relevant extrusion rule actions.
- 2 - Skip only duplicate extrusion rule action.

Show command

```
show skip_extrusion_on_sql_access_rule_match
```

show snif_alert_only_syslog_with_subject

Use this command to determine whether the subject of alerts displays in the syslog. Set to OFF to hide the subject of alert messages. The default is ON, which displays the alert subject in the syslog.

Syntax

```
store snif_alert_only_syslog_with_subject on|off
```

Show command

```
show snif_alert_only_syslog_with_subject
```

store snif_double_quote_literal

Use this command to control whether the sniffer handles double-quoted strings as literals and replaces them with question marks when generating masked SQL. By default, the sniffer assumes that double-quoted strings are literals and masks accordingly. The setting is available for several database types. Upon running the command, you are asked to select the database type from a list and define whether quoted strings are treated as literals. Use **restart inspection-core** to restart the inspection engine core after changing **snif_double_quote_literal** settings.

Example

```
> store snif_double_quote_literal
This command controls whether or not snif will consider double quoted strings literals, and replace them
with question marks when generating masked sql.
USAGE: store snif_double_quote_literal
```

DB type:

1. MySQL
2. MemSql
3. MsSql
4. Sybase

```
5. Informix
0. Quit

Please select DB type to modify (required) 1

Consider double quoted strings literals?
(y/n)? n
The parameter has been changed.
Please restart the inspection core for this change to take effect:
restart inspection-core
ok
```

Show command

```
show snif_double_quote_literal
```

Example of show command

```
> show snif_double_quote_literal
Database types in which snif considers double quoted strings as literals
```

```
Mysql: No (default Yes)
MemSql: Yes (default Yes)
MsSql: Yes (default Yes)
Sybase: Yes (default Yes)
Informix: No (default No)
ok
```

[store snif_log_level](#)

Use this command to set the logging level for the sniffer.

Syntax

```
store snif_log_level [TRACE | DEBUG | DEFAULT]
```

Where DEFAULT is the default log level, INFO.

Show command

```
show snif_log_level
```

[store snif_logger_destination_type](#)

Use this command to control the sniffer logger destination for Guardium Big Data Intelligence (GBDI) data streaming.

Syntax

```
store snif_logger_destination_type [LOCAL | REMOTE]
```

- LOCAL (default) sets the logger destination to the local database on the Guardium collector.
- REMOTE sets the logger destination to the intermediate database used by GBDI.

For more information, see [Big Data Intelligence with data streaming](#).

[store snif_mask_sql_value](#)

Use this command to mask SQL values that are logged when a SQL exception occurs.

Note: If the SQL string contains a syntax error, only literals (that is, values enclosed in single quotation marks) are masked in the GDM_EXCEPTION table. For example, if the SQL string contains a syntax error, then the following masking rules apply:

'literal123' is a literal, as shown by the single quotation marks, and is masked.

`identifier123` is an identifier, and displays in the table in clear text.

Syntax

```
store snif_mask_sql_value on|off
```

Show command

```
show snif_mask_sql_value
```

[store snif_db2z_alert_use_client_ip_for_host_name](#)

For Db2 z/OS systems only, use this command to enable using the client IP address as the host name for Alert messages. When enabled, the %%clientHostName variable displays the host IP address.

Syntax

```
store snif_db2z_alert_use_client_ip_for_host_name [on|off]
```

Note: For this command to take effect, you must also restart the inspection engine by calling the [restart inspection-engine](#) command.

Show command

```
show snif_db2z_alert_use_client_ip_for_host_name
```

[store snif_max_db2z_bind_variable_value_size](#)

For Db2 z/OS systems only, use this command to control the length, in KB, of bind variable values. The default length is 2 KB (2047 characters). The maximum length is 4096 KB.

Syntax

```
store snif_max_db2z_bind_variable_value_size <n>
```

Where <n> is a number between 2 and 4096, which is the maximum length of the bind variable values in KB.

Show command

```
show snif_max_db2z_bind_variable_value_size
```

store snif_use_feed_analyzer_thread

When Guardium processes S-TAPs on multiple ports, you can encounter issues in which multiple S-TAPs use the same queue and buffer. Specifically, if your site uses ports 16016 or 16018 (for UNIX S-TAPs) and ports 16022 (feed protocol) or 16023 (encrypted S-TAP TLS) the S-TAPs default to a shared queue, which can lead to unexpected issues.

The **store snif_use_feed_analyzer_thread** command allows you to have sniffer use a separate internal queue for these S-TAPs.

The default for **store snif_use_feed_analyzer_thread** is *OFF*. If you expect traffic on both ports (that is 16016 or 16018 and 16021 or 16022), set **store snif_use_feed_analyzer_thread** to *ON* before the S-TAPs start.

In addition, if the sniffer detects traffic from both ports, sniffer sets the parameter to *ON*, causing sniffer to use separate queues after the next restart.

Syntax

```
store snif_use_feed_analyzer_thread [ON | OFF]
```

Note: For this command to take effect, you must also restart the inspection engine by calling the [restart inspection-engine](#) command.

Show command

```
show snif_use_feed_analyzer_thread
```

store ssl_configuration

Use this command to specify the ciphers used by the Guardium sniffer for your operating system.

Syntax

```
store ssl_configuration
```

When you run this command, Guardium returns a list of ciphers and indicates whether your system uses each cipher (indicated by an x, for example. [x]). Specify the number of the cipher (or ciphers) to toggle on or off. Use a comma to separate multiple cipher numbers.

Click q to quit without making changes.

When you are done specifying the ciphers that you want, click s to save your changes, which restarts the sniffer to load the selected ciphers.

Show command

```
show ssl_configuration
```

For more information about supported ciphers, see [Cipher suites](#).

store stop approval

Use this function to block unauthorized S-TAPs from connecting to the Guardium appliance.

If ON, then S-TAPs can not connect until they are specifically approved.

If an unapproved S-TAP connects, it is immediately disconnected until the specific authorization of the IP Address of that S-TAP.

A pre-defined report for approved clients, Approved TAP clients, is available on the Daily Monitor tab.

Note:

A valid IP address is required, not the host name.

The CLI command, **store stap approval**, does not work within an environment where there is an IP load balancer.

Within a central manager environment, after adding the IPs to approved S-TAPs, there is a wait time associated with synchronization that might take up to an hour. After synchronization is complete the approved S-TAP status will appear green in GUI.

Syntax

```
store stap approval ON | OFF
```

Show command

```
show stap approval
```

GuardAPI command

```
grdapic store_stap_approval  
The new configuration takes effect after running the CLI command, restart inspection-core.
```

store stap certificate

Stores a certificate from the S-TAP host (usually a database server), on the IBM Guardium appliance. This command functions exactly like the store certificate console command, described later.

Syntax

```
store stap certificate
```

You will be prompted as follows:

Please paste your new server certificate, in PEM format.

Include the BEGIN and END lines, then press CTRL-D.

If you have not done so already, copy the server certificate to your clipboard. Paste the PEM-format certificate to the command line, then press CRTL-D. You will be informed of the success or failure of the store operation.

When you are done, use the **restart gui** command to restart the IBM Guardium GUI.

store stap network_latency

S-TAP verification is a feature by which customers can verify if a S-TAP is monitoring database traffic or not. The verification feature is affected by the customer's network traffic/latency. Since latency is different for each customer, there is a need for a way to list and change the default value that the verification feature uses.

Syntax

```
store stap network_latency
```

USAGE: store stap network_latency <N>

where N is the number greater than 0 seconds.

The default value is 5 seconds.

If the number goes higher the S-TAP verification process will become slower.

Show command

```
show stap network_latency
```

store storage-system

store storage-system

Adds or deletes a storage system type for archiving or system backup.

Syntax

```
store storage-system <NETWORK | Amazon_S3 | Centera | IBMCloud | IBMcos | NFS | TSM> <backup | archive> <on | off>
```

Show command

```
show storage-system
```

Restriction: External storage on IBM COS is not supported for IPV6.

Example

Assume you are currently using Centera for system backups, but want to switch to a TSM system. You must turn off the Centera backup option (unless you want to leave that as another option), and turn on the TSM backup option. The commands to do this are highlighted in the example. The show commands are not necessary, but are for illustration only.

```
CLI> show storage-system
```

```
show storage-system
NETWORK :
CENTERA :
TSM :
SCP      : archiving and backing-up
SFTP (formerly FTP)   : archiving and backing-up
AMAZON S3    : archiving and backing-up
IBMcloud   : archiving and backing-up
IBM COS (formerly Cleversafe) : archiving and backing-up
NFS        : backing-up
```

store support state

Enables (**on**) or disables (**off**) the sending of email alerts to the support email address, which can be configured using the **forward support email** command. By default, the support state is enabled (**on**), and the default support email address is support@guardium.com.

Syntax

```
store support state <on | off>
```

Show command

```
show support state
```

store tang server

Sets up the initial connection between the clevis client on a machine to a remote tang server.

You can enter the IP addresses of one or more tang servers. The IP address that is entered first is the primary server, the rest are backup servers. You can change the order of the tang servers by clearing the keys using the CLI command **reset luks keys** and then reentering the tang server addresses by running the **store tang server** command.

Syntax:

```
store tang server
```

Show command:

```
show tang server
```

Shows the most recent tang server to which the Guardium system is connected. The command also displays the backup servers, if any.

store throttle

This CLI command stores the throttle parameters. After entering this command, you must issue the CLI command, restart inspection-core for the changes to take effect.

This command is used to filter out (ignore) large packets. Throttling has two modes: Thresholds, per session - ignore sessions when identifying a long enough burst (duration configurable) of large packets (size configurable) and stop ignoring the session when traffic goes under a certain threshold (also configurable); and, Overall - ignore all packets larger than a certain size (configurable) in all sessions. This throttling mode completely ignores long and excessive non-database packets smaller than a predefined size (useful for VNC clients and other types of white-noise traffic). Use for network traffic through SPAM port or hardware TAP. For S-TAP traffic, only network TCP traffic picked up by PCAP. See also the CLI command, store s2c.

Syntax

```
store throttle [default | size <s> interval <i> trigger <t> release <r>]
```

USAGE: store throttle size S interval I trigger T release R

where 0<=S<=2^17 (bytes), 1<=I,T,R,<=2^31 (seconds)

OR store throttle default

Show command

```
show throttle
```

Throttle parameters:
Packet size: 228000
Time interval: 604800
Trigger level: 10000000
Release level: 10000000

Parameters

- default - Enter the keyword default to restore the system defaults (no other parameters are used). The default throttling parameters are never throttle.
- s - The packet size in bytes, up to a maximum of 217 (131072).
The remaining parameters are in seconds, up to a maximum of 231 (2147483648):
 - i - The time interval
 - t - The trigger level
 - r - The release level

Note: To restore the throttle defaults, use the CLI command, store throttle default.

store timeout

Sets the timeout value of a CLI session and or file server session. The default value is 600 seconds. A timeout will also close the CLI session.

If the file server is stopped because of a timeout, a message will appear, Warning : Fileserver stopped because of timeout. The file upload may not be complete. Stopping the process.

Use the CLI commands, **show timeout db_connection**, to show the socketTimeout value in the conf file, and **store timeout db_connection**, to set the value of the timeout. The value should be greater than 0. The default value is 25000 seconds. These CLI commands are used in managing the communications between the central manager and the managed unit when DNS is not configured.

Syntax

```
store timeout cli_session <n>
store timeout fileserver_session <n>
store timeout db_connection <n>
```

Show command

```
show timeout cli_session 600
show timeout fileserver_session 600
show timeout db_connection 25000
```

store timeout classifier

Sets the number of seconds (0 - 9999) to run classifier queries.

Syntax

```
store timeout classifier <count_query n | sample_query n>
```

Where:

- count_query n - The number of seconds (n) to run a query that determines how many rows are in a particular table.
- sample_query n - The number of seconds (n) to run a query that creates a sample set on which to run the classifier rules. The classifier determines if the table has sensitive data as defined by the rule.

Show syntax

```
show timeout classifier <count_query | sample_query>
```

store transfer-method

Sets the file transfer method. Specify FTP protocol for SFTP.

Syntax

```
store transfer-method <FTP | SCP>
```

Show command

```
show transfer-method
```

Note: Files sent from one IBM Guardium appliance to another (from a collector to an aggregator, for example) are always sent using SCP.

store uid_chain_polling_interval

Set the interval for UID Chain polling with this CLI command. UID chain is a mechanism which allows S-TAP (by way of K-Tap) to track the chain of users that occurred prior to a database connection.

Set the interval to 0 to turn off the UID Chain processing, in order to improve database performance. If the UID Chain processing is turned off, then calculating the UID Chain and updating children sessions are skipped.

Note: When using any database, the UID chain is not logged for all sessions if the session is very short.

Syntax

```
store uid_chain_polling_interval <n>
```

Where n is time in minutes (>= 1 minute; default is 2 minutes). Set N = 0 to turn off the UID Chain processing

Show command

```
show uid_chain_polling_interval
```

store upd_session_end

This CLI command adds an option to skip the update for the session_end time using Session Inference. For more information, see [Session Inference](#).

Syntax

```
store upd_session_end <on | off>
```

Show command

```
show upd_session_end
```

Note: Changes only take effect after the GUI is restarted.

store unit type

Use this CLI command to set unit type attributes for the Guardium appliance. See [Table 2](#) for a description of all unit type attributes you can display with this command.

Syntax

```
store unit type [<manager | standalone | netinsp | stap | mainframe | sink>]
```

Use **store unit type sink** to switch collected DRDA traffic timestamp granularity from 1 millisecond to 1 microsecond.

Show command

```
show unit type
```

The following table describes the Guardium system unit type attributes that you can display with the **show unit type** command. Except where noted, you can set these attributes using the **store unit type** command, and clear them using the **delete unit type** command.

Table 2. Unit type attributes. The unit types that you can see with the **show unit type** command.

| Attribute | Description |
|----------------------|---|
| mainframe | The unit is a mainframe (z/OS®) network inspection appliance. |
| manager | Central manager functions are enabled for this unit. |
| netinsp | Inspection of network traffic is enabled. |
| network route static | Removes one line off the static routing table |

| Attribute | Description |
|------------|---|
| standalone | Local management (independent of a central manager) |
| stap | The unit can receive data from and manage S-TAP and CAS agents. |

Note: You can set the aggregator attribute only when you install Guardium software, and you can only modify it by re-installing the Guardium software.

Unit type attributes

store update_success_value

This CLI command enables or disables the success value flag. When enabled, Guardium updates the SUCCESS field in the GDM_CONSTRUCT_TEXT table for each SQL record.

Syntax

```
store update_success_value [ enable | disable ]
```

Show command

```
show update_success_value
```

store va max_detail

This CLI command helps to regulate the maximum detail records for running query based security assessment tests.

Syntax

```
store va max_detail [on <num> | off]
```

Where

- on<num> enables the record with a value.
- <num> is a number within the range 10 and 2147483647. The default record value is 20000.
- off disables this functionality.

Show command

```
show va max_detail
```

store wkc_configuration

Use this CLI command to integrate and configure IBM Knowledge Catalog with Guardium on managed units. For more information, see [Integrating with IBM Knowledge Catalog for federated data protection](#). If enabled, the CLI requires the IBM Knowledge Catalog URI, user name, and password.

Before you enable the IBM Knowledge Catalog integration with Guardium, you need to store the IBM Knowledge Catalog root certificate on any managed units or stand-alone machines. For more information, see [store_certificate_wkc](#).

Note: The **store wkc_configuration** CLI works only on managed units and stand-alone machines. Use the Guardium to configure the IBM Knowledge Catalog integration on a central manager. For more information, see [Starting the IBM Knowledge Catalog and Guardium Data Protection integration](#).

Syntax

```
store wkc_configuration
```

A list of the available parameters displays,

1. wkc_enabled - false (not enabled)
2. wkc_persistent_cache_enabled - Default = false (disabled).
3. wkc_action_on_unsupported - Default = 1 (deny).

If Guardium receives an unexpected response (or no response) from IBM Knowledge Catalog, you can choose to allow (0) or deny (1) the user access to IBM Knowledge Catalog data assets. The default is 1, that is, treat access to the assets as if the IBM Knowledge Catalog policy rule action **Deny access to data** is triggered. Specify 0 to allow access to data assets, which treats the connection as approved.

4. wkc_cache_ttl - The time-to-live (in minutes) for each decision in the primary cache. Default = 60. Maximum = 1440.
5. wkc_persistent_cache_ttl - The time-to-live (in days) for each decision in the persistent cache. Default = 7. Maximum = 30.
6. wkc_cache_size - Maximum number of cache entries. Default = 1000.
7. wkc_persistent_cache_size - The maximum size of the persistent cache. Default = 100000.
8. wkc_log_level - Default = 4. Log levels range from 1 (FATAL) to 8 (TRACE), with the following meanings,

| Log level | Type | Meaning |
|-----------|-------------|---|
| 1 | FATAL | The application is likely to terminate. |
| 2 | CRITICAL | The application might not continue to run successfully. |
| 3 | ERROR | An operation did not complete successfully, but the application as a whole is not affected. |
| 4 | WARNING | An operation completed with an unexpected result. |
| 5 | NOTICE | An informational message, but with a higher priority. |
| 6 | INFORMATION | An informational message, usually denotes that an operation completed successfully. |
| 7 | DEBUG | A debugging message. |
| 8 | TRACE | A trace message. The lowest priority. |

9. wkc_log_max_files - Default = 10. Maximum = 100.
10. wkc_log_max_file_size - Default = 10 MB. Maximum = 50 MB.
11. wkc_dps_uri - The URI of the IBM Knowledge Catalog service.
12. wkc_asset_user - The owner of this asset. Can be either dbuser or appuser. Default = dbuser
13. wkc_server_auth_username - The IBM Knowledge Catalog user name.

14. wkc_server_auth_password - The password for the associated IBM Knowledge Catalog user.
 15. wkc_column_alias - Specify whether to use an alias for the column name, and if so, what type of alias. Specify one of the following, or click Return to use the default (Column_name).
 - C - Column-name: Default. Use the original COLUMN_NAME as the alias for the full UDF.
 - N - None. Do not use any alias for UDFs.
 - S - Short_udf. Use the short form of the UDF signature.
- For more information, see [Column alias parameter](#) in [Setting up a transformation integration](#).

Store each element of the IBM Knowledge Catalog configuration separately, and then select 0 (zero) to end and Yes to confirm.

To start the IBM Knowledge Catalog integration, you must to set the following parameters:

- 1. wkc_enabled
- 12. wkc_dps_uri
- 14. wkc_server_auth_username
- 15. wkc_server_auth_password

You can use the defaults for the remaining parameters.

Show command

```
show wkc_configuration
```

traceroute

This command is a diagnostic tool that follows the route packets across an IP network.

Syntax

```
traceroute <host> <max hops> <wait time>
```

- host: A valid IP address or hostname
- max hops: The maximum number of hops (default is 30).
- wait time: The timeout to wait for a response to a probe in seconds (default is 5s)

unregister management

The unregister command restores the configuration that was saved when the appliance was registered for central management.

Syntax

```
unregister management
```

Note:

- This command is intended for emergency use only, when the central manager is not available.
- After unregistering using this command, you should also unregister from the central manager (from the Administration Console), since that is the only way the count of managed units will be reduced. The count of managed units is authorized by the product key.

diag CLI command

Use the **diag** CLI command to access troubleshooting and maintenance utilities through the SQLGuard Diagnostics interface.

Use the **diag** command only as directed by Technical Support.

There are no functions that you would perform with this command on a regular basis. Each main menu entry is described in a separate topic.

Troubleshooting and Maintenance Utilities through DIAG:

- Aggregator Fix Schema – brings all imported tables that have older schema than that of the aggregator to the schema of the latest patch level of the aggregator (runs in the background and may take several hours to complete). Note: There may be scenarios in which (a) the aggregator will not have the latest patch level or (b) some of the imported tables are of the latest patch level—resulting in not all imported tables having the latest patch level.
- Aggregator Maintenance – full analysis and recovery of the Aggregator. This utility will collect AGG related logs and place it in the diag export folder, calls the Aggregator Fix Schema to sync the schema of all databases, clean AGG workspace and restart the merge process to ensure full analysis of all imported tables (runs in the background and may take several hours to complete).
- Clean Static Orphans on an Aggregator – This option should be used only by Technical Support and only in those cases where static tables grow too much and needed to be cleaned. This utility cleans all the old construct records that are no longer in use.

Opening the Diagnostics Main Menu

Use the **diag** command to open the SQLGuard Diagnostics menu as follows:

1. At the command line prompt, log into the Guardium® appliance with CLI.

Note: To use the CLI, the Guardium user must have a CLI or admin role, or CLI does not start. Use the **accessmgr** to assign CLI and admin roles.

Note: To use the **diag** command, the Guardium user must have an assigned CLI or admin role. The only user who has a CLI role by default is admin. A user with a CLI or admin role can enter the **diag** command, use the **unlock admin** and **unlock accessmgr** CLI commands, and use the **export audit-data** CLI command without restrictions. A user with the CLI role does not have to enter user name and password required of a GUI login and does not go through any further role check.

In addition, as a Guardium user, you must have an assigned diag role on the Guardium system to use the **diag** command. By default, only admin has this assigned role. Access to diag is allowed based on the role assignment of this user (access to diag is permitted only if this user has the diag role). The **accessmgr** assigns diag roles.

2. After starting CLI, enter the **diag** command (with no arguments) at the command line prompt to open the SQLGuard Diagnostics window.
3. Do one of the following to move the option selection cursor:
 - Type the desired entry number (the selection cursor moves to the selected entry).
 - Use the Up or Down arrow key to select an entry.
4. Click the Spacebar, the Left arrow key, or the Right arrow key to move the command selection cursor in the display.
5. Perform an action by selecting the appropriate option in the display area and then doing one of the following:
 - Select the appropriate command with the command selection cursor, then click Enter.
 - Click on the appropriate action command.

About the diag Output

The diag command creates output in two directories:

- .../guard/diag/current
- .../guard/diag/depot

You can access the output through the **fileserver** CLI command. For more information, see [fileserver](#).

Each directory is described in the following subsections.

.../guard/diag/current Directory

Most output from the diag commands is written in text format to the current directory. For most commands, this directory contains a separate output file. Each time you run the same command, output is appended to the single file for that command. For a smaller number of commands, a separate file is created for each execution, usually incorporating a date and time stamp in the filename.

We recommend that you “clean up” after each session, so that you are not looking at old information in subsequent sessions. When you pack files to a single compressed file for export, all of the files in the current directory are deleted. Alternatively, use the Delete recordings option from the Output Management menu to delete individual files.

The files in the current directory are easy to identify since the names are created from menu and command names. For example, after you use the File Summary command from the System Interactive Queries menu, a file named interactive_filesummary.txt is created in the current directory.

If you look at the current directory while in the process of using a command, you may see a hidden temporary file with the same name as the one that will contain the output for that command. The temporary file will be removed when the output is appended to the command output file.

.../guard/diag/depot Directory

When you pack the diag output files in the current directory to a compressed file (to send to Guardium Technical Support, for example), it is stored in the depot directory. The filename is in the format diag_session_<dd_mm_hhmm>.tgz, where the variable portion of the name indicates when the file was created. For example, a file created at 12:15 PM on May 20th would be named as follows: diag_session_20_5_1215.tgz.

After exporting files (see the Export recorded files topic), you can remove them from the depot directory using the Delete recordings command of the Output Management menu.

1 Output Management

The Output Management commands control what is done with the output produced by the diag command. Each Output Management command is described separately.

1.1 End and pack current session

Use this command to pack all diagnostic files in the current directory into a single compressed file, and remove those files from the current directory. When you enter this command, there is no feedback to indicate that the command has completed. You can verify that the command has finished by displaying the directory of the depot directory. When the command completes, there is a file named in the following format: diag_session_<mm_dd_hhmm>.tgz, where the variable portion of the name is a date and time stamp, as described previously. Use the Export recorded files command of the Output Management menu to send the file to another system.

1.2 Delete recordings

Use this command to delete files in the depot or current directory. (To delete only the current session files, use the Delete current session files command.) When you enter this command, the depot directory structure displays:

You can navigate the directories using the Up and Down arrow keys and clicking Enter. For example, selecting .. and clicking Enter moves the selection up one level in the directory structure.

You could then select the current directory and click Enter, to navigate down to that folder and delete individual command output files. Note that you can navigate to other directories, but you cannot delete files except from the current and depot directories.

When you have selected the file you want to delete, click Enter.

Caution: You will not be prompted to confirm the delete action

1.3 Export recorded files

Use this command to send a file from the depot directory to another site. To export a file:

1. Select Export recorded files from the Output Management menu. The depot directory displays.
2. Select the file to be sent or use the .. and ./ entries to navigate up or down in the directory structure. (However, keep in mind that you can only export files from the depot directory.)

3. With the file to be transmitted selected, click Enter.
4. You are prompted to select FTP or exit. Select FTP and click Enter.
5. You are prompted to supply a host name. Enter the host name of the receiving system (or its IP address), and click Enter.
6. You are prompted for a user name. Enter a user account name for the receiving system, and click Enter.
7. You are prompted for a password. Enter the password for the user on the receiving system.
8. You are prompted to identify a directory to receive the sent file on the receiving system. Enter the path relative to the ftp root of the directory to contain the file on the receiving system and click Enter.
9. You are prompted to confirm the details of the transfer (the file to be sent and its destination). Click Enter to perform the transfer, or select Cancel and click Enter to start over.
10. You are informed of the success (or failure) of the operation.

1.4 Delete current session files

Use this command to delete files created during the current session.

1.5 Exit

Use the Exit command to return to the main menu.

2 System Static Reports

Use the System Static Reports command of the Main Menu to produce an extensive set of reports.

1. Select System Static Reports from the Main Menu. You are informed that the process is running.
 2. After the report has been created, it displays in the viewing area. Note that this report is lengthy and may be easier to view using a text editor, after exporting it to a desktop computer).
- Use the Up and Down arrow keys to scroll up or down in the report. When you are done viewing the report, click Enter to return to the Main Menu.

System Static Reports Overview

The following subtopics provide an outline of the major components of the System Static Reports output. The fragments of output shown are intended to illustrate the type and level of information contained in the report, rather than provide a detailed description of the actual contents (that is beyond the scope of this document).

System Configuration Information

The System Static Reports output describes the build version, the patches applied, the current system up time, and name server information:

```
Build version: 34e1eb12eb68ba76cb49028251c9a0d6 /opt/IBM/guardium/etc/cvstag
Patches:
2009/02/22 16:16:50: START Installation of 'Update 5.0'
2009/02/22 16:18:04: Installation Done - Successfully Installed

< lines deleted... >

Current uptime:
09:03:43 up 6 days, 17:34, 1 user, load average: 0.44, 0.50, 0.41
System nameservers:
192.168.3.20
DB nameservers:
192.168.3.20
Gateway: 192.168.3.1 (system) 192.168.3.1 (def)
```

Next, the file system information displays (shown partially):

```
Filesystem      Size  Used Avail Use% Mounted on
/dev/hdc3       2.0G  1.1G  813M  58% /
/dev/hdc1        97M   9.2M  83M   10% /boot
none            504M    0   504M   0% /dev/shm
/dev/hdc2       71G   1.2G  66G   2% /var
              total: used: free: shared: buffers: cached:
Mem: 1055199232 1041711104 13488128          0 63275008 186220544
Swap: 536698880 295432192 241266688
MemTotal: 1030468 kB
MemFree: 13172 kB

< lines deleted... >
```

This is followed by information about the mail and SNMP servers configured:

```
SMTP server: 192.168.1.7 on port 25 : REACHABLE
SMTP user: undef
SMTP password: undef
SMTP auth: NONE
SNMP trapsink: undef UNREACHABLE
SNMP trap community: undef
SNMP read community: undef
```

The final section of the system configuration section describes the network configuration for the unit: IP address, host and domain names, etc:

```
ens32:          192.168.3.101 (system) 192.168.3.101 (def)
hostname:           (system) g1 (def)
domain:            (system) guardium.com (def)
mac address: 00:04:23:A7:77:F2 (MAC1) 00:04:23:A7:77:F2 (MAC2)
unit type: 548 Standalone STAP
```

Internal Database Information

The next major section of the System Static Reports output contains information about the internal database status and threads (only the first few threads are shown):

```
uptime 77097 seconds.
27 threads.
78545028 queries.

+-----+-----+-----+-----+
| Id | User      | Host          | db    | Command | Time   | State  |
+-----+-----+-----+-----+
1137	enchantedg	localhost	TURBINE	Sleep	26
1257	enchantedg	localhost.localdomain:33587	TURBINE	Sleep	0
1258	enchantedg	localhost.localdomain:60409	TURBINE	Sleep	7716
1259	enchantedg	localhost.localdomain:48233	TURBINE	Sleep	322

< lines deleted... >
```

The list of threads is followed by an analysis of table status.

Web Servlet Container Information

The next several sections of the System Static Reports output contain information about the Web servlet container environment (Tomcat):

```
=====
Currently defined Tomcat port is 8443.
The TOMCAT daemon is running and listening on port(s): 8005 8443.
Currently OPEN ports
java run by tomcat on port *:8443

< lines deleted... >
=====
```

```
These are the nanny latest actions:
May 19 14:13:09 guard nanny:[5528]: Also checking tomcat.
May 19 14:13:09 guard nanny:[5528]: Going for my initial nap.

< lines deleted... >
```

```
This is the TOMCAT command line:
 463 sh -c ps -o pid,cmd -e | grep Dcatalina.base
21917 grep Dcatalina.base.
```

Inspection Engine Information

The next major section of the System Static Reports output contains information about the inspection engine:

```
=====
This is the SNIF (pid: 13036) command line: 13036 /opt/IBM/guardium/bin/snif.
This is the SNIF status:
Name:           snif
State:          R (running)
Tgid: 13036

< lines deleted... >
=====
```

```
Current timestamp is 2009-05-20 11:56:41
This is the last timestamp at GDM_CONSTRUCT_INSTANCE: 2009-05-20 11:56:41
This is the last timestamp at GDM_EXCEPTION: 2009-05-20 11:56:41
This is the last timestamp at GDM_POLICY_VIOLATIONS_LOG: 2009-05-20 11:56:41

=====
```

```
Snif buf usage at Fri May 20 11:56:44 2009:
100 204800 buffers out of 204800
126 connection used, 32642 unused, 0 dropped (sniffer), 9 ignored (analyzer)
0 bytes lost, 60 connections ended, 601752099 bytes sent, 579063 request sent
Dropped Packets: 0 buffer full, 0 too short , 451 ignored
time now is 1116604603
Analyzer/Parser buffers size: 6 (66533) 0 (62902)
ms-tsql-logger 0 (11331)
syb-tsql-logger 0 (70)
ora-tsql-logger 79 (67803)
db2-sql-logger 0 (20544)

< lines deleted... >
```

IP Tables Information

The next major section contains information about the IP tables:

```
=====
IPTABLES:
-----
      tcp  --  192.168.2.0/24      192.168.1.0/24      tcp  spts:1521:60000  set 0x23
      tcp  --  192.168.1.0/24      192.168.2.0/24      tcp  dpts:1521:60000  set 0x22
< lines deleted... >
```

S-TAP Information

The next major section contains S-TAP® information:

```
=====
STAP:
-----
  0      0 ACCEPT    tcp  --  *      *  0.0.0.0/0      0.0.0.0/0      tcp spt:9500
  0      0 ACCEPT    tcp  --  *      *  0.0.0.0/0      0.0.0.0/0      tcp dpt:9500
2696  148K ACCEPT   tcp  --  *      *  0.0.0.0/0      0.0.0.0/0      tcp spt:16016
2835  175K ACCEPT   tcp  --  *      *  0.0.0.0/0      0.0.0.0/0      tcp dpt:16016

< lines deleted... >
```

IP Traffic Information

The next major section contains IP traffic information:

```
IP traffic statistics.
OUTPUT OF ens32
Fri May 20 11:57:04 2012; ***** Detailed interface statistics started *****
*** Detailed statistics for interface ens32, generated Fri May 20 11:58:04 2009

< lines deleted... >

OUTPUT OF ens192
Fri May 20 11:57:04 2012; ***** Detailed interface statistics started *****
*** Detailed statistics for interface ens192, generated Fri May 20 11:58:04 2009

Total:          82440 packets, 53892382 bytes
           (incoming: 82440 packets, 53892382 bytes; outgoing: 0 packets, 0 bytes)
IP:            82440 packets, 52632747 bytes
           (incoming: 82440 packets, 52632747 bytes; outgoing: 0 packets, 0 bytes)

< lines deleted... >
```

Information Engine STDERR and STDOUT Information

The next section contains the last messages output by the sniffer:

```
Snif  STDERR:
< lines deleted... >

Snif STDOUT:
Fri_20-May-2009_04:04:35 : Guardium Engine Monitor starting
Fri_20-May-2009_04:14:37 : Guardium Engine Monitor starting
Fri_20-May-2009_04:24:38 : Guardium Engine Monitor starting

< lines deleted... >
```

Import Directory Information

The next section lists the import directory contents:

```
These are the contents of the importdir directory:
total 0
```

Aggregator Activity Information

This section lists aggregator activities (there are none in the example):

```
=====
This is the aggregator last activities:
```

Audit Report

This section lists the following summary information (see example):

```
=====
Range of time in logs: 01/14/10 13:12:26.348 - 01/18/10 12:48:01.073
Selected time for report: 01/14/10 13:12:26 - 01/18/10 12:48:01.073
Number of changes in configuration: 4 - changes to the audit configuration
Number of changes to accounts, groups, or roles: 0
Number of logins: 22 - logins into the machine - ssh and console
Number of failed logins: 114
Number of authentications: 22 - "su", etc.
Number of failed authentications: 5
Number of users: 2
Number of terminals: 18
Number of host names: 9
Number of executables: 7
Number of files: 0
Number of AVC's: 0
Number of MAC events: 0
Number of failed syscalls: 0
Number of anomaly events: 3
Number of responses to anomaly events: 0
```

```
Number of crypto events: 0
Number of keys: 0
Number of process IDs: 9173
Number of events: 98669
=====
```

Anomaly Report

This section lists the following (see example):

```
=====
# Date Time Type Exe Term Host AUID Event
=====
1. 01/14/10 13:16:02 ANOM_PROMISCUOUS /usr/sbin/brctl (none) ? -1 8 - this is expected
to appear - it means the bridge is listening to all traffic
```

Authentication Report

This section lists the following (see example):

```
=====
# Date Time Type Exe Term Host AUID Event
=====
1. 01/14/10 13:13:22 tomcat ? console /bin/su yes 4
2. 01/14/10 13:16:44 tomcat ? console /bin/su yes 11
3. 01/14/10 13:16:44 tomcat ? console /bin/su yes 17
4. 01/14/10 13:16:45 tomcat ? console /bin/su yes 23
5. 01/14/10 13:16:48 tomcat ? console /bin/su yes 29
6. 01/14/10 13:22:29 tomcat ? ? /bin/su yes 155
7. 01/14/10 13:28:10 ? ? ttys /bin/login no 252
8. 01/14/10 13:28:20 ? ? ttys /bin/login no 254
```

Login Report

This section lists the following (see example):

```
=====
# Date Time Type Exe Term Host AUID Event
=====
1. 01/14/10 13:22:15 root 192.168.2.9 sshd /usr/sbin/sshd no 142
2. 01/14/10 13:22:15 root 192.168.2.9 sshd /usr/sbin/sshd no 143
3. 01/14/10 13:22:17 root 192.168.2.9 sshd /usr/sbin/sshd no 144
4. 01/14/10 13:22:17 root 192.168.2.9 sshd /usr/sbin/sshd no 145
5. 01/14/10 13:22:20 root 192.168.2.9 sshd /usr/sbin/sshd no 146
```

3 Interactive Queries

Select System Interactive Queries from the main menu to open the Interactive Queries menu. (Use the Down arrow key to scroll past the tenth item to see all items on this menu.)

In addition to displaying the requested information, each interactive query command creates output in a separate text file in the current directory. See the Overview topic for more information about the files created.

Each command is described in the following sections.

3.1 Files Changed

Use the Files Changed command to display a list of files changed either before or after a specified number of days.

1. Select Files Changed from the Interactive Queries menu. You are prompted to enter a number days. Type a number and click Enter.
2. You are asked if you are interested in the files changed before or after that number of days. Select 1 or 2 and click Enter.
3. The full directory path for each changed file is displayed. Note that if not all data fits in the display area, use the Up and Down arrow keys to scroll through the data. The current position in the file is indicated by the number in the display. The white bars in the display area indicate the presence of more data with a plus sign.

3.2 List Folder

Use this command to list the contents of various directories.

1. Select List Folder from the Interactive Queries menu.
2. You are prompted to select a directory. Select a directory and click Enter. The selected directory is displayed. Remember that if multiple commands of the same type are issued, the data for each execution of the command is appended to the single text file maintained for that command.
3. Click Enter or click Exit when you are done.

3.3 Summarize Folder

Use the Summarize Folder command to display the output of the du (Disk Usage) command:

1. Select Summarize Folder from the Interactive Queries menu. There are no prompts. You are presented with a display of disk use for various directories.
2. Use the Up and Down arrow keys to scroll through the directories.
3. Click Enter or click Exit when you are done.

3.4 File Summary and Export

Use this command to list all or some portion of a log file.

1. Select File Summary from the Interactive Queries menu.
 2. You are prompted to select a file. Use the Up and Down arrow keys to scroll the selection cursor to the file you want to view.
 3. Click Enter or click OK.
 4. You are prompted to select the number of lines to display. Make your selection and click Enter.
 5. You are prompted to enter an optional search string. Use this box if you are searching for a particular log message (you can enter a regular expression). Otherwise leave the box empty and click Enter.
 6. Following the prompt, click Enter to answer yes, meaning that only unique messages will be displayed. Otherwise select No and click Enter (all messages will be displayed).
- Be aware that when the Summary Style is used, variables are replaced by the pound sign character (#). For some log data containing variables such as IP addresses or dates, the replacements can be extensive.

3.5 Test Email

Use this command to send a test email using the configured SMTP server.

1. Select Test Email from the Interactive Queries menu.
2. You are prompted to select a recipient. Select Custom and click Enter.
3. You are prompted to supply an email address. Type an email address and click Enter. You will be informed of the output of the operation. Note that on the Administration Console, the Test Connection link in the SMTP pane of the Alerter configuration panel only tests that an SMTP port is configured, not that mail can actually be delivered via that server. You can use this command to test email delivery without having to configure and trigger a statistical or real-time alert, or an audit process notification.

3.6 Test SNMP

Use this command to send a test SNMP trap to the configured SNMP server.

1. Select Test SNMP from the Interactive Queries menu.
2. You are informed of the activity and the results. Note that on the Alerter Configuration panel, the Test Connection link in the SNMP pane only tests that an SNMP port is configured, not that a trap can actually be delivered via that server. You can use this command to test trap delivery without having to configure (and trigger) a statistical or real-time alert, or an audit process notification.

3.7 Report Query Data

Use this command to display the actual select statement used for a report query. This might be useful if a user-written report is producing unexpected output.

1. Select Report Query Data from the Interactive Queries menu.
2. You are prompted to make a selection from a list of report titles. Use the Up and Down arrow keys to select an entry and click the Enter key. Each entry in this list is a Report entity. All pre-defined reports are listed first. These are numbered in the range 100-225 (for version 3.6.1 – the numbers will most likely grow incrementally with each release, as more pre-defined reports are created). User written reports are listed following the pre-defined reports, beginning with number 20001 (for version 3.6.1).

The selected report select statement will be displayed.

3.8 GDM Queries

Use this command to display a count of observed SQL calls during a 100 second interval.

1. Select GDM Queries from the Interactive Queries menu.
2. A message displays requesting your patience. Select yes to continue. The CMD_CT column on the display lists the number of observed SQL calls from the specified clients to the specified servers.
3. Click Enter when you are done viewing the report.

3.9 Generate TCP Dump

Use this command to create a TCP dump. For this command, output is written to a command file only and not to the screen. Unlike most other commands, a separate file is created in the current directory for each execution of this command. The file name is in the format: tcpdump_<mmyyyy-hhmmss>, where the variable portion is a date and time stamp: mmyyyy is the month and year, and hhmmss is the hours, minutes, and seconds.

1. Select Generate TCP dump from the Interactive Queries menu.
2. You are prompted to select an interface. Select a port and click Enter.
3. You are prompted for an optional filter IP address. If you are interested in traffic from only a specific address, enter that IP address and click Enter. Otherwise, just click Enter.
4. You are prompted for an optional port number. If you are interested in traffic from only a specific port, enter that port number and click Enter. Otherwise, just click Enter.
5. You are prompted to select how many seconds of traffic to capture. Select a number of seconds and click Enter.
6. You are prompted to click Enter to start collecting data. Click Enter. You are returned to the menu after (approximately) the specified number of seconds.
7. To view the TCP dump data, select the Read TCP dumps command or export the file (see Export Reported Files on the Output Management menu, described previously).

3.10 Read TCP Dumps

Use this command to display a TCP dump file created previously.

1. Select Read TCP dumps from the Interactive Queries menu.
2. You are prompted to select file. The TCP dump files are listed from oldest to newest. The file name is in the format: `tcpdump_<mmddyy-hhmmss>`, where the variable portion is a date and time stamp: mmddyy is the month, day, and year; and hhmmss is the hours, minutes, and seconds. Select the file you want to view and click Enter.
3. The selected file displays. Use the Up and Down arrow keys to scroll through the display and click Enter when you are done.

3.11 Watch Buffer

Use this command to watch activity in the Guardium buffers:

1. Select Watch Buffer from the Interactive Queries menu. The display is updated every second.
2. Click Ctrl-C to close the display.

3.12 SLON Utility

Use this command to run the slon utility, which tracks packets. Typically, you would only run this command as directed by Technical Support. For this command, output is not written to the screen. Output is written to one of two command files in the current directory, for each execution of the command: `apks.txt.<day_dd-mmm-yyyy_hh.mm.ss.ttt>` OR `requests.txt.<day_dd-mmm-yyyy_hh.mm.ss.ttt>`

The variable portions or the file names are date and time stamps. For example, `apks.txt.Fri_20-May-2011_08.52.00.789`.

1. Select Slon Utility from the Interactive Queries menu.
2. Select the action to be performed and click OK. The choices are:
 - (a) to dump Analyzer rules info
 - (f) to filter Analyzer packets based on IP and/or mask
 - (p) to dump packets to apks.txt
 - (l) to dump logger requests to requests.txt
 - (m) to dump STAP packets (Select how long to run. Wait for completion and then check the msg-dump file under `/var/log/guard/diag/current/tap/`)
 - (r) to record IPQ traffic
 - (s) to dump State machine info
 - (t) to configure throttle parameters
3. Regardless of your selection, you will be prompted to select the time period for the activity. Select a time period and click Enter.
4. You are notified that the program will run for the specified time and prompted to click Enter. Click Enter and wait.
5. When processing completes, a message will be displayed. You can use the File Summary command to display the output of this command. Because this command can produce a large amount of data, you will probably want to export the file to another system, where you can view the contents using a text editor. (Pack the current session data, and export the recordings as described earlier in this section.)

3.13 Show Indexes

Use this command to show indexes for various internal tables:

1. Select Show Indexes from the Interactive Queries menu.
2. You are prompted to select a table. Select a table and click Enter to display the indexes for that table.
3. Use the Up and Down arrow keys to scroll through the display. Click Enter when you are done.

3.14 S-TAP Check

Use this command to display S-TAP definitions and traffic information:

1. Select S-TAP Check from the Interactive Queries menu.
2. The system's unit type displays in numeric format. Click Enter.
3. You are prompted to select the number of seconds to monitor the S-TAP traffic. Use the Up and Down arrow keys to make a selection and click Enter.
4. You are informed of approximately how long to wait for output, and prompted to click Enter. Click Enter.
5. The S-TAP Definitions and Server Traffic reports display. Click Enter when you are done viewing the report.

3.15 Interface Link Status

Use this command to display interface link status.

1. Select Interface link status from the Interactive Queries menu.
2. The status of all interfaces displays. Use the Up and Down arrows to scroll through the display.
3. Click Enter when you are done. Note that this command displays the link status only. To display interface configuration information, use the **show network interface all** CLI command.

3.16 Show Throttle Data

Use this command to display throttle data.

1. Select Show Throttle data from the Interactive Queries menu.
2. Click Enter and wait 3 seconds for throttle statistics.
3. Use the Up and Down arrows to scroll through the display, and click Exit when you are done.

3.17 Generate TCP dump and slon

Use this command to create a TCP dump and run the slon utility, which tracks packets. Only run this command as directed by Technical Support. For more information, see [Generate TCP dump](#) and [Slon utility](#).

3.18 Generate SSL dump

Use this command to create a SSL dump..

1. Select Generate SSL dump from the Interactive Queries menu.
2. Select an interface and click OK. Enter filter IP address and click OK. Enter filter port number and click OK.
3. Select how long to run and click OK. Click OK and wait the specified time in order to gather TCP dumps.
4. If you wish to view SSL dumps, click OK.
5. Click Exit when you are done.

3.19 View bash history

Use this command to display bash history.

1. Select View Bash History from the Interactive Queries menu.
2. Click OK.
3. Use the Up and Down arrows to scroll through the display, and click Exit when you are done.

3.20 Generate GDM_Error dump

Use this command to create GDM_ERROR dumps..

1. Select Show Generate GDM_ERROR dump from the Interactive Queries menu.
2. Click OK and then enter password. Click Enter.
3. Use the Up and Down arrows to scroll through the display, and click Exit when you are done.

3.21 Prepare Tomcat Memory dump

When Tomcat has a first outOfMemory error, it will do a memory dump to /var/tmp/tomcat/tomcat.dmp. Use this command to compress, encrypt and move this file to /var/log/guard/diag/tomcat/ for fileserv to retrieve.

1. Select Prepare Tomcat Memory dump from the Interactive Queries menu.
2. Click OK.
3. Use the Up and Down arrows to scroll through the display, and click Exit when you are done.

3.22 Extended Network Information

Click on Extended Network Information option under System interactive query to display the network diagnostics information.

Example

SQLGuard Diagnostics

Network Parameters from ADMINCONSOLE_PARAMETER:

SYSTEM_NETMASK1: 255.255.255.0

SYSTEM_DOMAIN:

SYSTEM_DEFAULT_ROUTE:

SYSTEM_DNS1:

SYSTEM_DNS2:

SYSTEM_DNS3:

TOMCAT_IP:

MANAGER_IP:

HOST_MAC_ADDRESS:

SECOND_DEVICE:

3.23 Generate TCP dump in rotation

This selection is different from other diag selections in the section called Generate TCP and Generate TCP and slon.

For Generate TCP dump in rotation, enter Filter IP address (enter blank for all IPs). Enter Filter Port number. For the question, How long to run? if the TCP dump in rotation is already running, choose the option “Rotation OFF” or “Rotation” (ON). If Rotation is selected, add file size.

The TCP dump will be output to /var/log/guard/tcp.bin1 and /var/log/guard/bin2 in rotation.

Select TCP dump in rotation again to stop the process loop_tcpdump.sh.

4 Perform Maintenance Actions

Select the Perform Maintenance Actions option from the Main Menu to open the Maintenance menu. Use these commands only under the direction of Technical Support. These do not need to be run on a regular basis.

4.1 TURBINE analyze (update index cardinality)

Use this command to optimize index cardinality on Guardium's internal database. A progress bar displays while the operation is running. When the operation completes, you are returned to the Maintenance menu.

4.2 TURBINE optimize (rebuild indexes, takes longer)

Use this command to analyze and re-index Guardium's internal database.

1. Select TURBINE optimize (index cardinality) from the Maintenance menu. A progress bar displays while the operation is running. When the operation completes, you are returned to the Maintenance menu.

4.3 Clean disk space

Use this command to clean unused disk space. You are returned to the Maintenance menu when the procedure completes.

1. Select Clean disk space from the Maintenance menu. You will be prompted to select a directory.
2. Select the directory from which you want to remove files. The contents of the directory will be listed, and you will be prompted to confirm that you want to remove all files.
3. When the operation completes, you are returned to the Maintenance menu.

4.4 RAID maintenance

Use this command only under the direction of Technical Support. This command provides access to the Management Menu of the RAID controller utility program, which can be used to display the status of the RAID drives. If your system does not have a RAID controller, an error message displays if you select this command. You must be extremely careful when using the RAID controller utility program, since several of the functions provided will erase all information on the disk.

4.5 Application Debugging Utility

Use this command to turn debugging on or off. You are prompted to enable or disable logging, or to reset the system defaults.

4.6 Modify TURBINE watchdog time threshold

Use this option to change the timeout limit for long queries.

4.7 Force unrecoverable MySQL to start

Use this option only when directed to do so by Technical Support.

4.8 Transfer Backups & System Recovery

Use this command to restore a backed up version of the internal database. You will be prompted to confirm the operation.

4.9 Tomcat logging level

Use this command to select the component debug level. Choose one of the following options:

Classifier, Data Level Security, Workflow, or Other.

Choose Classifier to select debug level options: ERROR, WARN, INFO, DEBUG, ALL.

Choose DLS (data level security), Workflow, or Other (text input) to select debug level options: ERROR, WARN, INFO, DEBUG, ALL.

If Other is chosen (text input separated by ';'), enter valid components (dls, workflow, audit, customtable, gui, other, job).

4.10 Aggregator Maintenance

Full analysis and recovery of the Aggregator. This utility will collect AGG related logs and place it in the diag export folder, calls the Aggregator Fix Schema to sync the schema of all databases, clean AGG workspace, and restart the merge process to ensure full analysis of all imported tables (runs in the background and may take several hours to complete).

4.11 Aggregator Fix Schema

Brings all imported tables to the schema of the latest patch level (runs in the background and may take several hours to complete).

4.12 Clean Static Orphans

This option should be used only by Technical Support and only in those cases where static tables grow too much and needed to be cleaned. This utility cleans all the old construct records that don't have any Instances associated with them. A progress message will display during the Clean Static Orphans (for use on collector or aggregator).

5 Exit to CLI

Select Exit to CLI on the Main Menu. Click Enter to close the diag command and return to the command line interface.

File handling CLI Commands

Use these commands to backup and restore system information. Many of these tasks can be performed from Guardium® user interface.

About Archived Data File Names

When Guardium data is archived (or exported to an aggregator), there is a separate file for each day of data. Depending on how your export/purge or archive/purge operation is configured, you may have multiple copies of data exported for the same day. Archive and export data file names have the same format:

<daysequence>-<hostname.domain>-w<run_datestamp>-d<data_date>.dbdump.enc

- daysequence is a number representing the date of the archived data, expressed as the number of days since year 0. The same date appears in yyyy-mm-dd format in the data_date portion of the name.
- hostname.domain is the host name of the Guardium appliance on which the archive was created, followed by a dot character and the domain name.
- run_datestamp is the date that the data was archived or exported, in yyymmdd.hhmmss format.
- data_date is the date of the archived data, in yyyy-mm-dd format.

For example: 732423-g1.guardium.com-w20050425.040042-d2005-04-22.dbdump.enc

backup config

These commands back up and restore configuration information from the internal administration tables. The backup config command stores data in the /media/backup directory. The backup config command removes license and other machine-specific information. The backup system command provides a more comprehensive backup of the configuration and the entire system.

Syntax

backup config

restore config

backup system

This topic applies to backup and restore operations for the Guardium internal database. You can back up or restore data, configuration information, or both. These commands stop all inspection engines and web services and restart them after the operation completes.

Use the **restore backup** command to restore a backup to the latest version of Guardium.

Note: The restore backup command can only restore files from Guardium V10.1.3 or later. For more information, see [restore backup](#).

For all backup, import, and restore commands, you receive a series of prompts to supply some combination of the following items, depending on which storage systems are configured, and the type of restore operation. Respond to each prompt as appropriate for your operation. [Table 1](#) describes the information for which you might be prompted.

Note:

- One copy of the SCP/SFTP/TSM/Centera file transfer is saved, whether or not the transfer is successful. Certain files can take hours to regenerate (such as system backup), so having an available copy (in particular if the file transfer failed) can be a valuable time-saver. Only one copy of each type of file is retained (that is, one archive, one system backup, one configuration backup, and so on).
- The **backup system** command copies the current license, metering and number of data sources, and then backs up the data. Use **restore backup** to restore the data and then restore the license, metering, and number of data sources.
- When configuring backups, a value of zero '0' for the port number indicates that the default port is being used for that protocol.

Table 1. backup system parameters

| Item | Description |
|--|--|
| • AmazonS3
• Centera
• IBM Cloud
• IBM COS
• NFS
• SCP
• SFTP
• TSM | Select the method to use to transfer the file. Storage methods display only if they are enabled. For more information, see the store storage-system command. |
| Data or Configuration | Select Configuration to back up definitions and configuration information only, or select Data to back up data in addition to configuration information. |
| restore from archive or restore from backup | Select restore from archive to restore archived data, or select restore from backup to restore configuration information. |

| Item | Description |
|-------------------|---|
| normal or upgrade | If restoring from the same software version of Guardium, select normal. If restoring configuration information following software upgrade of the Guardium appliance, select upgrade. |
| host | The remote host for the backup file. |
| remote directory | The directory for the backup file. For SFTP, the directory is relative to the SFTP root directory for the SFTP user account used. For SSH, the directory path is a full directory path. For Windows SSH servers, use Unix-style path names with forward slashes, rather than Windows-style backslashes. |
| username | The user account name to use for the operation (for backup operations, this user must have write/execute permission for the directory specified). Note: For Windows, a domain user is accepted with the format of domain\user |
| password | The password for the username. |
| file name | The file name for the archive or backup file.
You can select multiple files by using the wildcard character (*) in the file name when using FTP, SCP, and Snapshot transfer methods. The wildcard character is not supported with TSM or Centera. |
| Centera server | The Centera server name. If using PEA files, use the following format: <Host name/IP>?<full PEA file name>, for example: 128.221.200.56?var/centera/us_profile_rwqe.pea.txt |
| Centera clipID | For a Centera restore operation, the Content Address returned from the backup operation. For example: 6M4B15U4JM4LBeDGKCPF9VQO3UA |

After you supply all of the information required for the backup or restore operation, a series of messages displays informing you of the results of the operation. For example, at the end of a successful restore backup operation, a message similar to the following is sent to the

/var/IBM/Guardium/log/diag/depot/upgrade_<TimeStamp>.log file:

```
2019-05-16-165208 Upgrade of v10.0 to v11.0.0 completed successfully
```

Prevent backup or archive scripts from filling up /var

The backup process will check for room in /var before running and fail. This process will also warn the user if there is insufficient space for backup.

The archive process will check the size of the static tables and make sure there is room in /var to create the archive.

An error is now logged in the logfile and GUI if the backup is over 50%

Example:

```
ERROR: /var backup space is at 60% used. Insufficient disk space for backup. CLI> backup system 1. DATA 2.
CONFIGURATION Please enter the number of your choice: (q to quit) 1 1. SCP 2. CONFIGURED DESTINATION Enter the
number of your choice: (q to quit) 2 Make sure destination is configured in the GUI under the System Backup option Please wait,
this may take some time.
```

delete audit-data

Use this command only under the direction of Guardium Support. This command is used to remove compressed audit data files. You will be prompted to enter an index number to identify the file to be removed. See Archived Data File Names, for information about how archived data file names are formed.

You will be prompted to identify the file to be removed.

Syntax

```
delete audit-data
```

export audit-data

Exports audit data from the specified date (yyyy-mm-dd) from various internal Guardium tables to a compressed archive file. The data from a specified date will be stored in a compressed archive file, in the /var/dump directory. The file created will be identified in the messages produced by the system. See the example. Use this command only under the direction of Guardium Support.

Note: Only users with admin role may run this command .

Syntax

```
export audit-data <yyyy-mm-dd>
```

Example

```
export audit-data 2005-09-16 2005-09-16
```

Generates a set of messages similar to the following:

```
Extracting GDM_ACCESS Data ...
Extracting GDM_CONSTRUCT Data ...
Extracting GDM_SENTENCE Data ...
Extracting GDM_OBJECT Data ...
Extracting GDM_FIELD Data ...
Extracting GDM_CONSTRUCT_TEXT Data ...
Extracting GDM_SESSION Data ...
Extracting GDM_EXCEPTION Data ...
Extracting GDM_POLICY_VIOLATIONS_LOG Data ...
Extracting GDM_CONSTRUCT_INSTANCE Data ...
Generating tar file ... /var/csvGenerationTmp ~
GDM_ACCESS.txt
GDM_CONSTRUCT.txt
GDM_CONSTRUCT_INSTANCE.txt
GDM_CONSTRUCT_TEXT.txt
GDM_EXCEPTION.txt GDM_FIELD.txt
GDM_OBJECT.txt
GDM_POLICY_VIOLATIONS_LOG.txt
```

```
GDM_SENTENCE.txt
GDM_SESSION.txt ~
Generation completed, CSV Files saved to /var/dump/732570-supp2.guardium.com-w20050919110317-d2005-09-16.exp.tgz ok
```

The data from each of the named internal database tables is written to a text file, in CSV format. The name of the archive file ends with exp.tgz and the remainder of the name is formed as described in About Archived Data File Names.

You can use the export file command to transfer this file to another system.

export file

This command exports a single file named filename from the /var/IBM/Guardium/data/dump, /var/log or /var/IBM/Guardium/data/importdir directory.

Use this command only under the direction of Guardium Support. To export Guardium data to an aggregator or to archive data, use the appropriate menu commands on the Administration Console panel.

Syntax

```
export file </local_path/filename> <user@host:/path/filename>
local_path must be one of the following: /var/IBM/Guardium/data/dump, /var/log or /var/IBM/Guardium/data/importdir
```

export-public-transfer-key

This command starts a script that forces a new set of ssh keys onto the specified remote host.

Imports the public part of the ssh transfer key onto a remote host. For more information, see [Enabling ssh-key pairs for data archive, data export, data mart](#).

Syntax

```
export-public-transfer-key
```

export remotelog_config

Use this command to propagate either Venafi or remote logging configurations from a central manager to some or all of its associated managed units.

Syntax

```
export remotelog_config < file | scp >
```

Where:

- file - Exports the log to the default Guardium log location.
- scp - Follow the prompts to indicate where you want to store the log.

Examples

```
>export remotelog_config file
Remotelog config exported to /var/IBM/Guardium/log/remotelog_config_202208111122711.json
>export remotelog_config scp
Host: glab-123.mycompany.com
username: hadrian.swall
Full path: /hom/dev/hadrian.swall/test
Warning: Permanently added 'glab-123.mycompany.com, 2.2.2.2' (ECDSA) to the list of known hosts.
hadrian.swall@glab-123.mycompany.com's password:
remotelog_conf_202208111122711
```

export rotated_message_logs

Use this command to export message logs to a remote directory. Each log is created with a unique name.

When you specify this command, Guardium requests the following information:

- Remote host username
- Remote host: The IP address of the remote host
- Remote host directory: The directory for the remote logs.
- Password: The password for the host user (that is, the host username).
- Scp port: To specify a special port, enter it when requested. To use the default port, enter 0 or press Enter.

Syntax

```
export rotated_message_logs
```

fileserver

Use this command to start an HTTPS-based file server running on the Guardium appliance. This facility is intended to ease the task of uploading patches to the unit or downloading debugging information from the unit. Each time this facility starts, it deletes any files in the directory to which it uploads patches.

Note: Any operation that generates a file that the fileserver will access should finish before the fileserver is started (so that the file is available for the fileserver).

Syntax

```
fileserver <IP address> <duration>
```

- **IP address** - Allows access to a specified fileserver. IP address from the local computer you are using is required to retrieve the IP address that is used to bring up the fileserver. If an IP address is not your local computers IP address, the fileserver will not launch.
- **Duration** - Specifies the number of seconds (60 - 3600) to keep the fileserver active. After the specified number of seconds, the fileserver shuts down automatically.

In case of a security setup where browser sessions are redirected through a proxy server, the IP address of the fileserver client will not be the same as the SSH client that started the fileserver. Instead, the fileserver client will have the IP address of the proxy server, and this address must pass the **IP address** parameter. To find the proxy IP address, check your browser settings or the client IP addresses shown in the Logins to Guardium report in the Guardium Monitor interface.

Example

```
fileserver 10.0.0.1 3600
Starting the file server...
The file server is ready at https://guardium.system.com:8445
The timeout has been set to 3600 seconds and it may timeout during the uploading.

The upload will only be accessible from the IP you are logged in from: 10.0.0.1
Press ENTER to stop the file server.
```

Open the fileserver in a browser window, and do one of the following:

- To upload a patch, click Upload a patch and follow the directions.
- To download log data, click Sqlguard logs, navigate to the file you want and download as you would any other file.

When you are done, return to the CLI session and press Enter to terminate the session.

Access VA scripts using fileserver

- From the Guardium CLI, run fileserver <your computer's IP address> 3600.
- Using a browser, go to https://<IP address of your Guardium system>/log/debug-logs/gdmonitor_scripts/.
- Choose the file that matches your database type.

import file

Use this command to import a file.

Select the filetype from the list that displays when you run the command. You can use a wildcard (*) for the file name in the SCP, FTP, and snapshot methods.

Syntax

```
import file
```

For more information, see [backup config](#) and [restore config](#).

import scanner_agent

Import a vulnerability scanner agent. You can import a scanner agent with either SCP or the Guardium fileserver. Guardium supports the following agents:

- Nessus
- Qualys

Syntax

```
import scanner_agent <scp <agent> | sys <agent> <filename>
```

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

- **scp <agent>** - Follow the prompts to indicate where you want to store the scanner agent.
- **sys <agent> <filename>** - Follow the prompts to indicate where you want to store the scanner agent. Before you import the agent, it must be available on the Guardium fileserver. For more information, see [fileserver](#).

Required information:

- Hostname - The hostname or IP address where the agent resides.
- Username and password - The username and password to log into the host.
- Full filepath - The full path, including the filename of the agent to import, for example, /site/a-support/scanner_tools/agents/NessusAgent/NessusAgent-10.4.2-es8.x86_64.rpm

After you import the agent, then you need to configure it by using the [setup scanner_agent](#) CLI command.

For more information, see [Configuring vulnerability scanner agents](#).

import tsm config

Uploads a TSM client configuration file to the Guardium appliance. You must do this before performing any archiving or backup operations using TSM. You will always need to upload a dsm.sys file, and if that file includes multiple servername sections, you will also need to upload a dsm.opt file. For information about how to create these files, check with your company's TSM administrator.

You will be prompted for a password for the user account on the specified host.

Syntax

```
import tsm config <user@host:/path/[ dsm.sys | dsm.opt ]>
```

Parameters

user@host - User account to access the file on the specified host.

/path/[dsm.sys | dsm.opt] - Full path filename of the file to import.

Note: In setting up TSM on each collector, if the initial configuration fails, a notification error results which says the test file could not be sent. Logging into the collector as root, and then running a dsmc archive command to the TSM server, the TSM file, with the same credentials, now succeeds. Returning to the GUI, and configuring with the same options used before, the configuration now succeeds as well.

If tsm config has passwordaccess=generate, the password stored in a local file, is sought. The root user needs to run the dsmc command once to create this local password file.

After uploading the tsm config file, if tsm config has a passwordaccess generate prompt, passwordaccess is set to be generated.

Would you like to run a dsmc command now to ensure password is set locally (y/n)? If the answer is y, run a "dsmc query options>>/dev/null" command, which will prompt user for password.

import tsm property

Use this CLI command to upload a file to /opt/tivoli/tsm/client/ba/bin/guard_tsm.properties.

The file size should be 1K.

Syntax

import tsm property user@host:file

This command will upload the input file to /opt/tivoli/tsm/client/ba/bin/guard_tsm.properties

restart scanner_agent

Restarts the specified CVE scanner agent.

Syntax

restart scanner_agent <agent>

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

For more information, see [Configuring vulnerability scanner agents](#).

restore backup

With this command you can restore and upgrade Guardium data files, configuration files, or both from a previously installed system to a newer system. The **restore backup** command does not take any parameters, but provides a series of questions to determine which files you want to restore. In order for the command to work, restore backup needs to be called on the same type of machine on the same patch level.

For any restore, you can select one data backup (DATA) file, one configuration file (CONFIG), or one of each.

The **restore backup** command for CONFIG restores the following configuration information:

- Two-factor authentication configuration
- Authentication credentials for system users
- Universal connector configuration
- Aggregator keys
- CA certificates and repository
- PKI certificates
- Repository of keys and certificates
- Web server configuration and customization
- FIPS enabled/disabled state
- OCR configuration
- Outlier configuration
- Spectrum Protect configuration
- GBDI configuration
- Log rotate configuration

Note: The following data is overridden during a restore:

- User information that is defined by the accessmgr user.
- Information included in export definitions.

When you run **restore backup**, Guardium asks if you want to import backup files and then presents a series of questions to determine their location. Guardium suggests that you import the backup files before you call **restore backup**. Imported files are stored in the /var/dump/ directory.

Note: If you already have backup files on your Guardium system, **restore backup** lists those files. You can either select one of the available files to restore or import different files.

If you choose to import a backup file, then the script requests the following information:

- The file transfer method required for the storage type, such as AMAZONS3, FTP, SCP, SOFTLAYER, or TSM.
- The name of the backup host machine.
- The backup host username.
- The remote directory.

- The remote file to restore. You can use a wildcard (*) to select one or more files. For example, if you know that you want to restore a file from 2022, you can specify 2022* to show all files that include 2022 in the filename. If more than 10 files meet the criteria, Guardium will list up to 10 files at a time. You can select the file you want to import or show the next set of files.
- The password for the user on the host machine.

After you select the files to import and restore and specify the required information, Guardium restores the DATA, CONFIG, or both files to the latest supported version of Guardium.

Note: The restore backup command can only restore files from Guardium V10.1.3 or later. To restore a backup file prior to V10.1.3, first restore it to a V10.1.3 or higher appliance, take a backup from that appliance, then restore the new backup onto the latest release.

Syntax

restore backup

restore config

These commands back up and restore configuration information from the internal administration tables. The backup config command stores data in the /media/backup directory. The backup config command removes license and other machine-specific information. The backup system command provides a more comprehensive backup of the configuration and the entire system.

When restoring a configuration, you must restore a backup that is of the same version and patch level as the original appliance where the backup was created.

Syntax

backup config

restore config

restore keystore

Use this command only under direction from Technical Support.

Use this command to restore certifications and private keys used by the Web servlet container environment (Tomcat).

Syntax

restore keystore

restore pre-patch-backup

Use this command only under direction from Technical Support.

Use this command to recover the pre-patch-backup when the appliance database is up or down.

Syntax

```
restore pre-patchbackup Please enter the information to retrieve the file: Is the file in the local system? (y/n) n Start to
recover with the backup profile parameters. Please check the recovery status in the log
/var/log/guard/diag/depot/patch_installer.log ok ----- If answer 'n', abort the operation. If
answer 'y', need to enter the file name.
```

set up vmware tools

Use this CLI command to install VMware that runs on the ESX infrastructure.

Syntax

setup vmware_tools [install | uninstall]

Step 1: Open the VM client/console and select the VM instance that contains the IBM® Guardium appliance. Right-click the instance, select (from the popup menu) Guest => Install/upgrade VMware tools. This enables the instance to access the VMware tools via a mount point.

Step 2: Run the CLI command (from within the VM client/console), **setup vmware_tools install**, to install VM tools.

setup scanner_agent

Set up a CVE scanner agent.

Syntax

setup scanner_agent <configure | enable | proxy | uninstall> <agent>

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

- **configure <agent>** - Configure the specified agent that you imported (with the [import scanner agent](#) command), as follows:

For a Nessus agent:

- Linking key - Available from the Tenable Nessus agents dashboard.
- Agent name - Default value is the Guardium system hostname.
- Host - Tenable Nessus system hostname where the agent connects.
- Port - Port number to connect to the Tenable Nessus system.

For a Qualys agent:

- Customer ID - Available from the Qualys agent management dashboard.

- Activation ID - Available from the Qualys agent management dashboard.
- Server URI - Qualys system hostname where the agent connects.
- Proxy host - Proxy hostname, if needed.
- **enable <agent>** - For a Qualys agent, enable the agent after you configure it. Nessus agents start automatically after configuration.
- **proxy <agents>** - If you are using SSL with a proxy, then follow the prompts for your agent to enter proxy information.
- **uninstall<agent>** - Uninstalls the specified agent (*nessus* or *qualys*).

For more information, see [Configuring vulnerability scanner agents](#).

show audit-data

Use this command to display any files that were created by executing the CLI command, export audit-data. For more information about audit data files, see export audit-data.

Syntax

```
show audit-data <yyyy-mm-dd>
```

show scanner_agent

Syntax

```
ca_bundle | configuration <agent> | status <agent> | supported >
```

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

- **ca_bundle** - Show the certificate information to download with the [store certificate scanner ca_bundle](#).
- **configuration <agent>** - Shows configuration details for the specified agent.
- **status <agent>** - Displays the status for the specified agent.
- **supported** - Displays a list of supported CVE agents.

For more information, see [Configuring vulnerability scanner agents](#).

start scanner_agent

Start the CVE scanner agent.

Syntax

```
start scanner_agent <agent>
```

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

For more information, see [Configuring vulnerability scanner agents](#).

stop scanner_agent

Stop the CVE scanner agent.

Syntax

```
stop scanner_agent <agent>
```

Where:

agent - A supported CVE scanner agent, either *nessus* or *qualys*.

For more information, see [Configuring vulnerability scanner agents](#).

store language

Initial installation of Guardium is always in English. Use the **store language** CLI command after installation to convert the database from English to the desired language. Setting the desired language is considered part of the initial system set up: changing the language on an established system will impact the information already captured, stored, customized, archived or exported on that system.

Important:

- After switching from English to a desired language, it is not possible to revert back to English using this CLI command. The Guardium system must be reinstalled in English.
- To prevent the system from displaying a mixture of languages, set a central manager and all its managed units to the same language.

Syntax

```
store language
```

Example

```
store language
The following languages are available on this appliance:
 1. French
```

```

2. German
3. Italian
4. Japanese
5. Korean
6. Polish
7. Pseudo
8. Simplified Chinese
9. Spanish
10. Traditional Chinese
Please enter the number of the language you want or 0 to quit:

```

Show command

show language

store tsm authorization

When backupinitiationroot is set to ON in TSM servers, then only root and authorized users can perform backup/archive. When backupinitiationroot is set on and password access in DSM.SYS is set to "generate", Guardium backup and archive to TSM will fail with the error message:

ANS1708E Backup operation failed. Only a root user can do this operation

Non-root users must be authorized to perform backup and archive.

This authorization is enabled by executing the CLI command

Store tsm authorization backupinitiationroot on

This authorization is disabled by executing the CLI command:

Store tsm authorization backupinitiationroot off

Syntax

store tsm authorization backupinitiationroot <on/off>

Show command

show tsm authorization backupinitiationroot <on/off>

This CLI command displays on, if non-root Guardium users are authorized to perform backup and archive when backupinitiationroot is set to ON in TSM servers. Otherwise, it displays off.

Vmware kernel panic after a reboot

VMware ESX 4.1 Virtual machine running Guardium might get a kernel panic after a reboot.

To correct this situation, VMware recommends: Install update 2 on ESX4.1 or Set CPU/MMU virtualization to Use software only instruction set and MMU Virtualization. This option is found under Settings/ Options/ CPU/MMU Use software for instruction set and MMU Virtualization.

Inspection Engine CLI Commands

Use these CLI commands to configure the inspection engines.

An inspection engine monitors the traffic between a set of one or more servers and a set of one or more clients using a specific database protocol (Oracle or Sybase, for example). The inspection engine extracts SQL from network packets; compiles parse trees that identify sentences, requests, commands, objects, and fields; and logs detailed information about that traffic to an internal database.

add inspection-engines

Adds an inspection engine configuration to the end of the inspection engine list. The parameters are described. You can re-order your list of inspection engines after adding a new one by using the reorder inspection-engines command. Adding an inspection engine does not start it running; to start it running, use the start inspection-engines command.

Syntax

add inspection-engines <name> <protocol>

<fromIP/mask> <port> <toIP/mask>

<exclude client list> <active on startup>

Parameters

name - The new inspection engine name; must be unique on the unit.

protocol - The protocol monitored, which must be one of the following: Windows: CouchDB, Db2®, Db2 Exit, Informix®, MongoDB, MS SQL, Mysql, Oracle, PostgreSQL, Sybase; UNIX: Aster, Cassandra, CouchDB, Db2, Db2 Exit, exclude IE, FTP, GreenPlumDB, Hadoop, Hive, HTTP, Hue, IBM® iSeries, Impala, Informix, Informix Exit, Kerberos, MariaDB, MongoDB, Mysql, Netezza®, Oracle, PostgreSQL, SAP HANA, Vertica, Sybase, Teradata, Vertica, or WebHDFS.

fromIP/mask - A list of clients, identified by IP addresses and subnet masks. Separate each IP address from its mask with a slash, and multiple entries by commas. An address and mask of all zeroes is a wild card. If the exclude client list option is Y, the inspection engine monitors traffic from all clients except for those in this list. If the exclude client list option is N, the inspection engine monitors traffic from only the clients in this list.

port - The port or range of ports over which traffic between the specified clients and database servers will be monitored. To specify a range, separate the two numbers with a hyphen.

toIP/mask - The list of database servers, identified by IP addresses and subnet masks, whose traffic will be monitored. Separate each IP address from its mask with a slash, and multiple entries by commas. An address and mask of all zeroes is a wildcard.

exclude client list - A Y/N value; defaults to N. If Y, the inspection engine monitors traffic from all clients except for those identified in the client list. If N, the inspection engine monitors traffic from only the clients listed in the client list.

active on startup - A Y/N value; defaults to N. If Y, the inspection engine is activated on system startup.

delete inspection-engines

Removes the single inspection engine identified by its name. The name can include only letters, numbers and blanks. If the inspection engine name contains any special characters, use the administrator portal GUI to remove it.

Syntax

```
delete inspection-engines <name>
```

reorder inspection-engines

Specifies a new order for the inspection engines, using index values from the list produced by the list inspection-engines command.

Syntax

```
reorder inspection-engines <index>, <index>...
```

Example

If the displayed indices are 1, 2, 3, and 4, the following command will reverse order of the engines:

```
reorder inspection-engines 4,3,2,1
```

restart inspection-core

Restarts the inspection-engine core, but not the inspection engines. The collection of database traffic stops when this command is issued.

12.0 Syntax

```
restart inspection-core
```

12.1 and later Syntax

```
restart inspection-core [--yes]
```

Where --yes causes the command to run automatically.

Note: To restart the collection of traffic for one or more specific inspection engines, follow this command with one or more start inspection engine commands. Alternatively, to restart the collection of traffic for all inspection engines, use the restart inspection-engines command.

restart inspection-engines

Restarts the database inspection engine core and all inspection engines. The collection of database traffic stops temporarily while this occurs and restarts only when database connections re-initiate.

Syntax

```
restart inspection-engines
```

show inspection-engines

Displays inspection engine configuration information, as follows:

all - All inspection engines.

configuration <index> - Only the inspection engine identified by the specified index, which is from the list inspection-engines command.

type <db_type> -Displays configurations of a specific database type, which must be one of the supported monitored protocol types: Windows: CouchDB, Db2, Db2 Exit, Informix, MongoDB, MS SQL, Mysql, Oracle, PostgreSQL, Sybase; UNIX: Aster, Cassandra, CouchDB, Db2, Db2 Exit, exclude IE, FTP, GreenPlumDB, Hadoop, Hive, HTTP, Hue, IBM iSeries, Impala, Informix, Informix Exit, Kerberos, MariaDB, MongoDB, Mysql, Netezza, Oracle, PostgreSQL, SAP HANA, Vertica, Sybase, Teradata, Vertica, or WebHDFS.

Syntax

```
show inspection-engines <all | configuration <index> | log sqlstrings | type <type> >
```

Note: Use the CLI command, show inspection-engines all, to display non-STAP Inspection Engines like SPAN ports. The CLI command, list_inspection_engines, will display inspection engines created by STAP.

start inspection-core

Starts the inspection-engine core.

Syntax

start inspection-core

start inspection-engines

Starts one or more inspection engines identified using index values from the list produced by the list inspection-engines command.

Syntax

start inspection-engines <all | id>

start inspection-engines all

Starts all the inspection engines.

Syntax

start inspection-engine all

start inspection-engines id

Usage: start inspection-engines id <n>, where n is a numeric sniffer id.

Syntax

start inspection-engines id <n>

stop inspection-engines id

Usage: stop inspection-engines id <n>, where n is a numeric sniffer id.

stop inspection-core

Stops the inspection-engine core.

Syntax

stop inspection-core

stop inspection-engines

Stops one or more inspection engines identified using index values from the list produced by the list inspection-engines command. It can also stop all inspection-engines.

Syntax

stop inspection-engine <all | id>

stop inspection-engines all

Stops all the inspection engines.

Syntax

stop inspection-engines all

stop inspection-engines id

Stops one or more inspection engines identified using index values from the list produced by the list inspection-engines command.

Syntax

stop inspection-engine <n>, where <n> is numeric sniffer id

store ignored port list

Sets the complete set of port numbers to be ignored by all inspection engines. The list you specify completely replaces the existing list. Each number is separated from the next by a comma, and no blanks or other white-space characters are allowed in the list. Use a hyphen to specify an inclusive range of numbers.

Syntax

store ignored port list <n>

Example

store ignored port list 33,60-70

Show Command

show ignored port list

Investigation Dashboard CLI Commands

Use these CLI commands to configure the Investigation Dashboard .

show solr connection_timeout

Use this command to show the current connection_timeout value.

```
show solr connection_timeout
```

show solr so_timeout

Use this command to show the current so_timeout value.

```
show solr so_timeout
```

show solr time_allowed

Use this command to show the current time_allowed value.

```
show solr time_allowed
```

store solr connection_timeout

Use this command to set the connection timeout. If the Investigation Dashboard cannot connect to the collector within the specified timeout period, no results from that collector will be returned.

```
store solr connection_timeout [value]
```

| Parameter | Value | Description |
|--------------------|---------|---|
| connection_timeout | integer | The timeout is expressed as a value of 0 to 2147483647 milliseconds.
The default value is 100000 milliseconds. |

store solr so_timeout

Use this command to set the socket timeout.

```
store solr so_timeout [value]
```

| Parameter | Value | Description |
|------------|---------|---|
| so_timeout | integer | The timeout is expressed as a value of 0 to 2147483647 milliseconds.
The default value is 100000 milliseconds. |

store solr time_allowed

Use this command to set the socket timeout.

```
store solr time_allowed [value]
```

| Parameter | Value | Description |
|--------------|---------|--|
| time_allowed | integer | The timeout is expressed as a value of 0 to 2147483647 milliseconds.
The default value is 90000 milliseconds.

Note: Deep search uses 10x (ten times) the time_allowed value. |

Network Configuration CLI Commands

Use the network configuration CLI commands to set IP addresses, handle bonding and failover, handle secondary functionality, and reset networking.

Use the network configuration CLI commands to perform the following tasks:

- Identify a connector on the back of the machine (**show network interface port**).
- Reset networking after you install or move a network card (**store network interface reset**).
- Set IP Addresses (**store network interface ip**, **store network interface mask**, **store network resolver**, **store network routes**).
- Enable or disable high-availability (**store network interface high-availability**).
- Configure the network card if the switch it attaches to does not auto-negotiate the settings (**store network interface auto-negotiation**, **store network interface speed**, **store network interface duplex**).

Guardium uses predictable network interface names. The primary network interface is set during installation and can be changed by using the **store network interface**

`role` command.

restart network

Restarts just the network configuration. For example, change the IP address, then run this CLI command.

12.0 Syntax

```
restart network
```

12.1 and later Syntax

```
restart network [--yes]
```

Where `--yes` causes the command to run automatically.

show network interface all

This command shows settings for the network interface that is used to connect the Guardium® appliance to the desktop LAN. This command displays the IP address, mask, state (enabled or disabled), and high availability status. If IP high-availability is enabled, the system displays two interfaces. Otherwise, only one interface is displayed.

Syntax

```
show network interface all
```

show network interface inventory

Use the show command to display the port names and MAC addresses of all installed network interfaces.

Syntax

```
show network interface inventory
```

Example

```
CLI> show network interface inventory
Current network card configuration:
Device      | Mac Address          | Member of
-----
ens32       | 00:50:56:B8:18:75   |
ens33       | 00:50:56:3b:c3:73   |
ens34       | 00:50:56:8a:0d:fb   |
ok
```

The `Member of` column shows the NICs that are in the bond pair, if a bonding exists.

show network routes operational

Display the IP routing configuration in use.

Syntax

```
show network routes operational
```

Example

```
CLI> show net rout operational
Kernel IP routing table
Destination Gateway Genmask Flags Metric Ref Use Iface
192.168.3.0 0.0.0.0 255.255.255.0 U 0 0 0 nic1
169.254.0.0 0.0.0.0 255.255.0.0 U 0 0 0 nic2
0.0.0.0 192.168.3.1 0.0.0.0 UG 0 0 0 nic1
ok
```

show network verify

Display the current network configuration.

Syntax

```
show network verify
```

```
CLI> show network verify
Current Network Configuration
```

```
Hostname = test_system.guardium.ibm.com
```

| Device | Address | Prefix | Gateway | Member of |
|--------|---------|--------|---------|-----------|
| ens256 | -- | None | -- | br3 |
| -- | -- | None | -- | -- |
| ens224 | -- | None | -- | br2 |
| -- | -- | None | -- | -- |
| ens160 | -- | None | -- | br0 |
| -- | -- | None | -- | -- |

| | | | | |
|------------------------|----------------------------------|------------|------------|------------|
| ens34 | 9.70.165.96 | 24 | 9.70.165.1 | -- |
| -- | 2002:920:c000:3165:9:70:165:96 | 64 | -- | -- |
| ens192 | -- | None | -- | br1 |
| -- | -- | None | -- | -- |
| Ethtool Options | | | | |
| Device | Options (speed, autoneg, duplex) | | | |
| ens256 | | | | |
| ens224 | | | | |
| ens160 | | | | |
| ens34 | | | | |
| ens192 | | | | |
| DNS Servers | | | | |
| Index | DNS Server | | | |
| 1 | 9.32.193.11 | | | |
| Static Routes | | | | |
| Device | Index | Address | Prefix | Gateway |
| ens34 | 0 | 9.32.145.0 | 24 | 9.32.145.1 |

store network interface auto-negotiation

If auto-negotiation is available on the switch to which a Guardium port is connected, auto-negotiation is used, and only the restart option of this command has any effect. Use this command to enable, disable, or restart auto-negotiation for the specified network interface (NIC). Use **show network interface inventory** to display all port names.

Syntax

```
store network interface auto-negotiation <NIC> <on | off | restart>
```

Show command

```
show network interface auto-negotiation
```

store network interface duplex

Use this command only when auto-negotiation is not available on the switch to which the Guardium port is connected. This command configures duplex mode for the port. Use the **show network interface inventory** command to display all port names.

Syntax

```
store network interface duplex <NIC> <half | full>
```

Show command

```
show network interface duplex <NIC>
```

store network interface high-availability

Enables or disables IP Teaming (also known as bonding), which provides a fail-over capability for the Guardium system primary IP address.

The two ports used (the primary and secondary interfaces) must be connected to the same network. A slight delay might occur if the switch needs to relearn the port configuration. The default setting is off.

When the high-availability option is enabled, the Guardium system automatically fails over, as needed, to the specified secondary interface, which transfers the primary IP address to the secondary interface.

Note: You can specify either IP Teaming and Secondary Interface, but not both.

Syntax

```
store network interface high-availability [on <NIC> [mode <1|4>] | off]
```

If high-availability is enabled, you can optionally specify the NIC mode, which can be:

- 1 - active-backup - Provide fault tolerance features by using an active-backup policy.
- 4 - lacp/802.3ad - Provide load balancing and fault tolerance based on the 802.3ad specification.

store network interface ip

Sets the primary IP address for the Guardium appliance in CIDR (Classless Inter-Domain Routing) format. You might need to change the subnet mask when you change the network interface IP address. For more information, see **store network interface mask**.

See **store network interface secondary** to create and manage a secondary IP address. Bonding or failover is managed from the **store network interface high-availability** CLI command.

Syntax

```
store network interface ip <ip address>
```

store network interface mask

Sets the subnet mask for the primary IP address. If you change the network interface mask, you might also need to change its IP address. See [store network interface ip](#).

Note: The subnet mask for a secondary IP address can be assigned only from [Setup > Tools and Views > System](#).

Note: This command supports IPv4 addresses only.

Syntax

```
store network interface mask <ip mask>
```

store network interface mtu

Use this CLI command to set the maximum transfer unit (MTU).

```
CLI> store network interface mtu
```

Usage: store network interface mtu <interface> <mtu>]

Where *interface* is the interface name (ens32) and *mtu* is the number of transfer units (between 1000 and 9000).

Show command

```
show network interface mtu
```

show network interface port

Use this command to locate a physical connector on the back of the appliance. After you display all port names with [show network interface inventory](#), use this command to flash the light on the physical port specified by NIC (for example, ens32) 20 times.

Syntax

```
show network interface port <nic>
```

Example

```
CLI> show network interface port ens32
```

The orange light on interface ens32 will now blink 20 times.

store network interface reset

Use this CLI command to wipe the existing OS network configuration. This command also detects and builds configuration for the on-board NIC cards within the Guardium appliance.

Syntax

```
CLI> store network interface reset
```

WARNING: This command will clear existing network interface configuration.

Network will be disconnected due to this operation.

Are you SURE you want to continue? (y/n)

store network interface restore

Use this command to restore all of the network settings from your Guardium database settings. Restoring the settings can be useful if, for example, a patch introduces an error into the network configuration. In this case, the information in the database is still correct and you can quickly restore all of your settings.

Note: Static route settings are not saved in the database and are not restored.

Syntax

```
CLI> store network interface restore
```

WARNING: This command will overwrite the network configuration with the stored Guardium network settings.

It may disconnect your current ssh session.

Are you SURE you want to continue? (y/n)

store network interface role

Use this command to assign a role to a physical network interface. A network interface role can be primary, secondary or no role (undefined). Use undefined (`undef`) to clear the role of an interface that is currently set to `secondary`.

Syntax

```
store network interface role <NIC> <undef | primary | secondary>
```

Show command

```
show network interface role
```

store network interface secondary

Use this command to configure a port on the Guardium system as a secondary management interface with a different IP address, network mask, and gateway from the primary.

Note: You cannot use IP Teaming and Secondary Interface at the same time.

Syntax

```
store network interface secondary [on <interface> <ip[/prefix]> <gateway> | off [ipv4|ipv6]]
```

Where

- *interface* is a valid interface.
- *ip* and *gateway* are valid IP addresses.
- */prefix* is the IP address prefix length in CIDR. */prefix* is optional. The default values are 24 for ipv4 or 64 for ipv6.
- *ipv4* and *ipv6* are the IP versions.

Show command

```
show network interface secondary
```

store network interface speed

Use this command only when auto-negotiation is not available on the switch to which the Guardium port is connected. This command configures the speed setting for the port. Use the [show network interface inventory](#) command to display all port names.

Syntax

```
store network interface speed <NIC> <auto | 10 | 100 | 1000>
```

Show command

```
show network interface speed <NIC>
```

show network interface status

Use this command to display the physical link status of a network interface.

Syntax

```
show network interface status <NIC>
```

Example

```
show network interface status ens32
Network Interface Status
    Link detected: yes
ok
```

show network arp-table

Displays the address resolution protocol (ARP) table, which is an operational system value. This command is provided for support purposes only.

Syntax

```
show network arp-table
```

Example

```
CLI> sho net arp
IP address HW type Flags HW address Mask Device
192.168.3.1 0x1 0x2 00:0E:D7:98:07:7F * nic1
192.168.3.20 0x1 0x2 00:C0:9F:40:33:30 * nic1
ok
CLI>
```

show network macs

Displays a list of MAC addresses (like the show network interface inventory command).

Syntax

```
show network macs
```

Example

```
CLI> show network macs
ens32: 00:50:56:b8:18:75
lo: 00:00:00:00:00:00
```

store network resolvers

Sets the IP address for the first, second, or third DNS server to be used by the Guardium appliance. Each resolver address must be unique.

Syntax

```
store network resolvers <IP address 1 [IP address 2] [IP address 3] | null>
```

Enter a maximum of three space-separated IP addresses. To remove the DNS servers, enter null.

Note: This command replaces existing DNS settings.

For example,

- IPv4

```
store network resolvers 192.0.2.0 192.0.2.1 192.0.2.2
This change will take effect after restart network.
ok

• IPv6

store network resolvers 2001:0DB8:0:0:0:0:0:0 2001:0DB8:0:0:0:0:0:1 2001:0DB8:0:0:0:0:0:3
This change will take effect after restart network.
ok

• Dual mode (IPv4 and IPv6)

store network resolvers 2001:0DB8:0:0:0:0:1 192.0.2.0 2001:0DB8:0:0:0:0:3
This change will take effect after restart network.
ok
```

Show command

```
show network resolvers
```

store network routes defaultroute

Sets the IP address for the default router to the specified value.

Syntax

```
store network routes defaultroute <ip address>
```

Show commands

```
show network routes defaultroute
```

store network routes static

Allow the user to have only one IP address per appliance (through the primary interface) and direct traffic through different routers that use static routing tables. Add line to static routing table.

Syntax

```
store network routes static
```

Show command

List the current static routes, with IDs - Device, Index, Address, Netmask, Gateway.

```
show network routes static
```

Delete command

```
delete network routes static
```

store system domain

Sets the system domain name to the specified value.

Syntax

```
store system domain <value>
```

Show command

```
show system domain
```

store system hostname

Sets the system's hostname to the specified value.

Syntax

```
store system hostname <value>
```

Show command

```
show system hostname
```

Support CLI Commands

Use the following CLI commands only under the direction of Technical Support.

These commands are to assist Guardium Technical Support to analyze the status of the machine, troubleshoot common issues, and correct some common problems. You do not need to perform these commands regularly.

store active_parser_engine

This CLI command controls which parser engine that sniffer uses. This CLI command is only applicable to database types supported by ANTLR3 parsers (such as Oracle, Db2, MS SQL, and MySQL).

Syntax

```
store active_parser_engine <num>
```

Where *num* is

- 1 - ANTLR3 parser errors reparsed by ANTLR2 (default)
- 2 - ANTLR2 only
- 3 - ANTLR3 only

Show command

```
show active_parser_engine
```

store antlr3_cached_raw_context_count

Use this command to define how many cached results the sniffer antlr3 parser stores for each raw (prepared) statement map per sniffer thread. The typical workflow for raw statements is that first sniffer receives a raw SQL statement, which is parsed, stored in memory along with its ID, and logged. When sniffer later receives the bind data, the full SQL is reconstructed and reparsed.

With this feature, the cache creates a short-cut where the raw antlr3 parsed result is also stored in memory. It is much faster to retrieve and run the cached statements than having to reparse them on every retrieval. However, the caching also requires much more memory.

The command allows you to specify how many antlr3 raw statement parsed results are cached per sniffer thread, rather than reparsing the reconstructed statements.

Note: The **store antlr3_cached_raw_context_count** function allows the sniffer to process traffic more efficiently when raw statements are heavily used. However, caching the raw statements causes sniffer to consume more memory. It is recommended to enable only the **store antlr3_cached_raw_context_count** function on collectors that have at least 32 GB of memory.

Recommended values are 1000 - 2000 statements per GB of memory. For example, for a 32 GB collector, you can set **store antlr3_cached_raw_context_count** to 32 - 64 (that is, 32,000 - 64,000).

Syntax

```
store antlr3_cached_raw_context_count <num>
```

Where *num* is a number between 0 (disabled) and 1000 (in thousands) or -1 (default) to have sniffer allocate the number of cached results based on the amount of available memory.

Examples

```
store antlr3_cached_raw_context_count 24 - Sets the limit to 24,000.
```

```
store antlr3_cached_raw_context_count 1000 - Sets the limit to 1,000,000.
```

Show command

```
show antlr3_cached_raw_context_count
```

If **store antlr3_cached_raw_context_count** is set to -1, the response is "Available."

store antlr3_max

Use this command to help control data flow between the sniffer parser and logger for either the antlr2 or antlr3 parser.

If the sniffer is running out of memory and restarting, try lowering the antlr3_max logger size. Alternatively, if the sniffer isn't using enough of the available system memory, increase the logger size to allow sniffer to use more system memory.

Note: The **store antlr3_max** command is an advanced parameter for expert users and Customer Support. This command helps control the data flow between parser and logger component of the sniffer for Oracle, Db2, MySQL, or MSSQL.

Syntax

```
store antlr3_max <num>
```

Where *num* is the number of parsed SQL statements that can be processed by the logger queue and can be either:

- A number in the range 1000 - 10000000.
- 0 (the default) - Allows the sniffer to dynamically allocate space based on available memory. For every 500 MB of physical memory, this command allocates space for 1000 parsed SQL statements.

Show command

```
show antlr3_max
```

store antlr3_remove_comments

Use this CLI command to determine whether to log SQL comments in reports and alert messages.

Syntax

```
store antlr3_remove_comments [on | off ]
```

Where:

- *on* - Do not log comments in alerts and reports.
- *off* - Log comments in alerts and reports.

Note: You must restart the inspection engine after you change this command.
Show command

```
show antlr3_remove_comments
```

This command shows whether **store antlr3_remove_comments** is enabled or disabled.

support analyze

Use this CLI command to analyze content.

Parameters

```
support analyze mssql_decryption_config
support analyze sniffer
support analyze tables
support analyze tap_property
support analyze static-tables
```

Analyze the content of static tables by sorting them based on the largest group per value length and value occurrence.

Note: The analyzed reports can be retrieved from the access logs on the file server using the following path: Access logs>opt-ibm-guardium-log>analyze
The following example is a list of analyzed reports in the Guardium access log:

```
analyze_mssql_decryption_config.log
analyze_sniffer_errors.log
analyze_tap_property.log
```

support app_debug

Turns on app_debug for the specified number of minutes.

Syntax

```
support app_debug start
```

At the prompt, enter the number of minutes to run the app_debug function.

support check tables

Invokes the **mysqlcheck -c** command on tables (to check tables for errors). The default table is TURBINE.

Syntax

```
support check tables [dbname [tablename]]
```

Checks run in parallel, so the overall run time can vary. The command shows progress in percentages. All checks time out after 3 minutes. If a check times out, the table name displays after the command completes.

Any errors that are found are stored in the following file.

```
/opt/IBM/Guardium/log/<dbname>_check_tables
```

Where <dbname> is the name of the database that you checked.

Within the <dbname>_check_tables file, for each table that contains an error, the CLI command generates a log file called:

```
check_table_child.<tablename>.<date>.log
```

Where:

- <tablename> - The name of a table with errors
- <date> - Current date

Log files are not generated for healthy tables.

- Specify this command with no parameters to check all tables in TURBINE database.
- Specify *dbname* to check all tables in a specified database. If you do not specify a database, Guardium checks the tables in TURBINE.
- Specify *dbname* and *tablename* to check a single table in the database. Use this command to recheck individual tables where the check timed out. You can use a percent sign (%) as a wildcard in *tablename* parameter.

For example, to search for all tables in TURBINE that begin with the word RULE:

```
support check tables TURBINE RULE%
```

support clean audit_results

A way to manually purge audit results. Use this command only when absolutely necessary to deal with audit tasks that produce a high number of records and take up too much disk space.

Note: Consult with Technical Support before you run this command.

When you run the command, the following steps occur:

1. A Warning message displays and you must confirm that you really want to take this step.
2. This command lists the audit processes and tasks information. It presents the number of rows, ordered from the largest result set to the smallest. The number of report results is greater than or equal to the input value.
3. Select the line number to delete the audit data for the selected process name.

Syntax

```
support clean audit_results <rows>
```

Where *rows* is the number of rows to show. Default = 10.

Note: On a system with many audit tasks, this command can take some time to complete.

support clean log_files

This CLI command deletes the specified file after you confirm the delete. If it cannot find the file, it lists files larger than 10 MB in /var/log and provides a list of large files that you can select for deletion. A warning message is presented and a confirmation step is included.

Syntax

```
support clean log_file <filename>
  >> add filename.
```

support clean centera_files

Guardium archives and backups that are stored within Centera have a deletion date marker that is attached to them by Guardium. However, no facility is available to invoke the deletion. Centera does not have a GUI to allow maintenance of its own files, so it relies on API invocations from client applications.

Use this command to delete marked files within Centera.

Syntax

```
support clean centera_files
```

support clean DAM_data

A way to manually purge database activity monitoring data. Use this command only when absolutely necessary.

Consult with Technical Support before you run this command.

A Warning message and a confirmation step are included in the command.

Syntax

```
support clean DAM_data <purge_type> <start_date> <end_date>
```

Input parameters

purge_type options - agg, exceptions, full_details, msgs, constructs, access, policy_violations, parser_errors, flat_log

start_date - YYYY-mm-dd

end_date - YYYY-mm-dd

support clean hosts

Syntax

```
support clean hosts <IP address> <fully qualified domain name>
```

support clean InnoDB-dumps

Use this CLI command to purge InnoDB tables.

This command is password-protected (for Technical Support only)

Syntax

```
support clean InnoDB-dumps
```

support clean servlets

Deletes *.jsp*.java and *.jsp*.class files and restarts GUI.

Use this CLI command to delete generated Java™ servlets and their classes.

Syntax

```
support clean servlets
```

[support dump_gdm_exception_error](#)

Dumps GDM_ERROR and GDP_EXCEPTION tables to the Guardium log file location.

12.0 Syntax

```
support dump_gdm_exception_error
```

12.1 and later Syntax

```
support dump_gdm_exception_error [--yes]
```

Where --yes causes the command to run automatically.

[support execute](#)

This utility is designed to provide Guardium Advanced Support with the ability to assist with remote diagnostics and support when direct remote access is not available or permitted.

The **support execute** command is not a replacement for direct remote connections, but allows Guardium Support at least some level of root access in a secure way without direct access.

The commands that are provided by Guardium Advanced Support can be SQL statements, O/S Commands, Shell Scripts, or SQL scripts. The scripts are provided to the customer along with a Secure Key to allow the command to run using the CLI. The Secure key is tied to the system that Guardium Support is working on with the customer, and is not valid for any other system. The command can only be run the number of times that are permitted by Guardium Support and is only valid for seven days from the agreed date.

The feature is disabled by default. Enable it using the CLI command in either normal and recovery mode.

Syntax

```
support execute [enable | disable]
```

To permit the Guardium Advanced Support team to generate a Secure Key, the MAC address of the system in question must be provided for ens32.

Examples:

```
support execute <CMD String> <PMR #> <KEY>
```

main execute command provided by Guardium Advanced Support.

```
support execute showlog [<Secure Key>|main|files]
```

Show usage logs
'<Secure Key>' for full details of single entry
'main' to display the main execute log
'files' to display log directory list

```
support execute mac
```

ens32 MAC address required by support to generate secure key

```
support execute info
```

Show ens32 MAC address, root passkey & other system information

```
support execute version
```

Display the "Support Execute" internal binary code version

```
support execute help
```

Help details and purpose of utility information

Example of command provided by Guardium Advanced Support:

```
support execute "select * from GDM_ACCESS%5CG" 11111,111,111 6254130c0f0c3c504b33687c57f41363e4c00
```

[support gather_io_metrics](#)

This command manages the **gather_io_metrics** service to collect information about I/O statistics on the Guardium appliance when you run the command. With the **start** parameter, this command creates a **gather_io_metrics.txt** file. In addition, Guardium includes the **gather_io_metrics.txt** file with the output of any **must_gather** command. For more information, see [support must_gather commands](#).

Syntax

```
support gather_io_metrics [remove_log | start | status |stop]
```

Where:

- **remove_log** - Delete the current **gather_io_metrics.txt** file.
- **start** - Start to gather I/O metrics. By default, the service runs for 24 hours, unless you stop it sooner.
- **status** - Provide the current status of the **gather_io_metrics** service. Reports on **iostat** command output, whether the service is running, and other information.
- **stop** - Stops the **gather_io_metrics** service.

[support get_gdp_cluster_info](#)

This command gathers information about your Guardium® Data Protection environment to help you, and your support contact, determine the size required for a Guardium Insights cluster. Run the command on a central manager.

Syntax

```
support get_gdp_cluster_info
```

The data is sent to the Guardium fileserver at /opt/IBM/Guardium/log/gdp_cluster_info.csv. The .csv file displays a row for each managed collector that contains the following information:

- LAST_PING_DATE
- UNIT_HOST_NAME
- SQLGUARD_VERSION
- LAST_INSTALLED_PATCH
- DATA_PURGE_AGE
- MEMORY_SIZE
- CPU_CORES
- VAR_SPACE
- DB_SIZE
- NUMBER_OF_DATABASES
- SESSION_LINES
- SESSION_AVG_LINE_LENGTH
- INSTANCE_LINES
- INSTANCE_AVG_LINE_LENGTH
- POLICY_VIOLATIONS_LINES
- POLICY_VIOLATIONS_AVG_LINE_LENGTH
- EXCEPTION_LINES
- EXCEPTION_AVG_LINE_LENGTH
- FULL_SQL_LINES
- FULL_SQL_AVG_LINE_LENGTH
- VA_LINES
- VA_AVG_LINE_LENGTH
- CLASSIFIER_LINES
- CLASSIFIER_AVG_LINE_LENGTH

After you run the command, retrieve the gdp_cluster_info.csv from the Guardium fileserver and send it to Guardium Insights support for analysis.

support logrotate message

By default, log files rotate weekly and store the four most recent log files. Use this command to change the log rotation strategy for the log files.

Syntax

```
support logrotate message [frequency] [# of rotations] [# of steps]
```

Where:

- *frequency* - The frequency with which to rotate the files. Frequency can be one of *hourly* / *daily* / *weekly* / *monthly*.
- *# of rotations* (integer) - The number logs to keep. The default is 4. After Guardium reaches the specified number of logs, the oldest log is deleted. The following example rotates the logs every week and stores the three most recent logs:

```
support logrotate message weekly 3
```

- *# of steps* (integer) - The number of steps (an hour, day, week, or month) to skip in the specified frequency. The following example stores the five most recent logs and rotates the logs every second day:

```
support logrotate message daily 5 2
```

Show command

```
support show logrotate message
```

support must_gather commands

As the CLI user (that is, the user named CLI), you can run must_gather commands to generate specific information about the state of most Guardium systems. After you run the command, upload this information from the appliance and send it to Guardium Technical Support whenever a PMR (Problem Management Record) is logged.

The CLI user can run the must_gather commands at any time, as follows.

1. Open a PuTTY session (or similar) to the Guardium system of concern.
2. Log in as user *cli*.
3. Depending on the type of issue you are facing, enter the relevant must_gather commands into the CLI prompt in the following format.

Syntax

```
support must_gather <arg>
```

Where *arg* is a single must_gather command. You might need more than one must_gather command to diagnose the problem.

- **agg_issues** - Aggregation process issues.
- **alert_issues** - Alerting issues.
- **app_issues** - Application issues.
- **audit_issues** - Audit process issues.
- **auth_issues** - Authentication issues (including LDAP and multifactor authentication).
- **auto_create_ie** - Auto create inspection engines issues.

- **backup_issues** - Backup process issues.
- **big_data_issues** - Big data issues.
- **cm_issues** - Central manager issues.
- **compliance_mon_issues** - Compliance monitoring issues.
- **datamining_issues** - Data mining issues.
- **datastreams_issues** - Data streaming issues.
- **deploy_agents_issues** - Deployment agents issues.
- **deployment_issues** - Deployment issues.
- **eagle_eye_issues** - Advanced threat scanning issues.
- **enterprise_load_balancer_issues** - Enterprise load balancer issues.
- **entitlement_issues** - Entitlement optimization issues.
- **go_stream** - Go stream issues.
- **jproxy_issues** - Jproxy issues.
- **miss_dbuser_prog_issues** - System database user issues.
- **native_auditing_issues** - Native auditing issues.
- **network_issues** - Network architecture issues.
- **patch_install_issues** - Patch installation and upgrade issues.
- **purge_issues** - Purge process issues.
- **risk_spotter** - Risk spotter issues.
- **scanner_agent_issue**
- **scheduler_issues** - Scheduler issues.
- **slon_looper** - Slon looper output.
- **sniffer_issues** - Sniffer issues.
- **system_db_info** - Guardium system database or operating space performance issues.
- **universal_connector_issues** - Universal connector issues.

The following commands might take a few minutes to complete.

- **support must_gather miss_dbuser_prog_issues**
- **support must_gather sniffer_issues**

For the following commands, you are prompted for a time (in minutes) for how long you want to run the debugger to reproduce the problem.

- **support must_gather backup_issues**
- **support must_gather scheduler_issues**

Guardium writes the output to the must_gather directory with filenames, for example:

```
must_gather/system_logs/.tgz
```

4. Send the resulting output to IBM® Support.

Use the **fileserver** CLI command to upload the tgz files and send to them to support.

Send the output in an email or upload to ECUREP in, for example, the standard data upload specifying the PMR number and file to upload.

To purge must_gather files from the Guardium system, see [show must_gather file max age](#).

support must_gather datamining_issues

Collects necessary diagnostic information for Outliers, Quick search and data mart functionality. Information includes dumps of corresponding internal tables, necessary logs, state of corresponding processes, and standard must_gather diagnostics (general system and internal DB information).

Syntax

```
support must_gather datamining_issues
```

support must_gather network_issues

The command gathers all network information from the appliance and polls hosts that Guardium interacts with by using ping, traceroute, corresponding port probing, and other measures. If the optional parameter is specified, then it polls only the host that was specified (if Guardium is configured to do any activity on this host).

Syntax

```
support must_gather network_issues [--host=<HOST>]
```

Where optional parameter --host is the hostname or IP address.

support reset-managed-cli

Use this command from a central manager to login to each associated managed unit and set the CLI passwords and expirations to match the passwords and expiration dates as the central manager.

For this procedure to work, the root passkey must be set on each managed unit. For more information, see [Resetting the root password](#).

Syntax

```
support reset-managed-cli
```

support reset-password

This command resets a password on the IBM Guardium appliance. For root and cloudsupport accounts, only use this command when requested to do so by IBM Technical Support.

Syntax

```
support reset-password [ accessmgr | cloudsupport | root ]
```

Where:

- **accessmgr** - Resets the accessmgr password.
If the accessmgr email is set up, the system notifies the accessmgr account email.
- **cloudsupport** - For cloud images only, resets the password for the cloudsupport account.
The cloudsupport password uses a joint password mechanism for security. Your site holds the keys to the appliance in the form of an encoded numeric passkey. IBM holds the passkey decoder.

When you call Guardium support, the support analyst will start a remote desktop sharing session and request the cloudsupport passkey for the Guardium appliance in question. Guardium support uses the cloudsupport password to gain access to the appliance as cloudsupport user.

Use this command to reset the password key and **support show passkey cloudsupport** to view the passkey.

- **root** - Resets the root password on the IBM Guardium appliance.
This command requires that you provide a secret keyword in order to change the root password. Contact Technical Support if you need to change the root password.

Note: Do not reset the root password unless required by business rules.

support schedule find_crashed_tables

Use this CLI command to enable or disable the daily cron job of find_crashed_tables.sh script.

Syntax

```
support schedule find_crash_tables on ALL|db  
support schedule find_crash_tables off
```

This command enables or disables the daily schedule of find_crashed_tables script.

Note: Pay particular attention to the database entered. Enter "ALL" in order to process all five valid databases for crashed tables or just one of the five valid databases "TURBINE", "GDMS", "CUSTOM", "DATAMART" or "DIST_INT".

support server

The support server is an advanced diagnostic utility that generates a summarized report of your Guardium system.

Use the **support server** command to list all of the support server CLI commands.

Run this command to enable the support server on your Guardium system.

```
support server enable
```

Run this command to disable the support server on your Guardium system.

```
support server disable
```

Use this command to get a summarized report of your Guardium system.

```
support server info
```

support show boot check

Use this command to perform a health check on the boot order of kernels in the boot loader. If the boot order has not been customized and the latest kernel version is not the first entry in the boot order, the command returns **Failed**. Otherwise, the command returns **Passed**. If the boot order has been customized, the command always returns **Passed**.

support show boot order

Use this command to display the boot order of kernels in the boot loader.

support show db-processlist

This command lists all of the database processes sorted by running time.

Syntax

```
support show db-processlist all  
support show db-processlist locked  
support show db-processlist running  
support show db-process full
```

Parameters:

```
support show db-processlist [ ]
```

Where:

- *all* - Includes sleeping processes
- *full* [optional] - Displays SQL queries in expanded format
- *locked* - Displays all locked processes
- *running* - View all running SQL statements

support show db-struct-check

This command displays all the structure differences that are found during aggregation process.

Syntax

```
support show db-struct-check
```

support show db-top-tables

This command lists the 20 largest database tables sorted by size and lists tables sorted by used free table space for tables that use more than 80% free space. It allows filtering by table name. All table sizes are displayed in MB, free space usage in percentage.

Syntax

```
support show db-top-tables all
```

```
support show db-top-tables like
```

Parameters

```
support show db-top-tables all
```

Lists the largest tables out of the entire database sorted by size.

```
support show db-top-tables like
```

Lists the largest tables by matching criteria, which can be any portion of the table name.

support show db-status

This command shows database usage.

Parameters are *free*, *used*, *megabytes*, *percentage*.

Syntax

```
support show db-status free %
```

```
support show db-status used %
```

```
support show db-status free m
```

```
support show db-status used m
```

support show hardware-info

This command uses a script to collect hardware information and places this collected information in a directory for retrieval.

After running this CLI command, the following message displays:

```
Collected HW Info as /var/log/guard/Gather_hw_info-2012-06-25-17-43.tgz
```

Then run the **fileserver** CLI command to retrieve this .tar file from the server.

support show innodb-status

Use this CLI command to troubleshoot MySQL issues. Use this CLI command to check what is happening at runtime with MySQL tables. Use this CLI command to determine if long check times with MySQL tables are due to record lock or table lock.

Syntax

```
support show innodb-status
```

```
0 queries inside InnoDB, 0 queries in queue
0 read views open inside InnoDB
Main thread process no. 7959, id 139923805550336, state: sleeping Number of rows inserted 6894, updated 6934, deleted 93, read 2478'
-----
END OF INNODB MONITOR OUTPUT
```

support show iptables

This command displays the output of system iptables command.

Syntax

```
support show iptables diff
```

```
support show iptables list
```

Parameters

[diff | list] parameter controlling normal iptables output presentation versus displaying only differences/delta.

[accept | full] parameter filters output by accept row versus an unfiltered list.

support show large_files

This command lists all the files larger than <size> and older than <age> in the /var /tmp /root folders.

Syntax

```
support show large_files
```

This command lists all the files larger than MB and older than days in the /var /tmp /root folders.

Input parameters:

- * size - integer > 10 (in MB)
- * age - integer >= 0 (in days)

Syntax:

```
support show large_files <size> <age>
```

Where:

- size - The minimum size files to display (default 100M).
- age - The number of days since the last modification.

show must_gather_file_max_age

Use this command to change the number of days that a must_gather file is stored in the Guardium system before purging.

Syntax

```
store must_gather_file_max_age <num days>
```

Where the value for num days is any integer greater than 1 and the default value is 30.

The file **cleanup_must_gather_files.log** logs all the files that are purged by the **store must_gather_file_max_age** command.

support show netstat

This command displays the output of system netstat command. It allows filtering of the output by content using a grep parameter.

Syntax

```
support show netstat [ all | grep ]
```

Where:

- all - Shows the output of the system netstat command.
- grep - An alphanumeric string to search. The command returns the output that matches the search parameters.

support show passkey

This command displays a passkey that you created using the **support reset-password** command.

Syntax

```
show passkey < accessmgr | cloudsupport | root |
```

Where,

- *accessmgr* shows the passkey for the accessmgr.
- *cloudsupport* shows the passkey for cloud images, such as Azure, IBM Cloud, or Oracle OCI. Use **show passkey cloudsupport** to show the passkey (access key) that Guardium technical support requires to access a cloud image during a support call.
- *root* shows the passkey for the current (non-cloud) appliance. Use this command to show the passkey that Guardium technical support requires to access the appliance if you are locked out of root.

For more information, see [support reset-password](#). For more information about the root password, see [Resetting the root password](#).

support show port open

This command is similar to using telnet to detect an open TCP port locally or on a remote host.

If we are able to connect successfully, a message similar to the following displays:

```
Connection to 127.0.0.1 8443 port [tcp/*] succeeded!
```

If you are unable to connect, a message similar to the following displays:

```
Connect to 127.0.0.1 port 1 (tcp) failed:  
Connection refused
```

Syntax

```
support show port open
```

IP port - IP must be a valid IPv4 address (such as 127.0.0.1).

Port must be an integer with a value in 1-65535.

support show top

This command displays the output of system top command sorted by cpu, memory or running time. You can specify the number of iterations (default =1) and number of displayed rows (default =10).

Syntax

```
support show top [ cpu | memory | time ]
```

Parameters

- **CPU <N> <R>**
- **memory <N> <R>**
- **time<N> <R>**

Where *N* is number of iterations (between 1 and 10) and *R* is number of rows to display (minimum = 10).

support store boot custom

Use this command to manually define (customize) the first kernel entry in the boot loader. Use **support store boot custom** to show all installed kernels and the corresponding index value, then use the index value to define the first kernel entry in the boot loader. Use **support store boot custom off** to turn off boot loader customizations.

Syntax

```
support store boot custom [ <index> | off ]
```

support store boot sanitize

Use this command to reorder the kernels in boot menu. If the boot order has not been customized, the command sorts all currently installed kernels in descending order by version. If the boot order has been customized, the command does nothing.

Syntax

```
support store boot sanitize
```

support store datastreams_diag

Turn data stream debug level logging off or on. When logging is on, datastream logs are stored in ..//opt/IBM/Guardium/log/datastreams.

Syntax

```
support store datastreams_diag [ off | on ]
```

support store hosts

The **support store hosts** command appends an IP-address/domain-name pair to the operating system hosts file (/etc/hosts). The hosts file translates hostnames to IP addresses.

Syntax

```
support store hosts <IP_address> <fully_qualified_domain_name>
```

Example

```
support store hosts 1.2.3.4 mydomain.company.com
```

This example adds the following line to the end of the hosts file:

```
1.2.3.4 mydomain.company.com # CREATED BY CLI, DO NOT CHANGE
```

Show command

```
support show hosts
```

This command shows entries added to the /etc/hosts file using the **support store hosts** command.

support store ora_tns_errors

Controls handling of TNS errors early in processing, giving the option to not log them at all.

Syntax

```
support store ora_tns_errors [0 | 1]
```

- 0 - Do not store TNS errors
- 1 - Store TNS errors (default)

Show command

```
support show ora_tns_errors
```

[support store rdsdiag](#)

Manage Amazon Web Services (AWS) relational database service (RDS) monitoring.

12.0 Syntax

```
support store rdsdiag < clean | off | on >
```

where:

- *clean* - Attempts to delete all core dumps older than 3 minutes from /var/tmp/rds.
- *off* - When RDS monitoring is on, turn on RDS diagnostics.
- *on* - When RDS monitoring is on, turn off RDS diagnostics.

12.1 and later Syntax

```
support store rdsdiag < clean [--yes] | off | on >
```

- *clean* - Attempts to delete all core dumps older than 3 minutes from /var/tmp/rds.
Where --yes causes *clean* to run automatically.
- *off* - When RDS monitoring is on, turn off RDS diagnostics.
- *on* - When RDS monitoring is on, turn on RDS diagnostics.

For more information about turning on RDS monitoring, see [start rds monitoring](#).

[support store snif_auto_hostname_cache](#)

Use this command to toggle sniffer hostname caching.

Syntax

```
support store snif_auto_hostname_cache [ on | off ]
```

Where:

- *on* - Sniffer automatically detects and caches hostnames.
- *off* - Use CLI commands to control hostname caching.

Show command

```
support show snif_auto_hostname_cache
```

[support store snif_auto_os_name_cache](#)

Use this command to toggle sniffer operating system name caching.

Syntax

```
support store snif_auto_os_name_cache [ on | off ]
```

Where:

- *on* - Sniffer automatically detects and caches operating system names.
- *off* - Use CLI commands to control operating system caching.

Show command

```
support show snif_auto_os_name_cache
```

[support store snif_auto_service_name_cache](#)

Use this command to toggle sniffer service name caching.

Syntax

```
support store snif_auto_service_name_cache [ on | off ]
```

Where:

- *on* - Sniffer automatically detects and caches service names.
- *off* - Use CLI commands to control service caching.

Show command

```
support show snif_auto_service_name_cache
```

[support store snif-debug](#)

Use this command to turn the snif debug on or off.

Syntax

```
support store snif-debug [on | off]
```

Show command

```
support show snif-debug
```

support store snif_dump_invalid_msgs

Use this command to control the maximum number of invalid TAP messages that snif will write to a log file in a 5 minute period.

Syntax

```
support store snif_dump_invalid_msgs [ off | on | rate_limit | size_limit ]
```

Where:

- *off* - Do not write invalid messages to the log file.
- *on* - Write all messages to the log file, regardless of whether they are valid.
- *rate_limit <num-msgs>* - Sets the maximum number of invalid TAP messages that are written to the log file in a 5-minute period, where *num-msgs* is 0 or greater.
- *size_limit <file-size-mb>* - Sets the maximum file size for the snif log file containing invalid TAP messages. *file-size-mb* is the file size is between 1 and 4000, in MB.

Show command

```
support show snif_dump_invalid_msgs
```

support store snif_hostname_cache

Use this command to manage either IPv4 or IPv6 IP addresses cached for the sniffer hostname.

Syntax

```
support store snif_hostname_cache [ remove | set ]
```

Where:

- *remove <IP>* - Removes an IP address from the operating system name entry.
- *set <IP>* - Sets the IP address for a hostname entry. This command overwrites any existing entries.

Show command

```
support show snif_hostname_cache [ all | search ]
```

Where:

1. *all* - Show all cached hostname entries.
2. *search* - Enter a set of characters to search on (such as all or part of an IP address or hostname).

support store snif_memory_max

Syntax

```
support snif_memory_max <num>, where num is a number of | 33 | 50 | 75 |
```

This command applies to 64-bit systems only.

Show command

```
support show snif_memory_max
```

support store snif_os_name_cache

Use this command to manage either IPv4 or IPv6 IP addresses cached for sniffer operating system name.

Syntax

```
support store snif_os_name_cache [ remove | set | upload ]
```

Where:

- *remove <IP>* - Removes an IP address from the operating system name entry.
- *set <IP>* - Sets the IP address for an operating system name entry. This command overwrites any existing entries.
- *upload <file>* - Uploads one or more operating system name entries. The file name must be *os.arc.upload*, the first line is the number of operating system name entries in the file, each subsequent line contains the IP address and an OS name, separated by a space. For example:

```
2
192.168.1.100 test1.domain.com
192.168.1.101 test2.domain.com
```

Show command

```
support show snif_os_name_cache [ all | search ]
```

Where:

1. *all* - Show all cached operating system name entries.
2. *search* - Enter a set of characters to search on (such as all or part of an IP address or operating system name).

support store snif_service_name_cache

Use this command to manage either IPv4 or IPv6 IP addresses cached for sniffer service names.

Syntax

```
support store snif_service_name_cache [ remove | set ]
```

Where:

- *remove <IP>* - Removes an IP address from the service name entry.
- *set <IP>* - Sets the IP address for a service name entry. This command overwrites any existing entries.

Show command

```
support show snif_service_name_cache [ all | search ]
```

Where:

1. *all* - Show all cached service name entries.
2. *search* - Enter a set of characters to search on (such as all or part of an IP address or service name).

support store slon

Turns on SLON utility that captures packets gotten by sniffer for debug. Results files slon_packets.tar.gz, slon_messages.tar.gz or slon_all.tar.gz can be found using the **fileserver** CLI command. The /var partition must have at least 15GB of free space.

Syntax

```
support store slon [ on [parameter] | off [parameter] ]
```

Where:

- *on* - Turns the SLON utility on. You can specify the following optional parameters:
 - *packets* - Dump analyzer packets (default)
 - *snifsql* - Log sniffer SQL activities and dump analyzer packets
 - *secparams* - Log secure parameters information and dump analyzer packets
 - *sgate* - Log S-GATE debugging info and dump analyzer packets
 - *messages* - TAP message data dump
- *off* - Turn the SLON utility off. You can specify one of the following parameters:
 - *packets* - Stop dumping packets, logging secure parameters, S-GATE debug info and sniffer SQL activities (default)
 - *messages* - Stop TAP message data dump
 - *all* - Stop all activities

Show command

```
support show slo
```

support store tcpdump

Turns on TCPDUMP utility. After period ends, results file tcpdump.tar.gz can be found with the **fileserver** CLI command. The /var partition must have at least 15GB of free space.

Syntax

```
support store tcpdump [ on <type> <period> <loglimit> [interface] [IP] [port] [protocol] | off ]
```

Where:

- *on* - Turns TCPDUMP utility on. Specify the following parameters:
 - *type* - Dump type:
 - 'headers' - Capture headers only
 - 'raw' - Capture whole packets
 - *period* - Dump period, NUMBER[SUFFIX], where optional SUFFIX can be 's' for seconds, 'm' for minutes (default)
 - *loglimit* - Dump logfile limit, from 1 to 6 gigabytes
 - Optional filter arguments:
 - *interface* - Network interface name (default the primary interface)
 - *IP* - IP address
 - *port* - Port
 - *protocol* - Protocol, which can be one of: 'tcp', 'udp', 'ip', 'ip6', 'arp', 'rarp', 'icmp' or 'icmp6'
- *off* - Turns the TCPDUMP utility off. After stopping, the results file tcpdump.tar.gz can be found using the **fileserver** CLI command.

Example

```
support store tcpdump on headers 10m 1
```

This command runs TCPDUMP saving packets headers for 10 minutes and 1GB log file size limit.

Show command

```
support show tcpdump
```

support store zdiag

Toggles the Guardium for z/OS traffic diagnostics on or off. This includes collection of TCPDUMP and SLON, collections stop when corresponding files reach 2 GB size. After completion, the results files tcpdump.tar.gz and slon_all.tar.gz can be found using the **fileserver** CLI command. The /var partition must have at least 15GB of free space.

Syntax

```
support store zdiag [ on [N] | off ]
```

Where:

- **on** - Turns zdiag on. *N* (optional) is number of minutes to run diagnostics, from 10 to 600, 60 by default.
- **off** - Turns zdiag off.

Show command

```
support show zdiag
```

System CLI Commands

Use these CLI commands to view and configure system settings.

show openssh version

Shows the OpenSSH version of the Guardium system.

Syntax

```
show openssh version
```

show openssl version

Shows the OpenSSL version of the Guardium system

Syntax

```
show openssl version
```

show os version

Shows the operating system version of the Guardium system.

Syntax

```
show os version
```

start ecosystem

Use this command to restart the entire set of ecosystem processes. This restart is necessary after you install patches, run upgrades and some other operations.

Syntax

```
start ecosystem
```

stop ecosystem

Use this command to temporarily and gracefully stop the entire set of ecosystem processes. You need to stop the ecosystem for patching, upgrades and some other operations.

Syntax

```
stop ecosystem
```

store allow_reinstall

When you install Guardium from CD or DVD media, due to host server settings, the media is not always ejected correctly. In this case, when the system is rebooted, it can cause the system to keep reinstalling from the media, rather than rebooting only.

During a reboot, the installer searches the disk to see whether the requested version of Guardium is already installed. If it is installed, and **allow_reinstall** is set to *off*, Guardium pauses to prompt whether to continue the installation process (or reboot only without reinstalling). For example:

```
"Already installed 11.3.0, continue to reinstall (c) or reboot with any other key: "
```

In this case, click *c* to reinstall, or any other key to reboot.

If **allow_reinstall** is set to *on*, the system reinstalls from the media without prompting.

Tip: If **allow_reinstall** is set to *off* (the default) and the installer prompts you to reinstall, the media has a problem. Manually eject the CD or DVD before rebooting.

Syntax

store allow_reinstall [on | off]

The default is *off*.

Show command

show allow_reinstall

store system apc

Use this command to configure automatic powering down options when a UPS is attached. The UPS must be attached to a USB connector (serial connections for a UPS are not supported).

Sets the minimum charge percent (0-100) before powering down, or the number of seconds to run on battery power before powering down. The defaults are 25 (percent) and zero (seconds).

The following commands start and stop the apc process. The apc process is disabled by default.

Syntax

store system apc [battery-level <percent> | timeout <seconds>]

store system apc start

store system apc stop

Show command

show system apc [battery-level | timeout]

store system auditlog-passthrough

Use this command to enable or disable the passing-through of system audit log data from the auditd service to the local syslog. Because the system audit log is verbose, the **auditlog-passthrough** feature is best used along with remote logging. For more information about remote logging, see [Configuration and control CLI commands](#).

The **auditlog-passthrough** feature is disabled by default.

Syntax: **store system auditlog-passthrough [on | off]**

Example:

```
> store sys aud on
Restarting auditd service to pick up the change.
Reloading configuration: [ OK ]
Auditd to syslog passthrough is enabled.
ok
```

Show command: **show system auditlog-passthrough**

store system banner

Use this CLI command to create a banner at the CLI login. You can use the banner to create your own welcome message, warn about unauthorized access, or provide other useful information.

store system banner [message | clear | default]

Syntax

store system banner clear: Remove an existing banner message.

store system banner message: Create a banner message. Enter the banner message and then press CTRL-D.

store system banner default: Reset the banner to the default message.

Show command

show system banner

store system classifier profile

Use this command to adjust the memory available for classification.

Syntax

store system classifier profile [default|small|medium|large|max]

Where the profile values are not exact, but map to the following approximate sizes:

- **default** - 4 GB (same as large)
- **small** - 1 GB
- **medium** - 2 GB
- **large** - 4 GB

- **max** - 8 GB

Show command

show system classifier profile

store system clock datetime

Use this CLI command to set the system clock's date and time to the specified value.

Syntax

store system clock datetime <YYYY-mm-dd hh:mm:ss>

Where:

- *YYYY* - year
- *mm* - month
- *dd* - day
- *hh* - hour (in 24-hour format)
- *mm* - minutes
- *ss* - seconds.

The seconds portion is required, but is always set to 00.

Show command

show system clock <all |datetime |timezone>

Example

```
store system clock datetime 2018-10-03 12:24:00
```

store system clock timezone

Use this CLI command to list the allowable time zone value (list option), or set the time zone for this system to the specified time zone. Use the list option first to display all available time zones, and then enter the appropriate time zone from the list.

IBM® Guardium® also logs the local time zone in the standard audit trail to address cases where data is used in (or aggregated with) data that is collected in other time zones.

Syntax

store system clock timezone <list | timezone>

Show command

show system clock <all | timezone | datetime>

Example

Use the command first with the *list* option to display all available time zones. Then enter the command a second time with the appropriate zone.

```
CLI> store system clock timezone list
Timezone:          Description:
-----
Africa/Abidjan:
Africa/Accra
Africa/Addis_Ababa:
...
...output deleted
...
CLI> store system clock timezone America/New_York
```

store system conntrack

This CLI command sets the current status of the connection tracking subsystem of the Linux® kernel.

Syntax

store system conntrack <ON|OFF>

Show command

show system conntrack

store system cpu profile

Allow configuration of CPU scaling from a CLI command on hardware that supports CPU scaling.

Use this CLI command to set the appropriate CPU scaling policy for your needs:

- **conservative** - Less power usage, conservative scaling
- **balanced** - Medium power usage, fast scale up
- **performance** - Runs the CPUs at maximum clock speed

Guardium software sets the scaling policy to Performance upon installation.

Syntax

store system cpu profile [min|perf|max]

Show command

show system cpu profile

store system custom_db_size

Use this CLI command to set the maximum size of the custom database table (in MB). The Default value is 4000 MB.

Syntax

```
CLI> store system custom_db_max_size  
USAGE: store system custom_db_max_size <N>  
      where N is number larger than 4000.
```

Show command

show system custom_db_size

store system domain

Sets the system domain name to the specified value.

Syntax

store system domain <value>

Show command

show system domain

store system fipsmode

Use this command to enable or disable Federal Information Processing Standard (FIPS) cryptographic standards.

Syntax

store system fipsmode [on | off]

Note: Restart your system after enabling or disabling FIPS mode for the changes to take effect.

Show command

show system fipsmode

store system hostname

Sets the system's hostname to the specified value.

Syntax

store system hostname <value>

Show command

show system hostname

store system ipmode

Use this command to change the IP (Internet Protocol) mode of your Guardium system. For more information, see [Internet Protocol modes](#).

Syntax12.0

store system ipmode[ipv4|ipv6|dual]

Syntax12.1 and later

store system ipmode[ipv4|ipv6|dual] --{yes}

Where --yes causes the command to run automatically

Show command

show system ipmode

store system issue

Use this CLI command with the message parameter to receive input from the console until CRTL-D and write it to /etc/motd after removing from the input any \$,\, followed by single letter, and ` characters. Use this command to enter messages that make this system compliant with the security policies of customers.

Use this CLI command with the clear parameter to restore /etc/motd to the default version.

store system issue [message | clear]

Note: The version comes from /etc/guardium-release. For example, SG70 refers to 7.0, SG80 refers to 8.0. If the SG is not found in /etc/guard-release, the default version is an empty string.

store system netfilter-buffer-size

Use this CLI to set the maximum number of packets the kernel netfilter queue stores internally before dropping upcoming packets. The value is stored in an internal Sniffer configuration table.

Note: Do not use this command without consulting Guardium support.

Syntax

store system netfilter-buffer-size

Show command

Displays the S-TAP® netfilter buffer size. The default is 65536 packets.

show system netfilter-buffer-size

store system patch

The parameters for this command are cleanup, and install.

Store system patch cleanup

Deletes the patches that are selected from an itemized list.

Example:

```
> store system patch cleanup
Patches:
1. SqlGuard-11.Op118.tgz.enc.sig
2. SqlGuard-11.Op121.tgz.enc.sig
3. SqlGuard-11.Op123.tgz.enc.sig
4. SqlGuard-11.Op125.tgz.enc.sig

Please choose the patches to remove by item number (1 to 4)
Specify multiple patches with comma separated numbers
Specify ALL for all
q to quit

Patch item number(s): all
SqlGuard-11.Op118.tgz.enc.sig removed
SqlGuard-11.Op121.tgz.enc.sig removed
SqlGuard-11.Op123.tgz.enc.sig removed
SqlGuard-11.Op125.tgz.enc.sig removed
Ok
```

store system patch preservation [on | off]

When patch preservation is turned *on*, Guardium patches are not automatically deleted after an installation failure. You can attempt reinstallation after fixing issues, if any.

Store system patch install

Installs a single patch or multiple patches as a background process. The *ftp* and *scp* options copy a compressed patch file from a network location to the IBM Guardium appliance. A compressed patch file can contain multiple patches, but you can install only one patch at a time. To install more than one patch, choose all the patches that need to be installed, separated by commas. Internally the CLI submits requests for each patch on the list (in the order that is specified by the user). The first patch takes the request time that is provided by the user and each subsequent patch runs 3 minutes after the previous one. In addition, CLI checks to see whether any specified patches are already requested and does not allow duplicate requests.

Use the *sys* option when you install a second (or subsequent) patch from a compressed file that was copied to the IBM Guardium appliance by previously using this command.

To display a complete list of applied patches, see the Installed Patches report from the Guardium UI. Find this report from Manage > Reports > Install Management > Installed Patches, Manage > Maintenance > General > Installed Patches, or Reports > Guardium Operational Reports > Installed Patches.

In the **store system patch install** CLI command, you can choose multiple patches from the list.

Syntax

store system patch install <type> <date> <time>

type - The installation type - **cd** | **ftp** | **scp** | **sys**

date, time - The patch installation request time, date is formatted as *YYYY-mm-dd*, and time is formatted as *hh:mm:ss*

If no date and time are provided, or if you enter NOW, the installation request time is NOW.

Parameters

Regardless of the option selected, you are prompted to select a patch to apply, for example:

Please choose one patch to apply (1-n,q to quit):

cd - - To install a patch from a CD, insert the CD into the IBM Guardium CD ROM drive before you run this command. A list of patches that are contained on the CD are displayed.

ftp or scp -- To install a patch from a compressed patch file located somewhere on the network, use the *ftp* or *scp* option, and respond to the prompts shown. Be sure to supply the full path name for the patch, including the file name. For example:

```
Host to import patch from:  
User on hostname:  
Full path to the patch, including name:  
Password:
```

For **store system patch install scp**, you can use a wildcard (*) for the patch file name.

The compressed patch file is copied to the Guardium appliance, and a list of patches contained on file displays.

sys - Use this option to apply a second or subsequent patch from a patch file that has been copied to the IBM Guardium appliance by a previous store system patch execution.

The store system patch install command does not delete the patch file from the IBM Guardium appliance after the installation. While you need not remove the patch file, as same patches can be reinstalled over existing patches and keeping patch files around can aid in analyze various problems, a user may remove patch files by hand or use the CLI command diag (Note, the CLI command diag is restricted to certain users and roles.)

To delete a patch install request, use the CLI command **delete scheduled-patch**.

Show command

```
show system patch <available | installed | preservation | staged | status >
```

Where:

- **available** - Displays the patches that are available for installation.
- **installed** - Displays the patches that are being installed or already installed.
- **preservation** - Displays the patch preservation status. When preservation is turned *off*, a patch is deleted after a failed installation attempt. When preservation is turned *on*, the patch is not deleted and you can attempt installation again.
- **staged** - Displays the patch files that are residing in the patches directory.
- **status** - Displays the status of a patch that is currently being installed.

store system public key

This command shows the outbound public SSH key for the standard users. The outbound SSH key pair is generated internally by the appliance, rather than stored from user input. If you adopt the public SSH key generated by the appliance, you can set up SSH export for the standard users: cli, grdapi, and tomcat All of the standard users use a common outbound SSH key.

12.0 Syntax

```
store system public key <cli | grdapi| tomcat | reset>
```

```
store system signature [on | off]
```

Where:

- **cli, grdapi, or tomcat** - Stores an existing public SSH key in the respective path.
- **reset** - Regenerates the outbound SSH Keys for the standard users.
Where --yes causes the command to reset automatically.

Show command

Displays an existing system public key for the CLI, GuardAPI, or Tomcat. If the public key does not yet exist, use **show system public key** to generate new outbound SSH keys. The SSH key pair is associated with the standard users: cli, grdapi, tomcat, and root.

```
show system public key < cli | grdapi | tomcat >
```

store system public key authorized

This command allows users to connect to the Guardium appliance by using SSH keys instead of passwords.

Syntax

```
store system public key authorized
```

Create the public key either with the **ssh-keygen** command or with the **show system public key** CLI command.

Note: How you create and store a public key with the **ssh-keygen** command depends on your operating system. For more information, see documentation for using **ssh-keygen** for your operating system.

Show command

Display the contents of an existing authorized public key.

```
show system public key authorized
```

Note: You can use the **ssh-keygen** command to create a public key. The exact commands depend on your operating system and other factors. Guardium suggests that you use the default location when you create the key.

After you create the key, store and use it as follows:

1. Connect to the Guardium appliance as the **cli** user:

```
ssh cli@guardium_host
```

2. Add the newly created public key:

```
store system public key authorized
```

3. At the prompt, paste the contents of the public key:

```
Please paste the SSH public key content here. Then press <ENTER> to continue.
```

The following message displays if the key is added:

```
Key for your_email@example.com is added  
ok
```

4. Run the following command to make sure that the key is available.

```
show system public key authorized  
your_email@example.com  
ok
```

5. You can now connect to the Guardium appliance that uses public key authentication. For example:

```
ssh cli@guardium_host
```

Note: If you specify a file name (rather than using the default id_rsa), then use the -i option when you run the **ssh** command and specify the location of the private key. For example,

```
ssh -i ~/.ssh/different_key_name cli@guardium_host  
IBM Guardium, Command Line Interface (CLI)
```

Delete command

delete system public key authorized

Displays a list of available public keys. Specify the number of the key that you want to delete.

store system public-transfer-key

Creates, deletes, and regenerates the transfer ssh-key pair for transferring data to a remote host by using the ssh-key pairs. For more information, see [Enabling ssh-key pairs for data archive, data export, data mart](#).

Syntax

```
store system public-transfer-key <create | delete | regenerate >
```

Where:

create - Create the ssh-key pair.

delete - Delete the ssh-key pair.

regenerate - Delete the existing ssh-key pair and then creates a new ssh-key pair.

Show command

```
show system public-transfer-key
```

store system remote-root-login

Enable/disable SSH (root access). Secure Shell or SSH is a network protocol that allows data to be exchanged by using a secure channel between two networked devices.

Syntax

```
store system remote-root-login ON|OFF
```

Show command

```
show system remote-root-login
```

Returns the public part of the transfer key.

store system ssh

This command sets the security options on the ssh service for the system.

Syntax

```
store system ssh <secure|default>
```

Where:

- **secure** - Improves the SSH key exchange algorithm (KEX).
- **default** - Turns secure KEX off.

After you run this CLI, the SSH service restarts.

store system scp-ssh-key-mode

Enable/disable the scp-ssh-key-mode, for enabling ssh-key pairs for data archive, data export, and data mart, without passwords. For more information, see [Enabling ssh-key pairs for data archive, data export, data mart](#).

store system scp-ssh-key-mode on|off

Show command

show system scp-ssh-key-mode

store system serialtty

In some environments, the serial TTY is not available so it cannot ever be started successfully. Potentially, this can appear in the system log and be forwarded to SIEM. This is enabled by default to permit connectivity, but can be disabled later if it is determined that serial consoles are unavailable to the system.

Syntax

store system serialtty <on, off>

Show command

show system serialtty

Reports whether or not serial TTYs are enabled on the system.

Reports either:

Serial TTY consoles are enabled on this system.

Serial TTY consoles are disabled on this system.

store system scheduler

Scheduling is managed by a timing mechanism within the IBM Guardium application. If the timing function is disrupted, it will restart after the restart interval designated by this CLI command.

Use store system scheduler restart_interval [5 to 1440 or -1] to restart the timing function after 5 minutes to 1440 minutes. The default is -1, which means the timing restart mechanism is not installed.

Use store system scheduler wait_for_shutdown [ON | OFF] to restart the scheduler after all jobs currently running finish. The parameters are ON or OFF.

Syntax

store system scheduler restart_interval [5 to 1440 or -1]

store system scheduler wait_for_shutdown [ON | OFF]

Show command

show system scheduler

store system service_status

Use this CLI command to enable or disable certain Guardium appliance services.

Syntax

store system service_status [enable | disable] <service-name>

Where,

- enable, disable - Specify whether to enable or disable a specified service.
- *service-name* - The name of a Guardium service that you can start or stop.

Run **store system service_status** with *enable* or *disable* to see the list of services that you can change.

Show command

Syntax

show system service_status [all | <service-name>]

Display the status of all available Guardium appliance services or specify a service to view. Run **show system service_status** with no parameters to see the list of services that you can view.

store system shared secret

Sets the system's shared secret value to the specified value. This key must be the same for a Central Manager and all appliances it manages; or an Aggregator, and all appliances from which it aggregates data. After an appliance has registered for management by a Central Manager, the shared secret on that unit is no longer used. (You cannot unregister a unit from Central Management by changing this value.)

Dynamic password for aggregator OS user

The aggregator password is the <the current password> concatenated with the shared secret, meaning: password=<current passwd><share secret>

Users need to make sure the collectors' shared secret and the aggregator's shared secret is the same, otherwise the SCP transfer fails from the collector to the aggregator (This is a requirement for managed units and aggregators, collectors and aggregators, and export setup screen). The shared secret can be set both from CLI and from the System pane in the Admin Console tab.

Syntax

store system shared secret <key>

store system signature [on | off]

This command is deprecated in Guardium version 12.1.

When turned *off*, enables deployment of apps that do not have signatures. Turn *off* store system signature when you are testing an app on your Guardium system; otherwise the app is blocked. In production this parameter should be *on* since you are using certified apps from the App Exchange.

Syntax

store system signature [on | off]

store openssl_sha1_signature

12.1 and later Use this CLI command to enable or disable sha-1. Turn sha-1 *on* to upload the GIM bundles. After you upload the bundles, you can turn sha-1 *off*.

Syntax

store openssl_sha1_signature [on|off]

Show command

show openssl_sha1_signature

store system snif-alerts-facility

This parameter allows the user to configure the facility for snif generated alerts. Previously alerts directly generated by snif used the user facility while indirect alerts used the daemon facility (via the guard_sender utility).

Syntax

store system snif-alerts-facility <facility>

USAGE: store snif-alerts-facility <facility>

facility is one of: **daemon ftp local0 local1 local2 local3 local4 local5 local6 local7 lpr user**

The default facility is daemon.

Show command

show system snif-alerts-facility

store system snif-buffers-reclaim

Use this CLI command only when directed by IBM Guardium Technical Services.

The new configuration takes effect after you run the **restart inspection-core** CLI command.

Syntax

store system snif-buffers-reclaim [ON | OFF]

Show command

show system snif-buffers-reclaim

store system snif-thread-number

Use this CLI command to specify how many threads are running.

The new configuration takes effect after you run the **restart inspection-core** CLI command.

Syntax

store system snif-thread-number [new | default]

Show command

show system snif-thread-number

Snif is running with 6 threads on the 32-bit system.

show system snmp engineid

Use this CLI command to display the SNMP engine ID for the IBM Guardium appliance.

Syntax

show system snmp engineid

store system snmp contact

Stores the email address for the SNMP contact (syscontact) for the IBM Guardium appliance. The default is `info@guardium.com`.

Syntax

store system snmp contact <email-address>

Show command

show system snmp contact

store system snmp location

Stores the SNMP system location (syslocation) for the IBM Guardium appliance. The default is `Unknown`.

Syntax

store system snmp location <string>

Show command

show system snmp location

store system snmp query community

Stores the SNMP system query community for the IBM Guardium appliance. The default is `guardiumsnmp`. This command is valid only for SNMP version 2c.

Syntax

store system snmp query community <string>

Show command

show system snmp query community

store system snmp update_user

Use this command to update an existing SNMP user account for an SNMP version 3 system.

Syntax

store system snmp update_user

This command overwrites all the information for an existing SNMP user account. Similar to `store system snmp user create`, you need to provide a username, authentication protocol and passphrase, and encryption protocol and passphrase.

store system snmp user

Use this command to create or remove an SNMP user account for an SNMP version 3 system. You can create only one SNMP user account. The default encryption protocol is AES-128.

Syntax

store system snmp user [create | delete]

Where:

- `create` - Creates an SNMP user account for this machine. To create an SNMP user account, you need to provide a username, authentication protocol and passphrase. The CLI walks you through the process. For example,

```
> store system snmp user create
Enter SNMPv3 user name:
fred
Enter authentication protocol < MD5 | SHA > or 'q' to quit. (Default authentication protocol is MD5) :
md5
Create authentication passphrase (8 to 12 chars): *****
Re-enter authentication passphrase: *****
Enter Encryption protocol < DES | AES > or 'q' to quit. (Default encryption protocol is AES.):
des
Create encryption passphrase (8 to 20 chars): *****
Re-enter encryption passphrase: *****
ok
```

After you provide the required information, Guardium adds the SNMP user. For example:

```
adding the following line to /var/lib/net-snmp/snmpd.conf:
    createUser fred MD5 "fred1234" DES 1234fred
adding the following line to /etc/snmp/snmpd.conf:
    rouser fred
ok
```

- `delete` - Removes the current SNMP user account.

Show command

```
show system snmp user
```

store system snmp version

Use this CLI command to switch between SNMP version 2c and SNMP version 3. The default is v2c. If your system uses SNMPv3, use this command to update Guardium.

Syntax

```
store system snmp version [v2c | v3]
```

Where:

- v2c: SNMP version 2c
- v3: SNMP version 3

Show command

```
show system snmp version
```

Examples

```
test.usma.ibm.com> show system snmp version
SNMP Version : v2c
ok
test.ibm.com> store system snmp version v3
snmp version v3 enabled
ok
test.usma.ibm.com> show system snmp version
SNMP Version: v3
ok
```

store system ssh-dsa state

This command enables or disables SSH DSA authentication.

Syntax

```
store system ssh-dsa state [ON | OFF ]
```

Where:

- ON: Activates the DSA host keys that are propagated from an upgrade. If no such keys exist, then DSA host keys are generated on SSH start-up.
- OFF: Inactivates any DSA host keys. DSA is inactivated on SSH start-up.

Show command

```
show system ssh-dsa state
```

store system sshd-max-connection

This command allows the maximum number of concurrent sshd connections to be configured. The range is between 100-500. The default value is 250.

Note: This command stops existing connections and restarts the ssh daemon on the Guardium appliance.

12.0 Syntax

```
store system sshd-max-connection <value>
```

12.1 and later Syntax.

Where --yes causes the command to run automatically.

Show command

```
show sys sshd-max-connection
```

store system time_server

Sets the hostname of up to three time (Network Time Protocol, or NTP) servers. To enable the use of a time server, set the **store system time_server state** command to *on*. To define one or more time servers, use the **store system time_server hostnames** command.

Note: Guardium does not support hostnames for a time server when the underlying IP address for that hostname is dynamic. The hostname must resolve to a static IP address. If you change the IP address, restart the network to sync to the new time server IP address.

Syntax

```
store system time_server [ hostnames | state ]
```

Where:

- **hostnames** - Enter up to three time server IP addresses or hostnames. Click Enter to stop entering hostnames.
- **state <on | off>** - Toggle the time server *on* or *off*.

Delete command

```
delete time_server
```

Show command

```
show system time_server <all | diagnostics | hostnames | state>
```

Where:

- **all** - Displays the name or IP address of any chrony time servers along with their current status.
- **diagnostics** - Runs the time server daemon (chronyd) and sends the output directly to the screen. For example:

```
CLI> show system time_server diagnostics
Output from chronyc sources :
MS Name/IP address      Stratum Poll Reach LastRx Last sample
=====
^- 168.22.22.74          3   10   377   711   -1448us[-1472us] +/-   66ms
^- circle.ellipse.net     2   10   377   681   -976us[-1000us] +/-   45ms
^- h134-222-111-62.sample.b> 2   10   175   78m   -2451us[-3049us] +/-   33ms
^* time.example.com       3   10   377   542   -300us[-324us] +/-   11ms
^- ns01.abc.example.com   4   10   377   737   -3167us[-3191us] +/-   34ms
ok
```

- **hostnames** - Shows the names or IP addresses of currently active time servers.
- **state** - Displays the status of the chrony time service.

store system websmartcard

The command enables or disables smart card authentication. For more information, see [Enabling Smart card authentication](#).

Syntax

```
store system websmartcard [on | off]
```

Show command

```
show system websmartcard
```

store system admin-only

When smart card or SAML authentication is enabled, run the **store system admin-only on** command to allow the *admin* or *accessmgr* accounts to log in to the Guardium system by using a standard login and password screen.

When enabled, the *admin* or *accessmgr* access a separate login page by appending /admin to the URL of the Guardium system. Example URL: *https://www.[your_guardium_system's_domain_name].com:[port_number]/admin*.

For more information, see [Enabling Smart card authentication](#)

Syntax

```
store system admin-only [on | off]
```

Note: This command restarts the GUI.

Show command

```
show system admin-only
```

User account, password, and authentication CLI Commands

Use these CLI commands to configure user accounts, passwords, and authentication.

Authenticating GuardAPI commands with set guiuser

Before you can call any GuardAPI commands, you must log in to the command line interface (CLI) with one of the default CLI accounts (guardcli1, guardcli2...guardcli9), and then run the **set guiuser** CLI command. This authentication is required to prevent users with limited roles in the GUI from gaining unauthorized access to GuardAPI commands. For more information about the GuardAPI commands, see [Using GuardAPI commands](#).

Certain GuardAPI commands are available only for certain user roles. For example, you must set the *guiuser* role to *accessmgr* and *cli* to view or use the [create_user](#), [set_user_roles](#), or [update_user](#) GuardAPI commands. Create a user and password with appropriate roles from the *accessmgr*. For more information, see [Creating a user who can run GuardAPI commands](#).

set guiuser

To use the *guardcli* accounts with GuardAPI commands, you must use **set guiuser** to associate the *guardcli* account to the local user and password.

Note: If LDAP authentication is used, enter the LDAP user and LDAP password as the local user and password.

Syntax

```
set guiuser <gui_user or LDAP user> password <password or LDAP password>
```

Example

You must run **set guiuser** whenever you want to use GuardAPI commands. When you set the *guiuser* for the first time, you are prompted to change the password, as shown in the following example.

```
$ ssh guardcli2@mycorp.com
IBM
Guardium , Command Line Interface (CLI)
```

```
guardcli1@al.corp.com's password:  
Last login: Thu Nov  4 14:56:34 2020 from 123.al.corp.com  
123.al.corp.com> set guiuser Hadrian.Swall  
Enter current password:  
First login as Hadrian.Swall. Please change the default password.  
Enter new password:  
Re-enter new password:  
ok
```

Note: When you change the password, you cannot reuse the last 10 passwords.

Show command

```
show guiuser
```

Password Control Commands

Use the following commands to control user passwords, as follows:

- [store password disable](#): Sets the number of days after which an inactive account is disabled.
- [store password expiration](#): Sets the number of days after which a password expires.
- [store password validation](#): Enables or disables the hardened password validation rules.

Account Lockout Commands

Use the account lockout commands to disable a Guardium user account after one or more failed login attempts. Use these commands to:

- Enable or disable the feature. See [store account lockout](#).
- Set the maximum number of login failures allowed an account within the specified number of seconds. See [store account strike count](#) and [store account strike interval](#).
- Set the maximum number of failures allowed an account for the life of the Guardium appliance. See [store account strike max](#).
- To unlock the admin user account if it becomes locked, see [unlock admin](#).

After a Guardium user account is disabled, users with the accessmgr role, or the admin user, can enable the account from the Guardium portal.

Example

The following example locks out an account, locks an account after five login failures within 60 seconds, and sets the maximum number of failures that are allowed to 999.

```
store account lockout on  
store account strike count 5  
store account strike interval 60  
store account strike max 999
```

Note:

If the admin user account is locked, use the [unlock admin](#) command to unlock it.

If account lockout is enabled, setting the strike count or strike max to zero does not disable that type of check. On the contrary, it means that after just one failure the user account is disabled!

store account lockout

Enables (on) or disables (off) the automatic account lockout feature, which disables a user account after a specified number of login failures.

Syntax

```
store account lockout <on | off>
```

Show command

```
show account lockout
```

store account strike count

Sets the number of failed login attempts (n) in the configured strike interval before the account is disabled.

Syntax

```
store account strike count <n>
```

Show command

```
show account strike count
```

store account strike interval

Sets the number of seconds (n) during which the configured number of failed login attempts must occur to disable the account.

Syntax

```
store account strike interval <n>
```

Show command

```
show account strike interval
```

store account strike max

Sets the maximum number (n) of failed login attempts to be allowed for an account over the life of the server before the account is disabled.

Syntax

store account strike max <n>

Show command

show account strike max

store disable_sha1_passwords

By default, the Guardium GUI user passwords are hashed with a strong password hashing algorithm. The **store disable_sha1_passwords** CLI command allows admins to remove existing passwords that are weakly hashed from their Guardium appliances.

Note: In an upgrade scenario, this command removes only weak passwords for users who have logged in since the upgrade.

Syntax

store disable_sha1_passwords [true | false]

Run the **store disable_sha1_passwords true** command on the central manager and all backup central managers, if applicable.

Example:

```
>store disable_sha1_passwords true
> User passwords will now be hashed with a strong password hashing algorithm.

>store disable_sha1_passwords false
> User passwords will now be hashed with a weak password hashing algorithm.
Weak password hashing algorithms may violate your company compliance requirements.
```

Show command

show disable_sha1_passwords

The show command returns the current settings for password hashing.

Example:

```
>show disable_sha1_passwords
>SHA1 passwords are allowed.
```

Note: In an upgrade scenario, the show command returns the users who have not logged in since the upgrade.

store guarduser_state

From the cli account for your Guardium appliance, you can now enable or disable the guardcliN (that is guardcli1 to guardcli9) login IDs. You can only change or show the status of one ID at a time.

Syntax

store guarduser_state <disable|enable> <guardcli1..guardcli9>

For example, to disable guardcli4:

store guarduser_state disable guardcli4

Show command

show guarduser_state guardcli4

store password disable

Sets the number of days of inactivity after which user accounts are disabled. When set to 0 (zero), no accounts are disabled by inactivity. At installation, the default value is zero. You must restart the GUI after you change this setting (see **restart gui**).

Syntax

store password disable <days>

Show command

show password disable

store password expiration

Sets the number of days until a user's password expires. The default value is 60 for *cli* and *guardcli1 - guardcli9* users, and 90 for *gui* users. The minimum is 1 for *cli* and *guardcli1 - guardcli9* and 0 for *gui*.

Syntax

store password expiration [cli | guardcli1 - guardcli9 | gui] <days>

Where:

- - *cli*: The CLI user.
 - *guardcli1* through *guardcli9*: One of the guardcli users.
 - *gui*: The GUI user. If you change the GUI password expiration, you must restart the GUI.
- <days>: The number of days before the password expires.
 - The maximum number of days for *cli* and *guardcli* users is 60.
 - For *gui* users only, you can disable the password expiration in practice by setting the expiration days to a very high number (up to 7300 days, or 20 years).

The account user is prompted to reset the password the first time they log in after the current password expires.

Show command

show password expiration

store password requirements

If **store strong_password_enable** is enabled, then you can specify certain password requirements for *cli* and *guardcli* accounts to meet your corporate standards.

Syntax

store password requirements <parameter> <number>

Where *parameter* is one of the parameters in the following table, and *number* is the requirement for that parameter.

Table 1. Parameters for store password requirements CLI

| Parameter | Meaning |
|-----------------|---|
| max_repeats | Specify the maximum number of characters of a single type (that is: digits, upper case letters, lower case letters, or symbols) that can be consecutively repeated in a password. |
| minimum_length | Specify the minimum password length. |
| minimum_digits | Specify the minimum required number of digits (0 - 9). |
| minimum_lower | Specify the minimum required number of lower case letters (a - z). |
| minimum_upper | Specify the minimum required number of upper case letters (A - Z). |
| minimum_symbols | Specify the minimum required number of special characters (from Table 2). |

Example

```
>store password requirements max_repeats 2  
>store password requirements minimum_digits 2
```

Show command

show password requirements

Sample output

```
> show password requirements  
Passwords must conform to the following rules:  
    cannot be a dictionary word  
    maximum repeated characters: 2  
    maximum repeated characters within a class: 4  
    minimum digits: 2  
    minimum length: 15  
    minimum lower case: 3  
    minimum symbols: 1  
    minimum upper case: 3  
    At least one each of digits, uppercase, lowercase, symbols.
```

store password validation

Turns password validation on or off. The default value is on. Running this command restarts the GUI to apply this setting.

When password validation is enabled, passwords must be eight or more characters long, and must include at least one of each:

- An uppercase letter (A-Z)
- A lowercase letter (a-z)
- A number (0-9)
- A special character from [Table 2](#)

When password validation is disabled (not recommended), any length or combination of characters is allowed.

Syntax

store password validation <on | off>

Show command

show password validation

Table 2. Special characters for
Guardium passwords

| Character | Description |
|-----------|-------------|
| @ | At sign |
| # | Number sign |

| Character | Description |
|-----------|---------------------------|
| \$ | Dollar sign |
| % | Percent sign |
| ^ | Circumflex accent (carat) |
| & | Ampersand |
| . | Full stop (Period) |
| ; | Semicolon |
| ! | Exclamation mark |
| - | Hyphen (minus) |
| + | Plus sign |
| = | Equals sign |
| _ | Underscore |

store strong_password_enable

Use this command to enable or disable strong password checking. This setting applies only to local passwords and does not affect passwords that are validated against external directories such as LDAP. Restart the Guardium GUI for the changes to take effect.

Strong passwords must be at least 15 characters and follow the rules that are described in [store_password_validation](#).

If strong passwords are enabled, you can use [store_password_requirements](#) to specify your own password validation rules.

In addition, when **strong_password_enable** is on, Guardium ensures that the GUI password is not expired, based on the value of the [store_password_expiration](#) command.

Syntax

```
store strong_password_enable [on|off]
```

Show command

```
show strong_password_enable
```

store user password

Use this command to reset the CLI user password. To simplify the support process, Guardium suggests that you keep the CLI user password assigned initially by Guardium. You cannot retrieve the CLI user password after it is set. If you lose this password, contact Guardium Support to have it reset.

Syntax

```
store user password
```

You are prompted to enter the current password, and then the new password (twice). The password values that you enter on the keyboard do not display on the screen.

The CLI user password requirements differ from the requirements for user passwords. The CLI user password must be at least 8 characters long, and must contain at least one each of the following types of characters:

- Lowercase letters
- Uppercase letters
- Special characters from [Table 2](#).

Running this CLI command also updates the change-time record in the password expiration file.

unlock accessmgr

Use this command to enable the Guardium accessmgr user account after it is disabled. This command does not reset the accessmgr user account password.

Note: Only users with admin role are allowed to run this CLI command.

Syntax

```
unlock accessmgr
```

```
restart gui
```

unlock admin

Use this command to enable the Guardium admin user account after it is disabled. This command does not reset the admin user account password.

Note: Only users with admin role are allowed to run this CLI command.

Syntax

```
unlock admin
```

```
restart gui
```

Authentication commands

The following commands display or control the type of authentication used.

store auth

Use this command to reset the type of authentication that is used for login to the Guardium appliance, to SQL_GUARD (that is, the local Guardium authentication, the default).

Syntax

store auth SQL_GUARD

Show command

show auth

store cli_userauth

CLI users can be authenticated locally or by LDAP, but not both.

To enable LDAP authentication for CLI users, including GUARDCLI accounts, use the following command:

Syntax

store cli_userauth ldap --server <server> --basedn<basedn> --rdntype<rdntype> [port number] [usetls]

Note: The default TLS port number is 636 and the default plain is 389.

Example:

```
store cli_userauth ldap --server ldapserver.example.com --basedn ou=people,dc=guardium,dc=example,dc=com --rdntype uid
Validating server and port:
OK
Configuring LDAP authentication with
Server: 'ldapserver.example.com'
Port: '389'
Basedn: 'ou=people,dc=guardium,dc=example,dc=com'
RDN Type: 'uid'
Use TLS: '0'
Please confirm [y/n] y
Authentication is set to LDAP
OK
```

Note: Trusted certificates that are required for LDAP with SSL option must be imported from the GUI.

When LDAP authentication is enabled, the following commands are not available:

1. **show password expiration cli**
2. **store password expiration cli**
3. **store user password**

The following message is displayed when you run these commands:

CLI user authentication is managed externally. Please contact your system administrators.

To disable LDAP authentication for CLI users, including GUARDCLI accounts, use the following command:

Syntax

store cli_userauth default

Show command

show cli_userauth [details]

GuardAPI and REST API commands

GuardAPI commands provide access to Guardium® functionality from the command line. Many GuardAPI commands also have REST API equivalents.

REST API commands are described along with the GuardAPI commands. Use the [Guardium API A-Z Reference](#) to find information about individual GuardAPI and REST API commands.

- [**Using GuardAPI commands**](#)
Learn how to use the GuardAPI commands.
- [**Using Guardium REST APIs**](#)
Use the Guardium REST API to include many Guardium API commands in your applications or anywhere that a REST API is useful.
- [**Guardium API A-Z Reference**](#)
All of the Guardium GuardAPI commands, arranged alphabetically. Click the GuardAPI command for more information about that command. If the GuardAPI command has a REST API interface, the REST call is also provided.
- [**Access management APIs**](#)
Use these commands to manage access to the Guardium system. Many of these commands require the accessmgr role.

- [**Active threat analytics and risk spotter APIs**](#)
Use these commands to configure Active threat analytics and Risk spotter.
- [**Alerter APIs**](#)
Use these APIs to manage alerter functions.
- [**Archive, export, import, purge, and restore APIs**](#)
Use these functions to configure archive, restore, purge, export, and import, of results and data.
- [**Assessment APIs**](#)
Use these APIs to add, delete, and update Vulnerability Assessment (VA) functions.
- [**Auto-discovery APIs**](#)
Use these GrdAPI commands to create, modify, list and run the Auto-discovery processes.
- [**Big Data Intelligence APIs**](#)
Run these commands, on your central manager, to manage extraction of datamarts to the Big Data datasource (GBDI), and to pull big data into Guardium for monitoring, reports, and so on.
- [**Catalog entry APIs**](#)
Use these commands to manage catalog entries. Catalogs are used to track data archive files and result archive files that were created on the servers.
- [**Central management APIs**](#)
Use these APIs to view and set load balancing parameters, view the current load map, manage S-TAP® and managed unit group associations, and manage backup central managers.
- [**Classification APIs**](#)
Use the following GuardAPI commands for Classification policy configuration, for test automation and, for scripting of prerequisite data preparation.
- [**Cloud datasource APIs**](#)
Use these commands to define, manage, update, and delete cloud datasources.
- [**Configuration Auditing System \(CAS\) APIs**](#)
Use these commands to configure and manage Configuration Auditing System (CAS) hosts, templates, and template sets.
- [**Data mart APIs**](#)
Use these commands to manage your data marts.
- [**Database user APIs**](#)
Use these commands to maintain database user mapping, non-credential scans and manage debug levels.
- [**Datasource APIs**](#)
Use these commands to create, list, delete, and update datasource and datasource references.
- [**Datasource credential management APIs**](#)
Use these commands to manage datasource credentials.
- [**Entitlement optimization APIs**](#)
Use these API commands to enable and configure the Entitlement optimization datasources and reporting.
- [**External feed APIs**](#)
Use these commands to create mappings for external feeds.
- [**File Activity Monitor APIs**](#)
Use the following GuardAPI commands to enable and disable the file activity monitor, configure the file Investigation Dashboard activity and entitlement extractions schedule, and get information on the file activity monitor.
- [**Guardium Insights APIs**](#)
Use these APIs to manage the connection between Guardium Data Protection and Guardium Insights.
- [**Guardium Installation Manager \(GIM\) APIs**](#)
Use these APIs to assign, cancel, list, remove, and update Guardium Installation Manager (GIM) functions.
- [**Guardium universal connector APIs**](#)
Use these functions to start, stop, and check the status of the Guardium universal connector, and to modify the MongoDB filters.
- [**Group APIs**](#)
Use these commands to create, list, and delete groups, hierarchical groups, and group members and manage aliases for groups.
- [**Health analyzer APIs**](#)
Use these commands to configure the disk and database health analyzer.
- [**Hadoop monitoring APIs**](#)
Use these APIs to add, update, delete, and view the clusters and services on the clusters for all types monitoring on Hadoop.
- [**Investigation dashboard APIs**](#)
Use these APIs to enable, disable, or configure the investigation dashboard (quick search) features and parameters.
- [**Miscellaneous APIs**](#)
Use these commands for various tasks that do not fall into other categories.
- [**Native audit APIs**](#)
Use these commands to enable or disable DB Audit (native audit) on a cloud database, add and remove objects from the Object Audit (audit trail), and get configuration, collectors, and objects details.
- [**Outliers detection APIs**](#)
Use these API commands to enable, disable, and configure the Outliers Detection function.
- [**Policy and rule APIs**](#)
Use these commands to manage policies and policy rules.
- [**Process Control APIs**](#)
Use these commands to manage various process control functions.
- [**Query rewrite APIs**](#)
Use these commands to automate testing or create definitions for certain complex queries that cannot be done from the user interface.
- [**Reports and report generation APIs**](#)
Use report generation APIs to manage reports and distributed reports, and to take the output from one Guardium report or entity and feed it as the input for another Guardium entity.
- [**Schedule and job dependencies APIs**](#)
Use these APIs to set schedules for and dependencies between jobs.
- [**Solr APIs**](#)
Run these commands on your central manager and managed units to manage their (internal Guardium) Solr database.
- [**S-TAP and inspection engine APIs**](#)
Use these commands to manage your S-TAPs and their inspection engines.
- [**S-TAP for IBM i APIs**](#)
Use these commands to create, list, delete, restart, and set i-S-TAP functions.
- [**Threat detection analytics APIs**](#)
Use these GuardAPI commands to configure threat detection analytics.

Using GuardAPI commands

Learn how to use the GuardAPI commands.

Accessing GuardAPI commands

GuardAPI is a set of commands that you can use to automate repetitive tasks, which is especially valuable in larger implementations. Use the GuardAPI functions to quickly perform operations such as creating datasources, maintaining user hierarchies, or maintaining Guardium® features such as S-TAP®, just to name a few. For a list of the available GuardAPI commands, see [Guardium API A-Z Reference](#).

Before you can use GuardAPI commands, you need a local user and password (or an LDAP username) with appropriate roles and permissions. The GuardAPI commands that are available to you depend on your roles. For more information, see [Creating a user who can run GuardAPI commands](#).

To access GuardAPI commands:

1. From the CLI, log in as one of the guardcli users (that is, guardcli1 to guardcli9). For example:

```
ssh guardcli2@company.com
```

2. Run the **set guiuser** CLI command to associate the new user with the guardcli user. The first time you log in, you must change your password (except for LDAP users). For example:

```
company.com> set guiuser Hadrian.Swall
Enter current password:
First login as Hadrian.Swall. Please change the default password.
Enter new password:
Re-enter new password:
ok
```

Note: When you change the password, you cannot reuse the last 10 passwords.

For more information about **set guiuser**, see [Authenticating GuardAPI commands with set guiuser](#).

3. If your system has multi-factor authentication enabled, Guardium will request that you provide secondary authentication. Select the notification type by its number. For example:

```
mycompany.com> set guiuser Hadrian
Enter current password:
Secondary authentication is required for Hadrian
Please select a notification method:
0: cell phone (XXX-XXX-8846) : auto
1: cell phone (XXX-XXX-8846) : push
2: cell phone (XXX-XXX-8846) : sms
3: cell phone (XXX-XXX-8846) : phone
Q/q: Quit

2
Enter SMS passcode:
ok
```

Note: The available notification methods depend on how multi-factor authentication is configured for your site.

4. In this case, the user, Hadrian Swall, can now use any GuardAPI commands that are available for the associated roles.

Finding GuardAPI command information

GuardAPI is a subset of CLI commands, all of which begin with the keyword **grdapi**.

- To list all GuardAPI commands available for your role, enter **grdapi** or **grdapi commands** with no arguments. For example:

```
> grdapi
or
> grdapi commands
```

You can also find information about all of the GuardAPI commands in the [Guardium API A-Z Reference](#).

- To display information for a particular command, enter the command followed by **--help=true**. For example:

```
CLI> grdapi list_entry_location --help=true
ID=0
function parameters :
fileName
hostName - required
path - required
ok
```

Note: For some parameters, the available options depend on factors such as your operating system, available databases, or licenses. In these cases, look for the complete parameter list for your system by running **--help=true** for that GuardAPI in the CLI.

- To display a values list for a parameter, enter the command followed by **--get_param_values=<parameter>**. For example:

```
CLI> grdapi create_group --get_param_values=appid
Value for parameter 'appid' of function 'create_group' must be one of:
Public
Audit Process Builder
Classifier
DB2 zOS Groups
Express Security
IMS zOS Groups
Policy Builder
```

```

Security Assessment Builder
ID=0
ok

• To search for GuardAPI commands given a search string use grdapi commands <search-string>. For example:

CLI> grdapi commands user
ID=0
Matching API Function list :
create_db_user_mapping
create_user_hierarchy
delete_allowed_db_by_user
delete_db_user_mapping
delete_user_hierarchy_by_entry_id
delete_user_hierarchy_by_user
execute_appUserTranslation
execute_ldap_user_import
list_allowed_db_by_user
list_db_user_mapping
list_user_hierarchy_by_parent_user
update_user_db

```

GuardAPI syntax

- Both the keyword and value components of parameters are case-sensitive.
- If a parameter value contains one or more spaces, it must be enclosed in double quotation marks, for example,

```
grdapi create_datasource type ="MS SQL SERVER" ...
```

- NULL values and empty strings: In general, when a value for a non-required parameter is not specified or is set to an empty string ("") GuardAPI converts the parameter to NULL when the function is called. That is, the parameter is ignored as if it were not specified.
If for example, you want to clear out a group from a policy rule, you might set that group to space (" ") and not an empty string (""). Using an empty string ("") signals that GuardAPI can ignore that group and not change that group selection.

For example,

```
grdapi update_rule fromPolicy=V8 ruleDesc="LogFull Details" dbUserGroup=" "
dbUser=" " objectGroup=" " commandsGroup=" "
```

Return Codes

The GuardAPI always returns a code in the first line of output, in one of the following formats:

Table 1. Return Codes

| Return Code | Description |
|----------------|---|
| ID=identifier | Success. The identifier is the ID of the object that is operated upon; for example, the ID of a group that was just defined. |
| ERR=error_code | Error. The error_code identifies the error, and one or more additional lines provide a text description of the error. See Table 2 for a list of common error codes. |

For example, if you use **create_group** to successfully define an objects group named *agroup*, the ID of that group is returned:

```

CLI> grdapi create_group desc=agroup type=objects appid=Public
ID=20001
ok
CLI>

```

You can then use that ID in the **list_group_by_id** command to display the group definition.

```

CLI> grdapi list_group_by_id id=20001
ID=20001
Group GroupId=20001
Group GroupTypeId=3
Group ApplicationId=0
Group GroupDescription=agroup
Group GroupSubtype=null
Group CategoryName=null
Group ClassificationName=null
Group Timestamp=2008-05-10 07:34:11.0
Group type = OBJECTS
Application Type = Public
Tuple Group
ok

```

If the GuardAPI fails, an error code is returned. For example, if you enter the **list_group_by_id** command again with an invalid ID, you receive the following message:

```

a1.corp.com> grdapi list_group_by_id id=20123
ERR=140
Could not retrieve Group - check Id.
ok

```

Common Error Codes

Error codes with a value less than 100 are for common error conditions. Error codes greater than 100 apply to specific functions.

For a complete list of GuardAPI error codes, enter **grdapi-errors** at the CLI command prompt.

Table 2. Common Error Codes

| Error | Description |
|-------|-------------|
|-------|-------------|

| Error | Description |
|-------|---|
| 0 | Missing parameters or unknown errors such as unexpected exceptions |
| 1 | An Exception has occurred, please contact Guardium support |
| 2 | Could not retrieve requested function - check function name. To list all functions call either the "grdap" or "grdap commands" with no arguments. To search by function name given a search string, use the "grdap commands <search-string>". |
| 3 | Too many arguments. To get the list of parameters for this function call the function --help=true |
| 4 | Missing required parameter. To get the list of parameters for this function call the function with --help=true |
| 5 | Could not decrypt parameter, check if encrypted with the correct shared secret |
| 6 | Wrong parameter format, specify a function name followed by a list of parameters using <name=value> format. |
| 7 | Wrong parameter value for parameter type |
| 8 | Wrong parameter name, please note, parameters are case-sensitive. |
| 9 | User has insufficient privileges for the requested API function |
| 10 | Parameter Encryption not enabled - shared secret not set. |
| 11 | Failed sending API call request to targetHost |
| 12 | Error Validating Parameter |
| 13 | Target host must be the ip address of the central manager |
| 14 | Target host is not managed by this manager. |
| 15 | Target host is not online |
| 16 | Target host cannot be specified on a standalone unit |
| 17 | User is not allowed to operate on the specified object |
| 18 | Target host cannot be specified |
| 19 | Missing end quote |
| 20 | User is not allowed to run grdap commands |
| 21 | --username and --source-host are grdap reserved words and cannot be passed on the command line. |
| 22 | A parameter name cannot be specified more than once, please check the command line for duplicate parameters. |
| 23 | Value not in constant list. |
| 24 | Not a valid encrypted value. |
| 25 | Not a valid parameter format - parameters should be specified as <name=value>, spaces are not allowed. |

GuardAPI Activity Log

The Guardium Activity Log records all GuardAPI commands that are executed on the system. To view the commands from the administrator portal, navigate to the User Activity Audit Trail report on the Guardium Monitor tab.

All GuardAPI activity is attributed to the cli user. Double-click the cli row in that report, and select the Detailed Guardium User Activity drill-down report. For each row, the report lists the following information:

- Every command entered.
- Any changes made.
- The IP address from which the command was issued.

Encrypted Parameters

GuardAPI is intended to be invoked by scripts, which may contain sensitive information, such as passwords for datasources. To ensure that sensitive information is kept encrypted at all times, the grdap command supports passing of one encrypted parameter to an API Function. This encryption is done using the System Shared Secret which is set by the administrator and can be shared by many systems, and between all units of a central management and/or aggregation cluster; enabling scripts with encrypted parameters to run on machines that have the same shared secret.

Note: Trying to run an API call with encrypted parameter on a system where shared secret was not set results in the following error message:

Parameter Encryption not enabled - shared secret not set

For Guard API scripts generated through the GUI, if encryption is required it is done using the shared secret of the system where script generation is performed.

The optional parameter encryptedParam is available on every grdap call. This parameter can be used to pass an encrypted value for another parameter.

The procedure for manual encryption is as follows:

1. Use the Parameter Encryption API.
The encrypt_value API accepts a value to encrypt and the target system's shared secret (key) and then prints out the encrypted value. If the key is not the system's shared secret it will print out a warning.

```
a1.corp.com> grdap encrypt_value --help=true
ID=0
function parameters :
key - required
valueToEncrypt - required
api_target_host
ok
```

Table 3. Encrypted Parameter

| Parameter | Description |
|-----------------|--|
| key | The target system's shared secret. |
| valueToEncrypt | The value to be encrypted. |
| api_target_host | In a central management configuration only, allows the user to specify a target host where the API will execute. On a Central Manager (CM) the value is the host name or IP of any managed units. On a managed unit it is the host name or IP of the CM. |

Example

```
a1.corp.com> grdapi encrypt_value valueToEncrypt="some value" key=guard
ID=0
-----BEGIN PGP MESSAGE-----
Version: GnuPG v1.4.7 (GNU/Linux)
jA0EA9gMCTEIJShudn0tgyTB9GL7wR79UL9X9DCaa6RkUQRbegG52o1A4gwOzmpHF
0qEhsd6Uz718rUsheUyX9v4=
=c1Cq
-----END PGP MESSAGE-----
```

2. Copy the generated content and embed within your CLI script.

```
example of cli.gsh code :
set guimuser johny_smith password 3we19s887s
  grdapi create_datasource type=oracle name=myOra host=somehost application=AuditTask owner=admin user=sa serviceName=ora
encryptedParam=password
-----BEGIN PGP MESSAGE-----
Version: GnuPG v1.4.7 (GNU/Linux)
jA0EA9gMCTEIJShudn0tgyTB9GL7wR79UL9X9DCaa6RkUQRbegG52o1A4gwOzmpHF
0qEhsd6Uz718rUsheUyX9v4=
=c1Cq
-----END PGP MESSAGE-----
```

3. Run the script to invoke GrdApi:

```
user> ssh cli@a1.corp.com user> ssh cli@a1.corp.com
```

Role validation for certain GuardAPI commands

Role validation implements controls on selected GuardAPI commands to consider the roles of the specific components (and not only the application) and disallow actions if the roles do not match.

For example, a user with the appropriate roles for Policy Builder can run the delete_rule API on any policy, regardless of the roles of this specific policy.

If you try to run an API for which you do not have the appropriate role or permissions, the CLI returns an error message.

Display attributes for certain users in Query-Report Builder

The admin user can see all query attributes in Query-Report Builder and non-admin users can see query attributes in Query-Report Builder, except those that are designed as admin only (IDs, for example).

There are some entities (such as FULL SQL) that have large numbers of attributes in them. By default, all attributes display for all users (admin and non-admin).

Two GuardAPI commands, **enable_special_attributes** and **disable_special_attributes** determine whether certain attributes display for certain users. For more information, see [enable_special_attributes](#) and [disable_special_attributes](#).

Note: When using GuardAPI in a central manager environment, be sure that you understand which components are defined on the central manager, and which components are defined on managed units. For information, see [Central Management](#).

Using Guardium REST APIs

Use the Guardium® REST API to include many Guardium API commands in your applications or anywhere that a REST API is useful.

Guardium REST API overview

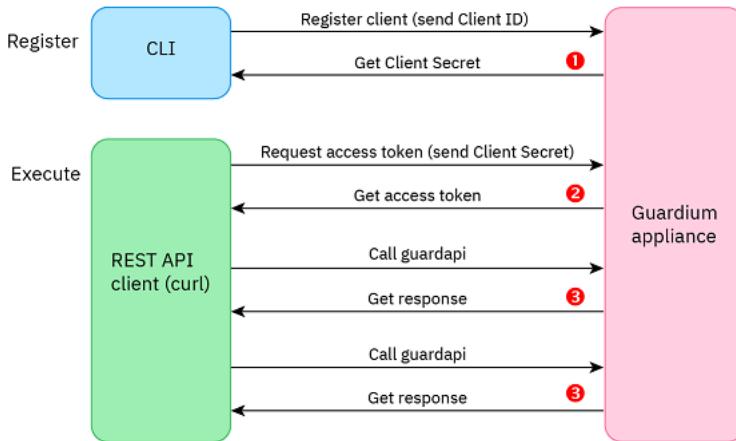

The Guardium REST API serves as a wrapper for the rich set of Guardium API (GuardAPI) command-line interface functions. After you register the REST API client on the Guardium collector, as described in [Calling REST APIs example](#), you can use REST API calls for many of the GuardAPI functions. Providing a REST interface to the Guardium API simplifies integrating Guardium into your system.

For more information about GuardAPI functions with REST API capabilities, see [Guardium API A-Z Reference](#).

As shown in [Figure 1](#), take the following steps to set up your Guardium system for the REST API:

1. Use the command-line interface (CLI) to register the client ID from the collector side. Each client needs to be registered only once. The CLI returns a client secret for the client ID.
2. Use the curl command-line tool from the REST client to send a request for an access token along with the client secret to the Guardium appliance.
3. After the REST client is authorized, you can use the access token to call the supported GuardAPI functions.

Figure 1. Getting started with the REST API

Example use cases

A few examples of when you might use a REST API:

- I want the ability to dynamically get a small amount of audit data for a certain IP address without having to login to the Guardium GUI.
- I want to populate an existing group, so I can update my policy to prevent unauthorized access to sensitive information.
- I want to get a list of all users within a certain authorized access group.
- I want my application development team to help identify which sensitive tables to monitor.
- I want to script access to GuardAPIs without using "expect" scripting language, which requires me to code response text from the target system.

Calling REST APIs example

The following scenario describes how to use the `register_oauth_client` GuardAPI to register the client and then call a GuardAPI function from the REST client.

1. Register the application and get the client secret.

Access to the collector from the CLI, and run the following `grdapi` command to register the application, as shown:

```
example.yourdomain.com> grdapi register_oauth_client client_id=client1 grant_types="password"
ID=0
```

The application returns the client secret, as shown in the following example:

```
{"client_id": "client1", "client_secret": "b1f242a2-1e86-46d6-bf42-6298556c2eea", "grant_types": "password"}
ok
example.yourdomain.com>
```

Note: You need to register the application only once.

2. From the REST client, include the client secret in a curl request for the access token:

```
C:\tools\curl-7.57.0-win64-mingw\bin>curl -k -X POST -d "client_id=client1&client_secret=b1f242a2-1e86-46d6-bf42-6298556c2eea&grant_type=password&username=admin&password=*****" https://example.yourdomain.com:8443/oauth/token
```

Guardium returns the access token:

```
{"access_token": "29ff4bb4-e622-41cf-97d0-de695ebd756b", "token_type": "bearer", "expires_in": 10799, "scope": "read write"}
C:\tools\curl-7.57.0-win64-mingw\bin>
```

3. Use the access token to call a Guardium API function from the REST API. The following example calls the equivalent of the `list_datasource_by_id id=20000` function from the REST client.

```
C:\tools\curl-7.57.0-win64-mingw\bin>curl \
-k --header "Authorization: Bearer 29ff4bb4-e622-41cf-97d0-de695ebd756b" \
--include --header "Content-Type: application/json" \
-X GET https://example.yourdomain.com:8443/restAPI/datasource?id=20000
```

This REST API call returns the following information about the specified data source:

```
HTTP/1.1 200 OK
X-FRAME-OPTIONS: SAMEORIGIN
Set-Cookie: JSESSIONID=C7854CAF60CE7B3A6CD585A8173B3222; Path=/; Secure; HttpOnly
Cache-Control: max-age=86400
Expires: Tue, 16 Jan 2018 09:21:52 GMT
Access-Control-Allow-Methods: POST, GET, PUT, DELETE
Access-Control-Allow-Headers: authorization, origin, X-Requested-With, Content-Type, Accept
Access-Control-Max-Age: 18000
Content-Type: application/json; charset=UTF-8
Content-Length: 914
Date: Mon, 15 Jan 2018 09:21:52 GMT
Server: SQL Guard
[
  {
    "DatasourceId": "https://example.yourdomain.com:8443/restAPI/datasource?id=20000",
    "DatasourceTypeId": "13",
    "Name": "System (9.70.148.141)",
    "Description": "null",
    "Host": "9.70.148.141",
    "Port": "0",
```

```
"ServiceName": "",  
...  
"
```

Additional API examples

This example uses the POST verb to create a new data source:

```
curl -k --header "Authorization:Bearer 04ce5d90-8d89-4e9c-a060-ec94b4409a71" \  
--include --header "Content-Type: application/json" \  
-X POST --data '{"application":"Classifier","host":"192.168.1.54","name":"mydbserver","type":"TEXT:HTTPS"}' \  
https://192.168.1.10:8443/restAPI/datasource
```

This example uses GET to return the status of all installed applications:

```
curl -k --header "Authorization:Bearer da186a7e-488d-4cd2-a35b-094b3cc4af86" \  
--include --header "Content-Type: application/json" \  
-X GET https://192.168.1.10:8443/restAPI/applications
```

This example updates an existing data source by its ID (which is 20001):

```
curl -k --header "Authorization:Bearer 04ce5d90-8d89-4e9c-a060-ec94b4409a71" \  
--include --header "Content-Type: application/json" \  
-X PUT --data '{"id":20001,"description":"My database server."}' \  
https://192.168.1.10:8443/restAPI/update_datasource_by_id
```

This example deletes an application (1500):

```
curl -k --header "Authorization:Bearer 14da5202-f3c6-45d0-bc10-77604e6cede7" \  
--include --header "Content-Type: application/json" \  
-X DELETE --data '{"application_id": 1500}' https://192.168.1.10:8443/restAPI/applications
```

For information about which GuardAPI functions also have REST API calls, see [Guardium API A-Z Reference](#).

For more information about Guardium REST API error codes, see [Return Codes for Guardium REST APIs](#) in the IBM Support database.

Guardium API A- Z Reference

All of the Guardium GuardAPI commands, arranged alphabetically. Click the GuardAPI command for more information about that command. If the GuardAPI command has a REST API interface, the REST call is also provided.

List of GuardAPI and REST API Functions

| | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| A | B | C | D | E | G | H | I | J | K | L | M | |
| N | O | P | Q | R | S | I | U | V | W | X | Y | Z |

A

API commands beginning with A.

| GuardAPI function name | REST enabled? | REST resource name | REST method |
|---|---------------|--|-------------|
| add_action_to_fam_rule | Yes | addActionToFAMRule | POST |
| add_all_to_schedule | Yes | addAllToSchedule | POST |
| add_approved_stap_client | Yes | addApprovedClient | POST |
| add_assessment_datasource | Yes | addAssessmentDatasource | POST |
| add_assessment_datasource_group | Yes | addAssessmentDatasourceGroup | POST |
| add_assessment_test | Yes | addAssessmentTest | POST |
| add_assessment_test_by_dsid | Yes | addAssessmentTestByDsType | POST |
| add_autodetect_task | Yes | addAutoDetectTask | POST |
| add_available_test_notes | Yes | addAvailableTestNotes | POST |
| add_classifier_datasource | Yes | clsAddDatasource | POST |
| add_classifier_datasource_group | Yes | clsAddDataSourceGroup | POST |
| add_cluster | Yes | addCluster | POST |
| add_connection_properties | Yes | addConProperties | POST |
| add_custom_property_to_datasources_in_group | Yes | addCustomPropToDatasourcesInGroup | POST |
| add_custom_property_to_datasource_by_id | Yes | datasourceAddCustomProp | POST |
| add_custom_property_to_datasource_by_name | Yes | datasourceAddCustomProp | POST |
| add_datasource_to_entitlement_optimization | Yes | addDatasourceToEntitlementOptimization | PUT |
| add_datasource_to_group | Yes | addDatasource | POST |
| add_dm_to_profile | Yes | addDMToProfile | PUT |
| add_domain_to_universal_connector_allowed_domains | Yes | addDomainToUcAllowedDomains | POST |
| add_group_to_quick_search | No | | |
| add_ip_to_sg | Yes | addCollectorsIPtoGSecurityGroup | POST |
| add_mfa_exempt_users | Yes | addExemptUsers | PUT |
| add_objects_native_audit | Yes | enableNativeAuditOnObjects | POST |
| add_ranger_config | Yes | addConfig | POST |
| add_ranger_hdfs_config | Yes | addHDFSConfig | POST |

| GuardAPI function name | REST enabled? | REST resource name | REST method |
|---|---------------|---------------------------|-------------|
| add_ranger_service | Yes | mapServiceToConfig | POST |
| add_receiver_to_rule_action | Yes | addReceiveToRuleAction | POST |
| add_stream | Yes | addStream | POST |
| add_threshold_to_rule | Yes | addRule | PUT |
| add_time_period | Yes | timePeriodAdd | POST |
| apply_rules_on_discoveredinstances | Yes | applyRulesToDIs | PUT |
| assign_analytic_case | Yes | assignAnalyticCase | PUT |
| assign_collectors | Yes | assignCollectors | PUT |
| assign_load_balancer_groups | No | | |
| assign_qr_condition_to_action | Yes | assignQrConditionToAction | POST |
| audit_process_run_status | Yes | AuditProcessRunStatus | GET |
| auto_execute_suggested_dependencies | No | | |

B

API commands beginning with B.

| GuardAPI function name | REST enabled? | REST resource name | REST method |
|---|---------------|--------------------|-------------|
| backup_cm_list_candidates | Yes | listCandidates | GET |
| backup_cm_set | Yes | setBackupCM | PUT |

C

API commands beginning with C.

| GuardAPI function name | REST enabled? | REST resource name | REST method |
|---|---------------|----------------------------------|-------------|
| cancel_distributed_report_target | No | | |
| change_cli_password | Yes | changeCliPassword | POST |

add_action_to_fam_rule

This command adds an action to an existing FAM rule.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/addActionToFAMRule
```

GuardAPI syntax

```
add_action_to_fam_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| actionName | String | Required. The action taken when the rule criteria are met. Valid values: <ul style="list-style-type: none">• <i>Alert and audit</i>: Send an alert directly generated from the sniffer with specific behavior, and log the event.• <i>Audit only</i>: Log the event in GDM tables• <i>Block, log violation, and audit</i>: Block access to the object, log a policy violation, and log the event. A blocking action requires an alert configuration as well.• <i>Ignore</i>: No action taken.• <i>Log as violation and audit</i>: Log this as a policy violation and log the event. |
| alertReceiver | String | AlertReceiver is any user of the appliance like admin, etc. |
| classDestination | String | For valid values, call add_action_to_fam_rule from the command line with --help=true . |
| command | String | The command name to be included in the rule. For valid values, call add_action_to_fam_rule from the command line with --help=true . |
| commandGroup | String | Name of command group to be included in the rule. |
| commandGroupId | Integer | ID of command group to be included in the rule. |
| messageTemplate | String | Name of message template. For valid values, call add_action_to_fam_rule from the command line with --help=true . |
| notificationType | String | For valid values, call add_action_to_fam_rule from the command line with --help=true . |
| policyName | String | Required. Valid values: For valid values, call add_action_to_fam_rule from the command line with --help=true . |
| ruleName | String | Required. Rule that is getting modified with this command. |

add_all_to_schedule

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_all_to_schedule
```

GuardAPI syntax

```
add_all_to_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_approved_stap_client

This command adds an approved database whose S-TAP® is allowed to access and communicate with the Guardium® system.

Prerequisite: `grdapib store_stap_approval=1`.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/approved_stap_client
```

GuardAPI syntax

```
add_approved_stap_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHost | String | Required. The host name or IP address of the database server on which the S-TAP is installed. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable communication between the Guardium system and S-TAPs on the database with the IP address 9.148.116.204:

```
grdapib add_approved_stap_client stapHost=9.148.116.204
```

Related tasks

add_assessment_datasource

This command adds a datasource to a security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/assessment_datasource
```

GuardAPI syntax

```
add_assessment_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. This string is a variable that is unique. Ensure that there is no previous assessment with the same description. If there is an existing one, an error occurs. |
| datasourceName | String | Required. This string is a variable, and must be the name of an existing data source. If a datasource with the defined string is not present, then an error occurs. |

Example

```
grdapapi add_assessment_datasource assessmentDescription=Assess1 datasourceName=DS1
```

add_assessment_datasource_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/assessment_datasource_group
```

GuardAPI syntax

```
add_assessment_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| assessmentDescription | String | Required. |
| groupName | String | Required. |

add_assessment_test

This command adds a test to an existing security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/assessment_test
```

GuardAPI syntax

```
add_assessment_test parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. |
| datasourceType | String | For valid values, call add_assessment_test from the command line with --help=true. |
| exceptionsGroup | String | |

| Parameter | Value type | Description |
|-----------------|------------|--|
| explanation | String | |
| fromDate | String | |
| severity | String | Valid values: <ul style="list-style-type: none">• <i>Critical</i>• <i>Major</i>• <i>Minor</i>• <i>Caution</i>• <i>Info</i> |
| testDescription | String | Required. |
| testseparator | String | The testseparator parameter specifies the delimiter that is used to separate tests when multiple test descriptions are included in the command. This parameter provides clarity when an individual testDescription also contains delimiters such as a comma. The GuardAPI uses the delimiter specified in the testseparator parameter to identify each test when the command is parsed. As an example, if a test description contains a comma, and multiple tests are separated by a semicolon, specify ';' as the testseparator.

Valid values: <ul style="list-style-type: none">• ,• ;• ^• ~• \\
• * The default value is ";". |
| threshold | String | |
| toDate | String | |

Example

```
grdapi add_assessment_test assessmentDescription="!DPS 2020 Q1 Testing - 2014 (MS SQL) EDS New Tests"
testDescription="Description 1 SQL Server must be configurable to overwrite audit log records, oldest first, in the event of
unavailability of space for more audit log records; Description 2 Another valid test description" testseparator=";"
```

This example adds the tests "Description 1 SQL Server must be configurable to overwrite audit log records, oldest first, in the event of unavailability of space for more audit log records" and "Description 2 Another valid test description" to the assessment "!DPS 2020 Q1 Testing - 2014 (MS SQL) EDS New Tests". The testseparator parameter specifies that the delimiter ";" is used to separate multiple tests in the command.

add_assessment_test_by_dsid

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/assessment_test
```

GuardAPI syntax

```
add_assessment_test_by_dsid parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. |
| dataSourceType | String | For valid values, call add_assessment_test_by_dsid from the command line with <code>--help=true</code> . |
| exceptionsGroup | String | |
| explanation | String | |
| fromDate | String | |
| severity | String | Valid values: <ul style="list-style-type: none">• <i>Critical</i>• <i>Major</i>• <i>Minor</i>• <i>Caution</i>• <i>Info</i> |
| threshold | String | |
| toDate | String | |

add_autodetect_task

Use this command to add an auto-discovery process to the specified host and port name(s).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_autodetect_task
```

GuardAPI syntax

```
add_autodetect_task parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| hosts_list | String | Required. Lists of hosts. Space separated list of IPs or IP ranges and wild cards such as 192.168.0.1 192.168.1.* |
| ports_list | String | Required. Comma separated list of ports or port ranges, such as: 22,23,1400-1600. |
| process_name | String | Required. Name of the auto-discovery process |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To add the auto-discovery task myProcess to the hosts 192.168.1.1 and 192.168.1.3, on ports 22 and 23:

```
grdap api add_autodetect_task process_name=myProcess hosts_list="192.168.1.1 192.168.1.3" ports_list="22,23"
```

Related concepts

add_available_test_notes

Add custom descriptions to vulnerability assessment test results. As an example, add a custom risk score for your test to a user-defined field. Then, use the Query-Report builder to add the custom field to your custom report. You can then view the custom risk score when you generate the custom report.

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/available_test_notes
```

GuardAPI syntax

```
add_available_test_notes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-------------------------|------------|---|
| datasourceType | String | Required. For valid values, call add_available_test_notes from the command line with --help=true. |
| override | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| testDescription | String | Required. |
| userDefinedNotes | String | Custom comment. |
| userDefinedReferenceOne | String | Custom comment. |
| userDefinedReferenceTwo | String | Custom comment. |

Example

The following example adds custom_notes and custom_reference_text to va_test:

```
grdapi add_available_test_notes testDescription="va_test" datasourceType="MS SQL SERVER" userDefinedNotes="custom_notes"
userDefinedReferenceOne="custom_reference_text"
```

add_classifier_datasource

This command adds classification datasources.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_datasource
```

GuardAPI syntax

```
add_classifier_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| datasourceName | String | Required. |
| processName | String | Required. |

add_classifier_datasource_group

This command adds classification datasource groups.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_datasource_group
```

GuardAPI syntax

```
add_classifier_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| groupName | String | Required. |
| processName | String | Required. |

add_cluster

Use this API to add a new S-TAP cluster or make changes to an existing S-TAP cluster.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_cluster
```

GuardAPI syntax

```
add_cluster parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| clusterName | String | Required. |
| connectivity | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| desc | String | |
| memberList | String | |
| traffic | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| virtualIp | String | |

add_connection_properties

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/con_properties
```

GuardAPI syntax

```
add_connection_properties parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fullReplace | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| name | String | Required. |
| properties | String | Required. |
| type | String | Required. For valid values, call add_connection_properties from the command line with <code>--help=true</code> . |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

add_custom_property_to_datasource_by_id

This command adds a custom property to a datasource that is identified by its identification key.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop_add
```

GuardAPI syntax

```
add_custom_property_to_datasource_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| customProps | String | Required. |
| id | Integer | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_custom_property_to_datasources_in_group

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_custom_prop_add
```

GuardAPI syntax

```
add_custom_property_to_datasources_in_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| customProps | String | Required. |
| name | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_datasource_to_entitlement_optimization

Adds the data from this datasource to the entitlement optimization data collection, and generates details to the individual entitlement optimization tabs as specified.

This API is available in Guardium V10.1.4 and later.

Use the following table to determine which data to extract for each feature:

Table 1. enable_entitlement_optimization parameters required per analysis type

| | What's New
(generateNews) | Users and
Roles | Recommendations
(generateRecommendations) | Browse
Entitlements | What If
(generateRoleClusters) |
|--------------------|------------------------------|--------------------|--|------------------------|-----------------------------------|
| extractActivity | | | | X | X |
| extractEntitlement | X | X | X | X | |

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

PUT https://[Guardium hostname or IP address]:8443/restAPI/addDataSourceToEntitlementOptimization

GuardAPI syntax

`add_datasource_to_entitlement_optimization parameter=value`

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| datasourceName | String | Required. Guardium datasource name. |
| extractActivity | Boolean | Required. Datasource is enabled or disabled for entitlement optimization. Set to true to generate data in the Browse Entitlements and What If? tabs. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| extractEntitlement | Boolean | Enables or disables extraction of entitlement data. Set to true to generate data in the What's New?, Users and Roles, Recommendations, and Browse Entitlements tabs. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| filterIgnoreVerbs | Boolean | For future use. Ignore verbs are filtered from the data source's collected data. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 |
| filterTempObjects | Boolean | For future use. Temporary objects are filtered from the data source's collected data. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 |
| generateNews | Boolean | Activity from this datasource is included in the What's New tab. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| generateRecommendations | Boolean | Activity from this datasource is included in the Recommendations tab. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| generateRoleClusters | Boolean | Enables or disables extraction of behavioral role clustering from the data source, used in the What If tab. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Set to true to generate data in the What If? tab.
Default = 0 |
| isEnabled | Boolean | Required. Datasource is enabled / disabled, for entitlement optimization. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| objectScope | String | Entitlement recommendations show results only for this specified object groups.
Valid values: One or more comma separated Guardium object group IDs (groups must contain only objects).
default = NULL |
| userScope | String | Entitlement recommendations show results only for the specified user groups (groups must contain only users).
default = NULL |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Enable entitlement optimization and generate data for the What's New? tab for data from the datasource SSQLSERVER.

```
grdapi add_datasource_to_entitlement_optimization datasourceName=SSQLSERVER isEnabled=1 generateNews=1
```

Enable entitlement optimization and generate data for the What's New? and Browse Entitlements tabs for data from the datasource SSQLSERVER.

```
grdapi add_datasource_to_entitlement_optimization datasourceName=SSQLSERVER isEnabled=1 generateNews=1 extractEntitlement=1 extractActivity=1
```

Adds data from this datasource to the Recommendations tab, filtered for the users in usergroup123 only.

```
grdapi add_datasource_to_entitlement_optimization datasourceName=SSQLSERVER extractEntitlement=1 generateRecommendations=1 userScope=usergroup123
```

Related concepts

add_datasource_to_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_add
```

GuardAPI syntax

```
add_datasource_to_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| datasourceName | String | Required. |
| groupName | String | Required. |

add_dm_to_profile

A profile is a group of data marts that are activated together. Use this command to create a profile from scratch.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamartInProfile
```

GuardAPI syntax

```
add_dm_to_profile parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| category | String | Informational. |
| cron_string | String | The schedule setting for the datamart. Omit this parameter to use the default. It's recommended to use the default, which takes into account all the schedules of Guardium's automatic processes. If you are adding a user-defined DM, there is no default cron_string. |
| datamart_name | String | Required. Adds this datamart to the profile. For valid values, call add_dm_to_profile from the command line with --help=true. |
| profile_name | String | Required. The datamart is added to this profile. For valid values, call add_dm_to_profile from the command line with --help=true. |
| unit_type | String | The type of Guardium® system. Valid values: <ul style="list-style-type: none">• ANY• CM• CM/STANDALONE• AGGREGATOR• COLLECTOR• STANDALONE |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Example

To add the data mart `Export:Full SQL` to the user defined profile `sql_all`.

```
add_dm_to_profile profile_name=sql_all datamart_name=Export:Full SQL
```

add_domain_to_universal_connector_allowed_domains

Run this API to authorize communication with cloud-based database domains.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/addDomainToUcAllowedDomains
```

GuardAPI syntax

```
add_domain_to_universal_connector_allowed_domains parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| domain | String | Required. Cloud-based domain name to add. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To authorize communication with AWS APIs:

```
grdapi add_domain_to_universal_connector_allowed_domains domain=amazonaws.com
```

add_group_to_quick_search

This command adds groups to the quick search facet drop-down menus, so that you can select the groups for filtering the investigation dashboard results.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
add_group_to_quick_search parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| facet | String | <p>Required. The facet of the group you are adding. Valid values:</p> <ul style="list-style-type: none"> • DB_USER • OS_USER • OBJECT • VERB • FAM_COMMAND • SERVER_IP |
| group_description | String | Required. Group name you are adding, of the specified facet type. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To add server_group5 to the quick search:

```
add_group_to_quick_search facet=SERVER_IP group_description=server_group5
```

add_ip_to_sg

This API adds the specified Guardium® IP to a cloud security group.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_ip_to_sg
```

GuardAPI syntax

```
add_ip_to_sg parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasource_name | String | Required. A cloud datasource defined in Guardium. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_mfa_exempt_users

Use this command to enter a list of users who are exempt from secondary authentication for multi-factor authentication.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/configure_mfa
```

GuardAPI syntax

```
add_mfa_exempt_users parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| exemptUsers | String | A comma-separated list of one or more users to exempt from multi-factor authentication. |
| mfaType | String | Required. The authentication type. For valid values, call <code>add_mfa_exempt_users</code> from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_objects_native_audit

This API adds objects to the object audit (audit trail) on the specified datasource.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_objects_native_audit
```

GuardAPI syntax

```
add_objects_native_audit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasource_name | String | Required. A cloud datasource defined in Guardium. |
| objects | String | Required. Comma-separated list of objects. View objects with the <code>get_native_audit_objects</code> API or in the GUI. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

[add_ranger_config](#)

Use this command to define a Ranger on an Ambari server for Hadoop monitoring.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. The Ambari administrator must restart the affected Hadoop components, so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_ranger_config
```

GuardAPI syntax

```
add_ranger_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| hostname | String | Required. Hostname or IP address of the Ambari server. |
| password | String | Required. Password for the admin user specified by <code>userName</code> |
| port | Integer | Port on the Ambari server for the user interface. Default = 8080. |
| sslEnabled | Boolean | Sets whether SSL is enabled for communication with this Ranger. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| userName | String | Required. Ambari server username; must be an admin or service admin user. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GrdAPI Example

To define a ranger cluster

```
grdapic add_ranger_config hostname=hw-cl4-05 userName=admin port=8080 password=xxxxxx clusterName=Cluster4
```

Sample output:

```
ID=0Configuration for Cluster: Cluster4 added.
```

REST API example

```
curl -k --header "Authorization:Bearer <access token>" -i -H "Content-Type: application/json" -X POST -d '{hostname="hw-cl4-05", userName="admin", port=8080, password="admin", clusterName="Cluster4"}' https://<Guardium server name>:8443/restAPI/add_ranger_config
```

Sample output:

```
[{"id": 2, "clusterName": "Cluster4", "serverHost": "hw-cl4-05", "serverPort": 8080, "userName": "admin", "lastRefresh": "2016-09-27 11:31:03", "status": []}]
```

add_ranger_hdfs_config

Use this command to add a Hadoop integration with Ranger HDFS.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_ranger_hdfs_config
```

GuardAPI syntax

```
add_ranger_hdfs_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------------|------------|---|
| ldLibraryPath | String | Locate libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server/libjvm.so) and set <code>ld_library_paths</code> to the directory that contains libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server). |
| principal | String | Required for Kerberos. The value of Ranger HDFS user. |
| rangerHdfsAuditDirs | String | Comma-separated list of directories where Ranger logs the service audits. Include one directory that contains the daily log directories, for each service you want to monitor. Usually the paths are located under /ranger/audit.

Example service directories for CDP 7: /ranger/audit/hive/hiveServer2,/ranger/audit/kafka/kafka,/ranger/audit/hbase/hbaseMaster,/ranger/audit/hbase/hbaseRegional,/ranger/audit/atlas/atlas,/ranger/audit/hdfs/hdfs

Example service directories for HW 3: /ranger/audit/hbaseMaster,/ranger/audit/hbaseRegional,/ranger/audit/hdfs,/ranger/audit/hiveServer2,/ranger/audit/kafka,/ranger/audit/solr,/ranger/audit/storm |
| rangerHDFSAuditHistoryLength | Integer | Required. |
| rangerHdfsKeytab | String | Required for Kerberos. Location of the Kerberos keytab that contains the principal used to connect to HDFS. |
| rangerHdfsLibLocation | String | Locate libhdfs.so provided by Hadoop cluster (for example, /usr/hdp/3.1.0.141-1/usr/lib/libhdfs.so) and set <code>ranger_hdfs_lib_location</code> to the directory that contains libhdfs.so (for example, /usr/hdp/3.1.0.141-1/usr/lib). |
| rangerHdfsNameNode | String | IP or hostname of the HDFS NameNode. |
| rangerHdfsPollMs | Integer | Time interval, in milliseconds, the S-TAP® waits between checking for new Ranger audits in HDFS. |
| rangerHdfsPort | Integer | The HDFS NameNode port the S-TAP connects to. |
| rangerHdfsUser | String | The user with which S-TAP connects to HDFS. If the HDFS setup is using Kerberos, set the parameter to the Kerberos principal. |
| stapHostName | String | Required. Host name or IP of the S-TAP that receives the Ranger audit messages from the Ranger. |
| useKerberos | Boolean | Enables Kerberos authentication for this connection. When enabled, requires values for Principal and Ranger HDFS keytab. Valid values: <ul style="list-style-type: none">• 0: Disabled• 1: Enabled Default = 0 |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

add_ranger_service

Use this command to map the Ranger service to an S-TAP®, using the S-TAP host and port from the output to `get_ranger_staps`.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/add_ranger_service
```

GuardAPI syntax

```
add_ranger_service parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| clusterName | String | Required. Ambari cluster name defined with <code>add_ranger_config</code> . |
| enableMonitoring | Boolean | Required. Enable Guardium® monitoring for this Hadoop service. Valid values: <ul style="list-style-type: none">• 0: false• 1: true Default = 0 |
| port | Integer | Port on the Ambari server for listening. Default = 5555. |
| serviceName | String | Required. Name of the service. Valid values: <ul style="list-style-type: none">• hdfs• hive• hbase• kafka• solr• storm |
| stapHostName | String | Required. Host name or IP of the S-TAP that receives the log4j audit messages from the Ranger. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GrdAPI example

To add a Ranger service on Cluster4, listening port on the Ambari server of 5555, and S-TAP host <db server>:

```
grdapic add_ranger_service clusterName=Cluster4 serviceName=HDFS stapHostName=<db server> port=5555 enableMonitoring=true
```

System response:

ID=0

The Hadoop service configuration has been changed. Ask the Hadoop administrator to restart the Hadoop service to activate the change.
HDFS Monitoring Enabled on <db server>:5565

REST API example

This example specifies DFS, HIVE, and HBASE:

```
curl -k --header "Authorization:Bearer <access token>" -i -H "Content-Type: application/json" -X POST -d
'{clusterName="Cluster4", serviceName="HDFS,HIVE,HBASE", stapHostName="<db server>", port=5534, enableMonitoring=true}'
```

Sample output:

```
[  
  {  
    "id": 3,  
    "ambariConfigId": 1,  
    "service": {  
      "id": 1,  
      "label": "HBase",  
      "value": "HBASE"  
    },  
    "stapHost": {  
      "id": 18,  
      "name": "<db server>",

add_receiver_to_rule_action

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/receiver_to_rule_action
```

GuardAPI syntax

```
add_receiver_to_rule_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| actionName | String | Required. |
| alertUserLoginName | String | |
| classDestination | String | |
| fromPolicy | String | Required. |
| notificationType | String | Required. |
| ruleDesc | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_stream

This command adds a data stream for cloud database service protection. After you define a Guardium cloud DB service account, you can discover or define available data streams and assign them to Guardium collectors.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasream
```

GuardAPI syntax

```
add_stream parameter=value
```

Amazon-specific parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| activate | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Start the data stream. Default = 0 (false) |
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call add_stream from the command line with <code>--help=true</code> . For more information, see Define, modify, and delete AWS DB service accounts . |
| cluster_resource_id | String | Required. The cluster resource ID for the AWS RDS cluster associated with the stream. |
| collectorHostNames | String | Required. The names of your Guardium collectors, for example: <code>collector01.yourcompany.com</code> For valid values, call add_stream from the command line with <code>--help=true</code> . |
| consumerGroupName | String | Required. The consumer group name that you assign from the Guardium® Cloud DB Service Protection page. For more information, see Discover and configure AWS data streams . |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| dbType | String | The database for this stream. Valid values: <ul style="list-style-type: none">• AuroraMySQL - Datastreams only• AuroraPostgreSQL - Datastreams only• Oracle - Native audit only Default = <code>AuroraPostgreSQL</code> |
| port | String | Required. The DB DNS endpoint port. |

| Parameter | Value type | Description |
|------------|------------|---|
| region | String | Required. For valid values, call add_stream from the command line with --help=true. |
| streamName | String | Required. The name of the stream from the RDS cluster configuration. |

| | | |
|-----------------|--------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |
|-----------------|--------|---|

Azure-specific parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| activate | Boolean | <p>Activates data streaming. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true): Start the data stream <p>Default = 0 (false)</p> |
| cloudTitle | String | Required. The name of the cloud DB service account. For more information, see Define, modify, and delete Azure cloud database service accounts . |
| collectorHostNames | String | Required. The names of your Guardium collectors, for example: <code>collector01.yourcompany.com</code> . For valid values, call add_stream from the command line with --help=true. |
| consumerGroupName | String | Required. The Azure consumer group name. |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| dbType | String | <p>The database for this event hub stream. Valid values:</p> <ul style="list-style-type: none"> • AzureSQL • CosmosSQL • CosmosMongoDB • CosmosCassandra • CosmosGremlin • CosmosTable <p>Default = AzureSQL</p> |
| namespace | String | The Azure event hub namespace. |
| port | String | Required. The DB DNS endpoint port. |
| storageConnectionString | String | The Azure storage connection string name |
| streamName | String | Required. The event hub name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

add_threshold_to_rule

You can use your policies' rules to create active threat analytics case types, by setting a threshold on specific violation policy rules that have a severity of high in the rule definition, and the rule action is **Alert per match**.

When the rule threshold is exceeded in any 1 hour, a case is created. The case type is the name of the rule. Cases that are created from a policy rule threshold appear in the active threat analytics cases table, and are treated like any other case.

Changes to installed policies are applied according to the policy schedule. When adding a threshold to a rule in an installed policy, cases are created for violations (according to the threshold) only after the policy is reinstalled.

You cannot define thresholds in the GUI.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/add_threshold_to_rule
```

GuardAPI syntax

```
add_threshold_to_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policy_name | String | The policy that has the rule you want to add a threshold to. Use the API <code>list_policy</code> to view policies. |
| rule_name | String | The rule you want to add a threshold to. Use the API <code>list_policy_rules</code> to view rules. |
| threshold_value | Integer | The threshold at which a case is created. |

Examples

To add the threshold 25 to ruleNNN in policyAAA:

```
grdapi add_threshold_to_rule policy_name=policyAAA rule_name=ruleNNN threshold=25
```

add_time_period

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/time_period
```

GuardAPI syntax

```
add_time_period parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| contiguous | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| hourFrom | String | Required. |
| hourTo | String | Required. |
| timePeriodDescription | String | Required. |
| weekdayFrom | String | Required. |
| weekdayTo | String | Required. |

aggregation

12.1 and later This API command is used to archive the data and export it.

REST API syntax

This API is available as a REST service with the `aggOnDemandApi` method. Call this API as follows:

```
https://[Guardium hostname or IP address]:8443/restAPI/agg_onDemand
```

GuardAPI syntax

```
aggregation parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| from | String | The from parameter should be less than to parameter, and should be earlier than the current date. |
| to | String | The to parameter should be earlier than the current date. |
| type | String | Valid values: <ul style="list-style-type: none">• <code>export</code>• <code>archive</code> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following command runs the export job.

```
grdapi aggregation type=export from=2024-01-01 to=2024-01-02  
ID=0  
Executing export using default interval
```

The following command runs the archive job.

```
grdapi aggregation type=archive from=2023-12-20 to=2024-01-02  
ID=0
```

The following command runs the archive job. If no from and to dates are provided, the default settings are used.

```
grdapi aggregation type=archive  
ID=0  
Executing archive job
```

apply_rules_on_discoveredinstances

This API pulls information that is defined in the Database Discovered Instances Rules UI and immediately applies the rules to the S-TAPs on the primary collectors. Run `apply_rules_on_discoveredinstances` only on Guardium managed units or stand-alone systems.

For more information about discovered instances rules, see [Database discovered instances rules](#).

This API is available in Guardium V10.6 and V11.1 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/applyRules
```

GuardAPI syntax

```
apply_rules_on_discoveredinstances parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
>grdapi apply_rules_on_discoveredinstances api_target_host=10.0.1.123
>grdapi apply_rules_on_discoveredinstances debug=2

Sample output

ID=0

assign_analytic_case

Use this command to assign a threat analytics or risk spotter case to a Guardium email, group, role, or user.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/analytic_case
```

GuardAPI syntax

```
assign_analytic_case parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| case_id | Long | Required for Advanced threat analytics only. The case ID is in the Case # column in the GUI. |
| DBUser | String | Required for Risk Spotter only. The DB user associated with the risk, as seen in the GUI. |
| emails | String | Required if receiver_type=email. Comma separated list of email addresses. |
| email_content_type | Integer | Required if receiver_type=email. <ul style="list-style-type: none">• 0: PDF• 1: CSV Default = 0 |
| isRiskSpotter | Boolean | Required for Risk Spotter only. Identifies the case as a RiskSpotter case. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| iterationID | Integer | Risk Spotter only. Indicates if this case is a Risk spotter case only. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| receiver | String | Required if receiver_type = one of group, role, or user. Valid values: <ul style="list-style-type: none">• For group: valid Guardium user group that has at least one member• For role: valid Guardium role that has at least one member• For user: valid Guardium user |
| receiver_type | Integer | Required. Determines who the ticket is assigned to. Valid values: <ul style="list-style-type: none">• 1: email• 2: role• 3: group• 4: user |
| serverIP | String | Required for Risk Spotter only. Server IP associated with the risk, as seen in the GUI. |

Examples

To assign the advanced threat analytics case 145 to the guardium group "group24":

```
grdapi assign_analytic_case case_id=145 receiver_type=3 receiver=group24
```

assign_collectors

This API assigns Guardium collectors for cloud-based service accounts in central manager configurations.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datasream
```

GuardAPI syntax

```
assign_collectors parameter=value
```

Amazon-specific parameters

| Parameter | Value type | Description |
|------------|------------|---|
| activate | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Start the data stream. Default = 0 (false) |
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call assign_collectors from the command line with --help=true
For more information, see Define, modify, and delete AWS DB service accounts . |

| Parameter | Value type | Description |
|---------------------|------------|---|
| cluster_resource_id | String | Required. The cluster resource ID for the AWS RDS cluster associated with the stream. |
| collectorHostNames | String | Required. The names of your Guardium collectors, for example: <code>collector01.yourcompany.com</code> . For valid values, call <code>assign_collectors</code> from the command line with <code>--help=true</code> . |
| consumerGroupName | String | Required. The consumer group name that you assign from the Guardium® Cloud DB Service Protection page. For more information, see Discover and configure AWS data streams . |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| port | String | Required. The DB DNS endpoint port. |
| region | String | Required. For valid values, call <code>assign_collectors</code> from the command line with <code>--help=true</code> . |
| streamName | String | Required. The name of the stream from the RDS cluster configuration. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group_name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Azure-specific parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| activate | Boolean | <p>Activates data streaming. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true): Start the data stream <p>Default = 0 (false)</p> |
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call <code>assign_collectors</code> from the command line with <code>--help=true</code> . For more information, see Define, modify, and delete Azure cloud database service accounts . |
| collectorHostNames | String | The names of your Guardium collectors, for example: <code>collector01.yourcompany.com</code> . For valid values, call <code>assign_collectors</code> from the command line with <code>--help=true</code> . |
| consumerGroupName | String | The Azure consumer group name. |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| namespace | String | The Azure event hub namespace. |
| port | String | Required. The DB DNS endpoint port. |
| storageConnectionString | String | The Azure storage connection string name |
| streamName | String | Required. The event hub name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group_name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. assign_load_balancer_groups

This command assigns a managed unit group to an application or S-TAP® group to help manage load balancing requirements.

Use this command to assign a specific S-TAP group to one or more load balance-enabled managed unit groups. When S-TAP needs to failover to a new managed unit, Guardium allocates a managed unit from one of the assigned load balancer (failover) groups.

Use failoverGroupPriority to assign specific priority to S-TAP or managed unit groups. If you do not assign a priority, Guardium randomly assigns the failover managed unit when required.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
assign_load_balancer_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| appGroupName | String | Required. The application or S-TAP group name. |
| isFailoverGroup | Boolean | If set to 1, this managed unit group is a member of a failover group. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| failoverGroupPriority | String | Required when isFailoverGroup = 1 (true) and one or more S-TAP groups already have assigned priorities. Must be an integer value.
If not specified, the priority is 1. |
| muGroupName | String | Required. The managed unit group name. |

assign_qr_condition_to_action

This command creates an association between a query rewrite condition and an associated action.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_condition_to_action
```

GuardAPI syntax

```
assign_qr_condition_to_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| actionName | String | Required. The name of the query rewrite action. |
| conditionName | String | Required. The name of the query rewrite condition to be associated with the specified action. |
| definitionName | String | Required. The name of the query rewrite definition that is associated with the specified condition and action. |

Examples

To associate the condition "qr cond15_2" with the action "qr action15_2", and give it the definition name "case 15":

```
grdapi assign_qr_condition_to_action definitionName="case 15" actionName="qr action15_2" conditionName="qr cond15_2"
```

Related concepts

- [Query rewrite](#)

Related reference

audit_process_run_status

Displays the run status for a specified audit process.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/audit_process_run_status
```

GuardAPI syntax

```
audit_process_run_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| processName | String | Required. The name of an audit process. Use list_audit_processes to find the audit process name. |

Related concepts

- [Building audit processes](#)

auto_execute_suggested_dependencies

This command enables job dependencies for the specified task.

This command is equivalent to selecting the option Auto run dependent jobs in the Scheduler of a task. Guardium automatically finds all the job's prerequisite jobs and runs them in order, before running this job. This ensures that the job runs with the latest, most accurate data.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
auto_execute_suggested_dependencies parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| jobTrigger | String | Required. The name of the task whose dependent tasks you want to run. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable the job dependencies for the job userSynchronizationTrigger:

```
grdapi auto_execute_suggested_dependencies jobTrigger=userSynchronizationTrigger
ID=0
ok
```

backup_cm_list_candidates

Use this command, on a central manager only, to identify the possible backup, or secondary, central managers from among the registered units in the environment.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/backup_cm_list_candidates
```

GuardAPI syntax

```
backup_cm_list_candidates
```

This API takes no parameters.

GrdAPI example

To list IPs of potential secondary central managers, enter:

```
grdapi backup_cm_list_candidates
```

Format of output:

```
<ip> (<hostname>)
<ip> (<hostname>)
<ip>
```

REST API example

To list IPs of potential secondary central managers, enter:

```
curl \
-k --header "Authorization:Bearer d51c41d0-a6b1-4aa3-90bc-5232a44e8b0d" \
--include --header "Content-Type: application/json" \
-X GET https://localhost:8443/restAPI/backup_cm_list_candidates
```

Format of output:

```
<ip> (<hostname>)
<ip> (<hostname>)
<ip>
```

Related concepts

- [Central manager redundancy](#)
-

backup_cm_set

Use this command, on a central manager only, to define a backup, or secondary, central manager.

This API is available in Guardium V11.2 and later.

Note: Switching to a backup central manager interrupts communication with collectors and may generate the following message: "Central manager experienced failed data transfer from collector." The issue is visible in the Scheduled Jobs Exceptions report and should clear within 24-hours.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/backup_cm
```

GuardAPI syntax

```
backup_cm_set parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| ip | String | Required. The IP of the backup central manager. For valid values, call <code>backup_cm_set</code> from the command line with <code>--help=true</code> . Enter this parameter with no IP value to delete the current secondary central manager. |

GuardAPI example

To set the backup central manager to 9.142.10.100, enter this command on the primary central manager:

```
grdapi backup_cm_set ip=9.142.10.100
Backup CM designated
```

Output if the IP is invalid or not one of the allowed candidates:

```
Wrong value: "ip" must be one of
<ip> (<hostname>)
<ip> (<hostname>)
<ip>
...
ERR=23
Value not in constant list.
```

REST API example

To set the backup central manager to 9.142.10.100:

```
curl \
-k --header "Authorization: Bearer d51c41d0-a6b1-4aa3-90bc-5232a44e8b0d" \
--include --header "Content-Type: application/json" \
-X PUT --data '{"ip":"9.142.10.100"}' https://<CM-hostname>:8443/restAPI/backup_cm
```

cancel_distributed_report_target

Use this API to remove a Guardium system from the list of distributed report targets.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
cancel_distributed_report_target parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| target_host_name | String | Required. IP or hostname of the Guardium system. |

Examples

To remove the Guardium system with the IP 11.11.11.11 from the list of targets for distributed reports:

```
grdapi cancel_distributed_report_target target_host_name=11.11.11.11
```

change_cli_password

The command changes the password for the cli user.

The minimum password length (8 or 15) depends on the [enable_strong_cli_password](#) setting.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/change_cli_password
```

GuardAPI syntax

```
change_cli_password parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| confirmpassword | String | Confirm the new password. |
| newpassword | String | The new password for this user. |
| username | String | The name of the user whose password you want to change. The name must be cli. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapic change_cli_password username=cli newpassword="Strong!Pass1234!" confirmpassword="Strong!Pass1234!"
```

Related reference

change_monitor_value

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/monitor_value
```

GuardAPI syntax

```
change_monitor_value parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| clusterName | String | Required. |
| parameter | String | Required. |
| value | Boolean | <p>Required. Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

change_rule_order

This command changes the order of a rule within a policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/change_rule_order
```

GuardAPI syntax

```
change_rule_order parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fromPolicy | String | Required. The name of the policy. |
| order | Integer | Required. The new location for this rule within the policy. |
| ruleDesc | String | Required. The name of the rule to move. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapic change_rule_order ruleDesc="My policy exception1" fromPolicy="policy1" order=7
```

change_to_microsoft

This API is available in Guardium V12.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/changeToMicrosoft
```

GuardAPI syntax

```
change_to_microsoft parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| microsoftDriver | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

change_to_opensource

This API allows you to change the database driver ID from DataDirect to open source .

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/changeToOpensource
```

GuardAPI syntax

```
change_to_opensource parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| datasourceType | String | Required. For valid values, call <code>change_to_opensource</code> from the command line with <code>--help=true</code> . |
| opensourceDriver | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

change_tracker_get_events

Displays change tracker events. You can filter the request by hostname or task type.

For use by IBM Guardium support only.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/change_tracker_get_events
```

GuardAPI syntax

```
change_tracker_get_events parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| host | String | A hostname or IP address. |
| taskType | String | The type of task for which you want to display the events. For a list of available tasks, see change_tracker_get_tasks . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

```
>grdapi change_tracker_get_events
ID=0
[
  {
    "unit": "my.company1.com",
    "events": [
      {
        "eventType": "IM_ALIVE_MSG",
        "eventDescription": "Unit not responding"
      }
    ],
    {
      "unit": "my.company2.com",
      "events": [
        {
          "eventType": "IM_ALIVE_MSG",
          "eventDescription": "Unit not responding"
        }
      ]
    }
]
```

change_tracker_reset

Reset the change tracker application to restart all of its internal tasks on the target host.

For use by IBM Guardium support only.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/change_tracker_reset
```

GuardAPI syntax

```
change_tracker_reset parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| host | String | Required. A host name or IP address. The host on which to restart the change tracker application. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

change_tracker_set_params

Set parameters for Guardium change tracker tasks.

For use by IBM Guardium support only.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/change_tracker_set_params
```

GuardAPI syntax

```
change_tracker_set_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| paramName | String | Required. The name of a parameter for the specified task. |
| paramValue | String | Required. The new value for the task parameter. |
| task | String | Required. The task for which you want to change a parameter value. For a list of available tasks, use the change_tracker_get_tasks API. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

The following command changes the RUN_INTERVAL parameter for the SCHEDULED_JOBS task to 62.

```
change_tracker_set_params task="SCHEDULED_JOBS"
paramName="RUN_INTERVAL"
paramValue="62"

curl -k --header "Authorization: Bearer bRVbgnfk0yfnJd1SVv6Mt532Zog" --include
--header "Content-Type: application/json" -X PUT --data
'{"task":"SCHEDULED_JOBS","paramName":"RUN_INTERVAL","paramValue":"62"}'
https://<appliance_hostname>:8443/restAPI/change_tracker_set_params
```

12.1 and later The following command sets the expiry threshold for certificates.

```
grdapic change_tracker_set_params
paramName=CERTIFICATE_EXPIRATION_ALERT_THRESHOLD
paramValue=365
task=CUSTOM_EVENTS
```

You need to update the CERTIFICATE_EXPIRATION_ALERT_THRESHOLD parameter across all managed units.

clear_cas_template_set

Remove all templates from an existing Configuration Auditing System (CAS) template set.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/cas_template_set
```

GuardAPI syntax

```
clear_cas_template_set parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| templateSetLabel | String | Required. The name of the template set to clear. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

clevis_bind

Use this command to bind a managed unit to a tang server. Run this command on a central manager if you want to bind all managed units to the tang server.

This API is available in Guardium V11.3 and later.

GuardAPI syntax

```
clevis_bind parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| server | String | Required. The IP address of the tang server. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

clone_assessment

This command clones an existing assessment.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/clone_assessment
```

GuardAPI syntax

```
clone_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|------------|---|
| assessmentDescription | String | Required. The name of the existing assessment that is cloned. |
| newAssessmentDescription | String | The name of the cloned assessment. |

Examples

Example 1:

```
grdapiclone_assessment assessmentDescription=Assessment1 newAssessmentDescription=ClonedAssessment1
ID=20000
Created assessment ClonedAssessment1
ok
```

Example 2:

```
grdapiclone_assessment assessmentDescription=Assessment2
ID=20004
Created assessment COPY OF Assessment2
ok

grdapiclone_assessment assessmentDescription=Assessment2
ID=20005
Created assessment COPY 2 OF Assessment2
ok
```

clone_cas_template_set

This command creates a clone of an existing Configuration Auditing System (CAS) template set.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/clone_cas_template_set
```

GuardAPI syntax

```
clone_cas_template_set parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|---|
| clonedTemplateSetLabel | String | Required. The name of the new template set. |
| templateSetLabel | String | Required. The name of the existing template set that you want to clone. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

clone_extraction_profile

Clones a GBDI (Big Data) profile.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/extractionProfile
```

GuardAPI syntax

```
clone_extraction_profile parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| clone_profile_name | String | Required. The name of the new profile. |
| profile_name | String | Required. The profile you are cloning. For valid values run <code>grdapic get_extraction_profile_info</code> or call <code>clone_extraction_profile</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To clone the profile Basic summary to a profile named Basics:

```
clone_extraction_profile profile_name=Basic summary clone_profile_name=Basics
```

clone_policy

This command clones an existing policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/clone_policy
```

GuardAPI syntax

```
clone_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clonedPolicyDes | String | Required. The name of the cloned policy. |
| policyDesc | String | Required. The name of the original policy. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi clone_policy policyDesc="Hadoop Policy" clonedPolicyDesc="My Hadoop Policy"
```

close_default_events

This command closes all of the events that are defined on a specific process, task, or execution for tasks of type *report*.

This command is useful if, for example, you have a task with a default event that returns numerous records, but the task cannot be signed unless all of the events are closed.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
close_default_events parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| eventStatus | String | Required. A final event status (such as Done). Must be a valid status for the default event that is defined for this audit task. |
| execDate | Date | Required. The execution date and time in the format <code>YYYY-MM-DD hh:mm:ss</code> . |
| processDesc | String | Required. The name of the audit process. |
| taskDesc | String | Required. The name of the audit task. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi close_default_events eventStatus=Done execDate="2020-03-01 08:00:00"
processDesc="Audit Process" taskDesc="Task Description"
```

configure_archive

Use this command to configure a data archive.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/configure_archive
```

GuardAPI syntax

```
configure_archive parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| accessKey | String | Required for Cleversafe; and for Amazon S3 when authType=Security-Credentials or authType=IAM-Role. Identifies user as the party responsible for service requests. It needs to be included in each request. It is not confidential and does not need to be encrypted. (20-character, alphanumeric sequence). |
| archiveOlderThan | Integer | Required. Specifies the number of days, older than which data is archived. For example, to archive data starting with yesterday's data, set this value to 1. |
| archiveValues | Integer | Required. Specify whether the archive data includes values from SQL strings. Valid values: <ul style="list-style-type: none"> • 0: no. Values are replaced with 'Value~Removed' in the archive, and are not available as part of a restore operation. • 1: yes. Values are maintained. |
| authType | String | Required for Amazon S3 only. Valid values: <ul style="list-style-type: none"> • Security-Credentials • IAM-Role • IAM-Instance-Profile |
| bucketName | String | Required for Amazon S3 and Cleversafe only. The unique bucket name. |
| destHost | String | Required for SCP, SFTP, Cleversafe only. Valid values: <ul style="list-style-type: none"> • SCP and SFTP: Host name of the target archive server. |
| ignoreOlderThan | Integer | Required. Together with archiveOlderThan, specifies the time interval of data to archive: data that is older than this value, in days, is not exported. |
| passwd | String | Required for SCP, SFTP. Valid values: Password for the target archive server. |
| passwdRetype | String | Required for SCP, SFTP. Password for the target archive server. |
| port | Integer | Required for SCP, SFTP only. Port on the target archive server. |
| protocol | String | Required. Protocol of the target destination.
For valid values, call configure_archive from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| region | String | Required for Amazon S3 only. Valid values: <ul style="list-style-type: none">• US_EAST_1• US_EAST_2• US_WEST_1• US_WEST_2• EU_CENTRAL_1• EU_WEST_1• EU_WEST_2• EU_WEST_3• EU_NORTH_1• CA_CENTRAL_1• AP_SOUTHEAST_1• AP_SOUTHEAST_2• AP_NORTHEAST_1• AP_NORTHEAST_2• SA_EAST_1• CN_NORTH_1• CN_NORTHWEST_1• AP_SOUTH_1• GovCloud• US_GOV_EAST_1 |
| retention | Integer | Required for Centera only. Number of days to retain the archive data on the target archive server. |
| roleARN | String | Required for Amazon S3 when authType=IAM-Role. The Amazon resource name (ARN) specifying this role. |
| secretKey | String | Required for Amazon S3 and Cleversafe only. The Secret Access Key is associated with the Access Key ID, used to calculate the digital signature that needs to be included in the request. (Only the user and AWS should have this 40-character sequence.) |
| ssh_key_active | Boolean | Enables data transfer using the SSH key. Enable the SSH key feature with the CLI command store system scp-ssh-key-mode on . Generate ssh-key pairs and copy the public part of the key, public-transfer-key , to the remote host. For more information, see Enabling ssh-key pairs for data archive, data export, data mart . Valid values: <ul style="list-style-type: none">• 0: Disable• 1: Enable Default = 0 |
| targetDir | String | Required for SCP, SFTP, Cleversafe only. Valid values: <ul style="list-style-type: none">• SCP, SFTP: The target directory on the target archive server.• Cleversafe: Authentication endpoint URL |
| userName | String | Required for SCP, SFTP only. User name for the target archive server. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To configure archive of data, with SQL strings, older than one day and younger than 2 days, on an SFTP server:

```
grdapi configure_archive archiveOlderThan=1 archiveValues=1 destHost=<full path to target archive host> ignoreOlderThan=2
passwd=pass1 passwdRetype=pass1 port=0 protocol=SFTP targetDir=/archive/dir

grdapi configure_archive archiveOlderThan=1 archiveValues=1 destHost="10.10.10.10" ignoreOlderThan=30 protocol="scp"
targetDir="/var/tmp" userName="root" ssh_keys_active=1
```

configure_data_streaming

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/dataStreaming
```

GuardAPI syntax

```
configure_data_streaming parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| dataToInclude | String | Valid values: <ul style="list-style-type: none">• <i>instance</i>• <i>exception</i>• <i>session</i>• <i>policy_violations</i>• <i>full_sql</i> |
| hostname | String | |
| PemKey | String | |
| port | Integer | |
| streamTo | String | Required. Valid values: <ul style="list-style-type: none">• <i>IBM_Security_Guardium</i>• <i>Guardium_Insights</i>• <i>Guardium_Big_Data_Intelligence</i>• <i>Datamart_For_Guardium_Insights</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

configure_export

This command defines the data export to a Guardium® aggregator or central manager.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/configure_export
```

GuardAPI syntax

```
configure_export parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| aggHost | String | Required. The target aggregator hostname. |
| aggSecHost | String | The secondary target aggregator hostname. |
| exportOlderThan | Integer | Required. The export includes data older than this number of days. For example, to export yesterday's data and older data, set <code>exportOlderThan</code> to 1. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| exportValues | Integer | Required. Whether the export data includes values from SQL strings. Valid values: <ul style="list-style-type: none"> 0: no. Values are replaced with question mark characters in the export, and are not available as part of a restore operation. 1: yes |
| ignoreOlderThan | Integer | Required. Together with exportOlderThan, specifies the time interval of data to export: data that is older than this value, in days, is not exported. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To export data older than one day, but not older than 2 days, without the SQL strings, to the specified aggregator:

```
grdapic configure_export aggHost=<full path to target aggregator> exportOlderThan=1 exportValues=0 ignoreOlderThan=2
```

Related tasks

configure_mfa

This command configures multi-factor authentication.

Before you run this command, make sure that your authentication application is configured. For DUO, define applications and users. For RSA SecurID, configure the RSA SecurID Authentication Manager.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/configure_mfa
```

GuardAPI syntax

```
configure_mfa parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| accessKey | String | RSA SecurID only.
From the RSA SecurID Console, generate the access key from the RSA SecurID Authentication API under Authentication Settings. |
| apiHost | String | The API host string. <ul style="list-style-type: none"> For DUO, the apiHost is from DUO. For RSA SecurID, the fully qualified domain name of the Authentication Manager. |
| clientId | String | RSA SecurID only.
The Hostname from the Add New Authentication Page of the RSA Security Console. |
| enable | Boolean | Required. Valid values: <ul style="list-style-type: none"> false: Disable multi-factor authentication. true: Enable multi-factor authentication. |
| exemptUsers | String | A comma-separated list of users to exempt from secondary authentication. You cannot exempt administrative OS (SSH) users. |
| iKey | String | DUO only. The integration key. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| loginPath | String | Required. Determines whether to provide multi-factor authentication to the Guardium GUI, CLI, or SSH. Valid values: <ul style="list-style-type: none"> • GUI: Guardium GUI • SET_GUIUSER: Guardium CLI • SSH: Guardium administrative OS users (cli and guardcli1 - guardcli9) who log in to the CLI via SSH. |
| mfaType | String | Required. The authentication type. . For valid values, call <code>configure_mfa</code> from the command line with <code>--help=true</code> . |
| port | Integer | RSA SecurID only. The communication port from the Add New Authentication Page of the RSA Security Console. The default is 5555. |
| sKey | String | DUO only. The secret key (from DUO). |
| verifySSL | Boolean | RSA SecurID only. Required for SSH users only. Determines whether to verify the server-side certificate for the RSA SecurID Authentication Manager. Before you run this command with <code>verifySSL='true'</code> , you need to upload the CA or self-signed certificate, which must be in PEM format. For more information, see either Configuring multi-factor authentication with RSA SecurID or store_certificate rsa_securid . Valid values: <ul style="list-style-type: none"> • <code>false</code>: Do not verify the SSL certificate. • <code>true</code>: Verify the SSL certificate. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI examples with DUO

This example configures multi-factor authentication for the Guardium GUI with DUO.

```
grdapi configure_mfa loginPath=GUI mfaType=DUO exemptUsers="admin, accessmgr" enable=true iKey=DIATOT8H1OXXXX
sKey=2gMRXVj2iQXXXX apiHost=api-ccccc.duosecurity.com
```

This example configures MFA with DUO for Guardium CLI users.

```
grdapi configure_mfa loginPath=SET_GUIUSER mfaType=DUO exemptUsers="admin, accessmgr" enable=true iKey=DINT141B9I2N91SXXXX
sKey=3gMRXVj2iQXXXX apiHost=api-ddddd.duosecurity.com
```

This example disables MFA with DUO for Guardium SSH users.

```
grdapi configure_mfa loginPath=SSH mfaType=DUO enable=false
```

GuardAPI examples with RSA SecurID

This example configures MFA for GUI users with RSA SecurID.

```
grdapi configure_mfa loginPath=GUI mfaType="RSA SecurID" exemptUsers="admin, accessmgr"
port=5555 verifySSL=false clientId=platform-vm10.mycompany.com
accessKey=t0qx4zg7agcd2gqtad414a353318i85808r428p5pbwgc33gn8381234567
apiHost=rsa88.mycompany.com enable=true
```

This example disables MFA for SSH users:

```
grdapi configure_mfa loginPath=SSH mfaType="RSA SecurID" enable=false
```

Related concepts

- [Configure multi-factor authentication](#).

configure_purge

Use this command to define a purge operation of data results on one or more Guardium® systems.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/configure_purge
```

GuardAPI syntax

```
configure_purge parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| purgeAtAge | Integer | Required. Number of days after which results data is purged. |
| purgeWithoutArchive | Boolean | Required. Determines whether or not results data that has not been archived can be purged. For results data that are archived outside of your Guardium system, set to 1. Valid values: <ul style="list-style-type: none">• 0: no• 1: yes |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To purge results data after 2 days, but only if the results have been archived:

```
grdapi configure_purge purgeAtAge=2 purgeWithoutArchive=0
```

Related tasks

- [Managing stored data](#)

Related reference

- [Archive, export, import, purge, and restore APIs](#)

configure_results_archive

Use this API to configure the results archive on one or more Guardium® systems.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/results_archive_comfiguration
```

GuardAPI syntax

```
configure_results_archive parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| accessKey | String | Required for Cleversafe; and for Amazon S3 when authType=Security-Credentials or authType=IAM-Role. Identifies user as the party responsible for service requests. It needs to be included it in each request. It is not confidential and does not need to be encrypted. (20-character, alphanumeric sequence). |
| archiveOlderThan | Integer | Required. The archive includes data older than this number of days. For example, to archive all data from yesterday and older than yesterday, set archiveOlderThan to 1. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| archiveValues | Integer | Required. Whether the archive data includes values from SQL strings. Valid values: <ul style="list-style-type: none"> 0: no. Values are replaced with question mark characters in the archive, and are not available as part of a restore operation. 1: yes |
| authType | String | Required for Amazon S3 only. Valid values: <ul style="list-style-type: none"> Security-Credentials IAM-Role IAM-Instance-Profile |
| bucketName | String | Required for Amazon S3 and Cleversafe only. The unique bucket name. |
| destHost | String | Host name of the target archive server. |
| ignoreOlderThan | Integer | Required. Together with archiveOlderThan, specifies the time interval of data to archive: data that is older than this value, in days, is not exported. |
| passwd | String | Required. Password for the target archive server. |
| passwdRetype | String | Required. Password for the target archive server. |
| port | Integer | Required. Port on the target archive server. |
| protocol | String | Required. For valid values, call configure_results_archive from the command line with --help=true. |
| region | String | Required for AmazonS3. Valid values: <ul style="list-style-type: none"> US_EAST_1 US_EAST_2 US_WEST_1 US_WEST_2 EU_CENTRAL_1 EU_WEST_1 EU_WEST_2 EU_WEST_3 EU_NORTH_1 CA_CENTRAL_1 AP_SOUTHEAST_1 AP_SOUTHEAST_2 AP_NORTHEAST_1 AP_NORTHEAST_2 SA_EAST_1 CN_NORTH_1 CN_NORTHWEST_1 AP_SOUTH_1 GovCloud US_GOV_EAST_1 |
| retention | Integer | Required for Centera only. Number of days to retain the archive data on the target archive server. |
| secretKey | String | Required for Amazon S3 and Cleversafe only. The Secret Access Key is associated with the Access Key ID, used to calculate the digital signature that needs to be included in the request. (Only the user and AWS should have this 40-character sequence.) |
| ssh_key_active | Boolean | Enables data transfer using the SSH key. Enable the SSH key feature with the CLI command store system scp-ssh-key-mode on . Generate ssh-key pairs and copy the public part of the key, public-transfer-key , to the remote host. For more information, see Enabling ssh-key pairs for data archive, data export, data mart . Valid values: <ul style="list-style-type: none"> 0: Disable 1: Enable Default = 0 |
| transferMethod | String | Required. Valid values: <ul style="list-style-type: none"> SCP FTP |
| targetDir | String | Required. The target directory on the target archive server. |
| userName | String | Required. User name for the target archive server. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To archive results older than 1 day but not older than 2 days, including the SQL strings, to an SCP server, with the username USER and password PASSW:

```
grdapi configure_results_archive archiveOlderThan=1 archiveValues=1 ignoreOlderThan=2 userName=USER passwd=PASSW  
passwdRetype=PASSW destHost=<full path to target archive host> port=<port> protocol=SCP targetDir=<directory on target archive  
server>
```

configure_results_export

This command defines the results export to Guardium® aggregators or central managers.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/configure_results_export
```

GuardAPI syntax

```
configure_results_export parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| destHost | String | Required. The target destination host name. |
| passwd | String | Required. Password for userName on the target destination host. |
| port | Integer | Required. Port on the target destination server. |
| protocol | String | Required. Valid values: <ul style="list-style-type: none">• SCP• FTP |
| ssh_key_active | Boolean | Enables data transfer using the SSH key. Enable the SSH key feature with the CLI command store system scp-ssh-key-mode on . Generate ssh-key pairs and copy the public part of the key, public-transfer-key , to the remote host. For more information, see Enabling ssh-key pairs for data archive, data export, data mart . Valid values: <ul style="list-style-type: none">• 0: Disable• 1: Enable Default = 0 |
| transferMethod | String | Required. Valid values: <ul style="list-style-type: none">• SCP• FTP |
| targetDir | String | Required. The target directory on the target destination server. |
| userName | String | Required. User name with write access for the target destination server. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To configure exporting of results older than one day, and not older than two days, using FTP, and where both username and password are admin:

```
grdapi configure_results_export destHost=<hostname of target> targetDir=<path to target directory> port=1111 userName=admin  
passwd=admin protocol=FTP
```

create_ad_hoc_audit_and_run_once

This command creates a new audit process report.

You can invoke this command automatically from any report.

When this command is invoked, it creates and runs a new audit process report. If such process for the user exists, then the parameters are updated and the same process is used. The behavior of this API is as follows:

- For a new process:
 1. The API creates one receiver per email in the sendToEmails list of the content type indicated in emailContentType.
 2. If includeUserReceiver parameter is set to true, the API also creates a user receiver for the user that is logged in
- For an existing process:
 1. All email receivers are removed and replaced with the emails from the new sendToEmails list (if any).
 2. If the list is empty, it removes all email receivers.
 3. If there is already a receiver for the user, it is not removed even if the includeUserreceiver is set to false. However if the parameter is true and there is no such receiver then it is added.

Once the audit process is generated, it is automatically executed (similar to a Run Once Now) and users should expect an item on their to-do list for that audit process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/ad_hoc_audit_and_run_once
```

GuardAPI syntax

```
create_ad_hoc_audit_and_run_once parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| changeParIfExist | Boolean | Required. Indicates whether to update the task parameters if the process exists. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| emailContentType | Integer | The type of content to send to users on the sendToEmails list. Valid values: <ul style="list-style-type: none">• 0: PDF• 1: CSV |
| includeUserReceiver | Boolean | Create a receiver for the logged-in user. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| isForReportRunOnce | Boolean | Required. Run the report once after it is created. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| processNameParam | String | If not blank, create a process with the specified name. |
| reportId | Integer | Required. The ID on the report to use for the only task in the Audit process. |
| sendToEmails | String | The email addresses of users to receive this report. A comma-separated list of email addresses. |
| taskParameter | String | All task parameters and their values concatenated with the characters ^^.
For example:

<code>PAR1=Val1^^PAR2=Val2^^</code>
You can leave a parameter empty. For example, to leave PAR2 empty: <code>PAR1=VAL1^^PAR2=^^PAR3=VAL3^^</code> |
| templateName | String | For valid values, call <code>create_ad_hoc_audit_and_run_once</code> from the command line with <code>--help=true</code> . |
| ticketAssignToGroup | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified group name or ID, and send the ticket to the external ticketing system (ServiceNow). |
| ticketAssignToMember | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified member name or ID, and send the ticket to the external ticketing system (IBM Resilient). |
| ticketAssignToUser | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified user name or ID, and send the ticket to the external ticketing system (ServiceNow). |

| Parameter | Value type | Description |
|----------------|------------|---|
| ticketReceiver | Boolean | If set to 1, add a receiver of type Ticket to the audit process result. When the audit process runs, Guardium creates a ticket and attaches the audit process result (as a PDF). Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| writeToSyslog | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |

create_ad_hoc_audit_for_security_assessment

This API creates a security assessment (and if needed, an audit process) for one or more specified datasources.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/ad_hoc_audit_for_security_assessment
```

GuardAPI syntax

```
create_ad_hoc_audit_for_security_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| datasourcesParam | String | A list of comma-separated datasource IDs. The security assessment runs all available tests of each datasource based on the datasource type. |
| includeUserReceiver | Boolean | Create a receiver for the logged-in user. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| processNameParam | String | The name of the audit process. If you do not specify an audit process name, Guardium creates the audit process and security assessment with the following names: <ul style="list-style-type: none"> • Audit process - Audit_SA_U_userId. • Security assessment - SA_U_userId. If you specify an audit process name, Guardium checks to see whether a security assessment with the same name as the audit process exists. If an audit process exists, but a security assessment does not, Guardium creates the security assessment. |
| sendToEmails | String | The type of content to send to users on the sendToEmails list. Valid values: <ul style="list-style-type: none"> • 0: PDF • 1: CSV |
| ticketAssignToGroup | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified group name or ID, and send the ticket to the external ticketing system (ServiceNow). |
| ticketAssignToMember | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified member name or ID, and send the ticket to the IBM Resilient external ticketing system. |
| ticketAssignToUser | String | If ticketReceiver is set to 1 (true), create an external ticket, assign the ticket to the specified username or ID, and send the ticket to the ServiceNow external ticketing system. |

| Parameter | Value type | Description |
|----------------|------------|---|
| ticketReceiver | Boolean | If set to 1, add a receiver of type Ticket to the audit process result. When the audit process runs, Guardium creates a ticket and attaches the audit process result (as a PDF). Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |

Example

For this example, `datasourcesPar=20000` represents the DATASOURCE_ID of an existing Guardium security assessment datasource.

```
grdapi create_ad_hoc_audit_for_security_assessment processNamePar=psa datasourcesPar=20000
sendToEmails="joan.darcy@mycompany.com" ticketReceiver=1 ticketAssignToGroup="database"
```

create_adhoc_policy_analyzer

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/create_adhoc_policy_analyzer
```

GuardAPI syntax

```
create_adhoc_policy_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| date | String | Required. |
| duration | String | Required. |
| unit | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

create_alias

Use this command to create or update a meaningful name for a data value or object in reports or queries.

Use `create_alias` to add a meaningful (or user-friendly) synonym to any of the objects listed in the `groupTypeDesc` parameter field.

For more information about using aliases, see [Aliases](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/alias
```

GuardAPI syntax

```
create_alias parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| aliasValue | String | Required. The alias for the object or data value. |
| dbValue | String | Required. The name of the database or other value for which you are creating an alias. |
| groupTypeDesc | String | Required. The type of object for which you are creating the alias. For valid values, call <code>create_alias</code> from the command line with <code>--help=true</code> . |
| overrideIfExist | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false) Default.• 1 (true)• If set to 1:<ul style="list-style-type: none">◦ If an alias does not exist for the specified object, the alias is created.◦ If the specified object already has an alias, the alias for that object is updated to the new alias name.• If set to 0, Guardium returns an error message if an alias exists for the object. |

GuardAPI example

```
grdapi create_alias aliasValue="New Central Manager" dbValue=1 groupTypeDesc="Server Hostname"
```

create_allowed_db

This command creates a User-DB association.

Note: To apply the changes to the active User-DB association map, run [update_user_db](#) after you run this command.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/allowed_db
```

GuardAPI syntax

```
create_allowed_db parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| instanceName | String | A specific instance name within the server. |
| serverIp | String | Required. The server IP. |
| userName | String | Required. The name of the user. |

Examples

```
grdapi create_allowed_db userName=Fred serverIp=192.168.1.1 instanceName=test
```

create_api_key

12.1 and later This command creates an API key for a Guardium user.

GuardAPI syntax

```
create_api_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| name | String | Required. The name of the API key must not contain the "-" character. |
| username | String | If not specified, the username is set to the logged-in user. If specified, the logged-in user must have the accessmgr role to associate the API key to the username. |

GuardAPI example

The following example shows the command to create an API key VAScanner_IT for the *admin* user.

```
grdapi create_api_key name=VAScanner_IT username=admin
```

create_api_parameter_mapping

Guardium® includes a battery of predefined reports. Many reports are mapped to GuardAPI functions to ease configuration. Use this command to define additional reports, including custom reports, and map them to GuardAPI functions for each report.

For more information about mapping GuardAPIs to domains, entities, and attributes, see [Mapping APIs to report results](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/param_mapping_for_function
```

GuardAPI syntax

```
create_api_parameter_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| attributeLabel | String | Required. An attribute within an entity. |
| domain | String | Required. One of the Guardium reporting domains such as Access, Alert, Discovered Instances, Exceptions, or Group Tracking. |
| entityLabel | String | Required. The name of the entity within the reporting domain. |
| functionName | String | Required. The API function to map. |
| parameterName | String | Required. The parameter within the API. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi create_api_parameter_mapping functionName="create_group" parameterName="desc" domain="Group Tracking"
entityLabel="Group" attributeLabel="Group Description"
```

Related concepts

- [Mapping APIs to report results](#)

create_assessment

This command adds a security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/assessment
```

GuardAPI syntax

```
create_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|---|
| assessmentDescription | String | Required. A unique variable to describe the assessment. |
| processName | String | |

Example

```
grdapi create_assessment assessmentDescription=Assess1
```

create_autodetect_process

Use this command to create an auto-discovery process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/autodetect_processes
```

GuardAPI syntax

```
create_autodetect_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| check_ICMP_echo | Boolean | Required. Whether or not Nmap sends an ICMP echo request. PE parameter to nmap. This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| host_timeout | Integer | Required. Timeout value, in seconds, for determining how long Guardium waits for a probe response before giving up or retransmitting the probe. This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. |
| process_name | String | Required. Name of the auto-discovery process |
| run_probe_after_scan | Boolean | Required. Determines whether or not to run a probe job immediately after the scan job completes. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| use_dns | String | Required. This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. Valid values: <ul style="list-style-type: none"> <i>true</i>: always <i>false</i>: never <i>n</i>: never <i>R</i>: always |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> <i>all_managed</i>: execute on all managed units but not the central manager <i>all</i>: execute on all managed units and the central manager <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To create a process named myProcess in the Guardium system on which you enter the command:

```
grdapi create_autodetect_process process_name=myProcess check_ICMP_echo=false host_timeout=3 run_probe_after_scan=false
use_dns=n
```

create_aws_secrets_manager_config

Use this command to create an AWS secrets configuration for your authentication scenario. You can create a configuration using security credentials, IAM role, or IAM instance profile.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/aws_secrets_manager
```

GuardAPI syntax

```
create_aws_secrets_manager_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| access_key_id | String | |
| auth_type | String | Required. Valid values: <ul style="list-style-type: none"> <i>Security-Credentials</i> <i>IAM-Role</i> <i>IAM-Instance-Profile</i> |
| name | String | Required. |
| role_arn | String | The Role Amazon Resource Name (ARN) |
| secret_access_key | String | |
| secret_key_password | String | The Secret key label for the password |
| secret_key_username | String | The Secret key label for the username |

Examples

Create an AWS secrets configuration using security credentials

```
grdapi create_aws_secrets_manager_config name="GRDAPI Security-Credentials" auth_type="Security-Credentials"  
access_key_id="home_markdown_jenkins_workspace_Transform_in_SSMPHH_12.x_com.ibm.guardium.doc.reference_grdapi_create_aws_secre  
ts_manager_config_ABCD123" secret_access_key="XYZ321" secret_key_password="password" secret_key_username="username"
```

Create an AWS secrets configuration using IAM role

```
grdapi create_aws_secrets_manager_config name="GRDAPI IAM-Role" auth_type="IAM-Role"  
access_key_id="home_markdown_jenkins_workspace_Transform_in_SSMPHH_12.x_com.ibm.guardium.doc.reference_grdapi_create_aws_secre  
ts_manager_config_ABCD123" secret_access_key="XYZ321"  
role_arn="arn:aws:iam::123456789:role/AWS_Secret_ManagerReadWrite_role" secret_key_password="password"  
secret_key_username="username"
```

Create an AWS secrets configuration using IAM instance profile

```
grdapi create_aws_secrets_manager_config name="GRDAPI IAM-Instance-Profile1" auth_type="IAM-Instance-Profile1"  
secret_key_password="password" secret_key_username="username"
```

create_cas_host_instance

Creates a Configuration Auditing System (CAS) host instance. Each host instance can define one or more CAS instances, which specify a CAS template set, and defines the parameters that are needed to connect to the database.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cas_host_instance
```

GuardAPI syntax

```
create_cas_host_instance parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| datasourceName | String | Required. The data source to use for this host instance. |
| templateSetLabel | String | Required. The name of the template set to associate with the host. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

REST API example

To create a CAS host instance associated with the `cas_temp_set_001` template set:

```
curl -k --header "Authorization:Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3" -i -X  
POST -d '{"datasourceName":"DB_for_CAS","templateSetLabel":"cas_temp_set_001"}'  
https://localhost:8443/restAPI/cas_host_instance
```

Related concepts

create_cas_template

This command creates a Configuration Auditing System (CAS) template item. A template, or template item is a specific file or file pattern, environment or registry variable, the output of an OS or SQL script, or a list of logged-in users.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cas_template
```

GuardAPI syntax

```
create_cas_template parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| auditType | String | Required. The type of item to monitor. Valid values: <ul style="list-style-type: none">• ENV_VAR: Environment variable• FILE• FILE_PAT: File pattern• OS_SCRIPT: OS script• REG_VAR: Registry variable• REG_PAT: Registry variable pattern• SQL query |
| enabled | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): The template is enabled after you create it. |
| isEditable | Boolean | This template can be modified. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): This template can be modified. |
| period | Integer | The number of minutes between tests. |
| saveData | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Previous versions of the item can be compared with the current version. |
| template | String | Required. The name of this template. |
| templateSetLabel | String | Required. The name of the template set to associate with this template. |
| useMD5 | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Guardium uses the MD5 algorithm to calculate a checksum and compare the latest value with the value calculated the last time that the item was checked. Default = 0 |

REST API example

To add a CAS template to a CAS template set:

```
curl -k --header "Authorization: Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3" -i -X  
POST -d  
'{"auditType":"File","template":"$DB2_HOME/sqlLIB/db2nodes.cfg","templateSetLabel":"cas_temp_set_001","saveData":true}'  
https://localhost:8443/restAPI/cas_template
```

create_cas_template_set

This command creates a template set for the Configuration Auditing System (CAS).

A CAS template set contains a list of item templates that are bundled together. Each CAS template set shares a common purpose such as monitoring a particular type of database (such as Oracle on UNIX). A database template set is always specific to both the database type and the operating system type.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cas_template_set
```

GuardAPI syntax

```
create_cas_template_set parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| dbType | String | Required. The database type.
If you enter a database type that is not supported (or you misspell it), Guardium displays a list of supported DBs. If the template set does not require a specific DB type, specify N_A. |
| isDefault | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): This template set is the default. |
| isEditable | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): This template set can be modified. |
| osType | String | Required. The operating system type can be either: <ul style="list-style-type: none">• UNIX: UNIX• WIN: Windows |
| templateSetLabel | String | Required. The name of this template set. |

REST API Example

To create a CAS template set for Db2 on UNIX:

```
curl -k --header "Authorization:Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3" -i -X POST -d '{"dbType":"DB2","osType":"UNIX","templateSetLabel":"cas_temp_set_001"}' https://localhost:8443/restAPI/cas_template_set
```

Related concepts

create_classifier_action

This command creates classification actions.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_action
```

GuardAPI syntax

```
create_classifier_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|---------------------|------------|---|
| accessPolicy | String | |
| accessRuleAction | String | |
| actionName | String | Required. |
| actionType | String | Required. For valid values, call <code>create_classifier_action</code> from the command line with <code>--help=true</code> . |
| actualMemberContent | String | |
| commandsGroup | String | |
| description | String | |
| excludeObjectGroup | String | |
| includeField | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| includeServerIP | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| notificationType | String | |
| objectFieldGroup | String | |
| objectGroup | String | |
| policyName | String | Required. |
| privacySet | String | |
| receiver | String | |
| replaceGroupContent | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| ruleDescription | String | |
| ruleName | String | Required. |
| SchemaGroup | String | |
| severity | String | |

create_classifier_document_rule

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_document_rule
```

GuardAPI syntax

```
create_classifier_document_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|------------|---|
| calculateConfidenceScore | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| category | String | Required. For valid values, call <code>create_classifier_document_rule</code> from the command line with <code>--help=true</code> . |
| classification | String | Required. |
| collectionNameLike | String | |
| collectionTypeCollection | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 1 (true)</p> |

| Parameter | Value type | Description |
|--------------------------------|------------|---|
| collectionTypeView | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| compareToValuesInGroup | String | |
| compareToValuesInSQL | String | |
| continueOnMatch | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| continueWithUnmatchedFieldOnly | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| dataTypes | String | |
| description | String | |
| evaluationName | String | |
| excludeCollection | String | |
| excludeCollectionField | String | |
| excludeDatabaseName | String | |
| fieldNameLike | String | |
| fireOnlyWithMarker | String | |
| hitPercentage | Integer | |
| policyName | String | Required. |
| ruleName | String | Required. |
| ruleType | String | Required. For valid values, call <code>create_classifier_document_rule</code> from the command line with <code>--help=true</code> . |
| searchExpression | String | |
| searchLike | String | |
| showUniqueValues | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| skipEmptyNull | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| uniqueValueMask | String | |

create_classifier_policy

This command creates classification policies.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_policy
```

GuardAPI syntax

```
create_classifier_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| category | String | Required. For valid values, call <code>create_classifier_policy</code> from the command line with <code>--help=true</code> . |
| classification | String | Required. |
| description | String | |
| policyName | String | Required. |

Examples

```
grdapi create_classifier_policy policyName=access_policy classification=class1 description="Access policy" category=Access
```

create_classifier_process

This command creates classification processes.

Use **create_classifier_process** after creating a classification policy and datasource.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_process
```

GuardAPI syntax

```
create_classifier_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| comprehensive | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| datasourceGroups | String | |
| datasourceNames | String | |
| datasourceType | String | Valid values: <ul style="list-style-type: none">• DOCUMENT• RELATIONAL Default = RELATIONAL |
| includeInternalTables | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false)

Enabling includeInternalTables indicates that you want to scan internal system databases and schema used by the database software provider. Internal system databases and schema are unlikely to contain sensitive data and are not scanned by default. When including internal tables, verify that the classifier datasource user has sufficient privileges to scan the internal databases and schema. Insufficient privileges may result in unexpected classification policy errors.

To view and edit the databases and schema impacted by the includeInternalTables parameter, use the Group Builder to edit one of the predefined Excluded Classification groups. |
| policyName | String | Required. |
| processName | String | Required. |
| sampleSize | Integer | |

Examples

```
grdapi create_classifier_process datasourceNames=sample_cls_0001 policyName=APITEST_Cls_Ply_10001_1  
processName=APITEST_Clps_10001_1
```

create_classifier_rule

This command creates classification rules.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

POST https://[Guardium hostname or IP address]:8443/restAPI/classifier_rule

GuardAPI syntax

```
create_classifier_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------------------|------------|--|
| calculateConfidenceScore | Boolean | Calculate a confidence score. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| category | String | Required. For valid values, call create_classifier_rule from the command line with --help=true. |
| classification | String | Required. |
| columnNameLike | String | |
| compareToValuesInGroup | String | |
| compareToValuesInSQL | String | |
| continueOnMatch | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| continueWithUnmatchedColumnsOnly | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| dataTypes | String | |
| description | String | |
| evaluationName | String | |
| excludeSchemaName | String | |
| excludeTable | String | |
| exclude TableColumn | String | |
| fireOnlyWithMarker | String | |
| hitPercentage | Integer | |
| maxLength | Integer | |
| minLength | Integer | |
| policyName | String | Required. |
| ruleName | String | Required. |
| ruleType | String | Required. For valid values, call create_classifier_rule from the command line with --help=true. |
| searchExpression | String | |
| searchLike | String | |
| showUniqueValues | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| skipEmptyNull | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| tableNameLike | String | |
| tableTypeSynonym | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| tableTypeSystemTable | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| tableTypeTable | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|--|
| tableTypeView | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| uniqueValueMask | String | |

create_cloudTitle

This API creates or defines a cloud service account.

Use `create_cloudTitle` to create or define a cloud database service account from the command line or by using a REST API. For more information, see [Cloud database service protection](#).

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/create_cloud_datasource
```

GuardAPI syntax

```
create_cloudTitle parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|---|
| access_key_id | String | The access key ID supplied by your cloud service provider. |
| audit_type | String | Valid values: <ul style="list-style-type: none">• <i>dataStream</i>• <i>native</i> Defines the audit type: <ul style="list-style-type: none">• To use data streams, specify <i>dataStream</i>.• To use native audit, specify <i>native</i>. |
| auth_type | String | Required for Amazon only. Valid values: <ul style="list-style-type: none">• <i>Security-Credentials</i>• <i>IAM-Role</i>• <i>IAM-Instance-Profile</i> |
| classification_process | String | For native audit only, optionally specify a classification process. |
| name | String | Required. An account name that is unique to your site. |
| object_limit | Integer | For native audit only, specify the maximum number of objects that are found in the classification process that are added automatically to the list of audited objects. |
| provider | String | Valid values: <ul style="list-style-type: none">• <i>Amazon</i>• <i>Azure</i> |
| role_arn | String | For Amazon only, the Amazon resource name (ARN) for this role. |
| secret_access_key | String | The secret access key ID supplied by your cloud service provider. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

create_cloud_datasource

This command creates a cloud datasource, for classification, vulnerability assessment, and object auditing on cloud databases (cloud database service protection).

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cloud_datasource
```

GuardAPI syntax

```
create_cloud_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| application | String | Required. The application type to be used with this data source. For valid values, call <code>create_cloud_datasource</code> from the command line with <code>--help=true</code> . |
| cloudTitle | String | Required. Name of a cloud account already defined in Guardium. For valid values, call <code>create_cloud_datasource</code> from the command line with <code>--help=true</code> .
For more information, see create_cloudTitle . |
| compatibilityMode | String | The mode used when monitoring a table. |
| conProperty | String | Use only if additional connection properties must be included on the JDBC URL to establish a JDBC connection with this data source. The required format is <code>property=value</code> , where each property and value pair is separated by a comma. |
| customURL | String | Connection string to the data source. If not provided the connection is made by using the host, port, instance, and other properties of the previously entered fields. You can, for example, use this method to create Oracle Internet Directory (OID) connections. |
| cyberarkConfigName | String | The name of the CyberArk configuration on your Guardium system. For valid values, call <code>create_cloud_datasource</code> from the command line with <code>--help=true</code> . |
| cyberarkObjectName | String | The CyberArk object name for the Guardium datasource. |
| dbInstanceAccount | String | Database Account Login Name that is used by the Configuration Auditing System (CAS). |
| dbInstanceDirectory | String | Directory where database software is installed that is used by CAS. |
| dbName | String | For a Db2® or Oracle data source, enter the schema name. For others, enter the database name. |
| description | String | Longer description of the data source. |
| externalPasswordType | String | For valid values, call <code>create_cloud_datasource</code> from the command line with <code>--help=true</code> . |
| host | String | Required. The hostname or the IP address of the server that is hosting the DB you are monitoring. |
| importServerSSLcert | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| KerberosConfigName | String | Name of Kerberos configuration already defined in Guardium system. |
| name | String | Required. A unique name for the data source in the Guardium system. |
| objectLimit | Integer | Required. The maximum number of sensitive objects found in the classification process that are added automatically to the list of audited objects. Default = 20. |
| password | String | Password for user. |
| port | Integer | Port number. |
| primaryCollector | Integer | The collector that extracts the audit data from the cloud database. |
| region | String | Required for AWS only. For valid values, call <code>create_cloud_datasource</code> from the command line with <code>--help=true</code> . |
| savePassword | Boolean | Saves and encrypts your authentication credentials on the Guardium appliance. Required if you are defining a data source with an application that runs as a scheduled task (as opposed to on demand). When set to yes, login name and password are required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| serviceName | String | Required for Oracle, Informix®, Db2, and IBM® i. For a Db2 data source, enter the database name; for others, enter the service name. |

| Parameter | Value type | Description |
|---------------------|------------|---|
| severity | String | Severity Classification (or impact level) for the data source. For valid values, call create_cloud_datasource from the command line with <code>--help=true</code> . |
| shared | String | Set to <code>true</code> or <code>Shared</code> to share with other applications. To share the data source with other users, you need to assign roles from the GUI. Valid values: <ul style="list-style-type: none"> <code>Shared</code> <code>Not Shared</code> <code>true</code> <code>false</code> |
| type | String | Required. Identifies the data source type. For valid values, call create_cloud_datasource from the command line with <code>--help=true</code> . |
| useExternalPassword | Boolean | Valid values: <ul style="list-style-type: none"> <code>0</code> (false) <code>1</code> (true) |
| useKerberos | Boolean | Set to yes to use Kerberos authentication. If yes, KerberosConfigName must be supplied. Valid values: <ul style="list-style-type: none"> <code>0</code> (false) <code>1</code> (true) |
| useLDAP | Boolean | Set to yes to use LDAP. Valid values: <ul style="list-style-type: none"> <code>0</code> (false) <code>1</code> (true) |
| user | String | User for the data source. If used, password must also be used. |
| useSSL | Boolean | Set to yes to use SSL authentication. Valid values: <ul style="list-style-type: none"> <code>0</code> (false) <code>1</code> (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> <code>all_managed</code>: execute on all managed units but not the central manager <code>all</code>: execute on all managed units and the central manager <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

This example defines a cloud data source that is named cloud9, associated with cloud account NYSW, by using the access policy application.

```
grdapicreate_cloud_datasource cloudTitle=nysw application="Access Policy" host=11.11.11.11 name=cloud9 primaryCollector=coll56
region=ca-central-1 type="Oracle (DataDirect - SID)"
```

Related concepts

create_computed_attribute

This API creates a custom attribute that is calculated based on a specified expression. The computed attribute is then available for reporting.

To help prevent an SQL injection attack, the following words and characters are not allowed in computed attributes:

ALTER, CREATE, DELETE, DROP, INSERT, TRUNCATE, UPDATE, semicolon (;), double-dash (--), or slash-asterisk /*)

To replace the disallowed characters, you can use the MySQL char function. For example, say that you want to create a computed attribute that includes a semicolon. The API call that includes a semicolon:

```
grdapicreate_computed_attribute
attributeLabel="app_user" entityLabel="Access Period"
expression="SUBSTRING_INDEX(APP_USER_NAME,';',1)"
```

Returns the following error:

```
create_computed_attribute:
ERR=2410
```

Error Creating New Computed Attribute - Invalid Expression Or expression includes not allowed characters

To correct the example, use the MySQL char function (where 59 is the code for a semicolon):

```
grdapi create_computed_attribute  
attributeLabel="app_user" entityLabel="Access Period"  
expression="SUBSTRING_INDEX(APP_USER_NAME,char(59),1)"
```

Which returns the following information:

```
ID=20000  
Attribute for Expression SUBSTRING_INDEX(APP_USER_NAME,char(59),1) Created
```

The char() equivalents are shown in [Table 1](#).

Table 1. MySQL character equivalents

| Character | MySQL char() |
|---------------------|---------------|
| ; (semicolon) | char (59) |
| -- (double dash) | char (45, 45) |
| /* (slash asterisk) | char (47, 42) |

This API is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/computed_attribute
```

GuardAPI syntax

```
create_computed_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| attributeLabel | String | Required. The name of the computed attribute, which appears in reports. |
| entityLabel | String | Required. The name of the main entity with which the attribute is associated, for example Session, Object, or FULL_SQL. |
| expression | String | Required. An SQL expression to generate the computed value for the new attribute. |

Examples

To create a computed attribute called app_user associated with the Access Period entity:

```
grdapi create_computed_attribute  
attributeLabel="app_user" entityLabel="Access Period"  
expression="SUBSTRING_INDEX(APP_USER_NAME,char(59),1)"
```

To create an Oracle_OS_user attribute associated with the Session entity:

```
grdapi create_computed_attribute  
attributeLabel="Oracle_OS_User" entityLabel="Session"  
expression="SUBSTRING_INDEX( SUBSTRING(REPLACE(UID_CHAIN,' ',''),1,LENGTH(REPLACE(UID_CHAIN,' ','')) - LOCATE('lqsi',REVERSE(REPLACE(UID_CHAIN,' ','')))-4),' ',1)"
```

create_constant_attribute

Defines a custom attribute that has a constant value.

This API is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/constant_attribute
```

GuardAPI syntax

```
create_constant_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| attributeLabel | String | Required. The name of the attribute, which appears in reports. |
| constant | String | Required. The value of this attribute, which can be any constant value. |
| entityLabel | String | Required. The name of the main entity with which the attribute is associated, for example Session, Object, or FULL_SQL. |

create_custom_table_ldap_import

This command configures a custom table to import data from LDAP.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/custom_data_ldap
```

GuardAPI syntax

```
create_custom_table_ldap_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------------------------|--|
| activateSchedule | Boolean-Constant values list | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| attributeMapping | String | Required. |
| baseDN | String | Required. |
| clearTable | Boolean-Constant values list | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| cronString | String | |
| filter | String | |
| filterScope | String | Valid values: <ul style="list-style-type: none">• one-level• sub-tree |
| hostName | String | Required. |
| importLimit | Integer | |
| password | String | |
| port | Integer | Required. |

| Parameter | Value type | Description |
|-----------------|-------------------------------------|---|
| serverType | String | Required. Valid values: <ul style="list-style-type: none"> • Active Directory • Novell Directory • Open LDAP • Sun ONE Directory • z/OS Security Server • Tivoli Directory |
| startDate | Date | |
| tableName | String | Required. |
| userName | String | |
| useSSL | Boolean-
Constant values
list | Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

create_cyberark_config

This command configures the CyberArk application IDs on your Guardium system. Obtain the application IDs, corresponding safe names, and folder names from your CyberArk administrator.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cyberark
```

GuardAPI syntax

```
create_cyberark_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| applicationId | String | Required. This is a unique variable that is created on CyberArk. |
| folderName | String | Required. The name of the folder where the CyberArk safe is located. |
| name | String | Required. The name that is used to configure the Guardium datasource to access the CyberArk vault. |
| safeName | String | Required. The name of the CyberArk safe that is assigned to the <code>applicationId</code> . |

create_datasource

Use this command to define new on-premises datasources.

Important: In a centrally-managed environment, datasources must be defined on the central manager. Datasources that are created on managed units cannot be seen or used.

For more information about creating a datasource in the cloud, see [create_cloud_datasource](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

POST https://[Guardium hostname or IP address]:8443/restAPI/datasource

GuardAPI syntax

create_datasource parameter=value

Parameters

| Parameter | Value type | Description |
|-----------------------------|------------|--|
| application | String | Required. For valid values, call create_datasource from the command line with --help=true. |
| awsSecretsManagerConfigName | String | For Amazon Web Services (AWS) systems only. This parameter is needed when authentication is externally managed by the AWS secrets manager.
For valid values, call create_datasource from the command line with --help=true. |
| compatibilityMode | String | Valid values: <ul style="list-style-type: none">• Default• MSSQL 2000
Set the compatibility mode to use when monitoring a table. |
| conProperty | String | Define conProperty if additional connection properties are needed on the JDBC URL to establish a JDBC connection with this datasource.
For a Sybase database with a default character set of Roman8, enter the following property: charset=utf8 |
| customProps | String | |
| customURL | String | Define the connection string to the datasource. By default, the connection is made using host, port, instance, and other defined datasource parameters. This is useful, for example, when creating Oracle Internet Directory (OID) connections. |
| cyberarkConfigName | String | The name of the CyberArk configuration on your Guardium system. For valid values, call create_datasource from the command line with --help=true. |
| cyberarkObjectName | String | The CyberArk object name for the Guardium datasource. |
| dbInstanceAccount | String | Database account login name used by CAS. |
| dbInstanceDirectory | String | Directory where database software is installed that will be used by CAS. |
| dbName | String | The schema name for a Db2 or Oracle database. Otherwise, provide the database name. |
| description | String | Description of the datasource. |
| externalPasswordType | String | For valid values, call create_datasource from the command line with --help=true. |
| hashicorpChildNamespace | String | |
| hashicorpConfigName | String | The name of the HashiCorp configuration on your Guardium® system. For valid values, call create_datasource from the command line with --help=true. |
| hashicorpPath | String | The custom path to access the datasource credentials. |
| hashicorpRole | String | The role name for the datasource. |
| host | String | Host name or IP address of the database. |
| importServerSSLcert | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| KerberosConfigName | String | Name of the Kerberos configuration already defined in the Guardium system. |
| name | String | Required.
A unique name for the datasource on the Guardium system. |
| password | String | Database user password. |
| port | Integer | Database port number. |
| region | String | For AWS only. For valid values, call create_datasource from the command line with --help=true. |
| savePassword | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 1 (true)

Save and encrypt database authentication credentials on the Guardium system. This is required if you are defining a datasource with an application that runs as a scheduled task, for example scheduled classification scans. When enabled, name and password parameters are required. |
| secretName | String | |
| serviceName | String | Required for Oracle, Informix, Db2, and IBM i. For a Db2 database, provide the database name. Otherwise, provide the service name. |
| severity | String | Severity classification (or impact level) for the datasource.
For valid values, call create_datasource from the command line with --help=true. |

| Parameter | Value type | Description |
|---------------------|------------|--|
| shared | String | <p>Valid values:</p> <ul style="list-style-type: none"> • <i>Shared</i>: share the datasource with other applications • <i>Not Shared</i> • <i>true</i>: share the datasource with other applications • <i>false</i> <p>To share the datasource with other users, assign roles from the GUI.</p> |
| type | String | Required. The type of datasource. For valid values, call <code>create_datasource</code> from the command line with <code>--help=true</code> . |
| useExternalPassword | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • <i>0</i> (false) • <i>1</i> (true) |
| useKerberos | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • <i>0</i> (false) • <i>1</i> (true) <p>Enable to use Kerberos authentication. If enabled, <code>KerberosConfigName</code> is required.</p> |
| useLDAP | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • <i>0</i> (false) • <i>1</i> (true) <p>Enable to use LDAP.</p> |
| user | String | Database user name. If defined, password is required. |
| useSSL | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • <i>0</i> (false) • <i>1</i> (true) <p>Enable to use SSL authentication.</p> |
| walletZip | String | |

Examples

```
grdapi create_datasource type=DB2 name=chickenDB2 password=guardium user=db2inst1 dbName=dn0chick application=Access_policy
shared=true port=50000 host=chicken.corp.com
```

create_datasourceRef_by_id

This command creates a datasource reference for a specific object of a specific application type. The datasource, object, and application type are referenced by identification keys.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref_by_id
```

GuardAPI syntax

```
create_datasourceRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| appId | Integer | <p>Required. Identifies the application type.
Valid values:</p> <ul style="list-style-type: none"> • 8 (security assessment) • 47 (custom tables) • 51 (classifier) |
| dataSourceId | Integer | Required. Identifies the datasource by its identification key. |
| objId | Integer | Required. Identifies an instance of the specified appId type. For example, if <code>appId=51</code> , <code>objId</code> is the identification key of a classification process. |

Examples

```
grdapi create_datasourceRef_by_id appId=51 dataSourceId=20000 objId=2
```

create_datasourceRef_by_name

This command creates a datasource reference for a specific object of a specific application type. The datasource, object, and application type are referenced by name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref_by_name
```

GuardAPI syntax

```
create_datasourceRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| application | String | Required. Identifies the application type. For valid values, call <code>create_datasourceRef_by_name</code> from the command line with <code>--help=true</code> . |
| datasourceName | String | Required. Identifies the datasource by its name. |
| objName | String | Required. Identifies an instance of the specified application type. For example, if <code>application=Classifier</code> , <code>objName</code> is the name of a specific classification process. |

Examples

```
grdapi create_datasourceRef_by_name application=Classifier datasourceName=swanSybase objName="class process1"
```

create_datasource_custom_property

This command defines a custom property for your datasource.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop
```

GuardAPI syntax

```
create_datasource_custom_property parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| name | String | Required. |
| values | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Example

The following command creates the custom property called "Business Unit". "Retail", "Banking", "Consulting", and "Mortgage" are the associated values.

```
grdapi create_datasource_custom_property name="Business Unit" values="Retail, Banking, Consulting, Mortgage"
```

create_datasource_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
create_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| appTypeCriteria | String | For valid values, call <code>create_datasource_group</code> from the command line with <code>--help=true</code> . |
| customPropsCriteria | String | A list of datasource custom properties on which to filter datasources that belong to the group. |
| dbTypeCriteria | String | For valid values, call <code>create_datasource_group</code> from the command line with <code>--help=true</code> . |
| groupName | String | Required. The name of the group. |
| groupType | String | Required. Valid values: <ul style="list-style-type: none">• <i>DYNAMIC</i>• <i>STATIC</i> |
| hostCriteria | String | Host name criteria on which to filter datasources for this group. |
| severityCriteria | String | Valid values: <ul style="list-style-type: none">• <i>ALL</i>• <i>INFO</i>• <i>NONE</i>• <i>LOW</i>• <i>MED</i>• <i>HIGH</i> |
| userCriteria | String | User name criteria on which to filter datasources for this group. |

create_datasource_groupRef_by_id

Create datasource groups in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
create_datasource_groupRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| appId | Integer | Required. For valid values, call <code>create_datasource_groupRef_by_id</code> from the command line with <code>--help=true</code> . |
| datasourceGroupId | Integer | Required. The datasource group ID in the <code>DATASOURCE_GROUP</code> table. |
| objId | Integer | Required. The object ID of the security assessment, discovery scenario, or custom table. |

create_datasource_groupRef_by_name

Create datasource groups in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
create_datasource_groupRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| application | String | Required. For valid values, call <code>create_datasource_groupRef_by_name</code> from the command line with <code>--help=true</code> . |
| datasourceGroupName | String | Required. The name of the datasource group. |
| objName | String | Required. The object ID of the security assessment, discovery scenario, or custom table. |

create_db_user_mapping

This command helps maintain the mapping between database users (that is, invokers of SQL that causes a violation) and email addresses for real-time alerts.

You can use wildcards as follows:

- `serverIp`: You can use the percent sign (%) as a wildcard instead of the character for any element in the IP address. For example, the following addresses are valid:
 - 192.168.2.%
 - 2620:1f7:807:%:920:%However, the following example is not valid: 192.%
- `serviceName`: Wildcards (%) are allowed.
- `dbUserName`: Wildcards are not valid. The % sign is not a special character.
- `emailAddress`: Wildcards are not valid. The % sign is not a special character.

Note: For `delete_db_user_mapping` and `list_db_user_mapping`, you can use the % wildcard for all parameters.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/db_user_mapping
```

GuardAPI syntax

```
create_db_user_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dbUserName | String | Required. The DB username. |
| emailAddress | String | Required. For real-time alerts, the email address that maps to the DB user. The at symbol (@) is required. |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi create_db_user_mapping serverIp=192.168.1.% serviceName=ora1 dbUserName=hadrian emailAddress=hadrian.swall@company.com
```

create_ef_mapping

This command creates an external feed mapping and populates tables based on a specified report.

Each mapping has a name stored in EF_MAP_TYPE_HDR.EF_TYPE_DESC, and that name is identical to the value of the reportName parameter. The target table name is also based on the reportName parameter, with underscores added between the words. For example, the report *My Report* becomes *MY_REPORT*.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/create_ef_mapping
```

GuardAPI syntax

```
create_ef_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| reportName | String | Required. Name of the report to use for external feed mapping. This parameter also determines the name of the mapping and the target table name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to create a mapping for the *Sessions per Day* report:

```
grdapi create_ef_mapping reportName="Sessions per Day"
```

create_entry_location

This command adds an archive catalog entry to the catalog location table.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/entry_location
```

GuardAPI syntax

```
create_entry_location parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| entryType | String | Required. The type of archive file. Valid values: <ul style="list-style-type: none">• CollectorDataArchive• AggDataArchive• AggResultArchive |
| fileName | String | Required. The name of the archive file in one of these formats: <ul style="list-style-type: none">• <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.dbdump.enc• <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.agg.<sql ver>.tar.gc.enc |
| hostName | String | Required. The hostname or IP address. |
| password | String | The user's password. <ul style="list-style-type: none">• Amazon S3: Secret Access Key• IBM COS: Secret Access Key• IBM Cloud: X-Auth-Key |
| path | String | Required. The path to the archive directory. <ul style="list-style-type: none">• Amazon S3: bucket name• IBM COS: bucket name• EMC Centera: Centera clipID• FTP: Specify the directory relative to the FTP account home directory.• SCP: Specify the directory as an absolute path.• IBM Cloud: Container• TSM: path |
| processDesc | String | Required when the entryType = AggResultArchive. |
| retention | Integer | The number of days to keep the entry in the catalog.
Default = 365 |
| storageSystem | String | Required. The type of archive storage system. For valid values, call create_entry_location from the command line with --help=true . |
| user | String | The user account to access the host. <ul style="list-style-type: none">• Amazon S3, Cleversafe: Access Key ID• Softlayer: X-Auth-User <p>Attention: For storageSystem type FTP, the user value cannot include any of the following characters: ! " \$ & ' () ; \ </p> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI Example

```
grdapic create_entry_location entryType=CollectorDataArchive  
fileName=733392-a1.corp.com-w20071223.133546-d2007-12-27.dbdump.enc password=somePassword  
user=someUser path=/var/dump/ hostName=192.168.1.241 storageSystem=scp
```

create_fam_rule

This command creates a FAM rule. Each rule defines a set of conditions, and an action that is taken by Guardium® when the rule matches.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/famPolicyRule
```

GuardAPI syntax

```
create_fam_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| actionName | String | Required. The action taken when the rule criteria are met. Valid values: <ul style="list-style-type: none">• <i>Alert and audit</i>: Send an alert directly generated from the sniffer with specific behavior, and log the event.• <i>Audit only</i>: Log the event in GDM tables• <i>Block, log violation, and audit</i>: Block access to the object, log a policy violation, and log the event. A blocking action requires an alert configuration as well.• <i>Ignore</i>: No action taken.• <i>Log as violation and audit</i>: Log this as a policy violation and log the event. |
| alertReceiver | String | Recipient of the alert: any user of the appliance, for example admin. |
| classDestination | String | Name of the custom class to be invoked. For valid values, call <code>create_fam_rule</code> from the command line with <code>--help=true</code> . |
| command | String | The command name to be matched. If not specified, all file system commands are counted as a match. For valid values, call <code>create_fam_rule</code> from the command line with <code>--help=true</code> . |
| commandGroup | String | Name of the group of commands to be matched. Either <code>commandGroup</code> or <code>commandGroupId</code> must be specified. |
| commandGroupId | Integer | ID of the group of commands to be matched. Either <code>commandGroup</code> or <code>commandGroupId</code> must be specified. |
| filePath | String | File path to be monitored, or excluded from monitoring. See <code>notfilePath</code> . Either <code>filePath</code> or <code>filePathGroup</code> must be specified. |
| filePathGroup | String | Group of file paths to be monitored, or excluded from monitoring. See <code>notfilePath</code> . Either <code>filePath</code> or <code>filePathGroup</code> must be specified. |
| includeSubDirectory | String | Required. Whether or not files in subdirectories are included or not. Valid values: <ul style="list-style-type: none">• <i>yes</i>: include files in all subdirectories• <i>no</i>: do not include files in subdirectories |
| messageTemplate | String | Message template name. For valid values, call <code>create_fam_rule</code> from the command line with <code>--help=true</code> . |
| notfilePath | String | Required. Valid values: <ul style="list-style-type: none">• <i>yes</i>: apply this rule to all files except those in the specified path, either <code>filePath</code> or <code>filePathGroup</code>• <i>no</i>: apply this rule to all files in the specified path, either <code>filePath</code> or <code>filePathGroup</code> |
| notificationType | String | Notification type. Valid values: <ul style="list-style-type: none">• <i>MAIL</i>• <i>SNMP</i>• <i>CUSTOM</i>• <i>SYSLOG</i> |
| notOSUser | String | Required. Valid values: <ul style="list-style-type: none">• <i>yes</i>: evaluate this FAM rule for all users except the specified <code>osUser</code> or <code>osUserGroup</code>.• <i>no</i>: evaluate this FAM rule for all users. |
| osUser | String | The OS user to whom this rule applies. If <code>osUser</code> or <code>osUserGroup</code> are unspecified, then the rule applies to all users (except root). |
| osUserGroup | String | The group of OS user names to whom this rule applies. If <code>osUser</code> or <code>osUserGroup</code> are unspecified, then the rule applies to all users (except root). |
| policyName | String | Required. Name of policy to which this rule is added. For valid values, call <code>create_fam_rule</code> from the command line with <code>--help=true</code> . |
| removableMedia | String | Required. Include removable media when evaluating criteria. Valid values: <ul style="list-style-type: none">• <i>yes</i>• <i>no</i> |
| ruleName | String | Required. A unique rule name. |
| serverHost | String | Host name to monitor. Use <code>x.x.x.x</code> to monitor all servers. Either <code>serverHost</code> or <code>serverHostGroup</code> must be specified. |
| serverHostGroup | String | Guardium group of server hostnames to monitor. Either <code>serverHost</code> or <code>serverHostGroup</code> must be specified. |

Examples

```
grdapi create_fam_rule policyName=policy1 ruleName=rule1 serverHost="x.x.x.x" filePath="/famtest/*" command="DELETE"  
actionName="Alert and Audit" notificationType="SYSLOG"
```

create_group

This command defines a group.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
create_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| appid | String | Required. For valid values, call <code>create_group</code> from the command line with <code>--help=true</code> . |
| category | String | A category is an optional label that is used to group policy violations and groups for reporting. |
| classification | String | A classification is an optional label that is used to group policy violations and groups for reporting. |
| desc | String | Required. Enter a unique description for the new group. |
| hierarchical | String | Valid values: <ul style="list-style-type: none">• <i>true</i>• <i>false</i> |
| tuple_parameters | String | Required. Valid values: <ul style="list-style-type: none">• <i>client_ip</i>• <i>client_host_name</i>• <i>server_ip</i>• <i>server_host_name</i>• <i>source_program</i>• <i>db_name</i>• <i>db_user</i>• <i>service_name</i>• <i>app_user_name</i>• <i>os_user</i>• <i>db_type</i>• <i>net_protocol</i>• <i>command</i>• <i>server_port</i>• <i>sender_ip</i>• <i>server_description</i>• <i>analyzed_client_ip</i>• <i>incident</i>• <i>session</i>• <i>client_os_name</i>• <i>server_os_name</i>• <i>db_prototype</i>• <i>field_name</i>• <i>error_code</i> |
| type | String | Required. For valid values, call <code>create_group</code> from the command line with <code>--help=true</code> . |

Examples

Use this command to create a *public OBJECTS* group named *A public group*:

```
grdapi create_group desc="A public group" type=OBJECTS appid=Public
```

create_hashicorp_config

This command creates a HashiCorp configuration on your Guardium® system.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/hashicorp
```

GuardAPI syntax

```
create_hashicorp_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| AuthType | String | Required. For valid values, call <code>create_hashicorp_config</code> from the command line with <code>--help=true</code> . |
| name | String | Required. The name of the HashiCorp configuration. |
| namespace | String | |
| password | String | The username. |
| username | String | The password. |
| useTLS | Boolean | Transport Layer Security (TLS) with server-side or client-side authentication.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| vaultHostName | String | Required. The vault hostname. |
| vaultPortNumber | Integer | Required. The port number. |

Examples

This example creates a configuration with a username and password with no Transport Layer Security (TLS):

```
grdapi create_hashicorp_config AuthType="Username & Password" name="No TLS User and password API" username="apps" password="guardium" useTLS="false" vaultHostName="hostname" vaultPortNumber="8300"
```

This example creates a configuration with TLS server authentication:

```
grdapi create_hashicorp_config AuthType="Username & Password" name="TLS User and password API" username="apps" password="guardium" useTLS="true" vaultHostName="hostname" vaultPortNumber="8500"
```

This example creates a configuration with TLS client authentication. The username and password is not required:

```
grdapi create_hashicorp_config AuthType="TLS Certificates" name="TLS Client Cert API" useTLS="true" vaultHostName="hostname" vaultPortNumber="8200"
```

create_hierarchical_member_to_group_by_desc

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/hierarchical_member
```

GuardAPI syntax

```
create_hierarchical_member_to_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| desc | String | Required. |
| member | String | Required. |

create_kafka_cluster

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/kafka_cluster
```

GuardAPI syntax

```
create_kafka_cluster parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| clusterName | String | Required. |
| memberList | String | Required
For valid values, call create_kafka_cluster from the command line with --help=true. |

create_member_to_group_DAMX_Standard_Activity

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
create_member_to_group_DAMX_Standard_Activity parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| member | String | Required. |

create_member_to_group_DAMX_Suspicious_Connections

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
create_member_to_group_DAMX_Suspicious_Connections parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| member | String | Required. |

create_member_to_group_by_desc

Add a member to a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/group_member
```

GuardAPI syntax

```
create_member_to_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| desc | String | Required. Identifies the group by its description. |
| member | String | Required. The group member name, which must be unique within the group. The group member name might be a tuple, that is, a single composite group member formed of multiple attributes. For more information, see Tuple groups . |

Examples

Use this command to add the group member *turkey* to the group "A group":

```
grdapi create_member_to_group_by_desc desc="A group" member=turkey
```

Use this command to add a group member to the group "A group". For this group, a 5-tuple member is required:

```
grdapi create_member_to_group_by_desc desc="A group" member=10.0.1.1+SrcApp+DBUser2+%+SvcName+OSUser2+%
```

Related concepts

- [Groups Overview](#)

create_member_to_group_by_id

Add a member to a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/group_member_by_group_id
```

GuardAPI syntax

```
create_member_to_group_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| id | Integer | Required. Identifies the group by its identification key. |
| member | String | Required. The group member name, which must be unique within the group. The group member name might be a tuple, that is, a single composite group member formed of multiple attributes. For more information, see Tuple groups . |

Examples

Use this command to add the group member *turkey* to the group with identification key *100005*:

```
grdapi create_member_to_group_by_id id=100005 member=turkey
```

Use this command to add a group member to the group with identification key *100005*. For this group, a 5-tuple member is required:

```
grdapi create_member_to_group_by_id id=100005 member=10.0.1.1+SrcApp+DBUser2+%+SvcName+OSUser2+%
```

create_online_report

This command creates an ad hoc online report in JSON format.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/online_report
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| reportName | String | Required. For valid values, call <code>create_online_report</code> from the command line with <code>--help=true</code> . |
| indexFrom | Integer | |
| inputTZ | String | For valid values, call <code>create_online_report</code> from the command line with <code>--help=true</code> . |
| reportParameter | String | |
| fetchSize | Integer | |
| sortColumn | String | |
| sortType | String | |
| showAll | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| showIndirect | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

Example

The following example creates an online Installed Policy Details report to find the currently installed policy:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/online_report \
{"reportName":"Installed Policy Details","indexFrom":"1", \
"reportParameter": {""QUERY_FROM_DATE" :"NOW -1 DAY", \
"QUERY_TO_DATE" :"NOW +1 HOUR", "REMOTE_SOURCE": "%"}}
```

create_policy

This command creates a new policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/policy
```

GuardAPI syntax

```
create_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| baselineDesc | String | |
| categoryName | String | An existing data or file policy. For valid values, call <code>create_policy</code> from the command line with <code>--help=true</code> . |

isFam

Boolean

Determines whether this policy is for file access monitoring. Valid values:

- 0 (false): This is a data access monitoring policy.
- 1 (true): This is a file access monitoring policy.

Default = 0 (false)

For more information, see [Using rules for file activity policies](#).

| Parameter | Value type | Description |
|-----------------|------------|---|
| logFlat | Boolean | Determine whether to use the flat log option for this policy. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false)
For more information, see Log flat . |
| pattern | String | A regular expression to match. For more information, see Pattern in Rule definition fields . |
| policyLevel | String | Valid values: <ul style="list-style-type: none">• REGULAR• SESSION• FAM• FAM_SP• FAM_NAS• 0• 1• 2• 3• 4 Default = REGULAR |
| ruleSetDesc | String | Required. The name of this policy. |
| rulesOnFlat | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false)
For more information, see Rules on flat . |
| securityPolicy | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

create_qr_action

This command creates a query rewrite action for a specified query rewrite definition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_action
```

GuardAPI syntax

```
create_qr_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | Required. The unique name of the query rewrite action. |
| definitionName | String | Required. The query rewrite definition that is associated with this action. |
| description | String | Text description of the action. |

Examples

To create a query rewrite action "qr action15_3" associated with the definition "case 15":

```
grdapicreate_qr_action definitionName="case 15" actionPerformed="qr action15_3"
```

Related concepts

create_qr_add_where

This command associates a query rewrite function to add a WHERE condition to the specified query rewrite action.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_add_where
```

GuardAPI syntax

```
create_qr_add_where parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| actionName | String | Required. The unique name of the query rewrite action. |
| addQualifierFlag | Boolean | Valid values: <ul style="list-style-type: none">• 0(false)• 1(true) Default = 1 (true) |
| definitionName | String | Required. The query rewrite definition that is associated with this action. |
| whereText | String | Text to add to a WHERE clause. |

Examples

To add a WHERE clause of "id=2" to the query rewrite definition "qrw_def_Oracle_1" and action name "qrw_act__addwhere_id2":

```
grdapicreate_qr_add_where definitionName="qrw_def_Oracle_1" actionPerformed="qrw_act__addwhere_id2" whereText="id=2"
```

Related concepts

- [Query rewrite](#)

create_qr_add_where_by_id

This command associates a query rewrite function to add a WHERE condition to the specified query rewrite action, where the action is specified by its ID.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/create_qr_add_where_by_id
```

GuardAPI syntax

```
create_qr_add_where_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| addQualifierFlag | Boolean | Valid values: <ul style="list-style-type: none">• 0(false)• 1(true) Default = 1 (true) |
| qrActionId | Long | Required. The unique ID of query rewrite action. |
| whereText | String | Text to add to a WHERE clause. |

Examples

To add a WHERE clause of id=2 to the action whose ID is 10002:

```
grdapi create_qr_add_where_by_id qrActionId=10002 whereText="id=2"
```

Related concepts

create_qr_condition

This command creates a query rewrite condition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_condition
```

GuardAPI syntax

```
create_qr_condition parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| conditionName | String | Required. The unique name of this query rewrite condition. |
| definitionName | String | Required. The query rewrite definition that is associated with this condition. |
| depth | Integer | Integer that specifies the depth of the parsed SQL that this condition applies to (1 and higher). The default -1 means that the query rewrite condition applies to any matching SQL at any depth. |
| isForAllRuleObjects | Boolean | Use this parameter to associate this condition with objects in a policy access rule. The default is false, which means neither option impacts any rule triggering behavior. Valid values: <ul style="list-style-type: none">• 0: False. the query condition is specified using the objects that are defined in this condition.• 1: True. The specified condition applies to all objects in the access rule's Object field or Object group for a fired rule. |
| isForAllRuleVerbs | Boolean | Use this parameter to associate this condition with objects in a policy access rule. The default is false, which means neither option impacts any rule triggering behavior. Valid values: <ul style="list-style-type: none">• 0: False. The query condition is specified using the verbs that are defined in this condition.• 1: True. The specified condition applies to all verbs in the access rule's Verb field or Verb group for a fired rule. |
| isObjectRegex | Boolean | Indicates that the specified object is specified by using a regular expression. Default is false. Valid values: <ul style="list-style-type: none">• 0: False• 1: True |

| Parameter | Value type | Description |
|-------------|------------|--|
| isVerbRegex | Boolean | Indicates that the specified verb is specified by using a regular expression. Default is false. Valid values: <ul style="list-style-type: none">• 0: False• 1: True |
| object | String | An object (table, view). The default "*" means all objects. This can also be specified as a regular expression, in which case set the isVerbRegex to True. |
| order | Integer | Specifies the order in which to assemble multiple related query rewrite conditions for complex SQL. Default is 1. |
| verb | String | A verb (select, insert, update, delete). The default "*" means all verbs. |

Examples

To create a query rewrite condition with the definition name "case 15" and condition name qr cond15_3, the verb SELECT, valid for any object, parsed down 2 levels:

```
grdapicreate_qr_condition definitionName="case 15" conditionName="qr cond15_3" verb=select object=* depth=2
```

create_qr_definition

This command creates a query rewrite definition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_definition
```

GuardAPI syntax

```
create_qr_definition parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| dataBaseType | String | Required. The type of database this query rewrite definition is associated with. For valid values, call create_qr_definition from the command line with --help=true . |
| definitionName | String | Required. A unique name for this query rewrite definition condition. |
| description | String | Textual description. |
| isNegateQrCond | Boolean | Specifies if there is a NOT flag on the set of query rewrite conditions that are associated with this definition. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| sampleSql | String | |

Examples

To create a query rewrite condition named case 15, for Oracle databases:

```
grdapicreate_qr_definition dataBaseType="ORACLE" definitionName="case 15"
```

create_qr_replace_element

This command creates a replacement element, or set of elements, such as an entire SQL sentence or a SELECT list.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/qr_replace_element
```

GuardAPI syntax

```
create_qr_replace_element parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| actionName | String | Required. The unique name of the query rewrite action this rewrite function is associated with. |
| columnAlias | String | Specify an alias for a column name. |
| definitionName | String | Required. A unique name for this query rewrite definition condition. |
| isFromAllRuleElements | Boolean | Indicates that this action applies to all FROM elements. Valid values: <ul style="list-style-type: none">• 0: False• 1: True Default is false. |
| isFromRegex | Boolean | Indicates that the 'from' element is specified by using a regular expression. Valid values: <ul style="list-style-type: none">• 0: False• 1: True Default is false. |
| isReplaceToFunction | Boolean | Indicates that the "replace to" is the name of a function, such as user-defined function. Valid values: <ul style="list-style-type: none">• 0: False• 1: True |
| replaceFrom | String | Required. The incoming string for a matching rule that is to be replaced. Use replaceType to indicate specifically which element of the incoming query to examine. |
| replaceTo | String | Required. The replacement string for the matching element. |
| replaceType | String | Required. Indicates what is to be replaced. For valid values, call create_qr_replace_element from the command line with --help=true. |

Examples

```
grdapi create_qr_replace_element definitionName="case 15" actionName="qr_action15_2" replaceType=VERB replaceFrom="select" replaceTo="select++"
```

Related concepts

- [Query rewrite](#)

create_qr_replace_element_byId

This command creates a replacement specification for a specified query rewrite action.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/create_qr_replace_element_byId
```

GuardAPI syntax

```
create_qr_replace_element_byId parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| columnAlias | String | Specify an alias for a column name. |
| isFromAllRuleElements | Boolean | Indicates that this action applies to all FROM elements. Valid values: <ul style="list-style-type: none">• 0: False• 1: True Default is false. |
| isFromRegex | Boolean | Indicates that the "from" element is specified by using a regular expression. Valid values: <ul style="list-style-type: none">• 0: False• 1: True Default is false. |
| isReplaceToFunction | Boolean | Indicates that the "replace to" is the name of a function, such as user-defined function. Valid values: <ul style="list-style-type: none">• 0: False• 1: True |
| qrActionId | Long | Required. The unique ID of query rewrite action. |
| replaceFrom | String | Required. The incoming string for a matching rule that is to be replaced. Use replaceType to indicate specifically which element of the incoming query to examine. |
| replaceTo | String | Required. The replacement string for the matching element. |
| replaceType | String | Required. Indicates what is to be replaced. For valid values, call create_qr_replace_element_byId from the command line with --help=true. |

Examples

```
grdapicreate_qr_replace_element_byId qrActionID="1116" replaceType=OBJECT replaceFrom="employee" replaceTo="employee_2"
```

create_quarantine_allowed_until

This command sets parameters to prevent a user from logging in after a specified length of time passes.

This API is available in Guardium® V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/quarantine_allowed_until
```

GuardAPI syntax

```
create_quarantine_allowed_until parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| allowedUntil | String | Required. The date and time to begin the quarantine in one of the following formats: <ul style="list-style-type: none">• YYYY-MM-DD hh:mm:ss• A relative time (such as NOW +1 HOUR) For more information about relative time, see Relative to NOW . |
| dbUser | String | Required. The name of the database user to quarantine. |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| type | String | Required. If the database is not IBM Z® or IMS, specify <i>normal</i> . Valid values: <ul style="list-style-type: none">• <i>normal</i>• <i>DB2Z</i>• <i>IMS</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

The following command starts the quarantine for this user to start 1 hour after the command is called:

```
grdapi create_quarantine_allowed_until allowedUntil="NOW +1 HOUR" dbUser="Hadrian.Swall" serverIp="9.32.0.255" serviceName="company.ibm.com" type="normal"
```

create_quarantine_until

This command sets parameters to prevent a user from logging in until a specified time.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/quarantine_until
```

GuardAPI syntax

```
create_quarantine_until parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dbUser | String | Required. The name of the database user to quarantine. |
| quarantineUntil | String | Required. The date and time to end the quarantine in one of the following formats: <ul style="list-style-type: none">• YYY-MM-DD hh:mm:ss• A relative time (such as NOW +1 HOUR) For more information about relative time, see Relative to NOW . |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |
| type | String | Required. If the database is not IBM Z® or IMS, specify <i>normal</i> . Valid values: <ul style="list-style-type: none">• <i>normal</i>• <i>DB2Z</i>• <i>IMS</i> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

The following command ends the quarantine for this user 1 hour after the command is called:

```
grdapi create_quarantine_until quarantineUntil="NOW +1 HOUR" dbUser="Hadrian.Swall" serverIp="9.32.0.255"
serviceName="company.ibm.com" type="normal"
```

create_role

This command creates a role on a stand-alone or central manager system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/create_role
```

GuardAPI syntax

```
create_role parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| roleName | String | Required. |

GuardAPI example

```
grdapi create_role roleName test_role
```

Related concepts

- [Understanding roles](#)

create_rule

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/rule
```

GuardAPI syntax

```
create_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| category | String | For valid values, call create_rule from the command line with --help=true. |
| classification | String | |
| fromPolicy | String | Required. |
| order | Integer | |
| ruleDesc | String | Required. |
| ruleLevel | String | |
| ruleType | String | Required. For valid values, call create_rule from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

create_rule_action

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/rule_action
```

GuardAPI syntax

```
create_rule_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|-------------|
| actionLevel | String | |
| actionName | String | Required. |
| actionParameters | String | |
| alertUserLoginName | String | |
| classDestination | String | |
| fromPolicy | String | Required. |
| messageTemplate | String | |
| notificationType | String | |
| paramSeparator | String | |
| ruleDesc | String | Required. |

create_sql_configuration

This command defines the connection between an S-TAP® and an Oracle server used for Oracle unified auditing.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/create_sql_configuration
```

GuardAPI syntax

```
create_sql_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| dbType | String | Required. The type of data repository being monitored. Valid value: <ul style="list-style-type: none">• Oracle |
| instance | String | Required. String that specifies the connection identifier in the tnsnames.ora that is used to connect to the database. |
| dataPullInterval | String | Time, in seconds, between attempts to pull data from the database.
Default=30 |
| dataPullRows | String | Number of rows of auditing data to pull in a single pass.
Default=100 |
| stapHost | String | Required. For valid values, call create_sql_configuration from the command line with --help=true. |
| timeout | String | Time, in seconds, to allow the database to respond.
Default=300000 |
| username | String | Required. Username for logging in to the Oracle DB. |
| userRole | String | Role for logging in to the Oracle DB. Valid values <ul style="list-style-type: none">• ''• sysdba• sysoper Default = '' |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

create_stap_inspection_engine

This command adds an inspection engine to the specified S-TAP®. S-TAP configurations can be modified only from the active Guardium® host for that S-TAP, and only when the S-TAP is online.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/inspection_engine
```

GuardAPI syntax

```
create_stap_inspection_engine parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|---|
| client | String | Restricts S-TAP to monitor traffic only from the specified sets of IP address and mask pairs, by using a list of addresses in IP address/mask format: n.n.n.n/m.m.m.m. If an improper IP address/mask is entered, the S-TAP does not start. Valid values: <ul style="list-style-type: none">• User-defined list• 0.0.0.0/0.0.0.0,::/0: select all clients.• 127.0.0.1/255.255.255.255,::1/0: local traffic only Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously. If the value of this parameter is not configured correctly, the value is replaced by the default value. |
| connectToIp | String | IP address for S-TAP to use to connect to the database. Some databases accept local connection only on the real IP address of the Guardium system, and not on the default (127.0.0.1,::1). When K-TAP is enabled, this parameter is used for Solaris zones and AIX® WPARs. Set it to the zone IP address to capture traffic. |
| db2SharedMemAdjustment | Integer | Required when Db2® is selected as the database type, and shared memory connections are monitored. The offset to the server's portion of the shared memory area. Offset to the beginning of the Db2 shared memory packet, depends on the Db2 version: 32 in pre-8.2.1, and 80 in 8.2.1 and higher. |

| Parameter | Value type | Description |
|--|------------|---|
| db2SharedMemClientPosition (DB2® only) | Integer | <p>The offset to the client's portion of the shared memory area. Required when Db2 is selected as the database type, and shared memory connections are monitored. Linux: Use the script <code>find_db2_shmem_parameters.sh</code> to find the value. The script is located in <code>stap_directory/bin</code>, and outputs what the Db2 shared memory parameters that are defined in the Inspection Engines should be. Run it either as root or Db2 user, by using the syntax: <code>find_db2_shmem_parameters.sh <instance name></code>. You can run it from any directory.</p> <p>Windows: The client offset can be calculated by taking the value of the Db2 parameter ASLHEAPSZ and multiplying by 4096 to get the appropriate offset. The default for this parameter is 61440 decimal. This parameter is calculated by taking the Db2 database configuration value of ASLHEAPSZ and multiplying by 4096. To get the value for ASLHEAPSZ, run <code>runexec</code> the following Db2 command: <code>db2 get dbm cfg</code> and look for the value of ASLHEAPSZ. This value is typically 15, which yields the 61440 default. If it's not 15, take the value and multiply by 4096 to get the appropriate client offset.</p> |
| db2SharedMemSize | Integer | Db2 shared memory segment size. Required when Db2 is selected as the database type, and shared memory connections are monitored. |
| dbInstallDir (Linux only) | String | <ul style="list-style-type: none"> Db2, Informix®: The full path name for the database installation directory. Db2 exit and Informix exit: value must be the same as the \$HOME value in the database (or \$Db2_HOME for Db2 Exit); otherwise tap_identifier does not function properly. Oracle: Database owner HOME directory. It must match db_base in the ATAP configuration. See Oracle-specific guardctl parameters. All other database types: NULL. |
| dbUser | String | OS username (case-sensitive) of the owner of the DB server process (for example, oracle). This parameter specifies which user is allowed to use the db_request_handler socket. It is required if you are not using the user root. If set to an invalid value, A-TAP cannot access the socket to retrieve permission for accessing K-TAP. In this case, it requires authorization with a group membership to log decrypted traffic to K-TAP (by using the <code>guardctl authorize-user</code> command). You can define a comma-separated string of multiple users. |
| dbVersion | String | The database version. The string must start with a numeral and not a letter. |
| encryption (Linux only) | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> 0: Unencrypted 1: Encrypted <p>Default = 0 (false)</p> <p>Activate ASO or SSL encrypted traffic for Oracle (versions 11 and 12) and Sybase on Solaris, HPUX, and AIX.</p> <p>For Oracle, specify db_version in the <code>guard_tap.ini</code> file (for example, <code>db_version=12</code>)</p> <p>For Oracle12 SSL, instrument on all platforms. For Oracle11 SSL, instrument on AIX.</p> <p>For any Oracle requiring instrumentation, if you are using encryption=1 in the <code>guard_tap.ini</code> (which is not supported on Linux®), you must instrument before setting that parameter.</p> <p>Some DBs require restart after enabling encryption.</p> <p>When using GIM to configure the S-TAP, <code>GIM_ROOT_DIR</code> must be set to the absolute path to the modules, for example <code>/usr/local/guardium/modules</code></p> |
| excludeClient | String | A list of client IP addresses and corresponding masks that are excluded from monitoring. Use this option to configure the S-TAP to monitor all clients, except for a certain client or subnet (or a collection thereof). Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously. |
| ieIdentifier | String | Used to distinguish inspection engines from one another. If unspecified, Guardium auto-populates the field with a unique name that uses the database type and sequence number. |
| informixVersion | Integer | Informix version. |
| instanceName (Windows only) | String | The name of the database instance on this server. Required for MS SQL Server that uses encryption; MS SQL Server that uses Kerberos Authentication; Db2 Exit traffic collection; Db2 SHM traffic. (Default is MSSQLSERVER.) |
| interceptTypes (Linux only) | String | DO NOT change this parameter unless it is absolutely necessary. Protocol types that are intercepted by the IE. Valid values: <ul style="list-style-type: none"> NULL: auto intercepts all protocols the Database supports Comma-separated list: IE intercepts these protocol types only. |
| ktapDbPort (Linux only) | String | With K-TAP and PCAP, identifies the database port or range of ports to be monitored. For exit libraries, use its value for db_home. |
| namedPipe (Windows only) | String | Specifies the named pipe that is used by MS SQL Server local access. If a named pipe is used, but nothing is specified in this parameter, S-TAP attempts to retrieve the named pipe name from the registry. |
| portMax | String | For monitoring network traffic only, the highest numbered port on which to listen for database traffic. |
| portMin | String | For monitoring network traffic only, the lowest numbered port on which to listen for database traffic. Together with portMax, this parameter defines the range of ports that are monitored for this database instance. Usually the range contains only a single port. For a Kerberos inspection engine, set the start and end values to 88-88. If a range is used, do not include extra ports in the range. Extra ports might result in excessive resource consumption while the S-TAP attempts to analyze unwanted traffic.
Examples:
To monitor range 1521-1525 (five ports) with no port forwarding: <ul style="list-style-type: none"> portMin=1521 portMax=1525 ktapDbPort=1521 To monitor range 2000-2004 (5 ports) where network port 2000 is mapped to local port 1521: <ul style="list-style-type: none"> portMin=2000 portMax=2004 ktapDbPort=1521 |

| Parameter | Value type | Description |
|------------------------------|------------|---|
| priorityCount | Integer | <p>Reduces the instances of a blank DB_USER or ? in the tables. At session creation, the first priority_count packets are marked with a high priority flag and are transferred to a special high priority queue on the collector. Valid values:</p> <ul style="list-style-type: none"> • 0: Disabled • Protocol 7: 1-2048: Number of packets • Protocol 8: positive integer: Number of packets <p>Default = 20</p> |
| procName (Linux only) | String | <p>The value of this parameter depends on whether it's in an exit, and whether there is A-TAP.</p> <ul style="list-style-type: none"> • Exit libraries: see Configuring Exit libraries • With A-TAP: see Database-specific guardctl parameters • Without A-TAP: The full path name for the database executable. For example: <ul style="list-style-type: none"> ◦ Oracle: /\$ORACLE_HOME/bin/oracle ◦ Informix: /INFORMIXTMP/.inf.sqlexec. Applies to all Informix platforms but Linux. ◦ Informix with Linux, example: /home/informix11/bin/oninit ◦ MYSQL: mysql |
| procNames (Windows only) | String | Database service executables that are to be monitored. For example, a Db2 IE would be TAP_DB_PROCESS_NAMES=Db2SYSCS.EXE. For Oracle or MS SQL Server only, when named pipes are used. For Oracle, the list usually has two entries: oracle.exe,tnslsnr.exe. For MS SQL Server, the list is usually one entry: sqlservr.exe. |
| protocol | String | Required. The type of data repository that is monitored.
Linux-UNIX: ASTERDB, Cassandra, CockroachDB, CouchDB, Db2, Db2 Exit, ElasticSearch, exclude IE, FTP, GreenplumDB, HADOOP, HIVE, HP-Vertica, HTTP, HUE, IMPALA, Informix, Informix Exit, KERBEROS, MariaDB, MemSQL, MongoDB, Mysql, Netezza®, Oracle, PostgreSQL, REDIS, SAP Hana, Sybase, Teradata, Teradata Exit, WebHDFS, Windows File Share
Windows: ASTER, Cassandra, CouchDB, Db2, Db2 Exit, exclude IE, FTP, GreenplumDB, HIVE, HTTP, HUE, IMPALA, Informix, Informix Exit, MariaDB, MongoDB, MSSQL, Mysql, Oracle, PostgreSQL, Sybase, Teradata, WebHDFS, Windows File Share. |
| stapHost | String | Required. The host name or IP address of the database server on which the S-TAP is installed. |
| teeListenPort | String | Deprecated. Replaced by the parameter real_db_port when the K-TAP monitoring mechanism is used. |
| teeRealPort | String | Deprecated. |
| unixSocketMarker(Linux only) | String | Specifies UNIX domain sockets marker for Oracle, MySQL, and Postgres. Usually the default is correct, but when the named pipe or UNIX domain socket traffic does not work then you need to make sure that this value is set correctly. For example, for Oracle, set unix_domain_socket_marker to the KEY of IPC defined in tnsnames.ora. If it is NULL or not set, the S-TAP uses defined default markers identified as: * MySQL - "mysql.sock" * Oracle - "./oracle/" * Postgres - ".s.PGSQL.5432" |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To create an inspection engine on an MYSQL database with IP 127.0.0.1:

```
grdapicreate_stap_inspection_engine connectToIp=127.0.0.1 db2SharedMemAdjustment=80 db2SharedMemClientPosition=0
db2SharedMemSize=131072 procName=/home/mysql57/mysql/bin/mysql dbInstallDir=/home/mysql57 protocol=Mysql dbUser=mysql
encryption=0 dbVersion=9
```

create_test_detail_exception

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/test_detail_exception
```

GuardAPI syntax

```
create_test_detail_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| assessmentDesc | String | |
| assessmentScope | String | |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | |
| datasourceType | String | |
| detailExceptionValue | String | Required. |
| exceptionType | String | Required. Valid values: <ul style="list-style-type: none">• <i>text</i>• <i>regex</i>• <i>0</i>• <i>1</i> |
| explanation | String | Required. |
| fromDate | String | |
| testDescription | String | Required. |
| toDate | String | Required. |

create_test_exception

This command adds records to the vulnerability assessment test exceptions.

If a test on a specific datasource fails, it checks the last record of the test exceptions table for that test and datasource. If the execution date is contained within the to and from dates of the last record, the test is set to PASS, the recommendation is set to the explanation from the exceptions record, and the result text is set as follows:

Test passed, based on exception approved by: effective from date to date.

The API only adds records to remove an exception. A new record should be created with new dates as needed.

This GuardAPI is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/test_exception
```

GuardAPI syntax

```
create_test_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| assessmentDesc | String | |
| assessmentScope | String | |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | |
| datasourceType | String | For valid values, call <code>create_test_exception</code> from the command line with <code>--help=true</code> . |
| explanation | String | Required. A recommendation as to why the test passes. |
| fromDate | String | |
| testDescription | String | Required. A valid test name within Security Assessments. |
| toDate | String | |

Examples

```
grdapi create_test_exception datasourceName=ORAPROD5 testDescription="CVE-2009-0997" fromDate="2012-07-01 08:00:00"  
toDate="2012-07-31 08:00:00" explanation="Currently in testing stage"
```

create_update_wkc_config

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/wkc
```

GuardAPI syntax

```
create_update_wkc_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------------|------------|--|
| action | String | Valid values: <ul style="list-style-type: none">• <code>allow</code>• <code>deny</code> |
| awsRegion | String | For valid values, call <code>create_update_wkc_config</code> from the command line with <code>--help=true</code> . |
| awsSecretManager | String | For valid values, call <code>create_update_wkc_config</code> from the command line with <code>--help=true</code> . |
| awsSecretName | String | |
| cacheSize | Integer | |
| cachetTL | Integer | |
| columnAlias | String | Valid values: <ul style="list-style-type: none">• <code>COLUMN_NAME</code>• <code>NONE</code>• <code>SHORT_UDF</code> |
| cyberarkConfig | String | For valid values, call <code>create_update_wkc_config</code> from the command line with <code>--help=true</code> . |
| cyberarkObject | String | |
| enableWkc | Boolean | Valid values: <ul style="list-style-type: none">• <code>0</code> (false)• <code>1</code> (true) Default = <code>1</code> (true) |
| hashicorpConfig | String | For valid values, call <code>create_update_wkc_config</code> from the command line with <code>--help=true</code> . |
| hashicorpPath | String | |
| hashicorpRole | String | |
| logLevel | Integer | |
| persistentCache | Boolean | Valid values: <ul style="list-style-type: none">• <code>0</code> (false)• <code>1</code> (true) Default = <code>1</code> (true) |
| persistentCacheMaxEntries | Integer | |
| persistentCacheMaxFiles | Integer | |
| persistentCacheTTL | Integer | |
| units | String | |
| userScope | String | Valid values: <ul style="list-style-type: none">• <code>dbuser</code>• <code>appuser</code> |
| wkcURI | String | |
| wkcUser | String | |
| wkcUserPwd | String | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

create_user

Add a user to your Guardium® system.

Users are created with the `user` role. Use the [set user roles](#) API to change or add other roles.

Note: Before a user can access the GuardAPIs with one of the default CLI accounts (guardcli1,...guardcli9), you must authenticate them by using the set guiluser CLI command. For more information, see [User account, password, and authentication CLI Commands](#).
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/user
```

GuardAPI syntax

```
create_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| confirmPassword | String | Required. Confirm the password. The confirmPassword must match the value of Password. |
| country | String | The ISO 3166 2-letter country code for this user, such as US or ES. For valid values, call <code>create_user</code> from the command line with <code>--help=true</code> . |
| disabled | Boolean | <p>Enables or disables this user. Valid values:</p> <ul style="list-style-type: none"> • 0 (false): The user is enabled. • 1 (true): The user is disabled. <p>Default = 0 (enabled)</p> |
| disablePwdExpiry | Boolean | <p>Enables or disables the requirement that a user to reset their password the first time they log in.</p> <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false): A user must reset their password on first login. • 1 (true): The password does not expire on first login. <p>Default = 0 (false)</p> |
| email | String | |
| firstName | String | Required. |
| lastName | String | Required. |
| password | String | Required. The password must be at least 8 characters long and include at least one of each: <ul style="list-style-type: none"> • An uppercase letter (A-Z) • A lowercase letter (a-z) • A number (0-9) • A special character, which can be: at sign (@), hashtag (#), dollar sign (\$), percent sign (%), caret (^), ampersand (&), asterisk (*), exclamation (!), hyphen (-), underscore (_), plus (+), or equals (=). |
| smartCardUserName | String | Common name in the certificate.
Enter the smart card user name when smart card authentication is turned on. |
| userName | String | Required. A username for this user.
The following characters are not allowed in usernames : semicolon (;), forward slash (/), dollar sign (\$), and percent sign (%). |

Examples

For example, the following API creates a user with the username Fred McDerf:

```
grdapi create_user firstName=Fred lastName=McDerf password=Furball123!
confirmPassword=Furball123! userName="Fred McDerf" disabled=false
```

Sample output:

```
ID=20001
ok
```

create_user_hierarchy

This command creates a relationship between a user and parent in the user data security hierarchy.

Note: An error occurs if the insert is circular (that is, a parent reports to a child).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/user_hierarchy
```

GuardAPI syntax

```
create_user_hierarchy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| parentUserName | String | Required. The name of the parent user. |
| userName | String | Required. The name of the user with a relationship to the parent user. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi create_user_hierarchy parentUserName=AdminManager userName=Admin1
```

datamart_copy_file_bundle

This command creates and manages data mart bundles for user-defined and predefined file data marts.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_copy_file_bundle
```

GuardAPI syntax

```
datamart_copy_file_bundle parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| action | String | Required. Valid values: <ul style="list-style-type: none">• <i>create</i>: creates a bundle• <i>delete</i>: deletes a bundle• <i>include</i>: adds a data mart to a bundle• <i>exclude</i>: removes a data mart from a bundle• <i>info</i>: returns details on a bundle |
| bundle_name | String | Required for all actions. Name of the bundle. |
| datamart_name | String | Required when action=include or exclude. The name of the data mart. |
| main_datamart_name | String | Required when action=create. The name of the main data mart. The main data mart must have the latest scheduled extraction time of all the data marts in the bundle, so that it can include all the other data marts' latest extracts. |

Examples

This example creates a bundle named DMbundle33, with a main data mart of Export:Access Log.

```
datamart_copy_file_bundle action=create bundle_name=DMbundle33 main_datamart_name="Export:Access Log"
```

This example adds the Export:Outliers List data mart to the bundle DMbundle33.

```
datamart_copy_file_bundle action=include bundle_name= datamart_name="Export:Outliers List"
```

datamart_include_file_header

This command controls whether the header line (column names) are included in the output CSV of a user-defined and predefined file data mart.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_include_file_header
```

GuardAPI syntax

```
datamart_include_file_header parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| includeFileHeader | String | Required. Valid values: <ul style="list-style-type: none">• Yes• No |
| Name | String | Required. Data mart name. |

Examples

This command enables the file header on the data mart Export:Exception Log.

```
grdapi datamart_include_file_header Name=Export:Exception Log includeFileHeader=Yes
```

Related concepts

datamart_refresh_metadata

Run this command to transfer data mart metadata from the central manager to the specified managed unit.

Data mart metadata is saved on a central manager and propagated to its managed units during the user synchronization job, which runs every 30 minutes by default. If, for example, you configured the data mart to send data to the external server by running `grdapip datamart_update_copy_file_info`. Now you want to run the data mart itself on one of the managed units, to extract data and send it to the target external server. But the server information is not there yet. Run this command `grdapip datamart_refresh_metadata` to transfer this information to this specific unit, so that you can successfully run the data mart.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_refresh_metadata
```

GuardAPI syntax

```
datamart_refresh_metadata parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| unit_hostname | String | Required. Guardium hostname or IP address. |

Examples

To send data mart metadata to the managed unit with IP 9.9.9.9:

```
grdapip datamart_refresh_metadata unit_hostname=9.9.9.9
```

Related concepts

- [Data mart](#)

datamart_run_once_now

This command runs the specified datamart, once, starting when you run the command.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_run_once_now
```

GuardAPI syntax

```
datamart_run_once_now parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|-------------|
| datamart_name | String | Required. |

Examples

To run the data mart Export:Full SQL:

```
grdapic datamart_run_once_now datamart_name="Export:Full SQL"
```

Related concepts

- [Data mart](#)

Related reference

datamart_set_active

This command activates extraction of the specified datamart.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_set_active
```

GuardAPI syntax

```
datamart_set_active parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------------------------|
| Name | String | Required. A defined data mart |

Examples

To activate the datamart Export:Full SQL:

```
datamart_set_active name="Export:Full SQL"
```

Related concepts

- [Data mart](#)

- [Data mart APIs](#)

datamart_set_date_format

Use this command if the default date format of a user-defined or predefined export datamart does not meet the requirements of your target server.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_set_date_format
```

GuardAPI syntax

```
datamart_set_date_format parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|--------------------------------|
| datamart_name | String | Required. |
| new_date_format | String | Required. New date format. |
| old_date_format | String | Required. Current date format. |

Examples

To change the date format to %Y-%m-%dT%TZ:

```
grdapi datamart_set_date_format datamart_name="Export:Full SQL" old_date_format="%Y-%m-%dT%T" new_date_format="%Y-%m-%dT%TZ"
```

Related concepts

- [Data mart](#)

datamart_set_inactive

This command de-activates extraction of the specified data mart.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_set_inactive
```

GuardAPI syntax

```
datamart_set_inactive parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---------------------------|
| Name | String | Required. Data mart name. |

Examples

To deactivate the data mart Export:Full SQL:

```
datamart_set_inactive name="Export:Full SQL"
```

Related concepts

- [Data mart](#)

Related reference

datamart_update_copy_file_info

This command modifies a user-defined and predefined file data mart export.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_update_copy_file_info
```

GuardAPI syntax

```
datamart_update_copy_file_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| destinationHost | String | Required. Hostname of target server. |
| destinationPass word | String | Required if you are using a username and password for authentication. Password for the user specified by destinationUser. |
| destinationPath | String | Required. Path to location to store the data mart extraction. |
| destinationPort | String | Required. The port number for the destination. |
| destinationUser | String | Required. User with write access to the destination path. |
| failoverDestinationHost | string | If the export to destinationHost fails, then Guardium attempts to export the files to failoverDestinationHost. destinationHost and failoverDestinationHost must have the same credentials and path (destinationPath). The output to get_datamart_info shows the server to which results were last sent. |
| Name | String | Required. Data mart name |
| ssh_key_active | Boolean | Enables data transfer using the SSH key. Enable the SSH key feature with the CLI command store system scp-ssh-key-mode on . Generate ssh-key pairs and copy the public part of the key, public-transfer-key , to the remote host. For more information, see Enabling ssh-key pairs for data archive, data export, data mart . Valid values: <ul style="list-style-type: none">• 0: Disable• 1: Enable Default = 0 |
| transferMethod | String | Required. Valid values: <ul style="list-style-type: none">• SCP• FTP |
| validate | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| withCOMPLETEfile | Boolean | A complete file is sent after a data file is successfully transferred. Valid values: <ul style="list-style-type: none">• 0 (false): The marker file is not sent and the data file is prefixed with "DMv2_". For example: DMv2_vmappibm_EXP_SYSTEM_INFO_20170508150000.gz• 1 (true): Two files are sent, one with data and another empty file with the word COMPLETE in it. The second file is a marker that the result is complete. The format of the file name is <global prefix ID>_<appliance name>_<datamart name>_<timestamp>.gz, for example: 1234567890123456789_vmappibm_EXP_SYSTEM_INFO_20170508150000.gz2. Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Example

To update the Export:Session Log transfer method to SCP:

```
grdapi datamart_update_copy_file_info destinationHost=server22 destinationPassword=passpass destinationPath=<destination server> destinationUser=useruser Name="Export:Session Log" transferMethod=SCP
```

datamart_validate_copy_file_info

This command validates the connection to the target host for user-defined or predefined file data mart export.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datamart_validate_copy_file_info
```

GuardAPI syntax

```
datamart_validate_copy_file_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|--|
| destinationHost | String | Required. Hostname of target server. |
| destinationPassword | String | Password for the user specified by destinationUser. |
| destinationPath | String | Required. Path to location to store the datamart extraction. |
| destinationUser | String | Required. User with write access to the destination path. |
| failoverDestinationHost | string | If the export to destinationHost fails, then Guardium attempts to export the files to failoverDestinationHost. destinationHost and failoverDestinationHost must have the same credentials and path (destinationPath). The output to get_datamart_info shows the server to which results were last sent. |
| ssh_key_active | Boolean | Enables data transfer using the SSH key. Enable the SSH key feature with the CLI command store system scp-ssh-key-mode on . Generate ssh-key pairs and copy the public part of the key, public-transfer-key , to the remote host. For more information, see Enabling ssh-key pairs for data archive, data export, data mart . Valid values: <ul style="list-style-type: none">• 0: Disable• 1: Enable Default = 0 |
| transferMethod | String | Valid values: <ul style="list-style-type: none">• SCP• FTP |
| transferMethod | String | Valid values: <ul style="list-style-type: none">• SCP• FTP |

Examples

```
grdapi datamart_validate_copy_file_info destinationHost=hostname destinationUser=user22 destinationPassword= destinationPath= Name= transferMethod=
```

delete_adhoc_policy_analyzer

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_adhoc_policy_analyzer
```

GuardAPI syntax

```
delete_adhoc_policy_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| scheduleId | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_alerter_snmp_settings

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_alerter_snmp
```

GuardAPI syntax

```
delete_alerter_snmp_settings parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_alias

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/alias
```

GuardAPI syntax

```
delete_alias parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|---|
| dbValue | String | Required. |
| groupTypeDesc | String | Required. For valid values, call delete_alias from the command line with <code>--help=true</code> . |

delete_allowed_db_by_entry_id

This command removes a User-DB association by the user's ID.

You can find the ID by using the [list_allowed_db_by_user](#) API.

Note: To apply the changes to the active User-DB association map, run [update_user_db](#) after you run this command.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/allowed_db
```

GuardAPI syntax

```
delete_allowed_db_by_entry_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Long | Required. The record ID of the User-DB association. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapic delete_allowed_db_by_entry_id id=2
```

Sample output

```
ID=0
Number of matches: 1
When complete, in order for synchronization to take effect, run update_user_db
ok
```

delete_allowed_db_by_user

This command removes a User-DB association by the user's name.

Note: To apply the changes to the active User-DB association map, run [update_user_db](#) after you run this command.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/allowed_db
```

GuardAPI syntax

```
delete_allowed_db_by_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| instanceName | String | A specific instance name within the server. |
| serverIp | String | The server IP. |
| userName | String | Required. The name of the user. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi delete_allowed_db_by_user userName=Fred
```

Sample output

```
ID=2
When complete, in order for synchronization to take effect, run update_user_db
ok
```

delete_analytic_user_feedback

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/delete_analytic_user_feedback
```

GuardAPI syntax

```
delete_analytic_user_feedback parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| feedback_id | Long | |

delete_api_parameter_mapping

Add a short description here.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/param_mapping_for_function
```

GuardAPI syntax

```
delete_api_parameter_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| attributeLabel | String | Required. |
| domain | String | Required. |
| entityLabel | String | Required. |
| functionName | String | Required. |
| parameterName | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_approved_stap_client

This command removes an approved database from the list of databases allowed to communicate with the S-TAP®. As a result, its S-TAPs are no longer allowed to access and communicate with the Guardium® system.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/approved_stap_client
```

GuardAPI syntax

```
delete_approved_stap_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHost | String | Required. The host name or IP address of the database server on which the S-TAP is installed. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete the database server with the IP of 12.12.12.12 from the list of databases that are allowed to communicate with the Guardium system:

```
grdapi delete_approved_stap_client stapHost=12.12.12.12
```

delete_archive_configuration

This command deletes the scheduled data archive on one or more Guardium® systems.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_archive_configuration
```

GuardAPI syntax

```
delete_archive_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete the configured archive on the system on which you enter the command:

```
grdapi delete_archive_configuration
```

delete_assessment

This command to deletes a security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/assessment
```

GuardAPI syntax

```
delete_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. |
| forceDelete | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |

Example

```
grdapi delete_assessment assessmentDescription=Assess1
```

delete_assessment_datasource

This command deletes a datasource from a security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/assessment_datasource
```

GuardAPI syntax

```
delete_assessment_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. This string is a variable that is unique. Ensure that there is no previous assessment with the same description. If a previous assessment exists, an error occurs. |
| datasourceName | String | Required. This string is a variable, and must be the name of an existing data source. If a datasource with the defined string is not present, then an error occurs. |

Example

```
grdapi delete_assessment_datasource assessmentDescription=Assess1 datasourceName=DS1
```

delete_assessment_datasource_group

This command deletes an assessment from a datasource group.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/assessment_datasource_group
```

GuardAPI syntax

```
delete_assessment_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| assessmentDescription | String | Required. |
| groupName | String | Required. |

delete_assessment_test

This command deletes a test from an existing security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/assessment_test
```

GuardAPI syntax

```
delete_assessment_test parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|---|
| assessmentDescription | String | Required. |
| datasourceType | String | For valid values, call delete_assessment_test from the command line with --help=true. |
| testDescription | String | Required. |

Example

```
grdapi delete_assessment_test assessmentDescription=Assess1
```

delete_audit_process

Deletes an audit process.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/audit_process
```

GuardAPI syntax

```
delete_audit_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| force | Boolean | Delete the audit process even if contains results. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| processName | String | Required. Use list_audit_processes to find the name of the audit process to delete. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

delete_audit_process_result

This command deletes certain specified audit process results.

To run this command you must have the audit-delete role.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/audit_process_result
```

GuardAPI syntax

```
delete_audit_process_result parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| ExecutionDateFrom | String | Required. Audit process start time. |
| ExecutionDateTo | String | Required. Audit process end time. |
| ProcessName | String | Required. Audit process name. For valid values, call delete_audit_process_result from the command line with --help=true. |

delete_autodetect_process

Use this command to delete an auto-discovery process and all of its associated tasks. You cannot run this command on a process that is running or is scheduled.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/autodetect_processes
```

GuardAPI syntax

```
delete_autodetect_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| process_name | String | Required. Name of the auto-discovery process |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To delete the auto-discovery process myProcess:

```
grdapi delete_autodetect_process process_name=myProcess
```

delete_autodetect_scans_for_process

Use this command remove all the tasks for a process on the specified hostnames and ports. You cannot run this command on a process that is running or scheduled, or has results.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/autodetect_scans_for_process
```

GuardAPI syntax

```
delete_autodetect_scans_for_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| hostList | String | Lists of hosts. Space separated list of IPs or IP ranges and wild cards such as 192.168.0.1 192.168.1.* |
| portList | String | List of ports. Comma separated list of ports or port ranges such as 22,23,1400-1600. |
| process_name | String | Required. Name of the auto-discovery process |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. delete_available_test_notes

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/available_test_notes
```

GuardAPI syntax

```
delete_available_test_notes parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| datasourceType | String | Required. For valid values, call <code>delete_available_test_notes</code> from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|-------------|
| testDescription | String | Required. |

delete_aws_secrets_manager_config

Use this command to delete an AWS secrets configuration.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/aws_secrets_manager
```

GuardAPI syntax

```
delete_aws_secrets_manager_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| name | String | Required. |

Examples

```
grdapapi delete_aws_secrets_manager_config name="GRDAPI IAM-Instance-Profile"
grdapapi delete_aws_secrets_manager_config name="GRDAPI IAM-Role"
grdapapi delete_aws_secrets_manager_config name="GRDAPI Security-Credentials"
```

delete_cas_host

This command removes a Configuration Auditing System (CAS) host configuration. A CAS host configuration defines one or more CAS host instances, and each CAS host instance specifies a CAS template set.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/cas_host
```

GuardAPI syntax

```
delete_cas_host parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| hostName | String | Required. The name or IP address of the host configuration to delete. |
| osType | String | Required. The operating system of this host. The OS type can be either: <ul style="list-style-type: none"> • UNIX • WIN |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

delete_cas_host_instance

This command removes a Configuration Auditing System (CAS) host instance. A CAS host configuration defines one or more CAS host instances, and each CAS host instance specifies a CAS template set.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/cas_host_instance
```

GuardAPI syntax

```
delete_cas_host_instance parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| datasourceName | String | Required. The data source of the host instance to delete. |
| templateSetLabel | String | Required. The name of the template set associated with this host instance. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_cas_template

This command removes a Configuration Auditing System (CAS) template from a template set.

Note: You cannot delete a predefined template.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/cas_template
```

GuardAPI syntax

```
delete_cas_template parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| templateId | Long | Required. The ID of the template you want to delete. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete a CAS template from a template set:

```
curl -k --header "Authorization: Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3" -i -X
DELETE -d '{"templateId":"20003"}'
https://localhost:8443/restAPI/cas_template
```

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_document_rule
```

GuardAPI syntax

```
delete_classifier_document_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| allowlist | String | |
| enable | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| type | String | Required. Valid values: <ul style="list-style-type: none">• ALL• SSH• GUI |

delete_classifier_policy

This command deletes classification policies.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_policy
```

GuardAPI syntax

```
delete_classifier_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| policyName | String | Required. |

Examples

```
grdapi delete_classifier_policy policyName=access_policy
```

delete_classifier_process

This command deletes classification processes.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_process
```

GuardAPI syntax

```
delete_classifier_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| processName | String | Required. |

Examples

```
grdapi delete_classifier_process processName=APITEST_Clps_10001_1
```

delete_classifier_rule

This command deletes classification rules.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_rule
```

GuardAPI syntax

```
delete_classifier_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| policyName | String | Required. |
| ruleName | String | Required. |

Examples

```
grdapi delete_classifier_rule policyName=access_policy ruleName=access_rule
```

delete_cluster

This API deletes a specified S-TAP cluster.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_cluster
```

GuardAPI syntax

```
delete_cluster parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| clusterName | String | Required. |

delete_computed_attribute

This API deletes a computed attribute.

To help prevent an SQL injection attack, the following words and characters are not allowed in computed attributes:

ALTER, CREATE, DELETE, DROP, INSERT, TRUNCATE, UPDATE, semicolon (;), double-dash (--), or slash-asterisk /*)

For more information, see [create_computed_attribute](#).

This API is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/computed_attribute
```

GuardAPI syntax

```
delete_computed_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| attributeLabel | String | Required. The name of the computed attribute to delete. |
| entityLabel | String | Required. The name of the main entity with which the attribute is associated, |
| expression | String | Required. The SQL expression to delete. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>; execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To delete the app_user computed attribute:

```
grdapicreate_computed_attribute  
attributeLabel="app_user" entityLabel="Access Period"  
expression="SUBSTRING_INDEX(APP_USER_NAME,char(59),1)
```

delete_constant_attribute

This API is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/constant_attribute
```

GuardAPI syntax

```
delete_constant_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| attributeLabel | String | Required. |
| constant | String | Required. |
| entityLabel | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_cust_table_distribution_schedule

This API deletes a previously created distribution schedule for custom tables.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/custTblDist
```

GuardAPI syntax

```
delete_cust_table_distribution_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_custom_table_ldap_import

This command deletes a custom table that was created to import data from LDAP.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/custom_data_ldap
```

GuardAPI syntax

```
delete_custom_table_ldap_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| importId | Integer | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_cyberark_config

This command deletes a CyberArk configuration from your Guardium system.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/cyberark
```

GuardAPI syntax

```
delete_cyberark_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| name | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_datasourceRef_by_id

This command removes a datasource reference for a specific object of a specific application type. The datasource, object, and application type are referenced by identification keys.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref
```

GuardAPI syntax

```
delete_datasourceRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| appId | Integer | <p>Required. Identifies the application type.
Valid values:</p> <ul style="list-style-type: none"> • 8 (security assessment) • 47 (custom tables) • 51 (classifier) |
| datasourceId | Integer | Required. Identifies the datasource by its identification key. |
| objId | Integer | Required. Identifies an instance of the specified appId type. For example, if <code>appId=51</code> , objId is the identification key of a classification process. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapic delete_datasourceRef_by_id appId=51 datasourceId=2 objId=1
```

delete_datasourceRef_by_name

This command removes a datasource reference for a specific object of a specific application type. The datasource, object, and application type are referenced by name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref
```

GuardAPI syntax

```
delete_datasourceRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| application | String | Required. Identifies the application type. For valid values, call delete_datasourceRef_by_name from the command line with --help=true. |
| datasourceName | String | Required. Identifies the datasource by its name. For valid values, call delete_datasourceRef_by_name from the command line with --help=true. |
| objName | String | Required. For valid values, call delete_datasourceRef_by_name from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_datasource_by_id

This command deletes a datasource definition identified by an identification key.

This command deletes the specified datasource definition regardless of who created it.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_datasource_by_id
```

GuardAPI syntax

```
delete_datasource_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| cascade | Boolean | <p>Lists all the applications where the datasource is referenced. It also displays a confirmation number. Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| confirmationNumber | Integer | When the confirmation number is used, all references of the datasource are deleted. Default = 0 |
| id | Integer | Required. The identification key of the datasource to be deleted. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to delete a datasource with identification key 2:

```
grdapi delete_datasource_by_id id=2
```

delete_datasource_by_name

This command deletes a datasource definition identified by name.

This command deletes the specified datasource definition regardless of who created it.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource
```

GuardAPI syntax

```
delete_datasource_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| cascade | Boolean | <p>Lists all the applications where the datasource is referenced. It also displays a confirmation number. Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| confirmationNumber | Integer | When the confirmation number is used, all references of the datasource are deleted. Default = 0 |
| name | String | Required. The datasource name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to delete a datasource with the name swanSybase:

```
grdapi delete_datasource_by_name name=swanSybase
```

delete_datasource_configuration

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
delete_datasource_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| ucDatasourceId | Integer | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_datasource_custom_property

This command deletes a custom property that was configured for your datasource.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop
```

GuardAPI syntax

```
delete_datasource_custom_property parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| force | Boolean | <p>When <code>force="1"</code> the custom property is deleted even if it's being used by a datasource.</p> <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| name | String | Required. The name of the property to delete. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

The following command deletes the custom property "Business Unit" and removes it from all the datasources and datasources groups to which the property is assigned.

```
grdapl delete_datasource_custom_property name="Business Unit" force="1"
```

delete_datasource_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
delete_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| groupName | String | Required. |

delete_datasource_groupRef_by_id

Delete datasource groups that are in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
delete_datasource_groupRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| appId | Integer | Required. For valid values, call delete_datasource_groupRef_by_id from the command line with --help=true. |
| datasourceId | Integer | Required. The ID of the datasource. |
| objId | Integer | Required. The object ID of the security assessment, discovery scenario, or custom table. |

delete_datasource_groupRef_by_name

Delete datasource groups that are in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
delete_datasource_groupRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| application | String | Required. For valid values, call delete_datasource_groupRef_by_name from the command line with --help=true. |
| datasourceGroupName | String | Required. The name of the datasource group. |
| objName | String | Required. The name of the security assessment, discovery scenario, or custom table. |

delete_db_user_mapping

This command deletes the mappings between DB user and email address for real-time alerts.

You can use a percent (%) wildcard for all parameters.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/db_user_mapping
```

GuardAPI syntax

```
delete_db_user_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dbUserName | String | Required. The DB username. |
| emailAddress | String | Required. For real-time alerts, the email address that maps to the DB user. The at symbol (@) is required. |
| serverIp | String | Required. The server IP address. You can use % wildcards for any element in the IP address. For example: <ul style="list-style-type: none">• 192.168.2.%• 2620:1f7:807%:920:% |
| serviceName | String | Required. The server name. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi delete_db_user_mapping serverIp=192.168.%.% serviceName=ora1 dbUserName=hadrian emailAddress=hadrian.swall@%..com
```

delete_distributed_report_result_for_period

Run this API to delete a distributed report result for the specified period.

For example, a distributed report has a one day time granularity, it collects data from aggregators, and is scheduled to run daily at 1am. One of the aggregators had not received data from all of its collectors before its previous run. To get a complete report, you need to delete the results of this incomplete run, and rerun the distributed report manually (with the API [rerun_distributed_report](#)) for this period.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
delete_distributed_report_result_for_period parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| endTime | Date | Required. |
| hostname | String | Required. |
| reportId | Integer | Required. |

| Parameter | Value type | Description |
|------------|------------|--|
| runOptions | String | Required. Valid values: <ul style="list-style-type: none"> • <i>fromHostname</i> • <i>fromAllUnits</i> |
| startTime | Date | Required. |

Related concepts

delete_ef_mapping

This function deletes an external feed mapping.

To protect predefined Guardium mappings, only mappings with an identification key greater than 20000 can be deleted.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_ef_mapping
```

GuardAPI syntax

```
delete_ef_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| reportName | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <i>api_target_host=10.0.1.123</i>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to delete the *Sessions per Day* mapping:

```
grdapic delete_ef_mapping reportName="Sessions per Day"
```

delete_entry_location

This command removes the specified catalog entry if you specify a file name. If you do not specify a file name, this command removes the catalog entries for the specified path and hostname.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/entry_location
```

GuardAPI syntax

```
delete_entry_location parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fileName | String | Identifies a single catalog entry to remove. If omitted, all catalog entries on the specified hostname and path are deleted. |
| hostName | String | Required. The hostname or IP address. |
| path | String | Required. The path to the archive directory. <ul style="list-style-type: none">• Amazon S3: bucket name• IBM COS: bucket name• EMC Centera: Centera clipID• FTP: Specify the directory relative to the FTP account home directory.• SCP: Specify the directory as an absolute path.• IBM Cloud: Container• TSM: path |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi delete_entry_location path=/var/dump/henry hostName=192.168.1.18
```

delete_export_configuration

Use this command to delete a defined data export configuration on one or more Guardium® systems.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_export_configuration
```

GuardAPI syntax

```
delete_export_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete the configured data export on the system on which you enter the command:

```
grdapi delete_export_configuration
```

Related tasks

delete_group_by_desc

This command deletes a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
delete_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| desc | String | Required. Identifies the group by its description. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to delete a group with the description *A group*:

```
grdapi delete_group_by_desc desc="A group"
```

delete_group_by_id

This command deletes a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
delete_group_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Integer | Required. Identifies the group by its identification key. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to delete a group with the identification key 100003:

```
grdapic delete_group_by_id id=100003
```

delete_group_from_quick_search

This command deletes a group from the quick search facet drop-down menus. After you delete it, you will not be able to select it to filter the investigation dashboard results.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
delete_group_from_quick_search parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| facet | String | Required. The facet of the group you are deleting. Valid values: <ul style="list-style-type: none">• DB_USER• OS_USER• OBJECT• VERB• FAM_COMMAND• SERVER_IP |
| group_descripti
on | String | Required. Group name you are deleting, of the specified facet type. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete server_group5 to the quick search:

```
delete_group_from_quick_search facet=SERVER_IP group_description=server_group5
```

delete_hashicorp_config

Use this command to delete a HashiCorp configuration from your Guardium® system.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/hashicorp
```

GuardAPI syntax

```
delete_hashicorp_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| name | String | Required. For valid values, call <code>delete_hashicorp_config</code> from the command line with <code>--help=true</code> . |

Example

```
grdapic delete_hashicorp_config name="No SSL User and password API"
```

delete_hierarchical_member_from_group_by_desc

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/hierarchical_member
```

GuardAPI syntax

```
delete_hierarchical_member_from_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| desc | String | Required. |
| member | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_imscheckpoint_record

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/ims_checkpoint
```

GuardAPI syntax

```
delete_imscheckpoint_record parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|-------------|
| agentName | String | Required. |
| context | String | Required. |
| imsName | String | Required. |
| logStreamName | String | Required. |

delete_inactive_stap

Use this command to delete an inactive S-TAP® (or all S-TAPs) on the specified S-TAP host, or all hosts, on one or all collectors that send data to the specified S-TAP host.

To identify inactive S-TAPs, use the API command `list_staps` or view the report Inactive S-TAPs Since.

Table 1. `stapHost` and `api_target_host` values and the resulting affected S-TAPs

| stapHost | api_target_host | Command affects: |
|---------------------|----------------------------------|------------------------------|
| specific S-TAP host | specific target host / collector | S-TAP on the collector |
| all | specific target host / collector | All S-TAPs on the collector |
| specific S-TAP host | all_managed | S-TAP on all collectors |
| all | all_managed | All S-TAPs on all collectors |

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/delete_inactive_stap
```

GuardAPI syntax

```
delete_inactive_stap parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| force | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| stapHost | String | Valid values: <ul style="list-style-type: none">• specific S-TAP host• all |
| api_target_host | String | Specifies where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• group:<group name>: execute on all managed units identified by <group name>• Host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123. |

Examples

To delete inactive S-TAPs that are configured to send data to the Guardium system on which you enter the command:

```
grdapi delete_inactive_stap
```

Related reference

- [S-TAP and inspection engine APIs](#)

delete_invalid_stap

Use this command to remove invalid S-TAPs from the Deployment Health Topology view, for example. This command deletes invalid S-TAPs, and not inactive S-TAPs.

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
delete_invalid_stap parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To delete invalid S-TAPs from a collector:

```
grdapi delete_invalid_stap debug=3
```

To delete invalid S-TAPs from the collector XXXX, enter this command on the collector's central manager:

```
grdapi delete_invalid_stap api_target_host=XXXX debug=3
```

To delete all invalid S-TAPs from in a centralized system, enter this command on the central manager:

```
grdapi delete_invalid_stap api_target_host=all debug=3
```

[delete_kafka_cluster](#)

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/kafka_cluster
```

GuardAPI syntax

```
delete_kafka_cluster parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| clusterName | String | |

[delete_member_from_group_by_desc](#)

Remove a member from a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/group_member
```

GuardAPI syntax

```
delete_member_from_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| desc | String | Required. Identifies the group by its description. |
| member | String | Required. Identifies the name of the group member to be removed. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to remove the member *boston* from the group *A group*:

```
grdapic delete_member_from_group_by_desc desc="A group" member=boston
```

[delete_member_from_group_by_id](#)

Remove a member from a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/group_member_by_group_id
```

GuardAPI syntax

```
delete_member_from_group_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| id | Integer | Required. Identifies the group by its identification key. |
| member | String | Required. Identifies the name of the group member to be removed. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group: <group name>; execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to remove the member `turkey` from the group with identification key `100005`:

```
grdapi delete_member_to_group_by_id id=100005 member=turkey
```

delete_oauth_clients

This API removes the API clients that were registered with the `register_oauth_client` API.

This API is available in Guardium V11.2 and later.

GuardAPI syntax

```
delete_oauth_clients parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| client_id | String | The ID of a specific client to delete. |
| all | String | Delete all API clients. |

Examples

```
grdapi delete_oauth_clients client_id=123
```

```
grdapi delete_oauth_clients all
```

Related reference

- [register_oauth_client](#)

delete_policy

This command deletes an existing policy.

[policy_uninstall](#) API uninstalls a policy, but does not delete it.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/policy
```

GuardAPI syntax

```
delete_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policyDesc | String | Required. The name of the policy to delete. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi delete_policy policyDesc="My Hadoop Policy"
```

Related reference

delete_quarantine

This command deletes an existing quarantine for a specified user.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/quarantine
```

GuardAPI syntax

```
delete_quarantine parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| dbUser | String | Required. The name of the quarantined database user. |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |
| type | String | Required. If the database is not IBM Z® or IMS, specify <code>normal</code> . Valid values: <ul style="list-style-type: none">• <code>normal</code>• <code>DB2Z</code>• <code>IMS</code> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

The following command ends the quarantine for this user.

```
grdapi delete_quarantine dbUser="Hadrian.Swall" serverIp="9.32.0.255" serviceName="company.ibm.com" type="normal"
```

delete_ranger_hdfs_config

Use this command to delete a Hadoop integration with Ranger HDFS that connects using the specified S-TAP.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/delete_ranger_hdfs_config
```

GuardAPI syntax

```
delete_ranger_hdfs_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHostName | String | Required. Host name or IP of the S-TAP® that receives the Ranger audit messages from the Ranger. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. delete_results_archive_configuration

Use this command to delete the configured archive of results on one or more Guardium® systems.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/results_archive_configuration
```

GuardAPI syntax

```
delete_results_archive_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete the configured results archive on the system on which you enter the command:

```
grdapic delete_results_archive_configuration
```

delete_results_export_configuration

Use this command to delete the configured export of results on one or more Guardium® systems.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/configure_results_export
```

GuardAPI syntax

```
delete_results_export_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete the configured results export on the system on which you enter the command:

```
grdapi delete_results_export_configuration
```

Related tasks

delete_rule

This command removes a rule from a specified policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/rule
```

GuardAPI syntax

```
delete_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fromPolicy | String | Required. The name of the policy. |
| ruleDesc | String | Required. The name of the rule to remove. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi delete_rule ruleDesc="My test exception" fromPolicy="policy1"
```

delete_schedule

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/schedule
```

GuardAPI syntax

```
delete_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| deleteJob | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| jobGroup | String | Required. |
| jobName | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

delete_sql_configuration

This command deletes the connection details between an S-TAP® and an Oracle server that is used for Oracle Unified Auditing.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/delete_sql_configuration
```

GuardAPI syntax

```
delete_sql_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| sequence | String | Required. The sequence number of the SQL configuration to be removed within the set of SQL configurations. Use the API <code>display_stap_config</code> to list the configuration with the SQL sequence numbers. Output appears similar to with SQL_X, where X is the sequence. |
| stapHost | String | Required. The hostname of the S-TAP that connects to this Oracle DB instance. For valid values, call <code>delete_sql_configuration</code> from the command line with <code>--help=true</code> . |
| waitForResponse | String | Specifies whether the API waits for a response from the S-TAP. Valid values: <ul style="list-style-type: none">• 0 (do not wait): API exits upon updating the DB.• 1 (wait for a response): API exits after receiving a successful acknowledgement from the STAP. Default = 1 |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_stap_inspection_engine

This command deletes one or more inspection engines on the specified S-TAP® host.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/inspection_engine
```

GuardAPI syntax

```
delete_stap_inspection_engine parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| sequence | Integer | The sequence number of the inspection engine to be removed within the set of inspection engines of the specified type. Use the <code>grdapi list_inspection_engines</code> command with the type option first to verify the sequence number. |
| stapHost | String | Required. The S-TAP host of the inspection engine. |
| type | String | Required. The type of data repository that is monitored.
Unix: ASTERDB, Cassandra, CockroachDB, CouchDB, DB2®, Db2 Exit, ElasticSearch, exclude IE, FTP, GreenplumDB, HADOOP, HIVE, HP-Vertica, HTTP, HUE, IMPALA, Informix®, Informix Exit, KERBEROS, MariaDB, MemSQL, MongoDB, Mysql, Netezza®, Oracle, PostgreSQL, REDIS, SAP Hana, Sybase, Teradata, Teradata Exit, WebHDFS, Windows File Share
Windows: ASTER, Cassandra, CouchDB, Db2, Db2 Exit, exclude IE, FTP, GreenplumDB, HIVE, HTTP, HUE, IMPALA, Informix, Informix Exit, MariaDB, MongoDB, MSSQL, Mysql, Oracle, PostgreSQL, Sybase, Teradata, WebHDFS, Windows File Share. |
| waitForResponse | String | <p>Specifies whether the API waits for a response from the S-TAP. Valid values:</p> <ul style="list-style-type: none"> • 0: do not wait • 1: wait for a response <p>Default = 1 when stapHost is a single host name or IP address; and 0 in all other cases.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To delete an inspection engine with sequence number = 3, from the MYSQL database with IP 11.45.12.12:

```
grdapi delete_stap_inspection_engine stapHost=11.45.12.12 sequence=3 type=mysql
```

delete_stream

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datasream
```

GuardAPI syntax

```
delete_stream parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call delete_stream from the command line with --help=true.
For more information, see Define, modify, and delete AWS cloud DB service accounts . |
| namespace | String | For Azure only. The Azure event hub namespace. |
| region | String | Required only for AWS streams. For valid values, call delete_stream from the command line with --help=true. |
| streamName | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

delete_system_backup_configuration

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/configure_system_backup
```

GuardAPI syntax

```
delete_system_backup_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_test_detail_exception

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/test_detail_exception
```

GuardAPI syntax

```
delete_test_detail_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| allowMultiDelete | Boolean | Required. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| approver | String | |
| assessmentDesc | String | |
| assessmentScope | String | |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | |
| datasourceType | String | |
| detailExceptionValue | String | |
| exceptionType | String | Valid values: <ul style="list-style-type: none"> • text • regex • 0 • 1 |
| fromDate | String | |
| testDescription | String | |
| toDate | String | |

delete_test_detail_exception_by_id

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/test_detail_exception
```

GuardAPI syntax

```
delete_test_detail_exception_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|-------------|
| detailExceptionId | String | Required. |

delete_test_exception

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/test_exception
```

GuardAPI syntax

```
delete_test_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| allowMultiDelete | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| approver | String | |
| assessmentDesc | String | |
| assessmentScope | String | Valid values: <ul style="list-style-type: none">• CURRENT• ALL• 0• 1 |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | Valid values: <ul style="list-style-type: none">• SINGLE• GROUP• ALL• 0• 1• 2 |
| datasourceType | String | For valid values, call delete_stream from the command line with --help=true. |
| explanation | String | |
| fromDate | String | |
| testDescription | String | |
| toDate | String | |

delete_test_exception_by_id

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/test_exception_by_id
```

GuardAPI syntax

```
delete_test_exception_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|-------------|
| testExceptionId | Long | Required. |

delete_user

This API removes a specified user from the Guardium system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/user
```

GuardAPI syntax

```
delete_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| userName | String | Required. The name of the user to delete. |

Example

For example, remove Fred McDerf from your Guardium system:

```
grdapi delete_user userName="Fred McDerf"
```

delete_user_hierarchy_by_entry_id

This command removes a user from a hierarchy by their ID.

You can find the ID of the user to delete with the [list_user_hierarchy_by_parent_user](#) command.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/user_hierarchy
```

GuardAPI syntax

```
delete_user_hierarchy_by_entry_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Long | Required. The ID of the child user. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

delete_user_hierarchy_by_user

This command removes a user from a hierarchy by their name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/user_hierarchy
```

GuardAPI syntax

```
delete_user_hierarchy_by_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| userName | String | Required. The name of the user to delete from the hierarchy. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi delete_user_hierarchy_by_user userName=George
```

disable_advanced_threat_scanning

This command disables threat detection analytics on the specified targets.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_advanced_threat_scanning
```

GuardAPI syntax

```
disable_advanced_threat_scanning parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| all | Boolean | In a central management configuration only, disables all threat detection scanners on all managed units. This is equivalent to the "all" option for the parameter api_target_host . Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To disable threat detection analytics on all managed units:

```
grdapi disable_advanced_threat_scanning all=1
```

Related concepts

- [Threat Detection Analytics](#)

disable_auto_execute_suggested_dependencies

This command disables job dependencies for the specified task.

This command is equivalent to deselecting the option Auto run dependent jobs in the Scheduler of a task: Guardium does not find and run all dependent jobs before running this specific jpb.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
disable_auto_execute_suggested_dependencies parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| jobTrigger | String | Required. Guardium does not run the dependent tasks before running the specified task.. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable the job dependencies for the job userSynchronizationTrigger:

```
grdapi disable_auto_execute_suggested_dependencies jobTrigger=DataMartExtractionJobTrigger_5
ID=0
ok
```

disable_big_data_interface

This command deactivates the active profile and removes its schedules, and optionally deletes the big data datasource definition and its metadata and reports. This command is valid for CM and standalone systems only.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/bigDataInterface
```

GuardAPI syntax

```
disable_big_data_interface parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| disable_readbac
k | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false): Deactivates the current big data interface profile, and removes its schedules but does not delete the datasource definition or the reporting metadata. (Use this option if you want to subsequently re-enable the profile.) • 1 (true): Deletes the big data interface datasource definition and its schedules, and hides its metadata and reports. <p>Default = 0 (false)</p> |

Examples

Delete all definitions of the big data interface profile, its datasource and schedules, and hide its reports and metadata.

```
enable_big_data_interface disable_readback=1
```

disable_datastream

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/cloud_datasource
```

GuardAPI syntax

```
disable_datastream parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_embed_eastern_font

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
disable_embed_eastern_font parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_entitlement_optimization

This command disables the entitlement optimization feature on the local or specified units.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableEntitlementOptimization
```

GuardAPI syntax

```
disable_entitlement_optimization parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. disable_fam_crawler

This command disables the file activity monitor crawler. The file quick search activity and entitlement extractions scheduler are removed. This function also disables remote group population.

This API is available in Guardium V11.4, 11.5 and 12.0

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_fam_crawler
```

GuardAPI syntax

```
disable_fam_crawler
```

Examples

To disable the FAM crawler

```
disable_fam_crawler
```

disable_health_analyzer

This command disables the disk and database health analyzer.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableHealthAnalyzer
```

GuardAPI syntax

```
disable_health_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to disable the disk and database health analyzer:

```
grdapicl disable_health_analyzer
```

Related reference

- [Health analyzer APIs](#)

disable_ip_to_host_aliases

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_ip_host_alias
```

GuardAPI syntax

```
disable_ip_to_host_aliases parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_monitoring_ranger_service

Use this command to disable a Ranger service (Hadoop monitoring).

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_monitoring_ranger_service
```

GuardAPI syntax

```
disable_monitoring_ranger_service parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| serviceName | String | Required. Name of the service. Valid values: <ul style="list-style-type: none"> • hdfs • hive • hbase • kafka • solr • storm |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To disable monitoring on the Cluster4 HDFS service:

```
grdapi disable_monitoring_ranger_service clusterName=Cluster4 serviceName=HDFS
```

System response:

ID=0

The Hadoop service configuration has been changed. Ask the Hadoop administrator to restart the Hadoop service to activate the change.
HDFS Monitoring Disabled on <server name>:5565

disable_native_audit

This API disables DB Audit (native audit) on the specified cloud datasource.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/disable_native_audit
```

GuardAPI syntax

```
disable_native_audit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasource_name | String | Required. A cloud datasource defined in Guardium. |
| should_restart | Boolean | Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

disable_outliers_detection

Run this command on a standalone system, or on a central manager.

The command affects the Guardium systems differently, depending on their setup.

Single CM environment

Run on a CM to disable outliers detection on all managed units registered with the CM, by running the API command with no additional parameters. You can limit the disable to a list of units.

When disabling on a collector, if this is the only collector sending data to the aggregator, then the collector stops sending data, and outliers detection is disabled on the aggregator.

Multi-CM environment

Run on a CM with no additional parameters, to disable outliers detection on all managed units registered to the CM. You can limit the disable to a list of units.

To disable on individual aggregators or collectors, use the commands [disable_outliers_detection_cross_cm_agg](#) and [disable_outliers_detection_cross_cm_collector](#).

Single Collector

Run the command on a collector that does not extract data to an aggregator, to disable it locally.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableOutliersDetection
```

GuardAPI syntax

```
disable_outliers_detection parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| managed_units_hostnames | String | Specific managed units on which the command is executed. Optional when running the API on the CM. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Run this command on the CM to disable the outliers detection on all the units under the CM and on all units registered to the CM thereafter:

```
grdapicl disable_outliers_detection
```

Related tasks

- [Enabling and disabling outliers detection](#)

Related reference

- [Outliers detection APIs](#)

disable_outliers_detection_agg

Run this API on a central manager to disable outliers detection on the specified aggregator.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableOutliersDetectionOnAgg
```

GuardAPI syntax

```
disable_outliers_detection_agg parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| aggregator_host_name | String | Required. The specific aggregator disabled for outliers detection. |

Examples

Run this command to disable outliers detection on the aggregator **agg-sw**:

```
disable_outliers_detection_agg aggregator_host_name=agg-sw
```

Related concepts

- [Outliers detection](#)

Related tasks

disable_outliers_detection_cross_cm_agg

Run on a central manager to disable outliers on the collector(s) that send data to the specified aggregator(s). This is for use in a multi-central manager environment; the aggregator is in this central manager's environment but the collectors are managed by a different central manager.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableOutliersDetectionOnAggCrossCm
```

GuardAPI syntax

```
disable_outliers_detection_cross_cm_agg parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| aggregator_host_name | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To disable outliers on the collectors that send data to the aggregator **agg12**, run this command on the CM that the aggregator **agg12** reports to:

```
disable_outliers_detection_cross_cm_agg aggregator_host_name=agg12
```

Related tasks

- [Enabling and disabling outliers detection](#)

Related reference

disable_outliers_detection_cross_cm_collector

Run on a central manager to disable outliers on the specified collector(s) in this central manager's environment. This is for use in a multi-central manager environment; the collector is in this central manager's environment but the data is sent to an aggregator in another central manager's environment.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disableOutliersDetectionOnCollectorsCrossCM
```

GuardAPI syntax

```
disable_outliers_detection_cross_cm_collector parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| collector_host_names | String | Required. Comma-separated list of collector names. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To disable outliers detection on the collectors `coll1a`, `coll2a`, run this command on the central manager of the collectors:

```
disable_outliers_detection_cross_cm_collector collector_host_names=coll1a,coll2a
```

Related concepts

disable_persistent_queue_universal_connector

Run this API to disable a Persistent Queue on Logstash inputs. Changes take effect only after reloading the configurations or restarting Logstash.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/disablePersistentQueue
```

GuardAPI syntax

```
disable_persistent_queue_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_policy_analyzer

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_policy_analyzer
```

GuardAPI syntax

```
disable_policy_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_purge

Use this command to disable the scheduled purge for one or more Guardium® systems.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/disable_purge
```

GuardAPI syntax

```
disable_purge parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. disable_quick_search

This command disables investigation dashboard functionality.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_quick_search
```

GuardAPI syntax

```
disable_quick_search parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| all | Boolean | <p>In an environment with a Central Manager, use this parameter to disable search on all managed units. Valid values:</p> <ul style="list-style-type: none">• 0 (false): Disable only on the unit where the command is executed.• 1 (true): Disable on all managed units. <p>Default = 0 (false)</p> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To disable quick search on the current unit and all of its managed units:

```
disable_quick_search all=true
```

Related concepts

disable_riskspotter

Run this command on a central manager to disable RiskSpotter on all of the central manager's managed units, or on a stand-alone Guardium system.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/disable_riskspotter
```

GuardAPI syntax

```
disable_riskspotter
```

This API takes no parameters.

Examples

Run this command on a central manager to disable RiskSpotter on all of its managed units:

```
grdapicl disable_riskspotter
```

Related concepts

- [Risk Spotter](#)

disable_special_attributes

This API removes access for non-admin users to view attributes for certain groups in Query-Report Builder.

Within Query-Report Builder, admin users can see all attributes while non-admin users can view only query attributes, except attributes that are designated as admin only (such as IDs). Use `disable_special_attributes` to disallow non-admin users to view all of the attributes within a specified `attributesGroup`.

Note: When an attribute group is disabled, all of the attributes within that group are unavailable to non-admin users.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
disable_special_attributes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| attributesGroup | String | Required. Valid values: <ul style="list-style-type: none">• <i>data set</i>• <i>ims</i>• <i>hive</i>• <i>apex</i>• <i>mapreduce</i>• <i>bi</i>• <i>ims/data set</i>• <i>f5</i>• <i>db2 i</i> |

Examples

The following example disables Hive attributes for all non-admin users:

```
grdapi disable_special_attributes attributesGroup=hive
```

Sample output

```
> grdapi enable_special_attributes attributesGroup=hive
Following Attributes have been Disabled: Hive Parsed SQL, Hive User, Hive Command, Hive Database,
Hive Table Name, Hive Error
ok
```

Related reference

- [enable_special_attributes](#)

disable_test_result_detail_string_setting

Use this API command to disable writing detailed test results of a vulnerability assessment into the Test Result entity.

This API is available in Guardium V11.4 and later.

This API takes no parameters.

For backward compatibility, Vulnerability Assessment (VA) continues to store all detailed test results in one record in addition to creating a separate record for each detailed finding. The API command **disable_test_result_detail_string_setting** disables the writing all detailed test findings into one record.

Important: After you run this API command, you cannot re-enable writing all detailed test results into the Test Result entity. However, VA continues to create a separate record for each detailed finding. When the test results are exported to an external location, you can normalize each detailed finding into a record of its own.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/detail_string_setting
```

GuardAPI syntax

```
disable_test_result_detail_string_setting
```

Example

```
grdapi disable_test_result_detail_string_setting
ID=0
Test details are written only to the TEST_RESULT_DETAIL table.
ok
```

Related reference

- [Assessment APIs](#)

disable_threat_detection_use_case

Use this command to remove use case types from the threat detection analysis.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/disable_threat_detection_use_case
```

GuardAPI syntax

```
disable_threat_detection_use_case parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| case_name | String | Required. For valid values, call disable_threat_detection_use_case from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">all_managed: execute on all managed units but not the central managerall: execute on all managed units and the central managergroup:<group name>: execute on all managed units identified by <group name>host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

disable_threat_finder

Run this command on a CM or on a standalone unit to disable the threat finder functionality of the Active threat analytics.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/disable_threat_finder
```

GuardAPI syntax

```
disable_threat_finder parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To disable threat finder on the standalone unit or on the CM environment:

```
grdapi disable_threat_finder
ID=0
ok
```

discover_streams

This API returns the number of AWS data streams for the specified cloud DB service account (cloudTitle) and region.

To find details about a stream, use the [get_streams](#) API.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/discover_datastream
```

GuardAPI syntax

```
discover_streams parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| cloudTitle | String | <p>Required. The name of the cloud DB service account. For valid values, call <code>discover_streams</code> from the command line with <code>--help=true</code>.
For more information, see Define, modify, and delete AWS cloud DB service accounts.</p> |
| regions | String | Requires for AWS only. For valid values, call <code>discover_streams</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi discover_streams cloudTitle=mytest-aws regions=us-east-1
```

Sample output:

```
ID=0
Number of Streams discovered for the given cloud Account: 3
ok
```

display_external_stap_config

This API displays the values of specified External S-TAP® parameters. You can also display all modifiable External S-TAP parameters.

Use [update_external_stap_config](#) to change the value of External S-TAP parameters. External S-TAPs are supported on UNIX or Linux machines only.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/display_external_stap_config
```

GuardAPI syntax

```
display_external_stap_config parameter=value
```

Parameters

| Parameter | Value type | Description |

display_stap_config

This command outputs the properties of all S-TAPs, including the inspection engines and SQL connections, on the specified host. Optionally, specify the S-TAP® parameters you want to output.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/display_stap_config
```

GuardAPI syntax

```
display_stap_config parameter=value
```

Parameters

| Parameter | Value type | Description |

edit.kafka.cluster

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/kafka_cluster
```

GuardAPI syntax

```
edit.kafka.cluster parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-------------|------------|--|
| action | String | Valid values: <ul style="list-style-type: none">• add• delete |
| clusterName | String | For valid values, call edit_kafka_cluster from the command line with --help=true. |
| memberList | String | For valid values, call edit_kafka_cluster from the command line with --help=true. |

enable_advanced_threat_scanning

This command enables the threat detection analytics processes to check for specific database attacks such as SQL injection and malicious stored procedures.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_advanced_threat_scanning
```

GuardAPI syntax

```
enable_advanced_threat_scanning parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| all | Boolean | In a central management configuration only, enables all threat detection scanners on all managed units. This is equivalent to the "all" option for the parameter <code>api_target_host</code> . Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| schedule_start | Date | Specifies the date and time to start running the processes, in the format yyyy-mm-dd hh:mm:ss (24-hour clock). |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To enable advanced threat analytics:

```
grdapi enable_advanced_threat_scanning all=true schedule_start="2016-03-24 12:00:05"
```

If threat analytics is enabled, but outlier detection is not enabled, the system responds:

```
Warning - Enabling advance threat scanning (AKA Eagle Eye) when Analytic anomaly detection is disabled.  
Advance threat scanning (AKA Eagle Eye) enabled.  
ok
```

enable_all_tls

Enables all versions of TLS (TLS 1.2 and TLS 1.3) on either the current system or on all associated managed units.

After you disable TLS 1.2 (with [enable_latest_tls](#)), you might find that you need to re-enable it. Use this API to add TLS 1.2 back to your Guardium configuration.

Tip: This API takes a few minutes to run.

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
enable_all_tls parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| all | Boolean | <p>Required. For a central manager, select whether to enable TLS 1.2 and TLS 1.3 on all associated managed units. Valid values:</p> <ul style="list-style-type: none">• 0 (false) - Enable TLS 1.2 and TLS 1.3 on this machine only.• 1 (true) - Enable TLS 1.2 and TLS 1.3 on this machine and associated managed units. <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

enable_big_data_interface

This command specifies the active profiles and schedule of the big data interface, activates extraction of all data marts in the profile according to the unit types, and defines the Big Data collection as a datasource.

This command can run on a central manager or standalone unit. You can define only one interface per Guardium® system.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/bigDataInterface
```

GuardAPI syntax

```
enable_big_data_interface parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| ds_desc | String | Datasource description. Default is Big Data Intelligence. |
| ds_host | String | Required. Hostname of Big Data storage place, from which data is pulled to Guardium for reports, monitoring, and so on. |
| ds_password | String | Required. Password for ds_user, which pulls Big Data from the datasource. |
| ds_port | Integer | Port via which Guardium pulls Big Data from the datasource. Default = 27117. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| ds_user | String | Required. User that pulls Big Data from the datasource. This user can be different from the target user. |
| profile_name | String | Required. Name of datamart extraction profile, either a default profile or a profile defined by add_dm_to_profile or clone_extraction_profile . For a list of the profiles, run grdapi get_extraction_profile_info . For valid values, call enable_big_data_interface from the command line with --help=true . |
| start_date | Date | When to start sending data to the Big Data datasource. Format is one of: <ul style="list-style-type: none"> • NOW -<n> <minute hour day week month • yyyy-mm-dd hh:mm:ss Default = time at which the command is executed. |
| target_host | String | Target data host for extracted data marts. This is usually the same as the ds_host. If you require a staging area before moving data to the host, then target_host is not the same as ds_host. |
| target_password | String | Password for target_user, or key pair authentication file. If left blank, defaults to ds_password. When using a key file, the syntax is fileName=<path/filename> |
| target_path | String | Target folder location for extracted data marts. Default = /local/raid0/sonargd/incoming. |
| target_port | Integer | Port on the target server. Default = 22 (SCP). |
| target_user | String | User for the target_host. If left blank, defaults to ds_user. |
| unit_group | String | Enables data export from the CM or the group's managed units. Default = ALL
For valid values, call enable_big_data_interface from the command line with --help=true . |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Enable the big data export profile for the Basic Summary data mart on the specified host.

```
enable_big_data_interface ds_host=<hostname> ds_user=<username> ds_password=<password> profile_name=Basic summary
```

enable_disable_ip_restriction

This command allows you to specify one or more IP addresses for which you can restrict access by user type (SSH, GUI, or ALL).

When IP restriction is enabled, users can log into Guardium® only if they log in from an address that is on the *allowlist*.

Warning: Always assign one or more IP addresses to the allowlist from which you can access Guardium. If you restrict access to all IP addresses available to users, you will permanently lock all of your users (and yourself) out of Guardium.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/ip_restriction
```

GuardAPI syntax

```
enable_disable_ip_restriction parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| allowlist | String | A comma-separated list of IP addresses for which you want to allow (or restrict) access. |
| enable | Boolean | Required. Specify whether logins are restricted to the IP addresses that are specified in the <i>allowlist</i> . Valid values: <ul style="list-style-type: none">• <i>false</i> (off) - Users can log in from any IP address.• <i>true</i> (on) - Users can log in only from specified addresses. Default = 1 (true) |
| type | String | Required. Specify whether to restrict access to the CLI (SSH), the GUI, or both (ALL) for the IP addresses in the <i>allowlist</i> . Valid values: <ul style="list-style-type: none">• <i>ALL</i> - Both SSH and GUI users.• <i>GUI</i> - Users who log into the Guardium GUI.• <i>SSH</i> - Users who log in to the CLI via SSH. Note: You can run this command multiple times to create allowlists for different login types. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

enable_disable_monitoring_streams

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/monitor_datastream
```

GuardAPI syntax

```
enable_disable_monitoring_streams parameter=value
```

Amazon-specific parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| activate | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Start the data stream. Default = 0 (false) |
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call enable_disable_monitoring_streams from the command line with --help=true.
For more information, see Define, modify, and delete AWS DB service accounts . |
| cluster_resource_id | String | Required. The cluster resource ID for the AWS RDS cluster associated with the stream. |
| collectorHostNames | String | Required. The names of your Guardium collectors, for example: collector01.yourcompany.com
For valid values, call enable_disable_monitoring_streams from the command line with --help=true. |
| consumerGroupName | String | Required. The consumer group name that you assign from the Guardium® Cloud DB Service Protection page. For more information, see Discover and configure AWS data streams . |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| port | String | Required. The DB DNS endpoint port. |
| region | String | Required. For valid values, call enable_disable_monitoring_streams from the command line with --help=true. |
| streamName | String | Required. The name of the stream from the RDS cluster configuration. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Azure-specific parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| activate | Boolean | Activates data streaming. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true): Start the data stream Default = 0 (false) |
| cloudTitle | String | Required. The name of the cloud DB service account. For more information, see Define, modify, and delete Azure cloud database service accounts . |
| collectorHostNames | String | The names of your Guardium collectors, for example: collector01.yourcompany.com |
| consumerGroupName | String | The Azure consumer group name. |
| db_DNS_endpoint | String | Required. The DB DNS endpoint. |
| namespace | String | The Azure event hub namespace. |
| port | String | Required. The DB DNS endpoint port. |
| storageConnectionString | String | The Azure storage connection string name |
| streamName | String | Required. The event hub name. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. enable_fam_crawler

This command enables the FAM file crawler, which sends the file metadata and data from its discovery and classification processes to the Guardium system. The results are automatically added to quick search index files. Use the parameters to schedule quick search for file activity, and entitlement extractions.

Note: The Investigation Dashboard must also be enabled with the command `grdapi enable_quick_search schedule_interval=1`.

This API is available in Guardium V11.4, 11.5 and 12.0.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_fam_crawler
```

GuardAPI syntax

```
enable_fam_crawler parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------------|------------|--|
| activity_schedule_interval | String | Required. The frequency at which the database sends file activity audits to enterprise search. The recommended interval is 2 with <code>activity_schedule_units</code> set to MINUTE. |
| activity_schedule_units | String | Required. The unit for <code>activity_schedule_interval</code> . The recommended unit is MINUTE. Valid values: |
| | | <ul style="list-style-type: none"> • <code>HOUR</code> • <code>MINUTE</code> |
| entitlement_schedule_interval | String | Required. The frequency at which the database sends file entitlements and classifier results to the Guardium system. The recommended interval is 1 with the <code>entitlement_schedule_units</code> set to DAY. |
| entitlement_schedule_units | String | Required. The unit for <code>entitlement_schedule_interval</code> . The recommended unit is DAY. Valid values: |
| | | <ul style="list-style-type: none"> • <code>DAY</code> • <code>HOUR</code> • <code>MINUTE</code> |
| extraction_start | Date | Initial date/time from which data is extracted to the file quick search. The default is current time; the earliest time you can specify is 2 days ago. If the <code>entitlement_schedule_units</code> is set to HOUR, then it is rounded to an hour. If it is set to DAY, then it is rounded to a day. |
| schedule_start | Date | The default is current time. |

Examples

To enable the FAM crawler with the recommended values: file activity audit details are sent are sent every two minutes, and entitlement details are sent daily.

```
grdapi enable_fam_crawler activity_schedule_interval=2 activity_schedule_units=MINUTE entitlement_schedule_interval=1  
entitlement_schedule_units=DAY
```

enable_fips_tls

The API disables TLS 1.3 on a standalone machine, a central manager, or a central manager and all associated managed units. Under some circumstances, for Guardium 12.0 or later, you must disable TLS 1.3 before you can enable FIPS 140 mode.

Before Guardium 12.0, Guardium supported TLS 1.0, 1.1, and 1.2. With the introduction of Guardium 12.0, Guardium supports TLS 1.2 and TLS 1.3. In all cases, Guardium supports the FIPS 140 protocol. However, in some cases, you must disable TLS 1.3 to enable FIPS 140 support.

Specifically, you might run into this issue if you upgrade your central manager to Guardium 12.x, but the managed units remain at pre-12.x releases. In this case, run `enable_fips_tls` on your central manager to disable TLS 1.3 and help ensure that Guardium supports the FIPS 140 protocol. For more information, see [Managing the TLS version](#).

Note: After you disable TLS 1.3, you need to enable FIPS mode and then reboot your server. There are two ways to enable FIPS mode.

- Run the [fipsmode](#) API. Guardium suggests that you set `restart = 1` to automatically restart your system.
- Run the [store_system_fipsmode](#) CLI command and then manually restart your system.

This API runs only on a central manager or standalone machine.

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
enable_fips_tls parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| all | Boolean | Required. Specify whether to disable TLS 1.3 on all associated managed units or only on the current unit. Valid values: <ul style="list-style-type: none">• 0 - Disable TLS 1.3 on the current unit only.• 1 - Disable TLS 1.3 on the current central manager (or standalone machine) and all associated managed units. Default = 0 (false) |
| force | Boolean | Valid values: <ul style="list-style-type: none">• 0 - Do not disable TLS 1.3 if the central manager and managed units are running different Guardium versions.• 1 - Disable TLS 1.3 even if there are differences between Guardium versions on the central manager and its associated managed units. Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

enable_health_analyzer

This command enables the disk and database health analyzer.

By default, the analyzer sends alerts when the system predicts that the database size or files on a disk (/var) will reach 50% in the next 14 days. When enabled, it runs at a predefined schedule with a start time of 05:07:07. The schedule resets any time the health analyzer is enabled or re-enabled.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enableHealthAnalyzer
```

GuardAPI syntax

```
enable_health_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to enable the disk and database health analyzer:

```
grdapicl enable_health_analyzer
```

enable_health_traffic_job

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/traffic_health
```

GuardAPI syntax

```
enable_health_traffic_job parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------|------------|--|
| enable | String | Required. Valid values: <ul style="list-style-type: none">• <i>true</i>• <i>false</i> |

enable_ip_to_host_aliases

This API enables the Guardium IP to hostname aliasing feature.

You can use

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_ip_host_alias
```

GuardAPI syntax

```
enable_ip_to_host_aliases parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|--|
| overrideExistingAliases | Boolean | <p>Required. If set to 1, override any existing found aliases.
Valid values:<ul style="list-style-type: none">• 0 (false)• 1 (true)</p> <p>Note: If your site has manually assigned alias names, you might not want to override them.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:<ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>.</p> <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

enable_latest_tls

Enable the most recent version of TLS (TLSv1.3) by disabling TLSv1.2 on either the current system or on all associated managed units.

Transport layer security (TLS) 1.3 provides a faster and more secure encryption protocol. Your Guardium central manager appliance must be at 12.0 or later. TLS 1.3 is automatically enabled with Guardium 12.x. You can choose to disable TLS 1.2 after your central manager, all associated managed units, S-TAPs, and the GIM client are at Guardium 12.x.

Note: Be very careful about forcing Guardium to disable TLS 1.2 if your configuration includes managed units that are not at Guardium 12.0. In addition, not all add-ons and features support TLS 1.3. For more information, see [Managing the TLS version](#).

Tip: This API takes a few minutes to run.

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
enable_latest_tls parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| all | Boolean | <p>Required. For a central manager, select whether to disable TLS 1.2 on all associated managed units. Valid values:</p> <ul style="list-style-type: none"> 0 (false) - Disable TLS 1.2 on this machine only. 1 (true) - Disable TLS1.2 on this machine and associated managed units. <p>Default = 0 (false)</p> |
| force | Boolean | <p>Specify whether to disable TLS 1.2 when appliance, GIM, or S-TAP versions are incompatible between the central manager and any managed units. Valid values:</p> <ul style="list-style-type: none"> 0 (false) - Do not disable TLS 1.2 if versions are incompatible. 1 (true) - Disable TLS 1.2 even if versions are incompatible. <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

enable_monitoring_ranger_service

Use this command to enable a configured Ranger service (for Hadoop monitoring).

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_monitoring_ranger_service
```

GuardAPI syntax

```
enable_monitoring_ranger_service parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| clusterName | String | Required. Ambari cluster name. |
| serviceName | String | Required. Name of the service. Valid values: <ul style="list-style-type: none"> hdfs hive hbase kafka solr storm |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GrdAPI example

To enable the HDFS service on Cluster4:

```
grdapiclusterName=Cluster4 serviceName=HDFS
```

Sample output:

```
ID=0
The Hadoop service configuration has been changed. Ask the Hadoop administrator to restart the Hadoop service to activate the changes.
HDFS Monitoring Disabled <server name>:5565
```

REST API Example

To enable the HIVE service:

```
curl -k --header "Authorization:Bearer <access token>" -i -H "Content-Type: application/json" -X PUT -d
'{clusterName="Cluster4", serviceName="HIVE"}' https://<guardium server>:8443/restAPI/enable_monitoring_ranger_service
```

Sample output:

```

enable_native_audit

This API enables DB Audit (native audit) on the specified datasource.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/enable_native_audit
```

GuardAPI syntax

```
enable_native_audit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasource_name | String | Required. A cloud datasource defined in Guardium. |
| should_restart | Boolean | Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

enable_outliers_detection

Run this command to enable outliers detection.

The command affects the Guardium systems differently, depending on their setup.

Single CM environment

Enable outliers detection on a CM to enable outliers detection on all managed units, and on all units registered to the CM thereafter, by running the API command with no additional parameters. You can limit the scope to a list of units.

Enable outliers detection on a collector that extracts data to an aggregator. Outliers detection is enabled on the aggregator (if not already enabled) and the collector starts sending data to the aggregator.

Multi-CM environment

Enable outliers detection on a CM to enable outliers detection on all managed units, and on all units registered to the CM thereafter, by running the API command with no additional parameters. You can limit the scope to a list of units.

When you enable outliers on a collector that extracts data to an aggregator that is not in the same CM environment as the collector:

- The collector starts sending data to the aggregator
- The API responds with the name of the aggregator that needs to be enabled for outliers detection

When you enable outliers on an aggregator, outliers detection is enabled and collectors in the same CM environment start sending data. If the aggregator receives data from collectors in a different CM environment, the API responds with list of all collectors that need to be enabled for outliers detection.

To enable on individual aggregators or collectors, use the commands [enable_outliers_detection_cross_cm_agg](#) and [enable_outliers_detection_cross_cm_collector](#).

Single Collector

Run the command on a collector that does not extract data to an aggregator, to enable it locally.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_outliers_detection
```

GuardAPI syntax

```
enable_outliers_detection parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|---|---|
| DAM_FAM | String | Specifies the type of outliers. Valid values: <ul style="list-style-type: none">• DAM• FAM Default = DAM. |
| extraction_start | date in format:
yyyy-mm-dd
hh:mm:ss | Delays the start of data extraction. When not specified, data extraction starts immediately. |
| managed_units_hostnames | String | Comma-separated list of specific managed units on which the command is executed. Optional when you run the API on the CM. |
| schedule_interval | String | Ignored. |
| schedule_start | Date | Ignored. |
| schedule_units | String | Ignored. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Run this command on the CM to enable the outliers detection on all the units under the CM and on all units that will be registered to the CM thereafter:

```
grdapicl enable_outliers_detection
```

Run this command on the CM to enable the outliers detection on all the managed units of groupA:

```
grdapicl enable_outliers_detection group_descriptions=groupA
```

Run this command on the central manager of a cross-CM environment to enable outliers detection on the cross-CM aggregator:

```
grdapicl enable_outliers_detection
Machines found: [<server1>, <server2>]
Machines not found: []
Aggs: []
Cross CM aggs: [<server2>]
```

```
Cross CM Col: []
Standalone Coll: []
Enabling outlier detection on cross cm aggregator: <server2>. Please make sure that you have enabled outliers detection on the
following Cross-CM Collectors: [<server1>].
Analytic anomaly detection is enabled.
ok
```

enable_outliers_detection_agg

Run this API on a central manager to enable outliers detection on the specified aggregator.

It also schedules the datamart that sends outlier data from the collectors (that are in this CM) to the aggregator. It does not enable outlier mining on the collectors.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enableOutliersDetectionOnAgg
```

GuardAPI syntax

```
enable_outliers_detection_agg parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|---|---|
| aggregator_host_name | String | Required. Outliers detection is enabled on this aggregator. |
| DAM_FAM | String | Optional. Specifies the type of outliers. Valid values: <ul style="list-style-type: none">• DAM• FAM The default is DAM. |
| extraction_start | date in format:
yyyy-mm-dd
hh:mm:ss | Use if you want to delay the start of data extraction. When not specified, data extractions starts immediately. |
| schedule_interval | String | Ignored. |
| schedule_start | Date | Ignored. |
| schedule_units | String | Ignored. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To enable outliers detection on the aggregator `agg-sw`, run this command on the central manager of `agg-sw`:

```
grdapiclent enable_outliers_detection_agg aggregator_host_name=agg-sw
```

Related concepts

enable_outliers_detection_cross_cm_agg

Run on a central manager to enable outliers detection on the collector(s) that send data to the specified aggregator(s). This is for use in a multi-central manager environment; the aggregator is in this central manager's environment but the collectors are managed by a different central manager.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enableOutliersDetectionCrossCMOnAgg
```

GuardAPI syntax

```
enable_outliers_detection_cross_cm_agg parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|---|---|
| aggregator_host_name | String | Required. |
| DAM_FAM | String | Optional. Specifies the type of outliers. Valid values: <ul style="list-style-type: none">• DAM• FAM The default is DAM. |
| extraction_start | date in format:
yyyy-mm-dd
hh:mm:ss | Optional. Delays the start of data extraction. When not specified, data extraction starts immediately. |
| schedule_start | Date | Ignored. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To disable outliers detection on the collectors that send data to the aggregator **agg-sw**, run this command on the CM of aggregator **agg-sw**:

```
disable_outliers_detection_agg aggregator_host_name=agg-sw
```

Related concepts

enable_outliers_detection_cross_cm_collector

Run on a central manager to enable outliers on the specified collector(s) in this central manager's environment. This is for use in a multi-central manager environment; the collector is in this central manager's environment but the data is sent to an aggregator in another central manager's environment.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enableOutliersDetectionCrossCMOnCollector
```

GuardAPI syntax

```
enable_outliers_detection_cross_cm_collector parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|---|---|
| collector_host_names | String | The collectors whose analytic data is getting sent to an aggregator outside of its central environment. |
| DAM_FAM | String | The type of outlier data. Valid values: <ul style="list-style-type: none">• DAM• FAM |
| extraction_start | date in the format: yyyy-mm-dd hh:mm:ss | Use if you want to delay the start of data extraction. When not specified, data extraction starts immediately. |
| group_descs | String | |
| schedule_start | | Ignored. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable outliers detection on the collectors `coll1a`, `coll2a`, run this command on the central manager of the collectors:

```
enable_outliers_detection_cross_cm_collector collector_host_names=coll1a,coll2a
```

enable_persistent_queue_universal_connector

Run this API to enable a Persistent Queue on Logstash inputs. Changes take effect only after reloading the configurations or restarting Logstash.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/enablePersistentQueue
```

GuardAPI syntax

```
enable_persistent_queue_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable on the current Guardium system:

```
grdapi enable_persistent_queue_universal_connector  
Guardium Universal Connector command has been executed.
```

enable_policy_analyzer

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_policy_analyzer
```

GuardAPI syntax

```
enable_policy_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

enable_quick_search

This command enables investigation dashboard functionality.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_quick_search
```

GuardAPI syntax

```
enable_quick_search parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| all | Boolean | On a central manager only, use this parameter to enable quick search (investigation dashboard) on all of its managed units. Valid values: <ul style="list-style-type: none">• 0 (false): Do not enable on the central manager's managed units. (Enable on the central manager only.)• 1 (true): Enable on the central manager and all of its managed units. Default = 0 (false) |
| extraction_start | Date | The date by which to start the extraction of audit data for quick search. If this parameter is omitted, extraction starts immediately. |
| includeViolations | Boolean | Whether or not to include violations in the search indexes. Omitting violations can help reduce the size of search indexes. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| schedule_interval | String | Required. Together with the schedule_units parameter, this defines the interval for extracting audit data. For example, schedule_interval=2 schedule_units=MINUTE. |
| schedule_start | Date | Date on which to begin extracting data. |
| schedule_units | String | Required. Together with the schedule_interval parameter, this defines the interval for extracting audit data. For example, schedule_interval=2 schedule_units=MINUTE. Valid values: <ul style="list-style-type: none">• HOUR• MINUTE |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values:
Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To enable quick search on the current unit and all of its managed units:

```
disable_quick_search all=true
```

enable_riskspotter

Run this command on a central manager to enable RiskSpotter on all of the central manager's managed units, or on a stand-alone Guardium system.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/enable_riskspotter
```

GuardAPI syntax

```
enable_riskspotter parameter=value
```

This API takes no parameters.

Examples

Run this command on a central manager to enable RiskSpotter on all of its managed units:

```
grdapicl enable_riskspotter
```

Related concepts

- [Risk Spotter](#)

enable_special_attributes

This API enables non-admin users to view attributes for certain groups in Query-Report Builder.

Within Query-Report Builder, admin users can see all attributes while non-admin users can view only query attributes, except attributes that are designated as admin only (such as IDs). Use `enable_special_attributes` to allow non-admin users to view all of the attributes within a specified `attributesGroup`.

Note: When an attribute group is enabled, all of the attributes within that group are available.

Note: With the following exception, you do not need to restart the GUI for changes to take effect. If a report with the attributes of group F5 is added to My New Reports, a non-admin user does not have privileges to view the report until the GUI is restarted.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
enable_special_attributes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| attributesGroup | String | Required. Valid values: <ul style="list-style-type: none">• <i>data set</i>• <i>ims</i>• <i>hive</i>• <i>apex</i>• <i>mapreduce</i>• <i>bi</i>• <i>ims/data set</i>• <i>f5</i>• <i>db2 i</i> |

Examples

The following example enables Hive attributes for all non-admin users:

```
grdapicl enable_special_attributes attributesGroup=hive
```

Sample output

```
> grdapicl enable_special_attributes attributesGroup=hive
Following Attributes have been Enabled: Hive Parsed SQL, Hive User, Hive Command, Hive Database,
Hive Table Name, Hive Error
ok
```

Related reference

- [disable_special_attributes](#)

enable_strong_cli_password

This command changes the password requirement from 8 to 15 characters for the CLI user.

After you change the password with this command, the CLI user must change their password again on first login.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/strong_cli_password
```

GuardAPI syntax

```
enable_strong_cli_password parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| confirmpassword | String | Required. Confirm the new password. |
| enable | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false): CLI password can be 8 characters.• 1 (true): CLI password must be 15 characters. |
| newpassword | String | Required. The new password for this user. |
| username | String | Required. The name of the user whose password you want to change. The name must be cli. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapic change_cli_password username=cli enable=1 newpassword="Strong!Pass1234!" confirmpassword="Strong!Pass1234!"
```

Related reference

enable_threat_detection_use_case

Use this command to specify which types of use cases are included in the threat detection analysis.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/enable_threat_detection_use_case
```

GuardAPI syntax

```
enable_threat_detection_use_case parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| case_name | String | Required. For valid values, call enable_threat_detection_use_case from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To add the grants use case to the threat detection analysis:

```
grdapi enable_threat_detection_use_case case_name=GRANTS
```

Related concepts

enable_threat_finder

Run this command on a CM or on a standalone unit to enable the threat finder functionality of the Active threat analytics.

Prerequisite: The investigation dashboard (quick search) is enabled.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/enable_threat_finder
```

GuardAPI syntax

```
enable_threat_finder parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To enable threat finder on the standalone unit or on the CM environment:

```
grdapi enable_threat_finder
ID=0
ok
```

encrypt_value

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/encrypt_value
```

GuardAPI syntax

```
encrypt_value parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| key | String | Required. |
| valueToEncrypt | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>; execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

execute_appUserTranslation

This command runs existing application user translations.

This command imports the user definitions for all of the configured applications from the Application User Translation Configuration page. Running this command is the same as selecting Run Once Now from Application User Translation Configuration.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/app_user_translation
```

GuardAPI syntax

```
execute_appUserTranslation parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. execute_assessment

This command submits a security assessment to run.

This command is equivalent to running **Run Once Now** from the Security Assessment Finder. Submitting the job places the process on the Guardium® Job Queue, from where the system runs a single job at a time.

You can see the job Status and the Process Run ID from the Guardium Job Queue.

Note: A Security Assessment must exist before you call this API.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/execute_assessment
```

GuardAPI syntax

```
execute_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|---|
| assessmentDescription | String | Required. The name of the assessment to run. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi execute_assessment assessmentDesc="assessment1"
```

execute_auditProcess

This command runs a specified audit process.

This command is equivalent to running **Run Once Now** from the Audit Process Builder.

Note: Due to a CLI command heap size limitation, if the audit report returns large amounts of data, run the audit process from the GUI.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/audit_process
```

GuardAPI syntax

```
execute_auditProcess parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| auditProcess | String | Required. The name of the audit process to run. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapic execute_auditProcess auditProcess="Appliance Monitoring"
```

execute_autodetect_process

Use this command to run the tasks associated with the specified process. It cannot run if no tasks are defined for the process, or if the process is already running.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/execute_autodetect_process
```

GuardAPI syntax

```
execute_autodetect_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| process_name | String | Required. Name of the auto-discovery process |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To run the process myProcess:

```
grdapi execute_autodetect_process process_name=myProcess
```

execute_cls_process

This command submits classification processes to the job queue.

Using `execute_cls_process` is equivalent to using Run Now from the Run discovery panel of the Discover Sensitive Data tool. It submits the process to the Guardium Job Queue which runs a single job at a time. Administrators can view the job status at Discover->Classification->Guardium Job Queue

Create a classification process before using this command.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/execute_cls_process
```

GuardAPI syntax

```
execute_cls_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| processName | String | Required. The name of the classification process to run. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. execute_incidentGenProcess_byDetails

This command generates incidents based on a defined query (by query name) against the policy violations log.

Use the parameters to filter for specific incidents. This command is the equivalent of running Run Once Now from the Incident Generation Process page.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/execute_incident_gen_process_by_details
```

GuardAPI syntax

```
execute_incidentGenProcess_byDetails parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| categoryName | String | The incident category name. |
| queryName | String | Required. The name of the query. |
| severity | String | The incident severity. |
| threshold | Integer | Threshold. |
| user | String | The username. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. ```
grdapi execute_populateGroupFromQuery groupDesc="A test"
```

Related tasks

- [Populating groups](#)

export_certificate

Use this command to distribute a certificate from a central manager to some or all of its associated managed units.

This API is available in Guardium v11.3 and later.

Note: This command restarts the GUI.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/export_certificate
```

GuardAPI syntax

```
export_certificate parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| alias | String | Required. |
| check_mu | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) • false • true <p>Default = 0 (false)</p> |
| file | String | |
| force | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| host | String | <p>Required. The hostname, where host can be one of the following options:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • group:<group name>: execute on all managed units identified by <group name> • Hostname or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |
| restart_gui | Boolean | Default = 1 (true) |

Example

The following command exports the 'tomcat' certificate to managed units in the 'eastern-mus' managed unit group. Force is enabled to proceed to the next unit if one or more units failed to retrieve the certificate.

```
grdapi export_certificate alias=tomcat host=group:eastern-mus force=true
```

export_config

Use this command to propagate either Venafi or remote logging configurations from a central manager to some or all of its associated managed units.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/export_config
```

GuardAPI syntax

```
export_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| force | Boolean | If set to 1 (true), propagate the requested configuration even if some managed units are offline. If set to 0 (false), all managed units must be online or the command fails with an error message.

Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)• <i>false</i>• <i>true</i>
Default = 0 (false) |
| host | String | Required. The host name, where host can be one of the following: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>group:<group name></code>: execute on all managed units identified by <group name>• Host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>host=10.0.1.123</code>.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |
| type | String | Required. Valid values: <ul style="list-style-type: none">• <code>venafi</code>• <code>remotelog</code> |

Example

The following command sends the remote logging configuration to managed units in the 'eastern-mus' managed unit group. Force is enabled to proceed to the next unit if one or more units fail to retrieve the configuration.

```
grdapi export_config type=remotelog host=group:eastern-mus force=true
```

The following command sends the Venafi configuration to managed units in the 'eastern-mus' managed unit group. Force is enabled to proceed to the next unit if one or more units fail to retrieve the configuration.

```
grdapi export_config type=venafi host=group:eastern-mus force=true
```

- [Remote loggers](#)

export_definition

Exported data is stored in /var/log/guard, for example /var/log/guard/exp_group_2023_05_03_18h28m15s.sql.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
export_definition parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dataSet | String | Required. For valid values, call <code>export_definition</code> from the command line with <code>--help=true</code> . |
| exportToCSV | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| exportToXacml | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| itemName | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

export_log_files

This command exports any compressed and rotated messages from /var/log to a specified target.

Messages (log files) must be in the format *messages-nnn* (for example *messages-1223232*).

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/export_logfiles
```

GuardAPI syntax

```
export_log_files parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| Port | String | |
| RemoteHost | String | Required. |
| RemotePassword | String | Required. |
| RemotePath | String | Required. |
| RemoteUser | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GrdAPI examples

To export log files to a remote host:

```
grdapi export_log_files RemoteHost=9.70.165.194 RemotePassword="password"  
RemotePath="/var/log/" RemoteUser="root"
```

To export log files on a specific port:

```
grdapi export_log_files RemoteHost=9.70.165.194 RemotePassword="password"  
RemotePath="/var/log/" RemoteUser="root" Port=22
```

REST API example

```
curl -k -i --header "Authorization: Bearer <token>" -i -H "Content-Type: application/json" -X POST -d '  
{\"RemoteHost\":\"9.70.165.194\", \"RemotePassword\":\"password\", \"RemotePath\":\"/var/log\", \"RemoteUser\":\"root\" }'  
' https://9.42.32.28:8443/restAPI/export_logfiles
```

export_transfer_key

Use this command to export the SSH transfer keys for the central manager and optionally for the managed units in a deployment, for SCP and SFTP file transfers for archive, data export, and system backup.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/export_transfer_key
```

GuardAPI syntax

```
export_transfer_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| host | String | Required. The remote host to which you send the key pair. |
| password | String | Required. The user for the remote host. |
| user | String | Required. The password for the remote host user. |

api_target_host String

Specifies the target hosts where the API executes. Valid values:

- all_managed: execute on all managed units but not the central manager
- all: execute on all managed units and the central manager
- group:<group name>: execute on all managed units identified by <group name>
- host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, `api_target_host=10.0.1.123`.
- host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, `api_target_host=10.0.1.123`.

IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.

Examples

On the central manager, copy the unique public-transfer-key of each managed unit to the remote host, by entering:

```
grdapi export_transfer_key host="remote_host_1" user="user1" password="password" api_target_host=all
```

On a managed unit, copy the specific, unique, public-transfer-key of the managed unit to the remote host, by entering:

```
grdapi export_transfer_key host="remote_host_1" user="user1" password="password"
```

f5_add_apps_config

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_add_apps_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| appsIP | String | Required. |
| bigIP | String | Required. |

f5_add_data_params

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_add_data_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| maxData | Integer | |
| minData | Integer | |
| paramName | String | Required. |

f5_delete_apps_config

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_delete_apps_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| appsIP | String | Required. |
| bigIP | String | Required. |

f5_delete_data_params

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_delete_data_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| paramName | String | Required. |

f5_list_apps_config

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_list_apps_config parameter=value
```

This API takes no parameters.

f5_list_data_params

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_list_data_params parameter=value
```

This API takes no parameters.

f5_update_data_params

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
f5_update_data_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| maxData | Integer | |
| minData | Integer | |
| paramName | String | Required. |

fipsmode

Enable or disable Federal Information Processing Standard (FIPS) cryptographic standards.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/fipsmode_status
```

GuardAPI syntax

```
fipsmode parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| enable | Boolean | Required. Enable or disable FIPS mode. Valid values: <ul style="list-style-type: none">• 0 (false) - Disable FIPS mode.• 1 (true) - Enable FIPS mode. |
| restart | Boolean | After you enable or disable FIPS mode, you must restart your system. Specify whether to automatically restart. Valid values: <ul style="list-style-type: none">• 0 (false) - Do not automatically restart the system after you enable or disable FIPS mode.• 1 (true) - Automatically restart after you enable or disable FIPS mode. Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group: <group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

GrdAPI example:

```
sys-vm01.rtp.raleigh.ibm.com> grdapic fipsmode enable=1 restart=0
ID=0
=====
Please reboot the machine to complete the process.
=====
```

REST API example:

```
curl -k -i --header "Authorization: Bearer <token>" -i -H "Content-Type: application/json" -X POST -d \
{enable:1, restart:1}
' https://9.32.132.87:8443/restAPI/fipsmode_status
```

flatten_hierarchical_groups

This command flattens all groups that exist in the group builder.

When flattening hierarchical groups, all members of all child groups become direct members of the parent group.

This API is available in Guardium V9.5 and later.

This API takes no parameters.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/flatten_hierarchical_groups
```

GuardAPI syntax

```
flatten_hierarchical_groups
```

Examples

```
grdapic flatten_hierarchical_groups
```

generate_ssl_key_universal_connector

Run this API to configure an SSL connection, instead of the default TCP/UDP connection. This API prints the private key and public certificate to CLI. You need to copy it, and configure it on Filebeat (uncomment the lines as described in the configuration file) on your MongoDB server.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/generateSSLKeyUniversalConnector
```

GuardAPI syntax

```
generate_ssl_key_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| expiration_days | Integer | Default = 100 |
| hostname | String | Hostname of the Guardium machine that generated the API, or wildcard (see default value). Default value: *.guard.swg.usma.ibm.com |
| overwrite | Boolean | Overwrite the existing key and certificate, if they exist. Valid values: <ul style="list-style-type: none">• 0: no• 1: yes Default = 0 (no) |

Examples

To generate the SSL key:

```
grdapi generate_ssl_key_universal_connector hostname=<collector name>
Guardium Universal Connector command has been executed.
```

generate_transfer_key

Use this command to generate individual sets of SSH key pairs for the central manager, and optionally for each managed unit in a deployment, used for SCP and SFTP file transfers of archive, data export, and system backup.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/generate_ssh_keys
```

GuardAPI syntax

```
generate_transfer_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Enter this command on the central manager to generate a key pair for the central manager:

```
grdapi generate_transfer_key
```

Enter this command on the central manager to generate a key pair for the central manager and all managed units:

```
grdapi generate_transfer_key api_target_host=all
```

Related tasks

- [Enabling SSH key pairs for data archive, data export, data mart](#)

getFieldsTitles

The search REST API returns the codes for column names, rather than the column (or field) names themselves. getFieldsTitles maps those codes to the actual column names.

The numbers that are returned are in response to search RESTAPI results.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the **GET** method. Call this API as follows:

GET https://[Guardium hostname or IP address]:8443/restAPI/fieldsTitles

This API takes no parameters.

Examples

Use this API to return a map of all column codes and their names in a search query. For example:

```
curl -k --header "Authorization: Bearer 3499f352-aa98-4046-89d8-aba3d8c7d0fc"  
"https://xxx.xxx.xxx:8443/restAPI/getFieldsTitles"
```

Returns the following information:

```
{  
    "Message": { "19": "Number of Instances",  
                "35": "Execute Privileged Groups",  
                "36": "Execute Privileged Users",  
                "18": "Anomaly Score",  
                "33": "Write Privileged Groups",  
                "15": "Violation",  
                "34": "Write Privileged Users",  
                "16": "Severity",  
                "39": "Modification Time",  
                "13": "Details",  
                "14": "Error",  
                .  
                .  
                .  
                "9": "Time",  
                "8": "Date"}},  
    "ID": 0  
}
```

The hostname is independent of IP mode and can be used with any mode.</p> |

get_cluster_members

This API returns all of the members of a specified S-TAP cluster.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_cluster_members
```

GuardAPI syntax

```
get_cluster_members parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| clusterName | String | Required. |

get_clusters

This API returns a list of all of the S-TAP clusters on this system.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_clusters
```

GuardAPI syntax

```
get_clusters parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_datamart_info

This command returns details on the datamart, for example, the report and query on which the datamart is based, creation date, results are extracted to file or initial start, time granularity, and so on.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
get_datamart_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| datamart_name | String | Required. |
| isExtended | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |

Examples

To output info on data mart Export:RD1:

get_datasource_custom_properties

This command lists all available custom property names and associated values.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop
```

GuardAPI syntax

```
get_datasource_custom_properties parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

The following command lists all datasource custom properties that are configured in your Guardium® system.

```
grdapi get_datasource_custom_properties
```

Related concepts

- [Datasource APIs](#)

get_debug_level

This command returns the debug level for IMS output.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
get_debug_level parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_definitions_data_sets

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_definitions_data_sets
```

GuardAPI syntax

`get_definitions_data_sets`

This API takes no parameters.

`get_definitions_items`

Run this command to return a list of the possible items to export for a given data set type or category.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_definitions_items
```

GuardAPI syntax

```
get_definitions_items parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| dataSet | String | A defined data set. For valid values, call <code>get_definitions_items</code> from the command line with <code>--help=true</code> . |

`get_distributed_report_target_info`

Run this API to see the list of Guardium systems defined as targets for distributed reports.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
get_distributed_report_target_info
```

This API takes no parameters.

Examples

To return the list of defined targets for distributed reports:

```
grdapic get_distributed_report_target_info
```

Related concepts

- [Distributed report builder](#)

`get_entitlement_optimization_info`

Displays the entitlement optimization configuration for all data sources on this Collector.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/getEntitlementOptimizationInfo
```

GuardAPI syntax

```
get_entitlement_optimization_info
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

```
grdapi get_entitlement_optimization_info
```

Sample output:

```
Entitlement Optimization is enabled
=====
Datasource: DB16
=====
isEnabled: true
userScope:
objectScope:

get_expiration_date_for_restored_day

This command returns the expiration date for data restored from the specified date.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/expiration_date_for_restored_day
```

GuardAPI syntax

```
get_expiration_date_for_restored_day parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| restoredDay | String | Required. Identifies the day whose data was restored. The format is one of: real day <code>yyyy-mm-dd hh:mi:ss</code> ; or relative day such as <code>NOW -10 day</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To return the expiration date for restored data, dated 10 days ago:

```
grdapi get_expiration_date_for_restored_day restoredDay=NOW -10 day
```

get_extraction_profile_info

Lists one or more GBDI (Big Data) profiles and whether they are active, and optionally the datamarts and schedules for each profile.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/extractionProfile
```

GuardAPI syntax

```
get_extraction_profile_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| profile_name | String | If specified, it is used as search filter, returning all profile names containing the specified string. |
| verbose | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false): lists the profile name and indicates if a profile is active. • 1 (true): lists the datamarts and schedules for each profile. <p>Default = 0 (false)</p> |
| verbosity_flags | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

View details of the profile `sql_all`.

```
get_extraction_profile_info profile_name=sql_all verbose=1
```

get_fam_crawler_info

Shows the status of the FAM crawler. If it is enabled, the response also shows the settings for the entitlement extraction and the quick search file activity schedule.

This API is available in Guardium V11.4, 11.5 and 12.0.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_fam_crawler_info
```

GuardAPI syntax

```
get_fam_crawler_info
```

Examples

```
grdapic get_fam_crawler_info
```

Two typical responses, for FAM crawler disabled, and FAM crawler enabled:

FAM Crawler (server side) is disabled.

FAM Crawler (server side) is enabled. Entitlement(1 DAY) Activity(2 MINUTE)

get_flatLogProcessType

This command displays the processType of the current flat log file.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/flatLogProcessType
```

GuardAPI syntax

```
get_flatLogProcessType parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi get_flatLogProcessType
```

Sample output:

```
ID=1
FLAT_LOG_PROCESS_TYPE:1 - Process
```

Related concepts

- [Flat Log Process](#)

get_guard_param

This generic command returns the current value of parameters that can be modified with the API `modify_guard_param`.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_guard_param
```

GuardAPI syntax

```
get_guard_param parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| paramdesc | String | |
| paramName | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi get_guard_param
```

```
grdapi get_guard_param paramName=classifier_running_timeout
```

get.hadoop_cluster_status

This API returns the status of a Hadoop cluster on a specified host. This command only checks to see that the S-TAP® has been set up as a remote logger for Ranger.

This command does not validate that auditing is turned on at Ranger or that traffic is actually flowing. You need to run reports or look in the investigation dashboard on the appliance to see if traffic is flowing to the appliance.

This API is available in Guardium V10.1.4 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_hadoop_cluster_status
```

GuardAPI syntax

```
get_hadoop_cluster_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| clusterName | String | Required. The name of the cluster. |
| password | String | Required. Password for the cluster. |
| serverHostName | String | Required. Ambari host name. |
| serverPort | Integer | Ambari port. |
| sslEnabled | Boolean | Valid values: <ul style="list-style-type: none">• 0: false• 1: true Default = 0 |
| userName | String | Required. Admin ID for Ambari. |

API example

```
grdapi get_hadoop_cluster_status serverHostName=<server name> serverPort=8080 userName=admin password=admin clusterName=c5HDFS
Monitoring EnabledHBASE
Monitoring EnabledHIVE
Monitoring EnabledKAFKA
Monitoring Enabled
```

get_health_traffic_status

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/traffic_health
```

GuardAPI syntax

```
get_health_traffic_status parameter=value
```

Parameters

get_inapplicable_test_result_status

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/inapplicable_test_result_status
```

GuardAPI syntax

```
get_inapplicable_test_result_status parameter=value
```

get_insights_agent_config

List all of the Guardium® Insights task manager parameters.

To update the Guardium Insights task manager parameters, use the [update_insights_agent_config](#) GuardAPI.

Important: Some parameters display for informational purposes only and cannot be changed.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/insights_agent_config
```

GuardAPI syntax

```
get_insights_agent_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| paramName | String | Displays the value of the specified parameter. |

Related reference

- [update_insights_agent_config](#)

get_ip_restriction_config

This command displays whether IP restriction is enabled or disabled.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/ip_restriction
```

GuardAPI syntax

```
get_ip_restriction_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. get_ip_to_alias_overwrites

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/ip_to_alias_overwrites
```

GuardAPI syntax

```
get_ip_to_alias_overwrites parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_ip_to_alias_selected

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/ip_to_alias_selected
```

GuardAPI syntax

```
get_ip_to_alias_selected parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_istap_config

Run this command to view the configuration parameters, including the current filtering options, for an S-TAP® on an IBM i server.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/istap_config
```

GuardAPI syntax

```
get_istap_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| datasourceName | String | Required. IP or name of the IBM i server. |

Examples

Run this command to see the S-TAP configuration on the IBM i server with the IP 11.11.11.11:

```
grdapic get_istap_config datasourceName=11.11.11.11
```

Related concepts

- [DB2 for IBM i S-TAP](#)

get_istap_status

Run this command to check whether the IBM i audit server is running. The output includes additional information (such as the number of messages on the queue, the size of the message queue, and so on) that can be useful for troubleshooting and performance tuning.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/istap_status
```

GuardAPI syntax

```
get_istap_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| datasourceName | String | Required. IP or name of the IBM i server. |

Examples

Run this to see the status of the IBM i server with the IP 11.11.11.11:

```
grdapi get_istap_status datasourceName=11.11.11.11
```

Related concepts

- [DB2 for IBM i S-TAP](#)

Related reference

get_job_process_concurrency_limit

This command shows the job process concurrency limit.

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
get_job_process_concurrency_limit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi set_job_process_concurrency_limit
```

get_kafka_clusters

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/kafka_cluster
```

GuardAPI syntax

```
get_kafka_clusters parameter=value
```

get_load_balancer_load_map

This API returns the current load balancer map.

You can filter the map by managed unit, S-TAP®, or IP address.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
get_load_balancer_load_map parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| muHost | String | The managed unit host name. |
| stapHost | String | Host name of the server where the S-TAP is installed. You can enter a full or partial name. Guardium finds partial values only if the S-TAP is stored as corresponding value. |
| stapIP | String | The S-TAP IP address. You can enter the full or a partial address. Guardium finds partial values only if the S-TAP is stored as corresponding value. |

get_mfa_configuration

This command displays the current multi-factor authentication settings for the GUI, CLI, and SSH.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/configure_mfa
```

GuardAPI syntax

```
get_mfa_configuration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_native_audit_collectors

This API returns the name of the collector, in your environment, that is receiving data from the specified host, port, and service name.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/nau_collectors_list
```

GuardAPI syntax

```
get_native_audit_collectors parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| host | String | Required. The hostname or the IP address of the server that is hosting the database that you are monitoring. |
| port | Integer | Required. |
| service_name | String | Required. For a Db2 data source, enter the database name. For other data sources, enter the service name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. get_ranger_config

This command returns the Ambari administrator ID, Ambari server name, and Ambari port for the specified Ambari cluster.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_ranger_config
```

GuardAPI syntax

```
get_ranger_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GrdAPI example

To view the configuration of the cluster named Cluster4:

```
grdapi get_ranger_config clusterName=Cluster4
```

System response:

```
admin@<server>:<port> Cluster4 SSL enabled: true
```

REST API example

To view the configuration of the cluster named Cluster4:

```
curl -k -i --header "Authorization:Bearer <access token>" https://<Guardium server name>:8443/restAPI/get_ranger_config?
clusterName=Cluster4
```

Sample output:

```
[{"id": 1, "clusterName": "Cluster4", "serverHost": "<server>", "serverPort": 8080, "userName": "admin", "lastRefresh": "2016-10-03 18:06:31", "status": []}]

get_ranger_services_status

Use this command to view status of the ranger services, optionally on a specified cluster. It does not necessarily indicate that traffic is flowing.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_ranger_services_status
```

GuardAPI syntax

```
get_ranger_services_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Use this parameter to restrict the output to the status of this cluster only. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GrdAPI example

To view the status on the cluster named Cluster4:

```
grdapic get_ranger_services_status clusterName=Cluster4
```

Sample output:

```
admin@hw-cl4-05:8080 Cluster4
```

REST API example

To view the services that are set up to be monitored:

```
curl -k -i --header "Authorization:Bearer <access token>" https://<Guardium server name>:8443/restAPI/get_ranger_services_status?clusterName=Cluster4
```

Sample output, showing services that are not currently monitored ("id": 0 and "ambariConfigId": -1):

```

get_registered_units

REST API syntax

12.1 and later This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/get_registered_units
```

GuardAPI syntax

```
get_registered_units parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| secretKey | String | Required. Default value = 0 |
| unitIp | String | Required. Default value = 0 |
| unitPort | String | Required. Default value = 0 |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> <code>all_managed</code>: execute on all managed units but not the central manager <code>all</code>: execute on all managed units and the central manager <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_secured_protocols_info

This API returns the version of TLS that is enabled or disabled on both a central manager and its managed units.

For Guardium 12.0 and later use this API to see the Guardium and TLS versions for the central manager, all managed units, the GIM client, and any S-TAPs As you upgrade managed units, S-TAPs and so on to Guardium 12.0, you can use the [enable_latest_tls](#) API to enable TLS 1.3.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
get_secured_protocols_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fullscan | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

get_solr_cluster_info

Use this command, on a central manager only, to output details on the Solr cluster: the registered managed units and their status.

The output is written to /var/IBM/Guardium /log/solr_cluster_info.txt. (The output can be very large if there are many MUs).

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
get_solr_cluster_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

```
grdapic get_solr_cluster_info
```

Sample response:

```
Please see the following file for results: /var/IBM/Guardium/log/solr_cluster_info.txt
```

get_solr_errors

This command outputs exceptions/warnings from the solr.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
get_solr_errors parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| logToFile | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

```
grdapic get_solr_errors
```

Related reference

- [Solr APIs](#)

get_solr_status

This command returns the status of solr installation on the specified Guardium® system(s).

This command can return a few outputs (which can be translated on ApplicationResources.properties). If solr is not enabled:

- If solr is not enabled: Solr is not enabled on this machine
- If solr is enabled but not running: Solr is not running
- If solr is enabled and running: Solr is running

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
get_solr_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| get_error_details | Boolean | If this parameter is set to true and solr is not running because of some exception, this exception is also written to console. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi get_solr_status get_error_details=true
```

Related reference

- [Solr APIs](#)

get_solr_status_extended

This command returns the status of solr installation on the specified Guardium® systems.

This API is similar to [get_solr_status](#), but get_solr_status_extended makes additional checks to determine if solr is running.

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
get_solr_status_extended parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| get_error_details | Boolean | <p>If this parameter is set to true and solr is not running because of some exception, this exception is also written to console. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_streams

This API returns configuration information for the AWS data streams or Azure event hubs for the specified cloud DB service account (cloudTitle).

For this API, the following rules apply for status information:

- REST API: When available, returns the status, along with configuration information, for the stream or event hub.
- GuardAPI:
 - On a central manager: Returns configuration information. In addition, if the stream is assigned to a collector, then the API also returns the status of the stream for that collector.
 - On stand-alone or managed units: Configuration information displays, but status is not available.

Status information is available in the UI at Discover > Database Discovery > Cloud DB Service Protection. Select a Cloud database service account to see status and other information.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasream
```

GuardAPI syntax

```
get_streams parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| cloudTitle | String | Required. The name of the cloud DB service account. For valid values, call <code>get_streams</code> from the command line with <code>--help=true</code> . For more information, see Define, modify, and delete AWS cloud DB service accounts . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_test_result_detail_string_setting

This command displays the tables into which the detailed test findings for a vulnerability assessment are written.

This API is available in Guardium V11.4 and later.

This API takes no parameters.

For backward compatibility, Vulnerability Assessment (VA) continues to store all detailed test results in one record in addition to creating a separate record for each detailed finding. The API command `get_test_result_detail_string_setting` displays the entities into which the detailed test findings are written.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/detail_string_setting
```

GuardAPI syntax

```
get_test_result_detail_string_setting parameter=value
```

Example

Example 1:

```
grdapi get_test_result_detail_string_setting
ID=0
Test details are written to the TEST_RESULT_DETAIL and TEST_RESULT tables.
ok
```

Example 2:

```
grdapi get_test_result_detail_string_setting
ID=0
Test details are written only to the TEST_RESULT_DETAIL table.
ok
```

- [Assessment APIs](#)

get_threat_detection_use_case_info

Run this command to see which types of use cases are included in the threat detection analysis.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/threat_detection_use_case_info
```

GuardAPI syntax

```
get_threat_detection_use_case_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To see which use case types are included in the threat detection analysis:

```
grdapi get_threat_detection_use_case_info
Use case: INSIDER_THREAT - disabled
Use case: GRANTS - enabled
Use case: STP - enabled
Use case: SQL_INJECTION - enabled
```

get_unit_data

This command returns details about the current appliance, including the host name and IP address, unit type, Guardium version, and information about the most recently installed patch.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/unit_data
```

GuardAPI syntax

```
get_unit_data parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

get_unit_pinger

This API queries the internal UnitPinger thread.

Note: This command must be called with `api_target_host=127.0.0.1` parameter.
This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
get_unit_pinger parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|-------------|
| name | String | |
| api_target_host | String | 127.0.0.1 |

Examples

```
grdapi get_unit_pinger api_target_host=127.0.0.1
```

Related reference

- [restart_unit_pinger](#)

get_universal_connector_allowed_domains

Run this API to output a list of cloud-based database domains that are authorized for communication with the local or specified Guardium system.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/getUcAllowedDomains
```

GuardAPI syntax

```
get_universal_connector_allowed_domains parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To list the allowed domains on the local system:

```
grdapi get_universal_connector_allowed_domains
ID=0
amazonaws.com
ok
```

Related reference

- [Guardium universal connector APIs](#)

get_universal_connector_status

Returns the status of the Guardium universal connector, on the local or the specified collectors.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/getUniversalConnectorStatus
```

GuardAPI syntax

```
get_universal_connector_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

This output indicates a fully running Guardium universal connector:

```
grdapi get_universal_connector_status
ID=0
Guardium Universal Connector is running.
ok
```

This output indicates a disabled universal connector:

```
grdapi get_universal_connector_status
ID=0
Guardium Universal Connector is disabled.
ok
```

Related concepts

get_va_summary_key

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/get_va_summary_key
```

GuardAPI syntax

```
get_va_summary_key
```

This API has no parameters.

get_wkc_config

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/wkc
```

GuardAPI syntax

```
get_wkc_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| units | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. The hostname is independent of IP mode and can be used with any mode.</p> |

gim_assign_bundle_or_module_to_client_by_version

Assigns a bundle a module to a client, based on the module version.

This API is similar to `gim_assign_latest_bundle_or_module_to_client`, except that you must specify the exact version of the module or bundle to assign.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_client_assign
```

GuardAPI syntax

```
gim_assign_bundle_or_module_to_client_by_version parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|------------------------------|
| clientIP | String | Required. Client IP address. |
| module | String | Required. |
| moduleVersion | String | Required. |

Examples

```
grdapic Gim_assign_bundle_or_module_to_client_by_version clientIP=192.168.1.100 module=BUNDLE-STAP moduleVersion="8.0_r1234_1"
```

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_assign_latest_bundle_or_module_to_client

Use the `gim_assign_latest_bundle_or_module_to_client` API to assign the latest (that is, the highest version) available bundle or module to a specified client.

This API is similar to `gim_assign_bundle_or_module_to_client_by_version`. However `gim_assign_latest_bundle_or_module_to_client` always assigns the most recent version of the bundle or module to the client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_assign_latest_bundle
```

GuardAPI syntax

```
gim_assign_latest_bundle_or_module_to_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |
| module | String | Required. |

Examples

```
grdapi gim_assign_latest_bundle_or_module_to_client clientIP=192.168.1.100 module=BUNDLE_STAP
```

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_cancel_install

Cancel the installation of a bundle or module for a specified client.

Use this API to cancel installing a module or bundle that is not being installed by a client (that is, STATE=IP or IP-PR).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_cancel_install
```

GuardAPI syntax

```
gim_cancel_install parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |
| module | String | Required. |

Examples

Cancel the installation of the BUNDLE-STAP module.

```
grdapi gim_cancel_install clientIP=192.168.1.100 module=BUNDLE-STAP
```

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_cancel_uninstall

Use this API to cancel the scheduled uninstall of a specified bundle or module for a client.

You can cancel an uninstall only if the module or bundle is not being uninstalled (that is STATE=IP or IP-PR).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_cancel_uninstall
```

GuardAPI syntax

```
gim_cancel_uninstall parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |
| module | String | Required. |

Examples

```
grdapi gim_cancel_uninstall clientIP=192.168.1.100 module=BUNDLE-STAP
```

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_get_available_modules

List the modules or bundles available to install on a specified server.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_available_modules
```

GuardAPI syntax

```
gim_get_available_modules parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |

Examples

```
grdapi gim_get_available_modules clientIP=192.168.1.100
```

Related concepts

- [Guardium Installation Manager](#)

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_get_client_last_event

List the latest operation executed for a specified client.

This API shows the last event that occurred during the latest installation attempt. For example, if there were errors during the latest installation of S-TAP, you can run `gim_get_last_event` to show the errors. However, if you manually fix the installation problem directly on the database server, this command still shows the same original error message (even though S-TAP is now running). Do not use `gim_get_last_event` to evaluate S-TAP status after you make manual fixes on the database server.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_client_last_event
```

GuardAPI syntax

```
gim_get_client_last_event parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |

Examples

Use the clientIP to specify where to look for the latest events. For example:

```
grdapi gim_get_client_last_event clientIP=192.168.1.100  
grdapi gim_get_client_last_event clientIP=winx64
```

Related concepts

- [Guardium Installation Manager](#)

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_get_global_param

Return the value of a GIM global parameter.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
gim_get_global_param parameter=value
```

Parameters

| Parameter | Value type | Description |
|---|------------|--|
| paramName | String | Required. Name of the parameter to set, listed in the following table. |
| Parameter name | Value type | Description |
| auto_install_on_db_server_os_upgrade | Boolean | If enabled, automatically upgrade modules when the client operating system vendor version changes. Valid values: <ul style="list-style-type: none">• 0: Disabled• 1: Enabled Default = 0
For more information, see Linux®-UNIX: Managing GIM clients when upgrading your database server operating system , and Managing S-TAP when upgrading your database operating system . |
| dynamic_alive_enabled | Boolean | Controls the dynamic alive feature. Valid values: <ul style="list-style-type: none">• 0: Disabled• 1: Enabled Default = 0
For more information, see GIM dynamic updating . |
| enable_secure_unauthenticated_communication | Boolean | If enabled, allow unauthenticated GIM communication over a secure port: communication between the GIM client and server are encrypted with SSL on port 8444, but the communication is handled without using certificates for peer authentication. Valid values: <ul style="list-style-type: none">• 0: Disabled• 1: Enabled Default = 0
The enable_secure_unauthenticated_communication allows distributing new GIM client certificates when it is time to replace certificates. |
| gim_auto_certificate_distribution | Boolean | Controls automatic distribution of certificates to GIM clients. Valid values: <ul style="list-style-type: none">• 0: disabled• 1: enabled Default = 0
For more information, see Create and manage GIM certificates . |
| gim_file_upload_token | string | Define the GIM file upload exchange token. |
| gim_listener_default_port | string | Define the GIM listener default port.
Default = 88445

For more information, see Gim server allocation . |
| gim_listener_default_shared_secret | string | Define the GIM listener encrypted shared secret.
For more information, see Gim server allocation . |
| gim_quick_start_enable | Boolean | Controls the GIM quick start feature. Valid values: <ul style="list-style-type: none">• 0: disabled• 1: enabled Default = 0 |

Examples

Return the value of the gim_listener_default_port parameter.

```
grdapi gim_get_global_param paramName=gim_listener_default_portID=0
8445
ok
```

gim_get_modules_running_status

List the modules or bundles currently running on a specific server.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
gim_get_modules_running_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| clientIP | String | Required. The client IP address |
| process | String | The process name |
| status | String | Valid values are: <ul style="list-style-type: none">• ON• OFF |

Examples

```
grdapi gim_get_modules_running_status clientIP=192.168.1.100 process= status=
```

Related concepts

gim_list_bundles

Use the gim_list_bundles API to list all of the available bundles for a client. A bundle is a group of modules that can be installed on a client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_bundle
```

GuardAPI syntax

```
gim_list_bundles
```

Examples

This API takes no parameters:

```
grdapi gim_list_bundles
```

Related concepts

- [Guardium Installation Manager](#)

Related reference

- [Guardium Installation Manager \(GIM\) APIs](#)

gim_list_client_modules

Lists all the modules that are assigned to a specific client along with their state.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_list_client_modules
```

GuardAPI syntax

```
gim_list_client_modules parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |

Examples

```
grdapi gim_list_client_modules clientIP=192.168.2.210
```

Related concepts

- [Guardium Installation Manager](#)

Related reference

gim_list_client_params

Lists all of the (module) parameters that are assigned to a specific GIM client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_client_params
```

GuardAPI syntax

```
gim_list_client_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|------------------------------|
| clientIP | String | Required. Client IP address. |

Examples

```
grdapi gim_list_client_params clientIP=192.168.12.210
```

Related concepts

gim_list_mandatory_params

Lists all of the required parameters for the specified version of a module.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
gim_list_mandatory_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| module | String | Required. |
| version | String | Required. |

Examples

Both the module name and module version number are required. For example:

```
grdapic Gim_list_mandatory_params module=name version=number
```

gim_list_registered_clients

Lists all the registered clients for Guardium Installation Manager (GIM).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_registered_clients
```

GuardAPI syntax

```
gim_list_registered_clients
```

Examples

List all of the registered GIM clients for your site.

```
grdapic Gim_list_registered_clients
```

gim_list_unused_bundles

Returns a list of unused (not installed on any database server) bundles and individual Windows modules that can be uploaded (for example, Windows CAS or Windows FAM).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_unused_bundles
```

GuardAPI syntax

```
gim_list_unused_bundles parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| includeLatest | Boolean | Required. If set to 1, the returned list includes the latest unused bundle. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following example returns a list of unused bundles, including the most recent:

```
grdapi gim_list_unused_bundles includeLatest=1
```

Related concepts

gim_load_package

Loads all of the modules within a specified filename.

Note: This command loads one or more files that reside on the local file system. Therefore, the procedure (cmd='fileserver') of loading a file to the CM/Guardium appliance must precede this command.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/gim_package
```

GuardAPI syntax

```
gim_load_package parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------|------------|-------------|
| filename | String | Required. |

Examples

The following example finds all files with the file type 'gim'. Use the * (asterisk) as a wildcard to find files.

```
grdapic Gim_load_package filename=*.gim
```

Related concepts

gim_remote_activation

Connects the collector's IP address to a server mode GIM agent or group of GIM agents.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
gim_remote_activation parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| connectToCollector | String | The appliance to which you want the GIM listener or client to connect to after it is activated. |
| sharedSecret | String | The shared secret that was configured during installation. |
| targetGroup | String | The group name of all the database servers that the collector connects to.
You can specify either targetGroup or targetHost, but not both. |
| targetHost | String | The database server on which the GIM listener is running.
You can specify either targetGroup or targetHost. |
| targetPort | Integer | The port server mode of the GIM agent. |

Examples

```
grdapic Gim_remote_activation targetGroup=<someGroup> sharedSecret=<password> targetPort=8445
```

gim_remove_bundle

Delete a bundle from both the database and the file system.

You can use the wildcard character (*) to delete all unassigned bundles.

The gim_remove_bundle API removes a specified bundle from both /var/log/guard/gim_packages, and, if the Guardium® system is a central manager, from /var/gim_dist_packages.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/gim_remove_bundle
```

GuardAPI syntax

```
gim_remove_bundle parameter=value
```

| Parameter | Value type | Description |
|-------------------|------------|--|
| bundlePackageName | String | Required. The value must be unique and refer to an existing bundle that is not assigned to any client. Specify an asterisk (*) to delete all unassigned bundles. |

Examples

To specify a bundle to delete:

```
grdapi gim_remove_bundle bundlePackageName= hadriansBundle
```

To delete all unassigned bundles:

```
grdapi gim_remove_bundle bundlePackageName=*
```

Sample output:

```
Failed removing bundle (Can't delete module BUNDLE-GIM 11.5.0_r105891_1 as part of bundle guard-BUNDLE-GIM-10.5.0_r105891_v10_5_1-r1)

gim_reset_client

Refresh connection to the specified client by disassociating and re-associating the GIM module.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
gim_reset_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |

Examples

```
grdapi gim_reset_client clientIP=192.168.1.100
```

Related concepts

gim_schedule_install

Schedules installation for all the modules or bundles that are assigned to a client, but are not yet installed.

Schedules the installation of modules or bundles that are, for example, in a PENDING state. If you specify the module parameter , only the requested module is scheduled.

Note: Schedule a past date to run the job immediately.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_schedule_install
```

GuardAPI syntax

```
gim_schedule_install parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| clientIP | String | Required. |
| date | String | Required. The installation date in the format now or yyyy-MM-dd HH:mm |
| module | String | If module is not specified, all of the modules for the specified clientIP are scheduled for installation. |

Examples

Schedule an installation for one or more modules.

```
grdapi gim_schedule_install clientIP=192.168.1.100 module=BUNDLE-STAP date="2019-07-02 14:50"
```

```
grdapi gim_schedule_install clientIP=192.168.1.100 date="2019-07-02 14:50"
```

gim_schedule_uninstall

Schedule an uninstall of the module or bundles that are assigned to a client but are not yet uninstalled (that is, in PENDING state).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_schedule_uninstall
```

GuardAPI syntax

```
gim_schedule_uninstall parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| clientIP | String | Required. |
| date | String | Required. The installation date in the format now or yyyy-MM-dd HH:mm |
| module | String | If module is not specified, all of the modules for the specified clientIP are scheduled for the uninstall. |

Examples

The following example schedules an uninstall for the BUNDLE-STAP module:

```
grdapi gim_schedule_uninstall clientIP=192.168.1.100 module=BUNDLE-STAP date="2019-07-02 14:50"
```

The following example schedules an uninstall for all of the client's modules:

```
grdapi gim_schedule_uninstall clientIP=192.168.1.100 date="2019-07-02 14:50"
```

gim_set_global_param

Use this API to set global parameters for GIM clients.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
gim_set_global_param parameter=value
```

Parameters

| Parameter | Value type | Description |
|---|------------|---|
| paramName | String | Required. Name of the parameter to set, listed in the following table. |
| paramValue | String | Required. The value for the paramName. |
| Parameter name | Value type | Description |
| auto_install_on_db_server_os_upgrade | Boolean | If enabled, automatically upgrade modules when the client operating system vendor version changes. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
For more information, see Linux®-UNIX: Managing GIM clients when upgrading your database server operating system , and Managing S-TAP when upgrading your database operating system . |
| dynamic_alive_enabled | Boolean | Controls the dynamic alive feature. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
For more information, see GIM dynamic updating . |
| enable_secure_unauthenticated_communication | Boolean | If enabled, allow unauthenticated GIM communication over a secure port: communication between the GIM client and server are encrypted with SSL on port 8444, but the communication is handled without using certificates for peer authentication. Valid values: <ul style="list-style-type: none"> • 0: Disabled • 1: Enabled Default = 0
The enable_secure_unauthenticated_communication allows distributing new GIM client certificates when it is time to replace certificates. |

| Parameter name | Value type | Description |
|------------------------------------|------------|--|
| gim_auto_certificate_distribution | Boolean | Controls automatic distribution of certificates to GIM clients. Valid values: <ul style="list-style-type: none">• 0: disabled• 1: enabled Default = 0
For more information, see Create and manage GIM certificates . |
| gim_file_upload_token | string | Define the GIM file upload exchange token. |
| gim_listener_default_port | string | Define the GIM listener default port.
Default = 88445

For more information, see Gim server allocation . |
| gim_listener_default_shared_secret | string | Define the GIM listener encrypted shared secret.
For more information, see Gim server allocation . |
| gim_quick_start_enabled | Boolean | Controls the GIM quick start feature. Valid values: <ul style="list-style-type: none">• 0: disabled• 1: enabled Default = 0 |

Examples

Set the value of gim_listener_default_port.

```
grdapi gim_set_global_param paramName=gim_listener_default_port paramValue=8445
```

gim_unassign_client_module

Unassign a module from a client.

Unlike gim_remove_module, this command undoes the connection between a module and a specific client on the central manager, but does not uninstall or remove the module on the actual database server.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_unassign_client_module
```

GuardAPI syntax

```
gim_unassign_client_module parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| clientIP | String | Required. |
| module | String | |

Examples

To unassign the STAP module from the client:

```
grdapi gim_unassign_client_module clientIP=192.168.1.100 module=STAP
```

Related concepts

- [Guardium Installation Manager](#)

gim_uninstall_module

Uninstalls a module or bundle for a specific client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/gim_uninstall_module
```

GuardAPI syntax

```
gim_uninstall_module parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| clientIP | String | Required. |
| date | String | The date and time to uninstall in the format now or yyyy-MM-dd HH:mm |
| module | String | Required. |

Examples

Uninstall the BUNDLE-STAP module immediately:

```
grdapi gim_uninstall_module clientIP=192.168.1.100 module=BUNDLE-STAP
```

Related concepts

- [Guardium Installation Manager](#)

gim_update_client_params

Updates a single module parameters in a specific client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/gim_client_params
```

GuardAPI syntax

```
gim_update_client_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| clientIP | String | Required. IP address of target client. |
| paramName | String | Required. |
| paramValue | String | |

Examples

```
grdapi gim_update_client_params clientIP=192.168.1.100 paramName=STAP_TAP_IP paramValue=192.168.1.100
```

grant_role_to_object_by_Name

This command assigns a role to a specified object by names.

Guardium checks the dependencies before it adds the role. For example, before Guardium adds a role to a Classification process, the role must be assigned to all components that are contained by that process (that is, the classification policy and any datasources that it references).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/grant_role_to_object_by_Name
```

GuardAPI syntax

```
grant_role_to_object_by_Name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| objectName | String | Required. The name of the object (such as a query or report) to which to assign the role. When objectName is set to <code>ALL</code> , the role that is specified is assigned to all objects. |
| objectType | String | Required. The type of object to which to assign the role. For valid values, call <code>grant_role_to_object_by_Name</code> from the command line with <code>--help=true</code> . |
| role | String | Required. The name of the role to assign. Specify any existing role. Specify <code>all_roles</code> to allow access by all roles. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI examples

```
grdapapi grant_role_to_object_by_Name objectType=Datasource objectName= "swanSybase" role=admin  
grdapapi grant_role_to_object_by_Name objectType="SecurityAssessment" objectName="ALL" role="user"
```

When the object Name is set to `ALL`, the role of `user` is assigned to all objects of type `SecurityAssessment`.

Related concepts

- [Understanding Roles](#)

grant_role_to_object_by_id

This command assigns a role to a specified object by IDs.

Guardium checks the dependencies before it adds the role. For example, before Guardium adds a role to a Classification process, the role must be assigned to all components that are contained by that process (that is, the classification policy and any datasources that it references).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/grant_role_to_object_by_id
```

GuardAPI syntax

```
grant_role_to_object_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| objectId | Integer | Required. The ID of the object to assign the role to. |
| objectTypeId | Integer | Required. The type of object. For valid values, call grant_role_to_object_by_id from the command line with --help=true. |
| roleId | Integer | Required. The ID of the role to assign to the object. Specify any existing role ID or specify -1 to allow access by all roles. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

| file | File | |

insights_registration

This API allows you to register Guardium® Data Protection to Guardium Insights that allows you to use Guardium Insights data with Guardium Data Protection features such as health and data mart reports.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/insights_registration
```

GuardAPI syntax

```
insights_registration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| insights_apikey_token | String | Required. An API token that is generated from Guardium Insights to allow external sources to execute RESTAPI calls on Guardium Insights. The token includes the encrypted Guardium Insights tenant ID. |
| insights_ca_cert_cn | String | The Insights certificate common name that is generated when the certificate is created. During the registration process, you can specify the certificate common name to verify the CN field as part of the standard certificate exchange authentication. |
| insights_url | String | Required. The Guardium Insights URL. |

Related reference

- [insights_unregistration](#)
- [update_insights_registration_config](#)

insights_unregistration

This API removes the registration information for Guardium® Insights from Guardium Data Protection.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/insights_registration
```

GuardAPI syntax

```
insights_unregistration
```

Related reference

- [insights_registration](#)
- [update_insights_registration_config](#)

kill_running_process

This API stops a long-running process.

Use the [list_running_processes](#) API to find the process ID of the process you want to stop.

For more information about long running processes, see [list_running_processes](#).

You can view or change the timeout duration from either the Running Query Timeout page in the UI or by using the [show_maximum_query_duration](#) and [store_maximum_query_duration](#) APIs.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/kill_running_process
```

GuardAPI syntax

```
kill_running_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| processID | Long | Required. The ID of the process to stop. |

Examples

The following examples both stop process 74 from running.

```
grdapi kill_running_process processID=74

curl \
-k --header "Authorization:Bearer 395fea0f-4cbf-487d-90ef-d2241c5843c6" \
-i -H "Content-Type:application/json" \
-X POST "https://test.usma.ibm.com:8443/restAPI/kill_running_process/?processID=74"
```

list_adhoc_policy_analyzer

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_adhoc_policy_analyzer
```

GuardAPI syntax

```
list_adhoc_policy_analyzer parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_aliases

Use the `list_aliases` command to show some or all of the current aliases for a specified object.

Use list_aliases to show any aliases that meet the specified criteria.
Note: Some special rules apply to the syntax for the API parameters:

- The groupTypeDescLike parameter always evaluates as Like. For example, if you pass in the value `IP`, the API evaluates the value as `%IP%`.
- The ampersand (&) character is required between each parameter and must have an escape, Enter it as `&&`.
- For the values of dbValueLike and aliasValueLike, use the Like operator (%) to return partial matches. However, % is a special character that is passed as `%25` (25 is the ASCII representation of %).

Therefore, the parameters in a curl command must appear as shown in the following example:

```
...aliasListing/?groupTypeDescLike=IP&&dbValueLike=%25&&aliasValueLike=%25
```

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/alias
```

GuardAPI syntax

```
list_aliases parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| aliasValueLike | String | All or part of an alias name. |
| dbValueLike | String | All or part of a database name. |
| groupTypeDescLike | String | Required. All or part of the Group Type description (such as ClientIP or Service Name) for an alias. |

Examples

The following example returns all of the aliases from IP objects (such as client or server IP) where the alias ends with the number one.

```
test.usma.ibm.com> grdapi list_aliases groupTypeDescLike="IP" aliasValueLike="%1" dbValueLike="%"
```

This command provides the following output:

```
ID=0
ERR=0
Group Type: Client IP DB Value: 1.2.3.4 Alias Value: A1
Group Type: Client IP DB Value: 2.3.3.6 Alias Value: B1
Group Type: Server IP DB Value: 5.6.7.8 Alias Value: C1
ok
```

The following example returns all of the aliases from IP objects (such as client or server IP) where the alias contains the letter "C".

```
[tester@oc3843647344 ~]$ curl \
-k --header "Authorization:Bearer 395fea0f-4cbf-487d-90ef-d2241c5843c6" \
-i -H "Content-Type:application/json"
-X GET "https://test.usma.ibm.com:8443/restAPI/aliasListing/?groupTypeDescLike=IP \
&&aliasValueLike=%25%C%25"
```

This command provides the following JSON output:

```
HTTP/1.1 200 OK
X-FRAME-OPTIONS: SAMEORIGIN
X-Permitted-Cross-Domain-Policies: none
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Date: Fri, 18 Jan 2019 20:02:59 GMT
Server: SQL Guard
[

list_all_reports

Run this command to output a list of all reports defined on the (specified) system.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_all_reports
```

GuardAPI syntax

```
list_all_reports parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To output a list of all reports on the system on which you enter the command:

```
grdapi list_all_reports
```

Sample response:

```

list_allowed_db_by_user

This command returns the available User-DB associations by the user's name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/allowed_db
```

GuardAPI syntax

```
list_allowed_db_by_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| userName | String | Required. The name of the user. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi list_allowed_db_by_user userName=Fred
```

Sample output

```
ID=0
Record Id = 1, Id = 20000, Type: USER, Instance: TEST
Servers associated with: Fred
Server Instance Access
-----
```

list_api_key

12.1 and later This command lists the API keys. If the logged-in user has an accessmgr role, all the API keys that are associated with the Guardium system are displayed. If the logged-in user does not have an accessmgr role, only the API keys that are associated with the user are displayed.

GuardAPI syntax

`list_api_key`

This API takes no parameters.

list_approved_stap_client

This command returns details on the approved S-TAP clients databases; database(s) whose S-TAPs are allowed (certified) to access and communicate with the specified Guardium® system.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/approved_stap_client
```

GuardAPI syntax

`list_approved_stap_client parameter=value`

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To view the databases certified to communicate with the Guardium system on which you enter the command:

```
grdapic list_approved_stap_client
```

list_assessment_tests

This command displays the list of tests for the security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/assessment_test
```

GuardAPI syntax

```
list_assessment_tests parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| assessmentDescription | String | |

Example

```
grdapi list_assessment_tests
```

list_assessments

This command lists security assessments.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/assessment
```

GuardAPI syntax

```
list_assessments parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| assessmentDescription | String | |

Example

```
grdapi list_assessments
```

list_associated_stap_mu_groups

This API returns a list of the managed unit groups of group type STAP that are associated with the specified Guardium system.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_associated_stap_mu_groups
```

GuardAPI syntax

```
list_associated_stap_mu_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|---|
| printFailoverGroupInfo | Boolean | If set to 1, includes failover group information. For more information, see assign_load_balancer_groups .
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To view the list of the managed unit groups of type S-TAP that are associated with the Guardium system on which you enter the command:

```
grdapi list_associated_stap_mu_groups
grdapi list_associated_stap_mu_groups printFailoverGroupInfo=1
```

list_audit_processes

This command displays a list of available audit processes.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/audit_process
```

GuardAPI syntax

```
list_audit_processes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. list_autodetect_tasks_for_process

Use this command to output a list of all tasks associated with a specified auto-discovery process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/autodetect_tasks_for_process
```

GuardAPI syntax

```
list_autodetect_tasks_for_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| process_name | String | Required. Name of the auto-discovery process |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To list all tasks associated with the process myProcess:

```
grdapic list_autodetect_tasks_for_process process_name=myProcess
```

list_available_test_notes

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/available_test_notes
```

GuardAPI syntax

```
list_available_test_notes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasourceType | String | Required. For valid values, call <code>list_available_test_notes</code> from the command line with <code>--help=true</code> . |
| testDescription | String | Required. |

list_available_tests

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/available_test
```

GuardAPI syntax

```
list_available_tests parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| datasourceType | String | Required. For valid values, call <code>list_available_tests</code> from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|-------------|
| testDescription | String | |

list_aws_secrets_manager_config

Use this command to list one or more AWS Secrets Manager configurations.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/aws_secrets_manager
```

GuardAPI syntax

```
list_aws_secrets_manager_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| name | String | |

Examples

```
grdapli list_aws_secrets_manager_config name="GRDAPI IAM-Instance-Profile"
grdapli list_aws_secrets_manager_config name="GRDAPI IAM-Role"
grdapli list_aws_secrets_manager_config name="GRDAPI Security-Credentials"
```

The following example lists all AWS Secrets Manager configurations:

```
grdapli list_aws_secrets_manager_config
```

list_cas_host_instances

This command returns a list of the Configuration Auditing System (CAS) host instances. You must specify either the `hostName` or the `datasourceName`.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cas_host_instance
```

GuardAPI syntax

```
list_cas_host_instances parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasourceName | String | The name of a data source with host instances. |
| hostName | String | The host name or IP address. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

The following example lists the host instance that is associated with an IP address:

```
grdapic list_cas_host_instances hostName=9.70.150.111
```

Which returns the following information:

```
Id, dataSourceName(#), dataSourceName, templateSetLabel(#), templateSetLabel, hostName, osType, dbType  
c0d2327c8dd550549f2579ab44819a54c3db5e6a, 20002, System (9.70.150.111), 16, Default Unix Template Set, 9.70.150.129, UNX, N_A  
ok
```

list_cas_hosts

This command returns a list of the Configuration Auditing System (CAS) hosts. You can filter the returned list by operating system.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cas_host
```

GuardAPI syntax

```
list_cas_hosts parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| osType | String | The operating system type can be either: <ul style="list-style-type: none">• UNIX: UNIX• WIN: Windows |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

To return a list of all UNIX-based CAS hosts.

```
grdapic list_cas_hosts osType=UNIX
```

Example output:

```
hostName, osType  
9.70.150.159, UNIX  
9.70.150.160, UNIX  
9.70.150.129, UNIX  
9.98.171.216, UNIX  
ok
```

REST API example

To return a list of all UNIX-based CAS hosts.

```
curl -k -i --header "Authorization: Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3"  
https://localhost:8443/restAPI/cas_host?osType=UNIX
```

- [Configuration Auditing System \(CAS\) APIs](#)

list_cas_template_sets

This command returns a list of the Configuration Auditing System (CAS) template sets. You can filter the returned list by database, operating system, or both.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cas_template_set
```

GuardAPI syntax

```
list_cas_template_sets parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| dbType | String | The database type.
If you enter a database type that is not supported (or you misspell it), Guardium displays a list of supported DBs.

To list templates that do not require a specific DB type, specify N_A. |
| osType | String | The operating system type can be either: <ul style="list-style-type: none">• UNIX: UNIX• WIN: Windows |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

To request a list of template sets on Windows for Oracle:

```
grdapic list_cas_template_sets osType=WIN dbType=Oracle
```

Example output:

```
Id, templateSetLabel, osType, dbType, Default, editable
17, Default Windows/Oracle Template Set, WIN, ORACLE, true, false
55, Default Windows/Oracle Template Set v8.0, WIN, ORACLE, true, false
34, Windows/Oracle Assessment, WIN, ORACLE, false, false
```

REST API example:

To list CAS template sets for Db2:

```
curl -k -i --header "Authorization: Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3"
https://localhost:8443/restAPI/cas_template_set?dbType=DB2
```

Example output

```
[{"audit_config_template_set_id": 20001, "label": "cas_temp_set_001", "os_type": "UNIX", "db_type": "DB2", "default": "true", "editable": "true"}, {"audit_config_template_set_id": 20000, "label": "ddi", "os_type": "UNIX", "db_type": "DB2", "default": "true", "editable": "true"}]
```

```
}
```

list_cas_templates

This command returns a list of the templates within a specified Configuration Auditing System (CAS) template set.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cas_template
```

GuardAPI syntax

```
list_cas_templates parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| templateSetLabel | String | Required. The name of the template set. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

To request a list of all templates in the template set named *tempSet*:

```
grdapi list_cas_templates templateSetLabel=tempSet
```

Example output:

```
ID=20001
Id, auditType, template, enabled, period, useMD5, saveData, isEditable
20000, FILE, templateTest, true, 3600, false, false, true
ok
```

REST API example

To list CAS templates by template set name:

```
curl -k -i --header "Authorization: Bearer 8ad14246-8815-4043-ab19-074d6bfcaad3"
https://localhost:8443/restAPI/cas_template?templateSetLabel=cas_temp_set_001
```

Example output:

```
[
  {
    "audit_config_template_id": 20002,
    "audit_type": "FILE",
    "template": "$DB2_HOME/sqllib/db2nodes.cfg",
    "enabled": "true",
    "period": 3600,
    "use_md5": "false",
    "save_data": "true",
```

```

        "is_editable": "true"
    },
    {
        "audit_config_template_id": 20001,
        "audit_type": "FILE",
        "template": "test.txt",
        "enabled": "true",
        "period": 3600,
        "use_md5": "false",
        "save_data": "true",
        "is_editable": "true"
    }
]

```

list_classifier_policy

This command lists information about classification policies, rules, and actions.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/classifier_policy
```

GuardAPI syntax

```
list_classifier_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| actionName | String | |
| policyName | String | |
| recursive | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| ruleName | String | |

Examples

List information about a specific action:

```
grdapiclient list_classifier_policy policyName=access_policy ruleName=access_rule actionName=log_access
```

Recursively list information about all actions for a specific rule:

```
grdapiclient list_classifier_policy policyName=access_policy ruleName=access_rule recursive=1
```

Recursively list information about all actions for all rules in all policies:

```
grdapiclient list_classifier_policy recursive=1
```

list_classifier_process

This command list information about classification processes.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/classifier_process
```

GuardAPI syntax

```
list_classifier_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| datasourceType | String | Valid values: <ul style="list-style-type: none">• DOCUMENT• RELATIONAL Default = RELATIONAL |
| processName | String | |

Examples

List information about all processes:

```
grdapi list_classifier_process
```

List information about a specific process:

```
grdapi list_classifier_process processName=APITEST_Clps_10001_1
```

list_cloud_datasource_by_name

This command outputs the configured details on the specified datasource.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cloud_datasource
```

GuardAPI syntax

```
list_cloud_datasource_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| name | String | Required. Cloud datasource defined in Guardium. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to view details on the datasource named cloud9.

```
grdapi list_cloud_datasource_by_name name=cloud9
```

list_compatibility_modes

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/compatibility
```

GuardAPI syntax

```
list_compatibility_modes parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_computed_attribute

This API lists the computed attributes available for a specified entity.

Use this API to find information about an existing computed attribute that was created with the [create_computed_attribute](#) API.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_computed_attribute
```

GuardAPI syntax

```
list_computed_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| attributeLabelLike | String | All or part of the computed attribute name that appears in reports. |
| entityLabel | String | Required. The name of the main entity with which the attribute is associated, for example Session, Object, or FULL_SQL. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi list_computed_attribute entityLabel="Object" attributeLabelLike="test"
```

Related reference

- [create_computed_attribute](#)

list_custom_table_ldap_imports

This command lists custom tables that were created to import data from LDAP.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/custom_data_ldap
```

GuardAPI syntax

```
list_custom_table_ldap_imports parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| tableName | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_cyberark_config

This command lists CyberArk configurations on your Guardium system.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cyberark
```

GuardAPI syntax

```
list_cyberark_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| name | String | The name of an existing CyberArk configuration. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_datasourceRef_by_id

This command lists all datasource references for a specific object of a specific application type. The object and application type are referenced by identification keys.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref
```

GuardAPI syntax

```
list_datasourceRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| appId | Integer | Required. Identifies the application type.
Valid values: <ul style="list-style-type: none">• 8 (security assessment)• 47 (custom tables)• 51 (classifier) |
| objId | Integer | Required. Identifies an instance of the specified appId type. For example, if <code>appId=51</code> , objId is the identification key of a classification process. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

```
grdapi list_datasourceRef_by_id appId=13 objId=1
```

list_datasourceRef_by_name

This command lists all datasource references for a specific object of a specific application type. The object and application type are referenced by name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_ref
```

GuardAPI syntax

```
list_datasourceRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|---|
| application | String | Required. Identifies the application type. For valid values, call <code>list_datasourceRef_by_name</code> from the command line with <code>--help=true</code> . |
| objName | String | Required. For valid values, call <code>list_datasourceRef_by_name</code> from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_datasource_by_id

This command displays a datasource definition identified by an identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource
```

GuardAPI syntax

```
list_datasource_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Integer | Required. The identification key of the datasource to be listed. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to view details about a datasource with identification key 2:

```
grdapic list_datasource_by_id id=2
```

list_datasource_by_name

This command displays a datasource definition identified by name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource
```

GuardAPI syntax

```
list_datasource_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| name | String | Required. The datasource name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to view details about a datasource with the name `chickenDB2`:

```
grdapi list_datasource_by_name name=chickenDB2
```

list_datasource_groupRef_by_id

List the datasource groups that are in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
list_datasource_groupRef_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| appId | Integer | Required. For valid values, call <code>list_datasource_groupRef_by_id</code> from the command line with <code>--help=true</code> . |
| objId | Integer | Required. The object ID of the security assessment, discovery scenario, or custom table. |

list_datasource_groupRef_by_name

List the datasource groups that are in security assessments, discovery scenarios, or custom tables.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_ref
```

GuardAPI syntax

```
list_datasource_groupRef_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| application | String | Required. For valid values, call <code>list_datasource_groupRef_by_name</code> from the command line with <code>--help=true</code> . |
| objName | String | Required. The name of the security assessment, discovery scenario, or custom table. |

list_datasource_group_hierarchy

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_listing
```

GuardAPI syntax

```
list_datasource_group_hierarchy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasourceName | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_datasource_group_members

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
list_datasource_group_members parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| groupName | String | Required. |

list_datasource_groups

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
list_datasource_groups parameter=value
```

list_db_drivers

This command lists the available database drivers.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/db_drivers
```

GuardAPI syntax

```
list_db_drivers parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapic list_db_drivers
```

list_db_drivers_by_details

This command details about the available database drivers.

The listed details include name, datasource class, driver class, URL, and datasource type ID.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_db_drivers_by_details
```

GuardAPI syntax

```
list_db_drivers_by_details parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi list_db_drivers_by_details
```

list_db_user_mapping

This command returns the mappings between DB user and email address for real-time alerts.

You can use a percent (%) wildcard for all parameters.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/db_user_mapping
```

GuardAPI syntax

```
list_db_user_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dbUserName | String | Required. The DB username. |
| emailAddress | String | Required. For real-time alerts, the email address that maps to the DB user. The at symbol (@) is required. |
| serverIp | String | Required. The server IP address. You can use % wildcards for any element in the IP address. For example: <ul style="list-style-type: none">• 192.168.2.%• 2620:1f7:807:%:920:% |
| serviceName | String | Required. The server name. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi list_db_user_mapping serverIp=192.168.1.% serviceName=ora% dbUserName=hadrian emailAddress=hadrian.swall@company.com
```

list_ef_mapping

This command lists all external feed mappings or details about a specified mapping.

If run without any parameters, this function returns a list of all user-created mappings. If run with the reportName parameter, this function returns details of the specified mapping (such as the table and column names used by the external feed).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_ef_mapping
```

GuardAPI syntax

```
list_ef_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| reportName | String | View details for the report mapping identified by reportName. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to view all user-created external feed mappings:

```
grdapi list_ef_mapping
```

Use this command to view details for the *Sessions per Day* mapping:

```
grdapi list_ef_mapping reportName="Sessions per Day"
```

list_ef_report

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_ef_report
```

GuardAPI syntax

```
list_ef_report parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_engine_config

Run this command to view the general inspection engine configuration. This configuration applies to all inspection engines that report to the specified Guardium system, and can be seen in the GUI Inspection Engine Configuration page.

You can change these settings either from the GUI Inspection Engine Configuration page or with the API update_engine_config.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/engine_config
```

GuardAPI syntax

```
list_engine_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To view the inspection engine configuration for the Guardium system on which you enter the command:

```
grdapi list_engine_config
```

Sample output:

```
ID=0
Inspection Engine Configuration
Default Capture Value OFF
Default Mark Auto Commit ON
Log Sequencing OFF
Log Exception Sql String ON
Log Records Affected OFF
Compute Avg. Response Time OFF
Inspect Returned Data OFF
Record Empty Sessions OFF
Parse XML OFF
Logging Granularity 60
Max. Hits per Returned Data 64
Ignored Ports List
Buffer Free 100%
ok
```

list_entry_location

This command returns a specific catalog entry if you include a file name. If you do not specify the file name, it returns details of all the catalog entries for this host and path.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/entry_location
```

GuardAPI syntax

```
list_entry_location parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| fileName | String | Specifies the file location for this archive location. If omitted, the command returns details of all the catalog entries on the specified hostname and path. |
| hostName | String | Required. The hostname or IP address. |
| path | String | Required. The path to the archive directory. <ul style="list-style-type: none">• Amazon S3: bucket name• IBM COS: bucket name• EMC Centera: Centera clipID• FTP: Specify the directory relative to the FTP account home directory.• SCP: Specify the directory as an absolute path.• IBM Cloud: Container• TSM: path |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi list_entry_location path=/mnt/nfs/archive_results/ hostName=192.168.1.33
```

list_existing_job_dependencies

Run this command to output the jobs on which the specified job has dependencies.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
list_existing_job_dependencies parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| jobTrigger | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To output the jobs on which `DataMartExtractionJobTrigger_5` has dependencies:

```
grdapi list_existing_job_dependencies jobTrigger=DataMartExtractionJobTrigger_5
ID=0
##### RUNNABLE AUTO-EXEC DEPENDENCY #0 #####
JOB_CATEGORY=distributedReportExtraction
JOB_OBJECT=distributedReportExtraction
ok
```

list_expiration_dates_for_restored_days

This command returns the expiration dates for all restored data.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/expiration_dates_for_restored_days
```

GuardAPI syntax

```
list_expiration_dates_for_restored_days parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
list_expiration_dates_for_restored_days
```

list_group_by_desc

This command displays the properties of a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
list_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| desc | String | Required. Identifies the group by its description. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to list details about the group `A group`:

```
grdapic list_group_by_desc desc="A group"
```

list_group_by_id

This command displays the properties of a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
list_group_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| id | Integer | Required. Identifies the group by its identification key. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to view details about the group with identification key `100003`:

```
grdapi list_group_by_id id=100003
```

list_group_members_by_desc

This command displays the members of a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/group_members_by_group_desc
```

GuardAPI syntax

```
list_group_members_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| desc | String | Required. Identifies the group by its description. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to list the members of the group `A group`:

```
grdapi list_group_members_by_desc desc="A group"
```

list_group_members_by_id

This command displays the members of a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/group_members_by_group_id
```

GuardAPI syntax

```
list_group_members_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Integer | Required. Identifies the group by its identification key. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to list the members of the group with identification key 100005:

```
grdapi list_group_members_by_id id=100005
```

list_groups

This API returns details about the groups defined in the local, or specified, Guardium system. The description does not include group members.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/group
```

GuardAPI syntax

```
list_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| skipEmpty | Boolean | <p>Whether or not empty groups are returned. Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Typical output:

```

grdapi list_groups
ID=0
Group Id: 80, Description: "Administrative Programs", Application: "Public", Type: "SOURCE PROGRAM", Hierarchical: false,
Member Count: 0, Tuple Count: 1
Group Id: 254, Description: "All Failed Authorization", Application: "Public", Type: "DB Error Codes", Hierarchical: false,
Member Count: 7, Tuple Count: 1
Group Id: 17, Description: "ALTER Commands", Application: "Public", Type: "COMMANDS", Hierarchical: false, Member Count: 35,
Tuple Count: 1
Group Id: 192, Description: "Analytic Exclude DB User", Application: "Public", Type: "USERS", Hierarchical: false, Member
Count: 0, Tuple Count: 1
Group Id: 193, Description: "Analytic Exclude OS User", Application: "Public", Type: "USERS", Hierarchical: false, Member
Count: 0, Tuple Count: 1
Group Id: 194, Description: "Analytic Exclude Server IP", Application: "Public", Type: "Server IP", Hierarchical: false, Member
Count: 0, Tuple Count: 1

```

list_hashicorp_config

Use this command to view the list of HashiCorp configurations on your Guardium® system.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/hashicorp
```

GuardAPI syntax

```
list_hashicorp_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| name | String | The name of the HashiCorp configuration. |

Examples

The following example lists the details of all available HashiCorp configurations:

```

grdapi list_hashicorp_config
ID=0
hashicorp_config_id: 1, name: "No SSL User and password API", auth_type: "Username & Password", vault_host_name: "hostname",
vault_port: 8300, user_name: "apps", password: "*****", use_ssl: "false"
hashicorp_config_id: 2, name: "SSL User and password API", auth_type: "Username & Password", vault_host_name: "hostname",
vault_port: 8500, user_name: "apps", password: "*****", use_ssl: "true"
ok

```

The following example lists the details of a specific HashiCorp configuration:

```

grdapi list_hashicorp_config name="SSL User and password API"
ID=0
hashicorp_config_id: 2, name: "SSL User and password API", auth_type: "Username & Password", vault_host_name: "hostname",
vault_port: 8500, user_name: "apps", password: "*****", use_ssl: "true"
ok

```

list_health_node

This command provides health and other information about the current machine. For a central manager, information also displays for all managed units.

For deployment health, the numbers are mapped as follows:

- -1 - Unavailable
- 0 - Healthy
- 1 - Unknown/Stale
- 2 - Medium severity
- 3 - High severity

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_health_node
```

GuardAPI syntax

```
list_health_node parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">all_managed: execute on all managed units but not the central managerall: execute on all managed units and the central managergroup:<group name>: execute on all managed units identified by <group name>host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

```
grdapi list_health_node
```

Sample output:

```
[{"id":0,"name":"my.system.com","unitHostIp":null,"type":"ag","patch":null,"status":0,"parent":"none","connectivity":0,"version":1}
```

list_imscheckpoint_records

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/ims_checkpoint
```

GuardAPI syntax

```
list_imscheckpoint_records
```

This API takes no parameters.

list_inspection_engines

This command lists all the defined inspection engines, and their configurations, on the specified S-TAP® host.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/inspection_engine
```

GuardAPI syntax

```
list_inspection_engines parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| stapHost | String | Required. IP or hostname of the S-TAP host. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| type | String | The type of inspection engine. One of: Windows: CouchDB, Db2®, Db2 Exit, Informix®, MongoDB, MS SQL, MySql, Oracle, PostgreSQL, Sybase; UNIX: Aster, Cassandra, CouchDB, Db2, Db2 Exit, exclude IE, FTP, GreenPlumDB, Hadoop, Hive, HTTP, Hue, IBM® iSeries, Impala, Informix, Informix Exit, Kerberos, MariaDB, MongoDB, MySql, Netezza®, Oracle, PostgreSQL, SAP HANA, Vertica, Sybase, Teradata, Vertica, or WebHDFS |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To view the inspection engines on the DB server with the IP 9.42.29.158:

```
grdapic list_inspection_engines stapHost=9.42.29.158
ID=7
S-TAP Host: 9.42.29.158 - Not Active
Inspection Engines:
  name =oracle1
  type =oracle
  sequence =1
  connect to IP=n.n.n.n

list_installed_policies

List all of the policies that are installed on the current machine.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_installed_policies
```

GuardAPI syntax

```
list_installed_policies parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_managed_units

Run this command on a central manager or a managed unit to output the list all managed units that are managed by the central manager.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/managed_units
```

GuardAPI syntax

```
list_managed_units parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| unit_type | String | <p>Specify to limit the out to units of the specified type only. Valid values:</p> <ul style="list-style-type: none">• <code>Col</code>• <code>Collector</code>• <code>Agg</code>• <code>Aggregator</code> |
| verbose | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• <code>0</code> (false): Lists the host names of the systems.• <code>1</code> (true): Lists the host names, IPs, IP mode, versions, whether the system is online, and the central manager or aggregator that the collector reports to (if data is aggregated). <p>Default = <code>0</code> (false)</p> |

Examples

To output a list of collectors only:

```
grdapic list_managed_units unit_type=col verbose=1
Unit Host = server-1, IP=n.n.n.n, type=ManagedCollector, IPMode-IPv4, version=11.4.0_r110686_trunk_1-e179-20210607_1543,online=true
Unit Host = server-2, IP=n.n.n.n, type=ManagedCollector, IPMode-IPv4, version=11.4.0_r110686_trunk_1-e179-20210607_1543,online=true
ok
```

To output a list of all managed units:

```

grdapi list managed_units verbose=1
Unit Host = server-1, IP=n.n.n.n, type=ManagedCollector, IPMode-IPv4, version=11.4.0_r110686_trunk_1-e179-
20210607_1543,online=true
Unit Host = server-2, IP=n.n.n.n, type=ManagedCollector, IPMode-IPv4, version=11.4.0_r110686_trunk_1-e179-
20210607_1543,online=true
Unit Host = server-3, IP=n.n.n.n, type=ManagedAggregator, IPMode-IPv4, version=11.4.0_r110686_trunk_1-e179-
20210607_1543,online=true
ok

```

list_members_of_groups_by_desc

This command displays members of one or more groups identified by their group descriptions.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/members_of_groups_by_desc
```

GuardAPI syntax

```
list_members_of_groups_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| groups | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_members_of_groups_by_id

This command displays members of one or more groups identified by their group IDs.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/members_of_groups_by_id
```

GuardAPI syntax

```
list_members_of_groups_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| groupIds | Integer | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_oauth_clients

This API lists the API clients that were registered with the `register_oauth_client` API.

This API is available in Guardium V11.2 and later.

GuardAPI syntax

```
list_oauth_clients parameter=value
```

This API takes no parameters.

Related reference

list_param_mapping_for_function

This command returns the parameter mappings for an API function.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
list_param_mapping_for_function parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| functionName | String | Required. The API name. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapic list_param_mapping_for_function functionName="create_group"
```

Related concepts

list_parameter_names_by_report_name

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_parameter_names_by_report_name
```

GuardAPI syntax

```
list_parameter_names_by_report_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| reportName | String | Required. |

list_policy

This command displays a list of available policies or displays details about a single policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/policy
```

GuardAPI syntax

```
list_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| detail | Boolean | Display details about a policy (or all policies if you do not specify a <i>policyDesc</i>). Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| policyDesc | String | The name of one policy to display. If not specified, Guardium returns information about all available policies. |
| verbose | Integer | |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI examples

Display details for a specific policy:

```
grdapic list_policy policyDesc="Hadoop Policy"
```

Display a detailed list of available policies:

```
grdapic list_policy
```

Display a list of available policy names (without details):

```
grdapi list_policy detail=false
```

list_policy_fam_rule

This command lists either all the rules, or the specified rule, in a FAM policy.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/famPolicyRule
```

GuardAPI syntax

```
list_policy_fam_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| policyName | String | Required. Name of FAM policy whose rules are returned in the response. |
| ruleName | String | If no ruleName is entered, all policy rules with details are returned. If a ruleName is entered, details are returned for that rule only. |

Examples

To view all rules in a policy named fam26:

```
list_policy_fam_rule policyName=fam26
```

list_policy_rules

Display the rules for a specified policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/rule
```

GuardAPI syntax

```
list_policy_rules parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-----------------------------------|
| policy | String | Required. The name of the policy. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi list_policy_rules policy="policy1"
```

list_qr_action

This command lists query actions for a specified query definition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/qr_action
```

GuardAPI syntax

```
list_qr_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | The name of the query rewrite action. |
| definitionName | String | Required. The query rewrite definition name. |
| detail | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0: False. Only the name is returned for false • 1: True. List all the associated attributes of the actions. <p>Default = 1 (true)</p> |

Examples

```
grdapi list_qr_action definitionName="case 2"
```

Output:

```
<servername>> grdapi list_qr_action definitionName="case 2"
#####
#####
```

```
QR actions of definition 'case 2' - (id = 1 )
#####
qr action ID: 1
qr action name: qr action2
qr action description: add where by id
```

ok

Example:

```
grdapi list_qr_action definitionName="case 2" detail=false
```

Output:

```
<servername>> grdapi list_qr_action definitionName="case 2" detail=false
#####
QR actions of definition 'case 2' - (id = 1 )
#####
qr action2
ok
```

list_qr_add_where

Lists "add where" functions for a specified query action and query definition pair.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/qr_add_where
```

GuardAPI syntax

```
list_qr_add_where parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | Required. The name of the query rewrite action. |
| definitionName | String | Required. The query rewrite definition name. |

Examples

Say something about the example

```
grdapi list_qr_add_where actionName="qrw_act_addwhere_id2" definitionName="qrw_def_Oracle_1"
```

list_qr_condition

Lists the query rewrite conditions that are associated with a particular query rewrite definition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/qr_condition
```

GuardAPI syntax

```
list_qr_condition parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| conditionName | String | The name of a query rewrite condition. |
| definitionName | String | Required. A query rewrite definition. |
| detail | Boolean | Valid values: <ul style="list-style-type: none">• 0: False. Returns the name only.• 1: True. Returns all the associated attributes of the conditions. Default = 1 (true) |

Examples

```
grdapi list_qr_condition definitionName="case 2" conditionName="qr cond2"
```

Output:

```
<servername>> grdapi list_qr_condition definitionName="case 2" conditionName="qr cond2"
#####
QR Conditions of Definition 'case 2' - (id = 1 )
#####

qr condition id: 1
qr condition name: qr cond2
qr definition ID: 1
qr condition verb: *
qr condition object: *
qr condition dept: -1
is verb regex: false
is object regex: false
is action for all rule verbs: false
is action for all rule objects: false
qr condition order: 1
```

list_quick_search_groups

This command returns a list of groups defined for quick search.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
list_quick_search_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To output the quick search groups:

```
grdapi list_quick_search_groups
```

Related concepts

- [Investigation dashboard](#)

Related reference

list_ranger_configs

This command lists all Ranger configurations on the specified Guardium host(s). The result is shown as the administrator account, the host and port, and the cluster name.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_ranger_configs
```

GuardAPI syntax

```
list_ranger_configs parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GrdAPI Example

List the current Ranger configuration (cluster) defined on this Guardium appliance:

```
grdapi list_ranger_configs
```

Sample output:

```
ID=0  
admin@<server>:8080 Cluster4
```

REST API Example

List the current Ranger configuration (cluster) defined on this Guardium appliance.

```
curl -k -i --header "Authorization:Bearer <access token>" https://<Guardium host name>:8443/restAPI/list_ranger_configs
```

Sample output when there is no configuration:

```
HTTP/1.1 200 OK  
X-FRAME-OPTIONS: SAMEORIGIN  
Set-Cookie: JSESSIONID=8B9581F4DA85E980DBD4C152CB8AD975; Path=/; Secure; HttpOnly  
Cache-Control: max-age=86400  
Expires: Tue, 20 Sep 2016 21:32:09 GMT  
Access-Control-Allow-Methods: POST, GET, PUT, DELETE  
Access-Control-Allow-Headers: authorization, origin, X-Requested-With, Content-Type, AcceptAccess-Control-Max-Age: 18000  
Content-Type: application/json;charset=UTF-8Content-Length: 62Date: Mon, 19 Sep 2016 21:32:09 GMTServer: SQL Guard
```

Sample output with all services configured:

```

list_ranger_hdfs_config

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_ranger_hdfs_config
```

GuardAPI syntax

```
list_ranger_hdfs_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_ranger_staps

This command lists all S-TAPs that are eligible for Ranger configuration or are currently configured for Ranger integration. (All S-TAPs that are not configured for Kafka (Cloudera integration).)

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_ranger_staps
```

GuardAPI syntax

```
list_ranger_staps parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GrdAPI example

To find databases that host Ranger-configured S-TAPs that report to this Guardium® system:

```
grdapic list_ranger_staps
```

System output:

```
ID=0
<DB server name>:5556
<DB server name>:5555
```

REST API example

To find databases that host Ranger-configured S-TAPs that report to the specified Guardium system:

```
curl -k -i --headere-492d-b3ef-23d1b073eb05" https://<Guardium server name>:8443/restAPI/list_ranger_staps
```

System output, which only displays S-TAPs with `stapStatus=2`, meaning the S-TAP® is active and properly synchronized:

```
[
{
"id": 18,
"name": "<DB server>",
"value": "<DB server>",
"port": "5534",
"stapStatus": 2
},
```

```
{
  "id": 24,
  "name": "<DB server>",
  "value": "<DB server>",
  "port": "5534",
  "stapStatus": 2
},
{
  "id": 25,
  "name": "<DB server>",
  "value": "<DB server>",
  "port": "5555",
  "stapStatus": 2
}
```

list_ready_files

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
list_ready_files parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_roles

This command lists the roles available on your Guardium system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/role
```

GuardAPI syntax

```
list_roles
```

This API takes no parameters.

Gaurd API example

```
grdapic list_roles
```

Related concepts

- [Understanding roles](#)

list_roles_granted_to_object_by_Name

This command returns the roles that are assigned, by name, to a specified object, such as a Classification process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/role
```

GuardAPI syntax

```
list_roles_granted_to_object_by_Name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| objectName | String | Required. The name of the object for which to list the roles. |
| objectType | String | Required. The name of the object type. For valid values, call <code>list_roles_granted_to_object_by_Name</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group: <group name>; execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi list_roles_granted_to_object_by_Name objectType=PrivacySet objectName="privacySet 1"
```

list_roles_granted_to_object_by_id

This command returns the roles that are assigned, by ID, to a specified object, such as a Classification process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/roles_granted_to_object_by_id
```

GuardAPI syntax

```
list_roles_granted_to_object_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| objectId | Integer | Required. The ID of the object for which to list the roles. |
| objectTypeId | Integer | Required. The ID of the object type. For valid values, call <code>list_roles_granted_to_object_by_id</code> from the command line with <code>--help=true</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi list_roles_granted_to_object_by_id objectTypeId=7 objectId=1
```

list_rules_with_threshold

Run this command to see which rules have thresholds (that trigger opening an active threat analytics case).

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_rules_thresholds
```

GuardAPI syntax

```
list_rules_with_threshold parameter=value
```

This API does not take any parameters.

Examples

To output a list of rules with thresholds, and their policies:

```
grdapi list_rules_with_thresholds
```

Sample output

```
grdapi list_rules_with_threshold
ID=0
Rule Name: "Failed Login - GDPR Personal Data -Alert if repeated", Policy Name: Rule1, Threshold: 3
Rule Name: NP, Policy Name: Rule3, Threshold: 5
```

list_running_processes

This API lists long-running processes that are running on the current Guardium system.

In some cases, processes continue to run past the time specified by the Report/Monitor Query Timeout setting (in [Manage > Maintenance > General > Running Query Monitor](#)). Use `list_running_processes` to find the process ID of any processes that run past the timeout. You can then stop the processes with the [kill_running_process](#) API.

You can also view or change the value of the Report/Monitor Query Timeout by using the [show_maximum_query_duration](#) and [store_maximum_query_duration](#) APIs.

The `list_running_processes` API takes no parameters.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_running_processes
```

GuardAPI syntax

```
list_running_processes
```

Examples

```
grdapi list_running_processes
```

Related concepts

list_schedules

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/schedules
```

GuardAPI syntax

```
list_schedules parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| jobName | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

list_stap_verification_results

This API returns the details and the verification results for each S-TAP® that reports to the specified Guardium® system.

This GuardAPI is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/list_stap_verification_results
```

GuardAPI syntax

```
list_stap_verification_results parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHost | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To return the verification status of the S-TAPs reporting to this Guardium system

```
grdapi list_stap_verification_results
S-TAP Host = 9.42.29.158
Protocol = oracle
Port Range = 1521-1521
Inspection Engine Identifier = oracle_9.42.29.158(1521,1521,DB_0)
Verification Status = Unverified

S-TAP Host = 9.42.29.158
Protocol = mysql
Port Range = 3357-33060
Inspection Engine Identifier = mysql_9.42.29.158(3357,33060,DB_2)
Verification Status = Unverified

S-TAP Host = 9.42.29.158
Protocol = db2
Port Range = 50000-50000
Inspection Engine Identifier = db2_9.42.29.158(50000,50000,DB_3)
Verification Status = Unverified
```

list_staps

This API returns a list of database servers that host S-TAPs that report to the specified Guardium® system, both as primary and secondary host. Optionally, return only the databases having S-TAPs for which the specified Guardium system is the active host.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/stap
```

GuardAPI syntax

```
list_staps parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| onlyActive | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0: list all hosts whose S-TAPs are configured to use this Guardium system as either a primary or secondary host.• 1: list only those hosts having S-TAPs for which this Guardium system is the active host. <p>Default = 1 (true)</p> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To find databases that host S-TAPs that report to this Guardium system, as both the primary and secondary host:

```
grdapi list_staps onlyActive=false
```

This command provides the following output:

```
staps:
stap host = 144.129.31.33
stap host = 144.129.31.17
stap host = 144.129.31.248
ok
```

list_test_detail_exception

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/test_detail_exception
```

GuardAPI syntax

```
list_test_detail_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| approver | String | |
| assessmentDesc | String | |
| assessmentScope | String | |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | |
| datasourceType | String | |
| detailExceptionValue | String | |
| displayLimit | Integer | |
| exceptionType | String | Valid values: <ul style="list-style-type: none"> • <code>text</code> • <code>regex</code> • <code>0</code> • <code>1</code> |
| testDescription | String | |
| validDate | String | |

list_test_exception

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/test_exception
```

GuardAPI syntax

```
list_test_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| approver | String | |
| assessmentDesc | String | |
| assessmentScope | String | Valid values: <ul style="list-style-type: none">• CURRENT• ALL• 0• 1 |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | Valid values: <ul style="list-style-type: none">• SINGLE• GROUP• ALL• 0• 1• 2 |
| datasourceType | String | For valid values, call <code>list_test_exception</code> from the command line with <code>--help=true</code> . |
| displayLimit | Integer | |
| explanation | String | |
| testDescription | String | |
| validDate | String | |

list_test_exception_by_id

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/test_exception
```

GuardAPI syntax

```
list_test_exception_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|-------------|
| testExceptionId | Long | Required. |

list_user_hierarchy_by_parent_user

This command returns the user hierarchy for a specified parent user.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/user_hierarchy
```

GuardAPI syntax

```
list_user_hierarchy_by_parent_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| create | String | Valid values: <ul style="list-style-type: none">• <i>true</i>• <i>false</i> When set to true, returns the value of the users in the format of a create_user_hierarchy statement. |
| userName | String | The name of the parent user. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI examples

In the following examples, George and Harry are both children of AdminManager.

```
grdapi list_user_hierarchy_by_parent_user userName=Fred
```

Sample output

```
ID=0
Name: George  Id =      1, Parent =    20000, Child =    20001, Type: user
Name: Harry   Id =      3, Parent =    20000, Child =    20002, Type: user
ok
```

The same command, but with `create=true`:

```
grdapi list_user_hierarchy_by_parent_user userName=AdminManager create=true
```

Sample output

```
ID=0
grdapi create_user_hierarchy userName="George" parentUserName="AdminManager"
grdapi create_user_hierarchy userName="Harry" parentUserName="AdminManager"
ok
```

list_user_roles

This API lists all the roles associated with a specified user.

To find a user name, use the [list_users](#) API. To change the roles for a user, use the [set_user_roles](#) API. To make other changes to a user's account, use the [update_user](#) API.

Note: You must have appropriate permissions to user the `set_user_roles` and `update_user` APIs.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/userRole
```

GuardAPI syntax

```
list_user_roles parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---------------------------------|
| userName | String | Required. The name of the user. |

Examples

To list the roles for user Fred McDerm:

```
grdapi list_user_roles userName="Fred McDerm"
```

Sample output:

```
ID=20001
Roles of User: Fred McDerm
admin
dba
diag
cli
ok
```

list_users

This API returns a list of Guardium users and account information.

The **list_users** API requires that the CLI account issuing the command is associated with a GUI account that has the *accessmgr* and *cli* roles. Associate CLI and GUI accounts using the **set guimuser** CLI command. For more information, see [User account, password, and authentication CLI Commands](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/user
```

GuardAPI syntax

```
list_users
```

Examples

This command returns a list of all users on this system. For example:

```
grdapi list_users
```

Returns the following information:

```
##### User 3 #####
Username: Fred McDerm
First Name: Fred
Last Name: McDerm
Email: fredmcd@company.com
Disabled: false

list_utilization_thresholds

This API is available in Guardium V9.5 and later.

This API takes no parameters.

GuardAPI syntax

```
list_utilization_thresholds
```

load_all_packages

This API loads universal connector packages to the specified path.

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
load_all_packages parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| path | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

load_mongodb

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
load_mongodb parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| collectionName | String | Required. |
| database | String | Required. |
| host | String | Required. |
| password | String | Required. |
| port | Integer | Required. |
| user | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

load_mongodb_by_datasource

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
load_mongodb_by_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| collectionName | String | Required. |
| datasourceName | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

local_disable_big_data_intelligence

Run this command on a managed unit to disable it (or the specified unit) from sending data to the active profile.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/local_disable_big_data_intelligence
```

GuardAPI syntax

```
local_disable_big_data_intelligence parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To stop the managed unit from sending data to the active profile:

```
local_disable_big_data_intelligence
```

Related concepts

- [Big Data Intelligence with data marts](#)

Related reference

- [Big Data Intelligence APIs](#)

local_enable_big_data_interface

Run this command on a collector that was offline or not in the MU group when the profile was activated; or on a collector that is not in the MU group, to add its data included the the extraction defined by the profile. Advanced users can use this command for extracting data from collectors that use a different profile.

For example, two managed units of a central manager run only VA, and the other managed units are tracking other data. You would create a second profile that is a subset of the main profile, and run it only on the specified units. However, the local profile does not have a target for the data; add it using the command:
`datamart_update_copy_file_info`.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/bigDataInterface
```

GuardAPI syntax

```
local_enable_big_data_interface parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| profile_name | String | Required. An existing profile. For valid values, run <code>grdapi get_extraction_profile_info</code> or call <code>local_enable_big_data_interface</code> from the command line with <code>--help=true</code> . |
| start_date | Date | When to start sending data to the Big Data datasource. Default = time at which the command is executed. Format is either <code>NOW - <n> <minute hour day week month; or yyyy-mm-dd hh:mm:ss</code> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To add the managed units adata to the profile sql_all:

```
local_enable_big_data_interface profile_name=sql_all
```

Related concepts

make_bundle_with_uploaded_kernel_module

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
make_bundle_with_uploaded_kernel_module parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

make_primary_cm

Run this API on the backup (secondary) central manager to change it to the primary central manager.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/make_primary_cm
```

GuardAPI syntax

```
make_primary_cm
```

This API takes no parameters.

Examples

Enter this command on the secondary central manager to change it to the primary central manager:

```
grdapic make_primary_cm
```

Related concepts

- [Central manager redundancy](#)

migrate_stap_config

This command configures and moves one or more S-TAPs to Guardium® Insights.

Before you can migrate the S-TAPs, you must push Guardium Insights certificate chain (either from the Guardium Data Protection GUI or by using the [push_insights_trust](#) API).

If the migrate_stap_config command is successful, the S-TAP® is removed from Guardium Data Protection.

Notes:

- Guardium Insights 3.1 or later is required.
- You can migrate only UNIX S-TAPs.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stap_config
```

GuardAPI syntax

```
migrate_stap_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| routeName | String | Required. The DNS hostname for the Guardium Insights deployment. The DNS hostname is the same as the URL for the UI (without the https:// prefix). |
| stapHost | String | Required. Specify the name of one or more S-TAP hosts (separated by a comma), or specify <i>all_unix_active</i> . For valid values, call migrate_stap_config from the command line with --help=true. |
| tenantId | String | Required. The Guardium Insights tenant ID, including the <i>TNT_</i> prefix. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: Run on all managed units but not the central manager• <i>group:<group name></i>: Run on all managed units identified by <group name>• host name or IP address of a managed unit: Specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. Note: IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Example

```
vm150.mycompany.com> grdapic migrate_stap_config stapHost=rh6u9x64t.mycompany.com api_target_host=sys-vm154.mycompany.com
routeName=sys.tokyo-0a94651246c65639d6ebe7da606c1234-0000.ca-tor.containers.appdomain.cloud tenantId=TNT_DARBESKTVGTGYAMF7RABCD
ID=0
sys-vm154.isslab.usga.ibm.com
ID=0
Insights data sent to active synchronized S-TAP hosts:
rh6u9x64t.mycompany.com
```

modify_autodetect_process

Use this command to modify an auto-discovery process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/autodetect_processes
```

GuardAPI syntax

```
modify_autodetect_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|---|
| check_ICMP_echo | Boolean | Whether or not Nmap sends an ICMP echo request. PE parameter to nmap. This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| host_timeout | Integer | Timeout value, in seconds, for determining how long Guardium waits for a probe response before giving up or retransmitting the probe. This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. |
| process_name | String | Required. Name of the auto-discovery process |
| run_probe_after_scan | Boolean | Determines whether or not to run a probe job immediately after the scan job completes. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| use_dns | String | This is an nmap parameter. nmap options are configurable only by API (not by GUI). For details of nmap parameters and their impact on scan performance, see man nmap. Valid values: <ul style="list-style-type: none">• true: always• false: never• n: never• R: always |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To change the configuration of the process myProcess to run the probe after the scan completes, enter:

```
grdapi create_autodetect_process process_name=myProcess run_probe_after_scan=true
```

modify_ef_mapping

This command modifies the table or column names used for an external feed mapping.

Sometimes the names generated by `create_ef_mapping` are not suitable for a particular database, and `modify_ef_mapping` can be used to adjust the names to fit database requirements. To protect predefined Guardium mappings, only mappings with an identification key greater than 20000 can be modified.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/modify_ef_mapping
```

GuardAPI syntax

```
modify_ef_mapping parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| modifyObj | String | Required. Specifies the database object to modify. Use the list_ef_mapping command to see the table and column names for a mapping.
Valid values: <ul style="list-style-type: none">• <i>table</i>• <i>column</i> |
| newName | String | Required. The new table or column name to use. |
| oldName | String | Required. The table or column name to modify. |
| reportName | String | Required. Name of the report mapping to modify. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to change the table name from *SESSIONS_PER_DAY* to *SESSIONS-PER-DAY* in the Sessions per Day report mapping:

```
grdapi modify_ef_mapping reportName="Sessions per Day" modifyObj=table oldName=SESSIONS_PER_DAY newName=SESSIONS-PER-DAY
```

modify_ef_sql_mode

Enables (or disables) an external feed report to run with dynamic SQL.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/modify_ef_sql_mode
```

GuardAPI syntax

```
modify_ef_sql_mode parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|---|
| reportName | String | Required. The name of a custom report for which you want to enable dynamic SQL. |
| useDynamicSQL | String | Required. Toggles the ability to use dynamic SQL on or off. Valid values: <ul style="list-style-type: none">• <i>yes</i>• <i>no</i>• <i>true</i>• <i>false</i> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

```
>grdapi modify_ef_sql_mode reportName="Test_API_Exception" useDynamicSQL=true
```

modify_guard_param

This generic API updates the values of specific parameters for various Guardium functions.

Functions that use this parameter include:

- [Alerting.parameters](#)
- [Analyze limits parameters](#)
- [Classification parameters](#)
- [CyberArk parameters](#)
- [Data mart parameters](#)
- [Datasource parameters](#)
- [Health analyzer parameters](#)
- [Inspection engine parameters](#)
- [Manage_SQL parameters](#)
- [Nanny parameters](#)
- [Offline help parameters](#)
- [Quartz scheduler parameters](#)
- [Smart card parameters](#)
- [Sniffer parameters](#)
- [SNMP parameters](#)
- [Syslog TCP parameters](#)
- [Threat analytics parameters](#)
- [Vulnerability Assessment parameters](#)
- [Other parameters](#)

Note: Use [get_all_modifiable_guard_params](#) to display a list of the parameters that can be modified with this API.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/modify_guard_param
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| paramName | String | Required. One of the parameters that are described in the following sections. |
| paramValue | String | The new value for the parameter. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Alerting parameters

| Parameter | Value Type | Description |
|------------------------|------------|---|
| ALERT_VERB_NUM_LIMIT | Integer | Sets the maximum number of SQL verbs to show in the Alert log. Valid value is a positive integer between 1 and 50. The default is 10. |
| ANTLR3_REMOVE_COMMENTS | Boolean | Enables or disables logging of comments.
Valid values: <ul style="list-style-type: none">• 0: logging of comments is enabled• 1: logging of comments is disabled Default = 0 |
| SMTP_TIMEOUT | Integer | Alerter SMTP Time-Out. |
| STARTTLS | String | Sets TLS data encryption for the alerter email server.
Valid values: <ul style="list-style-type: none">• <i>TLS</i>: Use TLS data encryption.• <i>SSL</i>: Use TLS data encryption.• <i>NONE</i>: Turn off TLS encryption. |

Analyze limits parameters

The *analyze limits* parameters define thresholds used for the *central manager limits* tile on the Deployment Health Dashboard and elsewhere. For more information, see [Deployment health dashboard](#).

| Parameter | Value Type | Description |
|---|------------|-----------------------|
| CLASSIFIER_MEMORY_USAGE_THRESHOLD | Integer | Valid values: 1 - 100 |
| HTTP_GIMSERVER_AUTH_CONNECTIONS_THRESHOLD | Integer | Valid values: 1 - 100 |
| HTTP_GIMSERVER_CONNECTIONS_THRESHOLD | Integer | Valid values: 1 - 100 |
| HTTP_GUI_CONNECTIONS_THRESHOLD | Integer | Valid values: 1 - 100 |
| MYSQL_CONNECTIONS_THRESHOLD | Integer | Valid values: 1 - 100 |
| OPEN_HANDLERS_THRESHOLD | Integer | Valid values: 1 - 100 |
| RUNNING_PROCESSES_THRESHOLD | Integer | Valid values: 1 - 100 |
| UNAUTHENTICATED_CONNECTIONS_THRESHOLD | Integer | Valid values: 1 - 100 |

CyberArk parameters

| Parameter | Value Type | Description |
|-------------------------------|------------------|---|
| CYBERARK_USER_NAME | String | Updates the CyberArk user name. |
| CYBERARK_USER_PASSWORD | Encrypted String | Updates the encrypted CyberArk vault user password. |
| CYBERARK_VAULT_WEBSERVER_NAME | String | Updates the CyberArk vault web server name. |

Classification parameters

| Parameter | Value Type | Description |
|----------------------------|------------|--|
| classifier_running_timeout | Integer | Sets a time limit, in minutes, for the housekeeping process (nanny). After the timeout period, the nanny considers the classifier process to be inactive and restarts it.
Valid values: 5 - 720
Default = 30 |
| classifier_gather_data | Boolean | Enables or disables the gathering of system data.
Valid values: <ul style="list-style-type: none">• 0: gathering of system data is disabled• 1: gathering of system data is enabled |
| compare_max_row_threshold | Integer | Changes the display threshold value.
Default and maximum value: 1000 rows |

Classifier examples

Use the following example to modify the value of the classifier_running_timeout parameter.

```
>grdapic modify_guard_param paramName=classifier_running_timeout paramValue=50
```

Use the following example to modify the value of the classifier_gather_data parameter.

```
>grdapic get_guard_param paramName=classifier_gather_data
ID=0
classifier_gather_data value: false

>grdapic modify_guard_param paramName=classifier_gather_data paramValue=1
ID=0
ok

>grdapic get_guard_param paramName=classifier_gather_data
ID=0
classifier_gather_data value: true
ok
```

Use the following example to view and modify the value of the compare_max_row_threshold parameter.

```
grdapi get_guard_param paramName=COMPARE_MAX_ROW_THRESHOLD
ID=0
COMPARE_MAX_ROW_THRESHOLD value: 1000
ok

grdapi modify_guard_param paramName=COMPARE_MAX_ROW_THRESHOLD paramValue=91935
modify_guard_param:
ERR=5059
Error Parameter Value is greater then MAX allowed : 1000
Error in modify_guard_param. Can not process the request
ok

grdapi modify_guard_param paramName=COMPARE_MAX_ROW_THRESHOLD paramValue=999
ID=0
ok

grdapi get_guard_param paramName=COMPARE_MAX_ROW_THRESHOLD
ID=0
COMPARE_MAX_ROW_THRESHOLD value: 999
ok
```

Data mart parameters

| Parameter | Value Type | Description |
|---|------------|---|
| COPYFILE_THREAD_POOL_CORE_SIZE | Integer | For internal use only, tunes the size of the data mart threadpool. |
| COPYFILE_THREAD_POOL_IDLE_KEEP_ALIVE_TIME_SEC | Integer | For internal use only, tunes the size of the data mart threadpool. |
| COPYFILE_THREAD_POOL_MAX_SIZE | Integer | For internal use only, tunes the size of the data mart threadpool. |
| COPYFILE_THREAD_POOL_MAX_TASKS_WAITING | Integer | For internal use only, tunes the size of the data mart threadpool. |
| CUSTOM_DATAMART_FILE_REMOVE_EXTRA_BACKSLASH | Binary | Removes an extra backslash from custom data mart files during extraction. |

Datasource parameters

| Parameter | Value Type | Description |
|---|------------|--|
| allow_datasource_full_control_by_role | Boolean | Controls whether assigning a role on a datasource gives the role full control over the datasource.
Valid values: <ul style="list-style-type: none">• false• true Default = false |
| customtable_running_timeout | Integer | Sets a timeout mechanism, in minutes, for a hung custom table data upload. When a datasource hangs, the custom data upload stops after the timeout period and skips to the next datasource in the queue. |
| DATASOURCE_CONFIRMATION_EXPIRATION_TIME | Integer | To delete a datasource (or a set of datasources) a confirmation number is required. By default the confirmation number expires after 5 minutes. Use this parameter to change the expiration time to between 4 to 60 minutes. |
| MIN_OPTIMIZE_SIZE | Integer | For a specified database, sets the minimum size for optimization. The size must be between 1000 and 10000000. |

Datasources example

Use the following command to modify the value of the customtable_running_timeout parameter.

```
grdapi modify_guard_param paramName=allow_datasource_full_control_by_role paramValue=true customtable_running_timeout
paramValue=5
```

Use the following command to modify the value of the datasources parameters.

```
grdapi modify_guard_param paramName=customtable_running_timeout paramValue=5
```

Health analyzer parameters

These parameters control the predictions of DB sizes and files on disk (/var). For more information, see [DB sizes and files on disk \(/var\)](#).

| Parameter | Value Type | Description |
|-------------------------------------|------------|--|
| HEALTH_ANALYZER_DB_LOOKAHEAD_DAYS | Integer | Alerts are sent if the HEALTH_ANALYZER_DB_USAGE_THRESHOLD is predicted to occur in the next HEALTH_ANALYZER_DB_LOOKAHEAD_DAYS.
Default = 14 |
| HEALTH_ANALYZER_DB_SAMPLE_DAYS | Integer | The number of immediately preceding days that the DB growth is monitored. Use this parameter to predict future usage.
Default = 7 |
| HEALTH_ANALYZER_DB_USAGE_THRESHOLD | Integer | The DB size threshold (in %) at which an alert is sent. 100% size varies according to the Guardium system type (50% of /var for collector, and 75% of /var for aggregator).
Range is 1 - 100%. Default = 50 |
| HEALTH_ANALYZER_VAR_LOOKAHEAD_DAYS | Integer | Alerts are sent if HEALTH_ANALYZER_VAR_USAGE_THRESHOLD is predicted to occur in the next HEALTH_ANALYZER_VAR_LOOKAHEAD_DAYS.
Default = 14 |
| HEALTH_ANALYZER_VAR_SAMPLE_DAYS | Integer | Number of days the /var growth is monitored. Use this parameter to predict future usage.
Default = 7 |
| HEALTH_ANALYZER_VAR_USAGE_THRESHOLD | Integer | The /var size threshold (in %) at which an alert is sent.
Range is 1 - 100%. Default = 50 |

Inspection engine parameters

Before you configure the Database Discovered Instances Rules in the GUI, you need to enable inspection engine creation by setting the IE_CREATION parameter to 1. For more information, see [Database discovered instances rules](#) and [apply_rules_on_discoveredinstances](#).

| Parameter | Value Type | Description |
|------------------------|------------|---|
| IE_CREATION | Boolean | Required for automatic inspection engine creation. Determines whether Guardium automatically creates inspection engines on a collector, based on whether inspection engine creation is enabled on the Database Discovered Instances Rules page.
Valid values: <ul style="list-style-type: none">• 0 (false): Disable automatic inspection engine creation.• 1 (true): Enable automatic inspection engine creation, according on the rules selected on the Database Discovered Instances Rules page. Default = 0 (false) |
| IE_PROCESSED_TIMESTAMP | Date | Timestamp for identifying already considered, discovered instances for IE creation functionality. |

Offline help parameters

To use IBM Documentation without requiring an internet connection, you can use IBM® Documentation Offline to access help files for Guardium and other IBM products. IBM Documentation Offline allows you to view IBM Documentation either as a desktop application or from your corporate intranet. For more information about installing and using IBM Documentation Offline, see <https://www.ibm.com/docs/en/offline>.

After installing and configuring IBM Documentation Offline, use the following parameters to enable IBM Documentation Offline with Guardium.

| Parameter | Value Type | Description |
|--------------|------------|--|
| HELP_DISABLE | Boolean | Enable or disable IBM Documentation Offline for Guardium help links. The setting is disabled by default.
Valid values: <ul style="list-style-type: none">• 0 (false): Disable IBM Documentation Offline. When disabled, the Guardium system uses help files from the public IBM Documentation site. This is the default behavior.• 1 (true): Enable IBM Documentation Offline. When enabled, the Guardium system links to help files from the IBM Documentation Offline instance identified by the HELP_HOST and HELP_PORT parameters. |
| HELP_HOST | String | Specify the host name of the system where IBM Documentation Offline is installed. If you leave the server name blank, the online help is directed to www.ibm.com . |
| HELP_PORT | String | Specify the port number for the IBM Documentation Offline configuration. The default value is 443. |

Offline help parameters examples

- The following example uses the GuardAPI to find and set the host name,

```
grdapic get_guard_param paramName=HELP_HOST  
ID=0  
HELP_HOST value: test.mycompany.com  
  
grdapic modify_guard_param parameter_name=HELP_HOST parameter_value=test.mycompany.com
```

- The following example uses the GuardAPI to set the port value,

```
grdapic modify_guard_param paramName=HELP_PORT paramValue=9443
```

Manage SQL parameters

These parameters allow you to manage various SQL details.

| Parameter | Value Type | Description |
|--------------------------|------------|--|
| ALERT_OBJECT_NUM_LIMIT | Integer | Maximum number of SQL objects in one alert message for an object template variable. |
| DB2_COMMAS_DECIMAL_POINT | Integer | Flag for the ANTLR3 DB2 parser to consider a comma as a numeric precision mark. |
| DUMP_DATA_FOR_FORENSICS | Integer | Determines whether to dump full SQL details into the Kafka server. The full SQL details are used for forensics and analysis. Valid values: <ul style="list-style-type: none">• 0 (off): Do not dump full SQL details• 1 (on): Dump full SQL details Default = 0 |
| LONG_VALUE_SPLIT_IN_CCSV | Binary | Allows text to be split into multiple lines during CSV export. |
| MAX_SAVED_CONSTRUCTS | Integer | Size of the SQL construct rule. Results are being saved in the session. |

Nanny parameters

These parameters enable and configure sending test messages to the alerter orrsyslog to verify that it is communicating with Guardium.

| Parameter | Value Type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value Type | Description |
|------------------------------|------------|---|
| GENERATE_TOMCAT_DUMP | Binary | Triggers Tomcat core dump. |
| NANNY_ALERT_RSYSLOG | Integer | Controls whether the nanny monitors rsyslog servers. |
| NANNY_ALERT_RSYSLOG_FREQ | Integer | Determines the frequency, in hours, with which the nanny monitors rsyslog servers. |
| NANNY_SNIF_CORE | Integer | Captures the nanny snif core count. Default = 0 (disabled)
A value of 1, 2, or 3 indicates the number of compressed and encrypted cores to save to the /var/IBM/Guardium/log/snif/cores directory as tar files.

Use the fileserver CLI command to upload the compressed snif core tar file. |
| NANNY_TEST_RSYSLOG | Integer | Determines whether the nanny process sends test messages to rsyslog. Valid values: <ul style="list-style-type: none">• 0 (false): Do not send test messages to rsyslog• 1 (true): Send test messages to rsyslog
Success messages are severity <i>info</i> , and error messages are severity <i>med</i> (<i>error</i>).

Default = 1 |
| NANNY_TEST_RSYSLOG_FREQ | Integer | Determines the frequency, in hours, with which the nanny sends test messages to rsyslog.
Default = 0, which sets the frequency to 5 minutes. |
| NANNY_TEST_SMTP_ALERTER | Integer | Determines whether the nanny process checks the status of the SMTP alerter.
If set to 1 (true), the nanny establishes that connectivity is available to the SMTP relay server on the server side and reports the results to Syslog. Success messages are severity <i>info</i> , and error messages are severity <i>med</i> (<i>error</i>).

If the SMTP alerter is down, Guardium attempts to restart it, and reports to Syslog indicating success or failure.

Valid values: <ul style="list-style-type: none">• 0 (false): Do not test the alerter• 1 (true): Test the alerter
Default = 1 |
| NANNY_TEST_SMTP_ALERTER_FREQ | Integer | Determines the frequency, in hours, with which the nanny tests the alerter.
Default = 0, which sets the frequency to 5 minutes. |

Quartz scheduler parameters

These parameters provide input to the Quartz Job Scheduler.

| Parameter | Value Type | Description |
|-----------------------------------|------------|--|
| QUARTZ_LONG_RUNNING_JOB_THRESHOLD | Integer | Defines the Quartz Scheduler long running job threshold in minutes.
Default = 600 (minutes). |
| QUARTZ_MAX_LONG_RUNNING_JOBS | Integer | Defines the maximum number of long running Quartz Scheduler jobs that is considered unhealthy.
Default = 3. |
| QUARTZ_SCHD_ENABLE_MONITOR | Boolean | Enable Quartz Scheduler monitoring.
The default is 0 (off).

To turn on, set to 1. |

Smart card parameters

This configuration is for logging into the Guardium UI using a smart card. For more details, see [Enabling smart card authentication](#).

| Parameter | Value Type | Description |
|--------------------------|------------|---|
| ENABLE_OCSP_CHECK | Binary | Check certificate status via OCSP if smart card authentication is turned on. |
| SMART_CARD_MAPPING_REGEX | String | Sets the value of the regular expression (regex) in the Guardium Portal page to match the user information on a smart card. |

Smart card example

Use the following command to modify the value of the SMART_CARD_MAPPING_REGEX parameter.

```
grdapic modify_guard_param paramName=SMART_CARD_MAPPING_REGEX paramValue="CN=?(.*) ,?OU=?Test Agency ,?OU=?Test Department ,?O=?Test Government ,?C=?US"
```

Sniffer parameters

Use the following parameters to manage Sniffer settings.

| Parameter | Value Type | Description |
|----------------------|------------|---|
| ACTIVE_PARSER_ENGINE | Integer | Controls which parser engine snif will use. Options are: <ul style="list-style-type: none">• 1 - Use ANTLR3 with errors re-parsed by ANTLR2 (default)• 2 - Use ANTLR2• 3 - Use ANTLR3 |

| Parameter | Value Type | Description |
|--------------------------------------|------------|---|
| HOST_SERVICE_OS_NAME_CACHE_SIZE | Integer | Allows you to change the size of sniffer held values in host name, service name, or OS user name caches. Default = 2048.

The cache size must be between 1 and 25000. |
| INTERNAL_REST_CLIENT_SECRET | Encrypted | The internal REST client secret to allow snif and other components to make internal REST calls. |
| INTERNAL_REST_CLIENT_SECRET_PASSWORD | Encrypted | The password for the internal REST client user. |
| LOG_GENERAL_RESPONSE_LENGTH | Number | Displays whether the store_log_general_response_length CLI command is enabled or disabled. Default = disabled |
| PE_TRAINING_PHASE_ONE_LENGTH | Integer | Minimum mandatory training period (in days) for the snif probability engine. |
| PE_TRAINING_PHASE_TWO_LENGTH | Integer | Minimum training period (in hours) where snif must see no new training data. Extended dynamically when new events are encountered. |
| SAVED_RESPONSE_QUEUE_SIZE | Integer | Allows you to change the queue size for saved responses. |
| SELECTIVE_AUDIT_PRESCREEN_THRESHOLD | Integer | Snif internally disables the prescreen functionality for performance purposes if total selective audit group member count exceeds this value. |
| SNIF_DQ_ARE_LITERALS | Integer | Controls which database types snif will consider double quoted strings literals by default. |
| SNIF_USE_FEED_ANALYZER_THREAD | Integer | Snif use feed analyzer thread. |
| UID_CHAIN_PROCESS_ASYNC | Integer | Control synchronous/asynchronous processing of the UID CHAIN in snif. |

SNMP parameters

Use the following parameters to set certain system SNMP settings.

| Parameter | Value Type | Description |
|-------------------------------|------------|--|
| GUARDIUM_SNMP_TR_AP_MSG_OID | String | The message for the Guardium SNMP trap OID. The default message is .1.3.6.1.4.1.18708.1.6 . |
| GUARDIUM_SNMP_TR_AP_OID | String | Specify the Guardium SNMP trap OID. Use this parameter to change how the Alerter sends SNMP traps to older values or to another value that you need to work with a particular server that monitors SNMP traps. For more information, see Configuring the alerter .

The default trap OID is .1.3.6.1.4.1.18708.1.1.1 |
| SNMP_AUTHENTICATION_PASSWORD | Encrypted | SNMP authentication passphrase. |
| SNMP_ENCRYPTION_PASSWORD | Encrypted | SNMP encryption passphrase. |
| SNMP_ENGINE_ID | String | If required, change the SNMP engine ID. Use the show system snmp engineid CLI command to see the current engine ID. Note: Engine ID must be unique. |
| SNMP_USER_AUTHENTICATION_TYPE | String | SNMP user authentication type for v3. |
| SNMP_USER_ENCRYPTION_TYPE | String | SNMP user encryption type for v3. |
| SNMPV3_USER | String | Create a new SNMP version 3 user account. Guardium recommends that you use the store_system_snmp_user CLI command to create a new user. |
| SNMP_VERSION | String | Set the SNMP version for this machine. Valid values = v2c or v3 |

Syslog TCP parameters

These parameters manage TPC reception in syslog.

| Parameter | Value Type | Description |
|---------------------------|------------|--|
| SYSLOG_TCP_RECEPTION_ON | Integer | Controls whether syslog TCP reception is on. Default = 1 (off)

Set to 0 to turn on. |
| SYSLOG_TCP_RECEPTION_PORT | Integer | Specify the port to use for syslog TCP reception. Default = 10514.

The port number must be between 1 and 65535. |

Threat analytics parameters

| Parameter | Value Type | Description |
|---------------------------------------|------------|--|
| EI_FAILED_LOGIN_DB_USER_THRESHOLD | Number | The database user threshold for threat analytics failed log ins. Default = 2. |
| EI_FAILED_LOGIN_DISPLAY_DB_USER_LIMIT | Number | The number of different database users threshold for a failed threat analytics login case. Default = 2. |
| EI_FAILED_LOGIN_PER_DB_USER_THRESHOLD | Number | The number of failed log ins per database user threshold for a failed threat analytics login case. Default = 10. |
| EI_GRANT_DORMANT_WEEKS_DEFINITION | Number | The number of weeks without activity to register a user as dormant for threat analytics. Default = 8. |
| EI_SQL_TIMEOUT_IN_SECONDS | Number | Timeout, in seconds, for executing threat analytics scanners on a query or stored procedure. Default = 300. |

Vulnerability Assessment parameters

| Parameter | Value Type | Description |
|-----------------------------------|------------|---|
| ALLOW_NULL_SERVICE_FOR_VA_SUMMARY | Binary | Name for the VA summary.
Set as DEFAULT in case of NULL in service. |
| INAPPLICABLE_TEST_RESULT_STATUS | Binary | Allows you to include or exclude test scores for unsupported database versions from the vulnerability assessment test report.

0: excludes tests with results that have the test score "NOT APPLICABLE".

1: includes tests with results that have the test score "NOT APPLICABLE".
Tip: For vulnerability assessment tests with a defined range of supported database versions, the test returns a score of "NOT APPLICABLE" when the datasource version is not within the range. |
| SAVE_TEST_RESULT_DETAIL_STRING | Binary | Controls detailed information of a test result.

Default = true, include detail information in the test result.

If false, the detail information is not included in the test result. |

Other parameters

| Parameter | Value Type | Description |
|--|------------|---|
| CM_HEALTH_VIEW_HOSTNAME | String | For the cross-CM health view. Hostname of the central manager that the machine is reporting to.

Note:
12.0 You can unregister central managers from the cross-CM health view system by providing an empty <code>paramValue</code> for <code>CM_HEALTH_VIEW_HOSTNAME</code> . Unregistered systems still appear on the aggregated health views of the cross-CM health view system, but their data is no longer updated and their status may not be listed accurately.

<code>grdapi modify_guard_param paramName=CM_HEALTH_VIEW_HOSTNAME paramValue=</code>

12.1 and later You can unregister 12.1 central manager from the cross-CM health view system by providing the central manager name.

<code>grdapi unregister_unit unitIplist=""</code>

To register a central management unit with version earlier to 12.1 and cross-CM health view with version 12.1, use the following API:

<code>grdapi modify_guard_param paramName=CM_HEALTH_VIEW_HOSTNAME paramValue=<CM of CMs hostname></code>

From 12.1, Guardium populates <code>CM_HEALTH_VIEW_HOSTNAME</code> during registration and it cannot be modified. |
| ENABLE_GUARDIUM_INSIGHT_STREAMING | Binary | For Guardium Insight streaming. Enable or disable data streaming to Guardium Insights.

Valid values: <ul style="list-style-type: none">• True: Enable Insights streaming• False (default): Disable Insights streaming |
| ESCAPE_FOR_ARCSIGHT | Binary | Deprecated. |
| FUTURE_PARTITION_EXPAND_DELAY_HOURS | Integer | The maximum number of hours to delay before creating future partitions. Change this parameter only on advice of Guardium Technical Support.
Default = 0. |
| INFORMIX_SAVED_RESPONSE_QUEUE_SIZE | Integer | Informix queue size for the Save response. |
| KEEP_NUMBER_OF_JAVACORE_BUNDLE | Integer | The number of javacore file bundles to keep. The number must be between 1 and 30. Default = 3. |
| LDAP_CONN_TIMEOUT_MILLISEC | Integer | Sets the number of milliseconds before the LDAP test connection times out.
Default = 5000 (5 seconds)

The value must be between 1000 and 300000 ms. |
| LOG_TO_APP_USER | String | Log specified attributes to the Application User field. |
| PASSWORD_MIN_DAYS | Integer | The minimum days required between a password change. Default = 1 (day). |
| PATCH_PRESERVATION | Integer | Controls whether to preserve failed patches. When set to 1 (on), if the patch fails, you can make corrections and then rerun the patch without having to download it again.
Default = 0 (off). |
| REMOTE_FILETRANSFER_RESERVED_SPACE_GB | Integer | The minimum reserve disk space required in remote file transfer between Guardium Data Protection and Guardium Insights. Default = 25. |
| SIZE_OF_RAW_STATEMENT_MAP | Integer | Controls the size of the raw statement map. To view the current size of the raw statement map, use the <code>get_guard_param</code> command. For example:

<code>>grdapi get_guard_param paramName="SIZE_OF_RAW_STATEMENT_MAP"</code>

Default = 2048 |
| 12.1 and later UNIVERSAL_CONNECTOR_CONFIGURATION_FLOW_FLEXTURE | Integer | When set to 1, allows you to use the <code>load_all_packages</code> API to load the universal connector package configuration from a specified folder. |
| WAF_F5_METHOD | Integer | Customer-specific parameter. No longer used. |

| Parameter | Value Type | Description |
|-------------------|------------|---|
| WKC_CONFIGURATION | Encrypted | For internal use only. When decrypted, displays the configuration parameters for the IBM Cloud Pak® for DataIBM Knowledge Catalog integration with Guardium. For more information, see Integrating with IBM Knowledge Catalog for federated data protection . |

modify_oauth_validity

This API is available in Guardium V11.2 and later.

GuardAPI syntax

```
modify_oauth_validity parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|-------------|
| client_id | String | Required. |
| validity_in_seconds | Integer | Required. |

modify_schedule

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/schedule
```

GuardAPI syntax

```
modify_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| cronString | String | Required. |
| jobGroup | String | Required. |
| jobName | String | Required. |
| startTime | Date | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

modify_va_summary_key

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/modify_va_summary_key
```

GuardAPI syntax

```
modify_va_summary_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| allowNullsServerName | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useDatasourceName | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useHost | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| usePort | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useServiceName | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

must_gather

This command collects information on the state of the Guardium system for use by Guardium Support.

For more information, see [Basic information for IBM Support](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/must_gather
```

GuardAPI syntax

```
must_gather parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| commandsList | String | Required. The information to gather. For valid values, call must_gather from the command line with --help=true. For more information, see Running must_gather from the CLI . |
| description | String | A description of the issue. |
| email | String | Email address for results.
If you specify an email, the logs are gathered for 10 minutes from the time you start the process and an email is sent afterward. |
| maxLogLength | Integer | Maximum number of rows to appear in the log. |
| pmrNumber | String | The PMR number for this issue. |
| runDuration | Integer | The length of time, in minutes, to gather information.
Default = 10 (minutes) |
| startRun | Date | Time to start the run. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi must_gather commandsList="alert_issues" description="Issues with real-time alerts"
```

non_credential_scan

Use this command to submit jobs that scan databases within the serversGroup for enabled default users in the usersGroup.

Submitted jobs run under the Classifier Listener and can be tracked in the Job Queue report. For more information, see the [Default DB Users Enabled](#) report in [Predefined admin reports](#).

Note: To cancel a submitted job from the Job Queue report, right-click the job name and select **Stop Job**.

Note: If a server within the serversGroup cannot be reached, an exception of type Scheduled Job Exception is added and the server is not scanned.
This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
non_credential_scan parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| databaseType | String | Required. The database type. Valid values are: <ul style="list-style-type: none">• DB2• IBM ISERIES• INFORMIX• MS SQL SERVER• MYSQL• NETEZZ• ORACLE• POSTGRESQL• SYBASE• TERADATA |
| serversGroup | String | Required. A valid group of servers (Server IP/Instance Name/Port) as defined with Group Builder. |
| usersGroup | String | Required. A valid group of users (DB User/DB Password) as defined with Group Builder. Default groups exist within Group Builder. |

Example

```
grdapi non_credential_scan databaseType=ORACLE serversGroup=oracleServers usersGroup="ORACLE Default Users"
```

nscd

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
nscd parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| state | String | |

patch_cleanup

This command deletes all the patches with the suffixes "enc" or "sig" in the patches directory .

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/patch_cleanup
```

GuardAPI syntax

```
patch_cleanup parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

patch_install

Use this API to install a Guardium patch. The patch number is required.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/patch_install
```

GuardAPI syntax

```
patch_install parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| mode | String | Valid values: <ul style="list-style-type: none">• <i>local_only</i>• <i>pull_only</i>• <i>pull_install</i> |
| patch_date | Date | A date and time in the format <i>yyyy-mm-dd hh:mm:ss</i> or a relative time such as <i>NOW +2 HOUR</i> . <ul style="list-style-type: none">• If <i>patch_date</i> is left blank or contains a date in the past, then Guardium installs the patch within 5 minutes after the command is called.• If <i>patch_date</i> is a future date and time, then the patch is installed within 5 minutes of the assigned date and time. For more information about date formats, see Dates and Timestamps . |
| patch_number | Integer | Required. |
| unitIpList | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following examples install patch number 4000 onto the test.guard.ibm.com machine in four hours. The first example uses the GuardAPI, the second example shows the REST API.

```
grdapi patch_install patch_number=4000, api_target_host=test.guard.ibm.com patch_date="NOW +4 HOUR"
curl -k --header "Authorization: Bearer ed272932-28e6-4b56-80a3-664e5e0220de" -i -H "Content-type: application/json" -X PUT -d
{"patch_number": "4000", "api_target_host": "test.guard.ibm.com", "patch_date": "NOW +4 HOUR"}
```

pause_or_resume_job

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/schedule
```

GuardAPI syntax

```
pause_or_resume_job parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| jobGroup | String | Required. |
| jobName | String | Required. |
| pause | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

pause_or_resume_scenarios

This command allows you to manage and schedule Discover Sensitive Data scenarios in batch. You can specify a set of scenarios by using a pattern, and then pause, restart, and preview the output.

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/schedule
```

GuardAPI syntax

```
pause_or_resume_scenarios parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| pause | Boolean | <p>Required. Acts the same way as Activate schedule in the Discover Sensitive Data Scenario definition. Valid values:</p> <ul style="list-style-type: none"> • 0 (false, pause a running job) • 1 (true, resume a paused schedule) <p>Default = 1 (true)</p> |
| preview | Boolean | <p>Run the command without applying any changes to see which scenarios are selected for a given scenarioNamePattern and make changes as needed. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| scenarioNamePattern | String | <p>Required. Specify Discover Sensitive Data scenario names using MySQL patterns. For example, underscores (_) and percent signs (%) are accepted, but an asterisk (*) is not.</p> <p>All scenarios that meet the specified criteria run when pause = 1.</p> |
| verbose | Boolean | <p>Controls the amount of information displayed in the output. Valid values:</p> <ul style="list-style-type: none"> • 0 (false, less verbose) • 1 (true, more verbose) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

policy_fam_rule_delete

This command deletes the specified rule from the specified FAM policy.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/famPolicyRule
```

GuardAPI syntax

```
policy_fam_rule_delete parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| policyName | String | Required. |
| ruleName | String | Required. Name of the rule to be deleted. |

Examples

To delete a rule named audit_read in the policy named fam26:

```
policy_fam_rule_delete policyName=fam26 ruleName=audit_read
```

policy_install

This command installs one or more policies.

Specify multiple policies by using a pipe (|) character as a delimiter between policy names. Specify the policies in the order that you want to install them.

Note: If you change one or more policies, you must reinstall all policies.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/policy_install
```

GuardAPI syntax

```
policy_install parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| policy | String | Required. The name of the policy or policies to install. Use a pipe () character to separate multiple policies. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

The following example installs three policies.

```
grdapi policy_install policy="policy 20|policy 30|policy 40"
```

Related tasks

| selectedDataSourceName | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

populate_group_from_query

This command populates a group from an existing query.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/group_query
```

GuardAPI syntax

```
populate_group_from_query parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| activateSchedule | Boolean | Activates the schedule specified by cronString. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| clearGroup | Boolean | Required. Valid values: <ul style="list-style-type: none"> 0 (false). Append new members to the group. 1 (true). Clear the existing members from the group before adding new members. |
| cronString | String | The schedule to run the query as a cron string. For example, to run the query every day at 2 AM:
<pre>0 2 * * *</pre> . |
| groupDesc | String | Required. A description of this group. |
| queryColumns | String | Required. The names of the columns to import into the group as a comma-separated string. For tuples, specify one column per tuple. |
| queryName | String | Required. The name of the query to use for populating the group. The query must already exist. |
| queryParams | String | Parameters for the query (specified as a key = value pair). For example,
<code>QUERY_FROM_DATE=NOW -3 DAY,QUERY_TO_DATE=NOW</code> |
| startDate | Date | The date to start using this API, based on the value of cronString. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

proxy

12.1 and later Use this API to create proxy connections. Guardium® supports a web proxy to connect to a remote source that requires a proxy server to connect.

REST API syntax

This API is available as a REST service with the `proxyConfig` method. Call this API as follows:

```
https://[Guardium hostname or IP address]:8443/restAPI/proxy
```

GuardAPI syntax

```
proxy parameter=value
```

Proxy API usage

```
grdapic proxy <options>
  Options: list=true

  clearall=true
    reload=true
  stop=true
    setup=true
  proxy_host=<proxy_server> proxy_port=<proxy_port> target_host=<target_server>
  target_port=<target_port>
    clear=true target_host=<target_server>
  target_port=<target_port> diagnostics=true
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| clear | Boolean | Deletes the proxy connections from the system.
Valid values: <ul style="list-style-type: none"> false true |
| clearall | Boolean | Deletes all the proxy connections from the system.
Valid values: <ul style="list-style-type: none"> false true |

| Parameter | Value type | Description |
|-----------------|------------|--|
| diagnostics | Boolean | Runs diagnostics on all the proxy connections and writes the output to a log file.
Valid values: <ul style="list-style-type: none">• <i>false</i>• <i>true</i>) |
| list | Boolean | Lists the proxy connections.
Valid values: <ul style="list-style-type: none">• <i>false</i>• <i>true</i> |
| proxy_host | String | IP or hostname of the proxy server. |
| proxy_port | String | Port number for the proxy connection. |
| reload | Boolean | Restart and refresh all the proxy connections.
Valid values: <ul style="list-style-type: none">• <i>false</i>• <i>true</i> |
| setup | Boolean | Setup the proxy connection.
Valid values: <ul style="list-style-type: none">• <i>false</i>• <i>true</i> |
| stop | Boolean | Stops all the proxy connections without deleting them from the system.
Valid values: <ul style="list-style-type: none">• <i>false</i>• <i>true</i> |
| target_host | String | Hostname/IP of the target resource for the proxy connection |
| target_port | String | Port number of the target resource for the proxy connection. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Setting up proxy

To configure a proxy for `myhost.example.com:443` via proxy server `proxy.example.com:3128`, use the following command:

```
grdapic proxy setup=true proxy_host=myhost.example.com:443 proxy_port=3128 target_host=proxy.example.com target_port=443
```

Listing target and proxy hosts

To list all the proxy connections, use the following command:

```
grdapic proxy list=true
```

Output: `myhost.example.com:443 via proxy proxy.example.com:3128`

Testing proxy server

To troubleshoot the proxy server, use the following command:

```
grdapic proxy diagnostics=true
```

Output: Please view `log/guard_proxy.txt` using the fileserver.

Verify proxy connection

To verify the proxy connection, use the following command:

```
support show port open <target_server> <target_port>
```

For more information, see [support show port open](#) CLI Command.

pull_external_stap_keystore

This command moves the External S-TAP® keystore between a central manager and its managed units.

This API is available in Guardium V10.6 and later.

The External S-TAP pull_external_stap_keystore command provides a mechanism to populate the External S-TAP keystore from either a central manager or a managed unit.

- To pull the External S-TAP keystore from the central manager to a managed unit, run this API on the managed unit.
- To pull the External S-TAP keystore from the central manager to one or all of the associated managed units, run this API on the central manager.

GuardAPI syntax

```
pull_external_stap_keystore parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI examples

- To pull the keystore from a managed unit to the central manager, run the following command from the managed unit:
`grdapi pull_external_stap_keystore`
- To pull the keystore from the central manager to all associated managed units, run the following command from the central manager:
`grdapi pull_external_stap_keystore`
- To pull the keystore from the central manager to a specific managed unit, run the following command from the central manager:
`grdapi pull_external_stap_keystore api_target_host=hostname`

Related concepts

- [External S-TAP](#)

push_insights_trust

This command pushes a trust certificate from Guardium® Insights to Guardium Data Protection S-TAPs.

The certificate must be in PEM format and include the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- tags.

The certificate chain that you paste needs to be downloaded (from the browser) from the Guardium Insights cluster that is targeted for S-TAP® migration. The certificate is not stored on the managed unit; but on the S-TAP host (database server).

Notes:

- If you run this command from a central manager, you must specify the api_target_host parameter to target a managed unit (because central managers don't have S-TAPs). You can also run this command directly from a collector or stand-alone machine.
- When you call this command as a GuardAPI, leave pemData blank, and follow the directions in the CLI to paste the entire certificate.
- You can push certificates only for UNIX S-TAPs.
- You can also add the Guardium Insights certificate from the Guardium Data Protection GUI. For more information, see the [Send command](#) under [Linux®-UNIX: Configuring S-TAP in the S-TAP Control page](#).

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/push_insights_trust
```

GuardAPI syntax

```
push_insights_trust parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| pemData | String | Required for REST API only. The certificate to send to the S-TAP hosts, in PEM format. <ul style="list-style-type: none">• For a REST API, paste the trusted Guardium Insights certificate in, including the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- tags.• For a GuardAPI, ignore this parameter. The CLI walks you through the required steps. |
| stapHost | String | Required. Specify the name of one or more S-TAP hosts, or specify <i>all_unix_active</i> to send the certificate to all active UNIX S-TAP hosts. For valid values, call <code>push_insights_trust</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: Run on all managed units but not the central manager• <i>group:<group name></i>: Run on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: Specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. <p>Note: IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

The following GuardAPI example runs on a stand-alone machine with a certificate chain that includes two certificates. The pemData parameter is not specified in the command. Follow the directions in the CLI to paste the certificate data in.

```
vm01.mycompany.com> grdapi push_insights_trust stapHost=9.55.254.111
```

The response from the CLI is as follows (be sure to paste in the entire certificate):

```
Please paste your Certificate below in PEM encoded format including tags.  
PEM encoded format should include the '-----BEGIN CERTIFICATE-----' and '-----END CERTIFICATE-----' tags. The Certificate Authority (CA) Root and Intermediate certificate(s) (if applicable) will also need to be pasted at this time for validation purposes. Please ensure that all certificates are in PEM format and include the aforementioned tags. When pasting multiple certificates, please make sure that each certificate is pasted on a new line in the following order:
```

```
-----BEGIN CERTIFICATE-----  
(End-Entity certificate)  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
(Intermediate certificate(s) - if applicable)  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
(Root certificate)  
-----END CERTIFICATE-----
```

```
Once done pasting your certificate(s), press ENTER followed by CTRL-D to continue.
```

```
-----BEGIN CERTIFICATE-----  
MIIDbzCCAlEqAwIBAgIQX+U115HoAr3cToMpY  
...  
01zSjANBgkqhkf+9tfN60rPSFmUp0CDTrew==  
-----END CERTIFICATE-----  
-----BEGIN CERTIFICATE-----  
MIIDMTCCAhmqAwIBAgIQCO/HN2U7x20Fsn4Df  
...

push_parameter_to_mu

Push the value of a modifiable parameter from the central manager to a managed unit or group of managed units.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/push_parameter_to_mu
```

GuardAPI syntax

```
push_parameter_to_mu parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| groupname | String | The name of a managed unit group. |
| paramname | String | The name of the parameter to push. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

quick_search

This REST API is a wrapper for Solr queries, which are used in the Investigation Dashboard. This command is similar to the search command, but has some improvements.

This API is available in Guardium v11.3 and later.

Note: The quick_search API returns codes that represent the titles of the columns (fields) in the returned tables. For example, quick_search might return the following rows:

```
"15": "Failed Login - Alert and Quarantine if Repeated",
      "16": "5",
```

To map the codes ("15" and "16", in this case) to the actual column names, use the [getFieldsTitles](#) API.

REST API syntax

This API is available only as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/quick_search
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| category | String | Required. The Guardium Solr collections. The categories generally map to the categories that are shown in the Investigation dashboard UI.
To view the valid categories, call this REST API with all of the required parameters but enter a clearly invalid value (for example, category=kookoo). Guardium returns all valid values for category. |
| endTime | String | Search for records that were created before the specified endTime. The time must be specified in the format:YYYYMMDD+HH:MM:SS. |
| fetchSize | Integer | The maximum number of records returned by the API. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| filters | String | Filters consume input and produce a stream of tokens. Filters must be in a specific format, for example:

<pre>"filters": "name=Database&value=9.147.31.113:5.6.27&isGroup=false&name=DB User&value=SYSTEM&isGroup=false&name=Server&value=9.147.31.113&isGroup=false"</pre> For more information about filters, see the Apache Solr Reference Guide > Schema and Indexing Guide . |
| firstPosition | Integer | The position in the result. Can be used together with fetchSize to iterate through the results. |
| inputTZ | String | The initials of a timezone, such as UTC or EST. If provided, startTime and endTime parameters are converted from that timezone to the Guardium appliance's timezone before the search is executed. All date fields in the results are converted from Guardium appliance's timezone to the inputTZ timezone provided before the results are returned.
To view the valid timezone codes, call this REST API with all of the required parameters but enter a clearly invalid value (for example, inputTZ=kookoo). Guardium returns all valid values for inputTZ. |
| pivotBy | String | |
| query | String | A Solr query. You can use this parameter to write free-form Solr query expressions. For more information, see the Apache Solr Reference Query Guide . |
| startTime | String | Search for records that were created after the specified startTime. The time must be specified in the format: YYYYMMDD+HH:MM:SS . |
| summaryBy | String | Group results by the selected field code. You can specify up to 2 field title codes to group by.
Note: To map the field codes to column names, use the getFieldsTitles API. |
| withFacets | String | Include facets in the search. For more information, see Investigation dashboard for data or Investigation dashboard for files . Valid values are: <ul style="list-style-type: none">• 0 (Off: Do not include facets)• 1 (On: Include facets) Default = 0. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

```
curl -k --header "Authorization: Bearer <token>" -i -H "Content-Type: application/json" -X POST --data '
{"category": "ERROR", "inputTZ": "UTC", "startTime": "20201019 00:00:01", "endTime": "20221225 10:11:11",
*"filters": "name=Server&value=9.55.205.70&isGroup=false"*)
' <Guardium host>:8443/restAPI/quick_search" class="external-link" rel="nofollow">https://<Guardium
host>:8443/restAPI/quick_search
...
...
{
  "2": "DB2_ZZ7I", "13": "2022-03-23 10:02:45", "3": "9.55.205.70", "14": "SESSION_GUESS", "_shard_": "my_company.com", "6":
  "9.55.205.70", "7": "DB2", "8": "2022-03-23", "9": "14:02:45", "id": "3" }

curl -k --header "Authorization: Bearer <token>" -i -H "Content-Type: application/json" -X POST --data '
{"category": "ERROR", "inputTZ": "UTC", "startTime": "20201019 00:00:01", "endTime": "20221225 10:11:11",
"filters": "",*,*,"query": "Server=9.55.205.70 AND DB_Type=DB2"*, "fetchSize": "1000"
}

' https://<Guardium host>:8443/restAPI/quick_search
...
...
{
  "2": "DB2_ZZ7I", "13": "2022-03-23 10:02:45", "3": "9.55.205.70", "14": "SESSION_GUESS", "_shard_": "my_company.com", "6":
  "9.55.205.70", "7": "DB2", "8": "2022-03-23", "9": "14:02:45", "id": "3" }
```

Use the [getFieldsTitles](#) REST API to map the column codes to column names. For example:

```
curl -k --header "Authorization: Bearer <token>" -i -H "Content-Type: application/json" https://il-
vm01.isslab.usga.ibm.com:8443/restAPI/fieldsTitles
...
...

reboot_image_universal_connector

After you run this grdapi, the UC stops the container that is currently running and starts a new one, which is loaded from the UC image that comes with the installation.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/restoreUniversalConnectorImage
```

GuardAPI syntax

```
reboot_image_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Related concepts

refresh_quick_search_groups

This command sends all defined groups to the specified target hosts. Use it when you have defined a new group(s) on the central manager, but the scheduled time for the central manager to update its managed units has not yet occurred.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
refresh_quick_search_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To update the groups on all managed units:

```
grdapi refresh_quick_search_groups
```

Related concepts

refresh_stap_info

Run this command to refresh the S-TAP configuration from the agent.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/refresh_stap_info
```

GuardAPI syntax

```
refresh_stap_info parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHost | String | Required. IP or hostname of the S-TAP® host. For valid values, call <code>refresh_stap_info</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To refresh the S-TAP details for the host 12.21.12.12:

```
grdapi refresh_stap_info stapHost=12.21.12.12
```

Typical response:

```
ID=0  
ok
```

Related reference

- [S-TAP and inspection engine APIs](#)

register_oauth_client

This API wraps supported GuardAPI functions in a REST API that uses JSON for input and output.

Note: The `register_oauth_client` API does not support the `redirect_uris` and `scope` parameters. These parameters are hard-coded for Guardium. If you make changes to `redirect_uris` or `scope`, the values are validated, but Guardium does not use them.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
register_oauth_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| client_id | String | Required. |
| GetToken | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| grant_types | String | For valid values, call register_oauth_client from the command line with --help=true. |
| password | String | The user password. |
| user | String | The username for the Guardium UI. |
| redirect_uris | String | Guardium does not support this parameter. Guardium suggests that you leave the redirect_uris parameter blank. If you must enter a value, the only valid value is https://someApp. |
| scope | String | Guardium does not support this parameter. Guardium suggests that you leave the scope parameter blank. If you must enter a value, you can enter one or more of the following comma-separated values, but Guardium ignores them: <ul style="list-style-type: none">• read• write• delete |

Example

```
grdapi register_oauth_client  
client_id=_home_markdown_jenkins_workspace_Transform_in_SSMPHH_12.x_com.ibm.guardium.doc.reference_grdapi_register_oauth_client_test12" grant_types="password" user="admin" password="password" GetToken=1
```

register_oauth_internal_client

This API manages the ROLE and USER for internal API requests.

For internal REST API requests, Guardium predefines a special ROLE and USER. This user cannot be removed or modified through the accessmgr UI and cannot be used to log in the UI. This user's password never expires, but is revoked if client ID is revoked.

On OAuth client registration, use this API to accept this user and client ID. The API generates and stores a random strong password for the user. The API then returns a client secret and the generated password. The internal (S-TAP, maybe others) client must secure the client secret and password.

To assign permissions for different functions, use the accessmgr UI.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
register_oauth_internal_client parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| getEncrypted | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| grant_types | String | For valid values, call register_oauth_internal_client from the command line with --help=true. |
| module | String | Required. For valid values, call register_oauth_internal_client from the command line with --help=true. |
| redirect_uris | String | |
| scope | String | |

register_unit

REST API syntax

12.1 and later This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/register_unit
```

GuardAPI syntax

```
register_unit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| secretKey | String | Required. |
| unitIp | String | Required. |
| unitPort | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

reinstall_policy

This command reinstalls the last uninstalled policy.

If you accidentally uninstall a policy, use this command to reinstall the policy.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/reinstall_policy
```

GuardAPI syntax

```
reinstall_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policy | String | Required. The name of the policy to reinstall. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi reinstall_policy policy="policy1"
```

Related reference

- [policy_uninstall](#)

reinstall_policy_rule

This command reinstalls one or more rules into a specified policy.

Specify multiple rules by using a pipe (|) character as a delimiter between rule names.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/reinstall_policy_rule
```

GuardAPI syntax

```
reinstall_policy_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policy | String | Required. The name of the policy. |
| ruleName | String | Required. The name of the rule or rules to reinstall. Use a pipe () character as a delimiter between rule names. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI examples

Uninstall a single policy rule:

```
grdapi reinstall_policy_rule policy="Hadoop Policy" ruleName="Low interest Objects: Allow"
```

Uninstall multiple policy rules:

```
grdapi reinstall_policy_rule policy="Hadoop Policy" ruleName="Low interest Objects: Allow|Low Interest Commands: Allow"
```

remove_all_from_schedule

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/remove_all_from_schedule
```

GuardAPI syntax

```
remove_all_from_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_all_gr_replace_elements

This command deletes query replacement specifications from the system.

This API is available in Guardium V10.1.4 and later.

RestAPI syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_all_gr_replace_elements
```

GuardAPI syntax

```
remove_all_gr_replace_elements parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | Required. A query rewrite action. |
| definitionName | String | Required. |
| replaceType | String | Specifies which replacement types are to be deleted. For valid values, call <code>remove_all_gr_replace_elements</code> from the command line with <code>--help=true</code> . |

Examples

```
grdapli remove_all_gr_replace_elements definitionName="new case 2" actionName="new qr action2"
```

remove_all_gr_replace_elements_byId

Deletes query replacement specifications from the system.

This API is available in Guardium V10.1.4 and later.

Rest API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_all_gr_replace_elements_byId
```

GuardAPI syntax

```
remove_all_gr_replace_elements_byId parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| qrActionId | Long | Required. A query rewrite action identifier. |
| replaceType | String | Specifies which replacement types are to be deleted. If not specified, then all replacements for the specified action are deleted.
Valid values: <ul style="list-style-type: none">• SELECT• VERB• OBJECT• SENTENCE• SELECTLIST |

Examples

```
grdapi remove_all_gr_replace_elementsById qrActionName="qr_action15_2" replaceType="OBJECT"
```

remove_classifier_datasource

This command removes classification datasource.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_datasource
```

GuardAPI syntax

```
remove_classifier_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| datasourceName | String | Required. |
| processName | String | Required. |

remove_classifier_datasource_group

This command removes classification datasource groups.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/classifier_datasource_group
```

GuardAPI syntax

```
remove_classifier_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| groupName | String | Required. |
| processName | String | Required. |

remove_connection_properties

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/con_properties
```

GuardAPI syntax

```
remove_connection_properties parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| name | String | Required. |
| properties | String | |
| removeAll | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| type | String | Required. For valid values, call remove_connection_properties from the command line with --help=true. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

remove_custom_property_from_datasource_by_id

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop_remove
```

GuardAPI syntax

```
remove_custom_property_from_datasource_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| customProps | String | Required. |
| id | Integer | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_custom_property_from_datasource_by_name

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop_remove
```

GuardAPI syntax

```
remove_custom_property_from_datasource_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| customProps | String | Required. |
| name | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_custom_property_from_datasources_in_group

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group_custom_prop_remove
```

GuardAPI syntax

```
remove_custom_property_from_datasources_in_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|-------------|
| customProps | String | Required. |
| name | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_datasource_configuration_from_collector

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
remove_datasource_configuration_from_collector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| ucDatasourceId | Integer | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_datasource_from_entitlement_optimization

Removes the data of the specified datasources from the entitlement optimization data collection.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/removeDatasourceFromEntitlementOptimization
```

GuardAPI syntax

```
remove_datasource_from_entitlement_optimization parameter=value
```

| Parameter | Value type | Description |
|----------------|------------|-------------|
| datasourceName | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Disable entitlement optimization for the datasource SSQLSERVER.

```
grdapi remove_datasource_from_entitlement_optimization datasourceName=SSQLSERVER
```

remove_datasource_from_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
remove_datasource_from_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| datasourceName | String | Required. |
| groupName | String | Required. |

remove_dm_from_profile

Removes the DM from the profile. If the profile is Active, running this command also unschedules the DM.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datamartInProfile
```

GuardAPI syntax

```
remove_dm_from_profile parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|--|
| datamart_name | String | Required. The DM to delete from the profile. A datamart that belongs to the profile. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| profile_name | String | Required. The profile from which to delete the DM. For valid values, run <code>grdapi get_extraction_profile_info</code> or call <code>remove_dm_from_profile</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

Remove the data mart **Export:Full SQL** from the user defined profile **sql_all**

```
remove_dm_from_profile profile_name=sql_all datamart_name=Export:Full SQL
```

remove_domain_from_universal_connector_allowed_domains

Run this API to remove authorization for communication with cloud-based database domains.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/removeDomainFromUcAllowedDomains
```

GuardAPI syntax

```
remove_domain_from_universal_connector_allowed_domains parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| domain | String | Required. The name of the domain to remove. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

To remove authorization for communication with [amazonaws.com](#):

```
grdapi remove_domain_from_universal_connector_allowed_domains domain=amazonaws.com
```

remove_extraction_profile

Removes an inactive, user-defined GBDI (Big Data) profile.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/extractionProfile
```

GuardAPI syntax

```
remove_extraction_profile parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| profile_name | String | Required. The inactive profile you are removing. For valid values, run <code>grdapiget_extraction_profile_info</code> or call <code>remove_extraction_profile</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To remove the profile `sql_all`:

```
remove_extraction_profile parameter=sql_all
```

Related concepts

remove_members_of_groups_by_desc

Remove all members from a group identified by its description.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_members_of_groups_by_desc
```

GuardAPI syntax

```
remove_members_of_groups_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| desc | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

Use this command to remove all the members from the group "group one":

```
grdapi remove_members_of_groups_by_desc desc="group one"
```

remove_members_of_groups_by_id

Remove all the member from a group identified by its identification key.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_members_of_groups_by_id
```

GuardAPI syntax

```
remove_members_of_groups_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| id | Integer | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

Use this command to remove all the members from the group with identification key 100005:

```
grdapi remove_members_of_groups_by_id id=100005
```

remove_mfa_exempt_users

This command removes users from the exempt list for multi-factor authentication.

After a user is removed from the exempt list, Guardium will request secondary authentication to log in.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/configure_mfa
```

GuardAPI syntax

```
remove_mfa_exempt_users parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| exemptUsers | String | A comma-separated list of one or more users to remove from the list of exempt users. |
| mfaType | String | Required. The authentication type. For valid values, call remove_mfa_exempt_users from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group: <group name>; execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi remove_mfa_exempt_users exemptUsers="Hadrian,Fred" mfaType=DUO
```

remove_objects_native_audit

This API disables the object audit (audit trail) on the specified objects in the specified datasource.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/remove_objects_native_audit
```

GuardAPI syntax

```
remove_objects_native_audit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| datasource_name | String | Required. A cloud datasource defined in Guardium. |
| objects | String | Required. A comma-separated list of objects. View objects with the get_native_audit_objects API or in the GUI. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_populate_group_from_query

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/group_query
```

GuardAPI syntax

```
remove_populate_group_from_query parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| groupDesc | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

remove_qr_action

This command deletes a specified query rewrite action from the system.

This API is available in Guardium V10.1.4 and later.

Rest API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/qr_action
```

GuardAPI syntax

```
remove_qr_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---------------------------------------|
| actionName | String | Required. A query rewrite action. |
| definitionName | String | Required. A query rewrite definition. |

Examples

```
grdapic remove_qr_action actionName="qr_action15_2" definitionName="case_15"
```

remove_qr_add_where_by_id

Deletes a specified "add where" function from the system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_qr_add_where_by_id
```

GuardAPI Syntax

```
remove_qr_add_where_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|------------------------------------|
| qrAddWhereId | Long | Required. An "add where" function. |

Examples

```
grdapic remove_qr_add_where_by_id qrAddWhereId=22666
```

Related concepts

remove_qr_condition

Deletes a query rewrite condition from the system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/qr_condition
```

GuardAPI syntax

```
remove_qr_condition parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---------------------------------------|
| conditionName | String | Required. A query rewrite condition. |
| definitionName | String | Required. A query rewrite definition. |

Examples

```
grdapic remove_qr_condition conditionName="qr_cond15_1" definitionName="case 15"
```

Related concepts

remove_qr_replace_element_byId

Deletes a specified query element replacement, specified by ID, from the system.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_qr_replace_element_byId
```

GuardAPI syntax

```
remove_qr_replace_element_byId parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|--|
| qrReplaceElementId | Long | Required. A replacement definition ID. |

Examples

```
grdapi qrReplaceElementId=333333
```

remove_ranger_config

This command deletes the Ranger configuration for the specified cluster. All monitoring for these services is disabled upon restart of the affected Hadoop components.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_ranger_config
```

GuardAPI syntax

```
remove_ranger_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Name of the cluster. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

API examples

To delete the cluster named Cluster4:

```
grdapi remove_ranger_config clusterName=Cluster4
```

Sample output:

```
ID=0
The Hadoop service has been configured to disable monitoring. Ask the Hadoop administrator to restart the Hadoop services to
activate the changes
Configuration with ID: 2 deleted successfully
```

RestAPI example

```
curl -k --header "Authorization:Bearer ec4e55b5-79a9-4d02-9c5f-7a42672675a8" -i -H "Content-Type: application/json" -X DELETE -
d '{clusterName="hw3"}' https://<Guardium server name>:8443/restAPI/remove_ranger_config
```

remove_ranger_service

This command removes a ranger service from monitoring, from the specified cluster.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/remove_ranger_service
```

GuardAPI syntax

```
remove_ranger_service parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| serviceName | String | Required. Name of the service. Valid values: <ul style="list-style-type: none">• hdfs• hive• hbase• kafka• solr• storm |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GrdAPI Example

To remove the ranger service HDFS, on the cluster named Cluster4:

```
grdapi remove_ranger_service clusterName=Cluster4 serviceName=HDFS
```

Sample output:

```
ID=0
Service: HDFS deleted successfully
```

RestAPI example

```
curl -k --header "Authorization:Bearer 27d21f39-0978-4c8f-9525-990876f092e0" -i -H "Content-Type: application/json" -X DELETE -d '{clusterName="hw3cl1"}' https://<guardium server>:8443/restAPI/remove_ranger_config
```

[remove_threshold_from_rule](#)

Use this API to remove a threshold from a violation policy rule that creates an active threat analytics case type.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/remove_threshold_from_rule
```

GuardAPI syntax

```
remove_threshold_from_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| policy_name | String | Required. The policy that has the rule that you want to delete. Use the API <code>list_policy</code> to view policies. |
| rule_name | String | Required. The rule that you want to delete the threshold from. Use the API <code>list_policy_rules</code> to view rules. |

Examples

To remove the threshold from ruleNNN in policyAAA:

```
grdapli remove_threshold_from_rule policy_name=AAA rule_name=ruleNNN
```

Related tasks

[replace_active_profile](#)

Changes the active profile of the GBDI (Big Data) interface, only if the interface is enabled.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/extractionProfile
```

GuardAPI syntax

```
replace_active_profile parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| new_active_profile | String | Required. An existing profile, which replaces the current profile. For valid values, run <code>grdapli get_extraction_profile_info</code> or call <code>replace_active_profile</code> from the command line with <code>--help=true</code> . Valid values: |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Change the active profile to `sql_all`.

```
new_active_profile profile_name=sql_all
```

Related concepts

reregister_agg_collector

Use this command to un-register a collector from its current aggregator, and register it with the specified aggregator.

This API is available in Guardium V10.1.4 and later.

GuardAPI syntax

```
reregister_agg_collector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| newDomain | String | The domain name of the new host. |
| newHostName | String | Required. Aggregator you are registering the collector with. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To reregister the aggregator with the collector named coll44:

```
grdapic reregister_agg_collector newHostName=coll44
```

rerun_datamart

This command reruns a datamart for a period it already ran. It is useful if not all relevant data was available during the previous datamart run. For example, a datamart runs on an aggregator, but export data from one of the collectors hadn't been received in time.

This API is available in Guardium V11.0 and later.

GuardAPI syntax

```
rerun_datamart parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| datamartName | String | Required. |
| periodEnd | Date | Required. The end time of the period you are rerunning in the format: YYYY-MM-DD H24:MI:SS. |
| periodStart | Date | Required. The start time of the period you are rerunning in the format: YYYY-MM-DD H24:MI:SS. |

Examples

To rerun the data mart Export:Full SQL:

```
grdapi rerun_datamart datamartName="Export:Full SQL" periodStart="2019-08-01 00:00:00" periodEnd="2019-08-01 23:59:59"
```

Related concepts

rerun_distributed_report

Use this API to manually rerun a distributed report, typically used if the automatic run results were not complete.

For example, a distributed report runs daily at 1AM, and it collects data from aggregators. Data from one of the collectors was not received before the previous run of the report. To get a complete report, you need to verify that all data is in the aggregator; delete the results of this incomplete run (with the API [delete_distributed_report_result_for_period](#)); and rerun the distributed report manually for this period.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
rerun_distributed_report parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| endTime | Date | Required. |
| hostname | String | Required. |
| reportId | Integer | Required. |
| runOptions | String | Required. Valid values: <ul style="list-style-type: none">• <i>forHostname</i>• <i>forAllFailed</i>• <i>forceRerunForHostname</i>• <i>forceRerunForAllUnits</i> |
| startTime | Date | Required. |

Related concepts

- [Distributed report builder](#)

Related reference

reset_unit_utilization_data

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/reset_unit_utilization_data
```

GuardAPI syntax

```
reset_unit_utilization_data parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| hostName | String | Required. |
| resetDate | Date | Required. |

reset_va_summary_by_id

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/reset_va_summary_by_id
```

GuardAPI syntax

```
reset_va_summary_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| resetCumulativeFailTo | Integer | |
| resetCumulativePassTo | Integer | |
| summaryId | Integer | Required. |

reset_va_summary_by_key

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/reset_va_summary_by_key
```

GuardAPI syntax

```
reset_va_summary_by_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|-------------|
| datasourceName | String | Required. |
| hostName | String | Required. |
| port | Integer | Required. |
| resetCumulativeFailTo | Integer | |
| resetCumulativePassTo | Integer | |
| serviceName | String | Required. |

rest_export_definition

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/export_definition
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| dataSet | String | Required. For valid values, call rest_export_definition from the command line with --help=true. |
| itemNames | String | |
| exportToCSV | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| exportToXacml | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| excludeGroupMembers | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |

restart_all_managed_units

Run this command on a central manager to restart the GUIs on all of its managed units.

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
restart_all_managed_units parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To restart the GUIs of all of the managed units of the central manager, enter on the central manager:

```
grdapic restart_all_managed_units
```

restart_cloud_instance

Restarts the specified cloud instance (defined for cloud database service protection).

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/restart_cloud_instance
```

GuardAPI syntax

```
restart_cloud_instance parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasource_name | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi
```

restart_job_queue_listener

This command restarts the job queue listener. Run this command if the job queue fails to start, does not run waiting jobs, or if a job appears stuck in running or stopping status.

Calling this command immediately restarts the job queue, and any currently running jobs are halted and restarted.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/restart_job_queue_listener
```

GuardAPI syntax

```
restart_job_queue_listener parameter=value
```

This API takes no parameters.

GuardAPI example

```
grdapi restart_job_queue_listener
```

restart_solv

This command restarts the solv process on the specified Guardium® system(s).

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
restart_solv parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| restart_all | Boolean | <p>This parameter is only relevant when running the command on a CM. Valid values:</p> <ul style="list-style-type: none">• 0 (false): solv is restarted only on CM• 1 (true): solv is restarted on CM and all managed units. <p>Default = 0 (false)</p> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi restart_solr restart_all=true
```

Related reference

- [Solr APIs](#)

restart_stap

This command restarts the S-TAP on the specified database server.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stap
```

GuardAPI syntax

```
restart_stap parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| restartMode | Integer | <p>Controls the S-TAP behavior when it receives a restart command. Valid values:</p> <ul style="list-style-type: none"> • 0: Restarts the S-TAP • 1: Requests new collectors from the central manager (enterprise load balancer), and does not restart the S-TAP <p>Default = 0</p> |
| stapHost | String | Required. Hostname |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To restart the S-TAP® on the database server with the IP address 9.42.29.158:

```
grdapi restart_stap stapHost=9.42.29.158
```

restart_unit_pinger

This API restarts the internal UnitPinger thread.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
restart_unit_pinger parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

restore_units_after_bad_shift

Run this command if, after a switch to a backup central manager, some or all of the managed units are not registered with the new primary central manager.

This API is available in Guardium V11.0 and later.

GuardAPI syntax

```
restore_units_after_bad_shift parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

retrieveUpdatedUsers

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/retrieveUpdatedUsers
```

GuardAPI syntax

```
retrieveUpdatedUsers parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|-------------|
| dcName | String | Required. |
| lastUpdateTime | String | Required. |

retrieveAPIs

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/restapi
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| withParameters | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| apiNameLike | String | |

retrieveApiParameters

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/restapi
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| resourceId | Integer | |

revokeOAuthClient

This API revokes access to the REST APIs for a specified client.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/revokeClient
```

GuardAPI syntax

```
revokeOAuthClient parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| client_id | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

revokeOAuthToken

This API revokes a specified REST API token.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
revokeOAuthToken parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| token | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

revoke_api_key

12.1 and later This command deletes an API key for a Guardium user.

GuardAPI syntax

```
delete_api_key parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| name | String | Required. |
| username | String | If not specified, deletes the API key for the logged-in user. If specified, the logged-in user must have the accessmgr role to delete the API key for the user associated with the username. |

GuardAPI example

The following example shows the command to delete the API key `VAScanner_IT` for the `guard` user.

```
grdapi revoke_api_key name=VAScanner_IT username=guard
```

revoke_ignore_stap

This command revokes existing IGNORE S-TAP SESSION (REVOKABLE) policy rule actions that ignore S-TAP® session traffic. This command only revokes soft ignore rules (marked as REVOKABLE) and cannot revoke hard rules (not marked as REVOKABLE).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/revoke_ignore_stap
```

GuardAPI syntax

```
revoke_ignore_stap parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stapHost | String | For valid values, call <code>revoke_ignore_stap</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi revoke_ignore_stap
```

revoke_role_from_object_by_Name

Removes a role from the specified object.

Guardium automatically handles dependencies. For example, if you remove role `accessmgr` from a specific query, role `accessmgr` is also removed from any report based on that query.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/revoke_role_from_object_by_Name
```

GuardAPI syntax

```
revoke_role_from_object_by_Name parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| objectName | String | Required. The name of the object from which to revoke the role. |
| objectType | String | Required. The name of the object type. For valid values, call <code>revoke_role_from_object_by_Name</code> from the command line with <code>--help=true</code> . |
| role | String | Required. The name of the role to revoke. Specify any existing role. Specify <code>all_roles</code> to remove access to all roles. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi revoke_role_from_object_by_Name objectType=Datasource objectName="swanSybase" role=admin
```

revoke_role_from_object_by_id

Removes a role from the specified object.

Guardium automatically handles dependencies. For example, if you remove role 7 from a specific query, role 7 is also removed from any report based on that query.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/revoke_role_from_object_by_id
```

GuardAPI syntax

```
revoke_role_from_object_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| objectId | Integer | Required. The ID of the object from which to revoke the role. |
| objectTypeId | Integer | Required. The ID of the object type. For valid values, call <code>revoke_role_from_object_by_id</code> from the command line with <code>--help=true</code> . |
| roleId | Integer | Required. The ID of the role to revoke from the object. Specify any existing role ID or specify -1 to revoke access to all roles. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi revoke_role_from_object_by_id objectId=13 objectTypeId=13 roleId=-1
```

Related reference

riskspotter_set_config

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/riskspotter_set_config
```

GuardAPI syntax

```
riskspotter_set_config parameter=value
```

This API takes no parameters.

rule_info_from_policy

This command displays information about all of the rules that make up a specified policy.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/ruleInfoFromPolicy
```

GuardAPI syntax

```
rule_info_from_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| localeLanguage | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| policyDesc | String | Required. The name of the policy. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

GuardAPI example:

```
> grdapi rule_info_from_policy policyDesc="Copy of Basel II [template]"
```

REST API example:

```
curl -k --header "Authorization:Bearer 57c9bcc5-b7af-441b-a836-94d72c28174c" -i -H "Content-Type: application/json" -X GET  
"https://example.com:8443/restAPI/ruleInfoFromPolicy/?policyDesc=testPol"
```

run_custom_table_ldap_import

This command imports LDAP data into a custom table.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/custom_data_ldap
```

GuardAPI syntax

```
run_custom_table_ldap_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| importId | Integer | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

run_database_instance_discovery

This API is available in Guardium v10.1.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/run_database_instance_discovery
```

GuardAPI syntax

```
run_database_instance_discovery parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------------|------------|---|
| replaceInspecti
onEngine | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| stapHost | String | Required. For valid values, call <code>run_database_instance_discovery</code> from the command line with <code>--help=true</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

run_diagnostics

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/run_diagnostics
```

GuardAPI syntax

```
run_diagnostics parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| durationInSec | Integer | |
| level | Integer | |
| stapHost | String | Required. For valid values, call run_diagnostics from the command line with --help=true. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

run_populate_group_from_query

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/group_query
```

GuardAPI syntax

```
run_populate_group_from_query parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| groupDesc | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

run_universal_connector

Enables the Guardium universal connector on the local or specified collectors.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/runUniversalConnector
```

GuardAPI syntax

```
run_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|--|
| enable_metrics | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| overwrite_old_instance | Boolean | Determines whether to overwrite the container (erase all saved data and restart the Guardium universal connector).Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| uc_debug_level | String | Valid values: <ul style="list-style-type: none">• <i>all</i>• <i>debug</i>• <i>info</i>• <i>warn</i>• <i>error</i>• <i>fatal</i>• <i>off</i>• <i>trace</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To start the Guardium universal connector on your local Guardium system:

```
grdapi run_universal_connector
ID=0
Universal-Connector container was started
ok
```

sched_cust_table_distribution

This API schedules the distribution of custom tables.

This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/custTblDist
```

GuardAPI syntax

```
sched_cust_table_distribution parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| cronString | String | Required. The schedule to distribute the table as a cron string. For example, to run the job every day at 2 AM:

0 2 * * * |
| customTableName | String | Required. The name of the custom table to distribute. |
| startTime | Date | The time to start running the distribution job, in the format yyyy-mm-dd hh:mm:ss. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

schedule_generate_mongo_filter_job

This API defines the lists of groups IDs of the users, objects, and commands that are used to create a Guardium universal connector filter for MongoDB.

The groups in this API are used to continuously update the value of the GIM parameter GUC_AUDIT_LOG_FILTER. The GIM parameter specifies which events to include in the data forwarded to the Guardium universal connector.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/scheduleGenerateMongoFilterJob
```

GuardAPI syntax

```
schedule_generate_mongo_filter_job parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| clientIp | String | The IP of the GIM client whose GIM parameter GUC_AUDIT_LOG_FILTER gets updated. |
| commandGroupId | String | String of comma separated IDs of groups whose members specify tuples of DB name and command to be included in the native log audit that is forwarded to the Guardium universal connector. If this parameter is not required for the filter, use <code>usersGroupId=""</code> . |
| cronStr | String | Optional. Cron string that defines when to run the code that updates the filter in the GIM parameter GUC_AUDIT_LOG_FILTER. Default is every night at 00:15: "0 15 0 * * ? *" |
| objectsGroupId | String | String of comma separated IDs of groups whose members specify the tuples of DB name and collection to be included in the native log audit that is forwarded to the Guardium universal connector. If this parameter is not required for the filter, use <code>usersGroupId=""</code> . |
| startTime | Date | When to start the scheduling.
Default: now (null) |
| usersGroupId | String | String of comma separated IDs of groups whose members specify the tuples of DB Name and user name to be included in the native log audit that is forwarded to the Guardium universal connector. If this parameter is not required for the filter, use <code>usersGroupId=""</code> . |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi schedule_generate_mongo_filter_job clientIp="9.42.135.95" usersGroupId="20000,20001" objectsGroupId="20004,20005"
commandGroupId="20002,20003"
```

schedule_job

This API schedules a specified job type to run at a specific time.

Note: Some job types do not require an object name. No validation is performed on the object name parameter for the following job types. When you run the API with anything entered as the objectName parameter, the standard 'OK' prompt is returned:

- AppUserTranslation
- CSVExport
- DataArchive
- DataExport
- DataImport
- InstallPolicy
- IpHostToAlias
- ResultsArchive
- SystemBackup

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/schedule_job
```

GuardAPI syntax

```
schedule_job parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| cronString | String | Required. |
| jobType | String | Required. For valid values, call <code>schedule_job</code> from the command line with <code>--help=true</code> . |
| objectName | String | |
| startTime | Date | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

search

This REST API is a wrapper for Solr queries, which are used in the Investigation Dashboard.

Note: The [quick_search](#) REST API provides similar capabilities to this command, but provides more flexibility.

Note: The search API returns codes that represent the titles of the columns (fields) in the returned tables. For example, search might return the following rows:

```
"15": "Failed Login - Alert and Quarantine if Repeated",
"16": "5",
```

To map the codes ("15" and "16", in this case) to the actual column names, use the [getFieldsTitles](#) API.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available only as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/search
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| CATEGORY | String | The Guardium Solr collections. The categories generally map to the categories that are shown in the Investigation dashboard UI. For valid values, call search from the command line with <code>--help=true</code> . |
| COUNT | Integer | The number of records to return.
Default = 50. |
| END_TIME | String | Search for records that were created before the specified END_TIME. The time must be specified in the format: <code>YYYYMMDD+HH:MM:SS</code> . |
| QUERY | String | A Solr query. |
| START | Integer | The record on which to start searching.
Default = 0. |
| START_TIME | String | Search for records that were created after the specified START_TIME. The time must be specified in the format: <code>YYYYMMDD+HH:MM:SS</code> . |
| SUMMARY_BY | String | Group results by the selected field code. You can specify up to 2 field title codes to group by.
Note: To map the field codes to column names, use the getFieldsTitles API. |
| WITH_FACETS | String | <p>Include facets in the search. For more information, see Investigation dashboard for data or Investigation dashboard for files. Valid values are:</p> <ul style="list-style-type: none"> • 0 (Off: Do not include facets) • 1 (On: Include facets) <p>Default = 0.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use the START and COUNT parameters to specify the starting record and the number of records to return. The following example returns 20 records from the Violation category, starting with the 10th record:

```
curl -k --header "Authorization: Bearer 3499f352-aa98-4046-89d8-aba3d8c12345"
"https://xxx.xxx.xxx:8443/restAPI/search?CATEGORY=VIOLATION
&START_TIME=20190115+03:59:00&END_TIME=20190215+15:39:39&START=10&COUNT=20"
```

Returns the following information.

```

secure_settings

12.1 and later This API command is used to manage the security commands in Guardium.

REST API syntax

This API is available as a REST service with the **secureSettings** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/secure_settings
```

GuardAPI syntax

```
secure_settings parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| component | String | Valid values are: <ul style="list-style-type: none"> • <i>sshd</i> • <i>ciphers</i> • <i>services</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <i>api_target_host=10.0.1.123</i>.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Secure settings for ssh

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------|------------|--|
| show | String | Valid values are: <ul style="list-style-type: none">• <i>all</i>• <i>dsa_state</i>• <i>max_connection</i>• <i>port_number</i>• <i>secure_state</i>• <i>ssh_key_mode</i>• <i>ssh_match_address</i>• <i>version</i> |
| store | String | Valid values are: <ul style="list-style-type: none">• <i>dsa_state</i>• <i>max_connection</i>• <i>port_number</i>• <i>secure_state</i>• <i>ssh_key_mode</i>• <i>ssh_match_address</i> |
| value | String | Options are: <ul style="list-style-type: none">• <i>on</i>• <i>off</i>• <i>secure</i>• <i>default</i>• <number>• <address_expression> |

Secure settings for ciphers

| Parameter | Value type | Description |
|-----------|------------|--|
| type | String | Valid values are: <ul style="list-style-type: none">• <i>java</i>• <i>inspection_core</i> |
| delete | String | Valid value is: <ul style="list-style-type: none">• <cipher_list> |
| disable | String | Valid values are: <ul style="list-style-type: none">• <ciphers> |
| enable | String | Valid values are: <ul style="list-style-type: none">• <i>default</i>• <i>cbc</i>• <i>dhe</i>• <i>cipherlist</i> |
| show | String | Valid values are: <ul style="list-style-type: none">• <i>current</i>• <i>disabled</i> |
| show_like | String | Valid value is: <ul style="list-style-type: none">• <pattern> |
| store | String | Valid values are: <ul style="list-style-type: none">• <i>default</i>• <i>cipherlist</i> |

Secure settings for services

| Parameter | Value type | Description |
|-----------|------------|---|
| disable | String | Valid value is: <ul style="list-style-type: none">• <servicename> |
| enable | String | Valid value is: <ul style="list-style-type: none">• <servicename> |
| status | String | Valid value is: <ul style="list-style-type: none">• <servicename> |

Examples

The following command lists the secure settings.

```
grdapi secure_settings  
ID=0  
Usage: grdapi secure_settings component={sshd|ciphers|services}  
arguments as necessary for the components
```

The following command is used to manage the ssh daemon sshd component.

```
grdapi secure_settings component=sshd <options>  
options:  
  show=all  
  show=dsa_state  
  show=max_connection  
  show=port_number  
  show=secure_state  
  show=ssh_key_mode  
  show=ssh_match_address  
  show=version  
  
  store=dsa_state value={on|off}  
  store=max_connection value=<number>  
  store=port_number value=<number>  
  store=secure_state value={secure|default}  
  store=ssh_key_mode value={on|off}  
  store=ssh_match_address value=<address_expression>
```

The following command is used to manage the ciphers component.

```
grdapi secure_settings component=ciphers <options>  
options:  
  type=java show={current|disabled}  
  type=java show_like=<pattern>  
  type=java disable=<ciphers>  
  type=java enable={cbc|dhe|cipherlist}  
  
  type=inspection_core show={default|all|current}  
  type=inspection_core show_like=<pattern>  
  type=inspection_core store={default|cipherlist}  
  type=inspection_core delete=<cipherlist>
```

The following command is used to manage the services component.

```
grdapi secure_settings component=services  
  
usage:  
grdapi secure_settings component=services status=<service>  
grdapi secure_settings component=services enable=<service>  
grdapi secure_settings component=services disable=<service>  
  
Possible services to view status:  
  all  
  cas (16019)

```

session_inference_control

Use the session_inference_control command to start or stop Session Inference.

Use session_inference_control to start or stop Session Inference from the command line. For more information, see [Session Inference control](#).

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/session_inference
```

GuardAPI syntax

```
session_inference_control parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| action | String | Required. Action can be: <ul style="list-style-type: none">• start: Start the session inference servlet.• stop: Stop the session inference servlet. |
| api_target_host | String | Required for GRD API. For REST APIs, this parameter is optional. If not specified for a REST API, defaults to the localhost.

Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To start Session Inference from the command line with a GuardAPI:

```
test.swg.usma.ibm.com> grdapic session_inference_control action=start api_target_host=127.0.0.1
```

Related concepts

session_inference_setup

Use the `session_inference_setup` command to configure Session Inference from the Guardium command line.

The `session_inference_setup` command provides a method of changing the Session Inference parameters from the command line. You can also set these parameters from the Guardium UI. Browse to `Setup > Tools and views > Session Inference`.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/session_inference
```

GuardAPI syntax

```
session_inference_setup parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| activeOnStartup | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Determines whether Session Inference starts automatically when the GUI starts |
| maxInactivePeriod | Integer | Number of minutes of inactivity before a session is marked as closed. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| pollingInterval | Integer | Frequency (in minutes) with which Session Inference checks for open sessions. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. | hostName | String | Required. |
| secondaryHostN
ame | String | |
| secondaryTrapC
ommunity | String | |
| trapCommunity | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

set_certificate_host_validation

Enable this API to ensure that the central manager verifies that the SSL certificates contain a valid host name for all of its managed units.

When enabled, the central manager verifies that the SSL certificates contain a valid host name for all of the managed units. The default setting is `0` (false).

To ensure that all managed units have a valid SSL Certificate for the GUI, create a CSR and obtain a valid SSL certificate. Valid SSL certificates can also be obtained by using the `create self-signed gui` CLI command.

For more information about `create self-signed gui`, see [Certificate CLI Commands](#)

Note: If `set_certificate_host_validation` is enabled on a central manager when a managed unit has an invalid SSL Certificate, the communication between the central manager and managed unit fails.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/setHostValidation
```

GuardAPI syntax

```
set_certificate_host_validation parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| enable | Boolean | Required. Valid values: <ul style="list-style-type: none">• <code>0</code> (false) - Default.• <code>1</code> (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

set_debug_level

This command controls IMS output.

Note: If you set the IMS debug_level = 1, IMS debug fields such as mvs_is_plex, mvs_ipaddr, mvs_dlta_sign, and mvs_dlta_val are output to internal database tables, GDM_CONSTRUCT_TEXT.FULL_SQL, or GDM_EXCEPTION.FULL_SQL.

This API is available in Guardium® V9.5 and later.

GuardAPI syntax

```
set_debug_level parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| component | String | Required. Valid values: <ul style="list-style-type: none"> • <i>IMS</i>: IBM IMS • <i>DS_MSG</i>: Datasource message |
| level | Integer | Required. The debug level for this component. Valid values: <ul style="list-style-type: none"> • 0: Debug is off. • 1: Debug is on. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

To turn on debug for IMS:

```
grdapi set_debug_level component=IMS level=1
```

Sample output

```
This api will restart sniffer, please wait.
ID=0
ok
```

set_distributed_report_target

Use this API to define a Guardium system as a target for distributed reports. After you define it here, it appears in the GUI as a defined target.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
set_distributed_report_target parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| target_host_name | String | Required. Hostname of the Guardium system. |

Examples

To define the Guardium system with the IP 11.11.11.11 as a target for distributed reports:

```
grdapic set_distributed_report_target target_host_name=11.11.11.11
```

Related concepts

- [Distributed report builder](#)

Related reference

- [Reports and report generation APIs](#)

set_enterprise_search_options

Use this command to specify which data is included in the investigation dashboard: data from all managed units in a centrally managed system, or an individual Guardium system. By default, a collector dashboard shows data from that collector, and the Central Manager dashboard shows data of the entire cluster.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
set_enterprise_search_options parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|---|
| distributed_search | String | Required. Controls the sources of data that is displayed in the investigation dashboard. Valid values: <ul style="list-style-type: none"><i>cm_only</i>: Use this option on a central manager to retrieve data from all managed units in the centrally managed environment that have enable_quick_search=1. (If you enter <i>cm_only</i> on a managed unit, only data from that managed unit is displayed.)<i>all_machines</i>: Use this option on a managed unit in a centrally managed environment to include data from all units in the environment. <i>all_machines</i> mode requires open network access on port 8983 between all nodes, which might not comply with your security policies. Data retrieval might be slower than on the central manager. Default = <i>cm_only</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"><i>all_managed</i>: execute on all managed units but not the central manager<i>all</i>: execute on all managed units and the central manager<i>group:<group name></i>: execute on all managed units identified by <i><group name></i>host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To configure the investigation dashboard to search data across the entire Guardium environment, from any Guardium system in that environment:

```
grdapic set_enterprise_search_options distributed_search=all_machines
```

Related concepts

- [Investigation dashboard](#)

set_entitlement_datasource_parameter

Modifies the configuration for a data source that is already enabled for entitlement optimization.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/setEntitlementDatasourceParameter
```

GuardAPI syntax

```
set_entitlement_datasource_parameter parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datasourceName | String | Required. |
| parameterName | String | Required. Valid values: <ul style="list-style-type: none">• <code>isEnabled</code>• <code>userScore</code>• <code>objectScore</code>• <code>extractActivity</code>• <code>extractEntitlement</code>• <code>generateRoleClusters</code>• <code>generateNews</code>• <code>generateRecommendations</code>• <code>filterTempObjects</code>• <code>filterIgnoreVerbs</code> |
| parameterValue | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Enabled data from this datasource to the Recommendations tab.

```
grdapi set_entitlement_datasource_parameter datasourceName=SSQLSERVER extractEntitlement=1 generateRecommendations=1
```

Related concepts

- [Entitlement optimization](#)

set_expiration_date_for_restored_day

This command overwrites the expiration date for data that has been restored, specified by the date of the restored data, on one or more Guardium® systems. The original expiration date is defined in the restore operation (the parameter Don't purge restored data for at least).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/expiration_date_for_restored_day
```

GuardAPI syntax

```
set_expiration_date_for_restored_day parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| newExpDate | String | Required. The new expiration date for the restored data. The format is one of: real day <code>yyyy-mm-dd hh:mi:ss</code> ; or relative day such as <code>NOW -10 day</code> . |
| restoredDay | String | Required. Identifies the day whose data was restored. The format is one of: real day <code>yyyy-mm-dd hh:mi:ss</code> ; or relative day such as <code>NOW -10 day</code> . |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

This command sets the expiration date for restored data that was collected 10 days ago, to 10 days from now:

```
grdapi set_expiration_date_for_restored_day newExpDate=NOW +10 day restoredDay=NOW -10 day
```

set_flatLogProcessType

This command sets the behavior of the flat log file.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/flatLogProcessType
```

GuardAPI syntax

```
set_flatLogProcessType parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|--|
| processType | String | <p>Required. The type and action for this log file. The options are:</p> <ul style="list-style-type: none"> • ARCHIVE_AGGREGATE_PURGE: Archive or aggregate, and optionally purge, the flat log. • DEFAULT: No options are selected. • PROCESS : Merge the flat log information to the internal database. • PURGE_ONLY: Purge the flat log data. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi set_flatLogProcessType processType="PROCESS"
```

Related concepts

set_health_traffic_job_interval

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/traffic_health_job
```

GuardAPI syntax

```
set_health_traffic_job_interval parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| interval | Integer | Required. |

set_import

Use this command to start or stop the import of data from an aggregator to one or more Guardium® collectors.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/set_import
```

GuardAPI syntax

```
set_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| state | String | Required. Starts or stops the import of aggregator data to the collector. Valid values: <ul style="list-style-type: none"> • START • STOP |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

This command starts the import process:

```
grdapi set_import state=start
```

set_inapplicable_test_result_status

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/inapplicable_test_result_status
```

GuardAPI syntax

```
set_inapplicable_test_result_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| includeScore | Boolean | Required. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 1 (true) |

set_ip_to_alias_overwrites

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/ip_to_alias_overwrites
```

GuardAPI syntax

```
set_ip_to_alias_overwrites parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| ipToAliasOverwrites | Boolean | Required. Valid values: <ul style="list-style-type: none"> 0 (false) 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. set_ip_to_alias_selected

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/ip_to_alias_selected
```

GuardAPI syntax

```
set_ip_to_alias_selected parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| ipToAliasSelected | Boolean | Required. Valid values: <ul style="list-style-type: none"> 0 (false) 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

set_job_process_concurrency_limit

This command sets the job process concurrency limit.

Guardium can run multiple threads in parallel to optimize the performance and utilization of the CPU. To take advantage of this multi-threading feature, use the `set_job_process_concurrency_limit` command. This command defines the number of assessment and classifier processes that can run concurrently.

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
set_job_process_concurrency_limit parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| limit | Integer | <p>Required.</p> <p>The limit value defines the number of assessment and classifier processes that can run concurrently. The limit value is the lesser of 100 or twice the number of CPU cores installed on the Guardium system.</p> <p>For example, if a system has 8 CPU cores, the maximum limit value is 16. If a system has 64 CPU cores, the maximum limit value is 100.</p> <p>The default limit value is 1.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi set_job_process_concurrency_limit limit=10
```

set_ktap_debug

Add a short description here.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stap_debug
```

GuardAPI syntax

```
set_ktap_debug parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| ktapDebugInterVal | Integer | Required. |
| ktapFunctionNames | String | |
| stapHost | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Say something about the example

```
grdapi set_ktap_debug
```

Related reference

-

set_load_balancer_param

This API sets load balancer configuration parameters.

For a list of available parameters and their values, see [Enterprise load balancing configuration parameters](#).

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
set_load_balancer_param parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| paramName | String | Required. One of the parameters described in Enterprise load balancing configuration parameters . |
| paramType | String | Required. The value must be STAP. |
| paramValue | String | Required. The value for this parameter. |

Related reference

- [Enterprise load balancing configuration parameters](#)
-

set_outliers_detection_demo_mode

This command puts the outlier process in demo mode: time intervals that have no activity at all are ignored and do not affect the statistics.

Attention: Use this mode for demonstrations only. In demo mode, the system is sensitive to small anomalies so that it shows many outliers from relatively normal traffic, including many false positives.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/set_outliers_detection_demo_mode
```

GuardAPI syntax

```
set_outliers_detection_demo_mode
```

This command does not take any parameters. Run it on the system where outlier mining runs.

Examples

To put outliers in demo mode, on the system on which you enter the command:

```
grdapic set_outliers_detection_demo_mode
```

Related concepts

- [Outliers detection](#)

Related reference

- [Outliers detection APIs](#)
-

set_outliers_detection_parameter

Use this command to modify one or more parameters of the outliers detection configuration.

Important: Do not modify the defaults unless you are working with someone knowledgeable in outlier mining.
This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
set_outliers_detection_parameter parameter_name=name parameter_value=value
```

Parameters

| Parameter | Value type | Description |
|--|---------------------------------|--|
| cleanupKeepDays | String | The number of days to retain model data on the collector. Default = 90 |
| sensitiveObjectGroup | Comma separated list of strings | Adds additional object groups (tables, views, and more) to the outliers detection algorithm. Use this command to find a group name: grdap list_group_by_desc desc=<group name> . Factory setting: privUsersGroup=Sensitive Objects |
| sensitiveFileGroup | Comma separated list of strings | Adds additional groups to the outlier detection algorithm. Use this command to find a group name: grdap list_group_by_desc desc=[group name] Factory setting: privUsersGroup=Sensitive Files |
| privUsersGroup | Comma separated list of strings | Adds additional user groups to the outlier detection algorithm. Use this command to find a group name: grdap list_group_by_desc desc=[group name] Factory setting: privUsersGroup=Admin Users |
| minDaysForAlerts | | The number of days of activity required before outlier alerts are produced. The value for this parameter cannot exceed the value of the parameter budgetTrainingDays.
Default = 7 |
| intervalAlertsThreshold | numeric | The score at which an anomaly becomes an outlier. If lowered, the system is more sensitive to anomalies: anomalies with a lower score are issued as outliers and there can be false positives. If raised, then the system is less sensitive to anomalies.
Default = 0.99 |
| maxMessageAlertsTopScores | integer | High volume outliers only. The number of rows in the Details tab of a high volume outlier. The rows present details of the highest scoring anomalies that occurred during the hour.
Default = 500 |
| maxMessageAlertsSampleSizePerAlertType | integer | Non-high-volume outliers only. This is the number of sample anomalies for a summary alert. Non-high-volume outliers have maxMessageAlertsSampleSizePerAlertType sample rows in no specific order since: the score is not relevant for these outliers; no object is newer than another. Default = 500 |
| messageAlertsThreshold | | Internal use only. Do not modify. |
| minNumIntervalsForFirstClustering | integer | The time period, in hours, until users are initially assigned to clusters. Valid values: <ul style="list-style-type: none">• 0: disable clustering, together with clusteringScheduleIntervals=0• 1 and higher: the number of hours until users are clustered
Default = 168 |
| minNumIntervalsForMessageScores | | Internal use only. Do not modify. |
| minNumIntervalsForIntervalScorers | | Internal use only. Do not modify. |
| numOfAnalyzeThreads | | Internal use only. Do not modify. |
| alertsPerDay | integer | The target number of outliers you want to receive per day. The threshold of the alert score is based on statistics for the last budgetTrainingDays parameter. The system sends the outliers with the highest score per hour.
There may be fewer outliers than the value of alertsPerDay in a day simply because there weren't a lot of outliers that day. If there are suddenly many outliers with a score above the threshold, they are reported (and not limited by this parameter). This prevents suppression of an acute situation. |
| budgetTrainingDays | integer | The number of days the system looks back for learning. The value for this parameter cannot be less than the value of the parameter minDaysForAlerts. Default = 14. |
| demoMode | boolean | Used for demo only. Valid values: <ul style="list-style-type: none">• 0: not in demo mode• 1: periods where there's no activity at all are ignored, and do not affect the statistics.
Default = 0 |
| nanny.duration.analysis | | Internal use only. Do not modify. |
| nanny.duration.clean | | Internal use only. Do not modify. |
| nanny.duration.reconfig | | Internal use only. Do not modify. |
| nanny.duration.maintenance | | Internal use only. Do not modify. |
| runCaseAnalysis | boolean | Used for Advanced threat analytics. Valid values: <ul style="list-style-type: none">• false: the case analysis process does not run.• true: the case analysis process runs right after the outlier mining process. |

| Parameter | Value type | Description |
|-----------------------------|------------|---|
| debugMode | boolean | <p>Controls writing debug details into the debug log. Valid values:</p> <ul style="list-style-type: none"> false: debug data is not written into debug tables. true: debug data is written into debug tables. Use this when there is a problem and you want to send “must gather” to Guardium Support. This parameter automatically reverts back to False after 3 days. <ol style="list-style-type: none"> Set the parameter to true. Wait for 3-4 hours. Run ‘data mining’ must gather. Set the parameter back to false. <ul style="list-style-type: none"> Default = false |
| clusteringScheduleIntervals | integer | The frequency at which the clustering algorithm runs. To disable clustering, set both this parameter and minNumIntervalsForFirstClustering = 0 |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Add the sensitive object groups 5, 333, and 156 to the outliers detection algorithm:

```
grdapic set_outliers_detection_parameter parameter_name=sensitiveObjectGroupIds parameter_value=5,333,156
```

set_outliers_detection_to_factory_settings

This command reverts all outliers parameters to their default, factory settings.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/set_outliers_detection_to_factory_settings
```

GuardAPI syntax

```
set_outliers_detection_to_factory_settings
```

This command does not take any parameters. Run it on the system where outlier mining runs.

Examples

To revert all outliers parameters to their default, factory settings:

```
grdapic set_outliers_detection_to_factory_settings
```

Related concepts

- [Outliers detection](#)

set_outliers_user_detection_mode

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/set_outliers_user_detection_mode
```

GuardAPI syntax

```
set_outliers_user_detection_mode parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| mode | String | |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

set_populate_group_from_query_schedule

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/group_query
```

GuardAPI syntax

```
set_populate_group_from_query_schedule parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|--|
| activateSchedule | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 1 (true)</p> |
| cronString | String | |
| groupDesc | String | Required. |
| startDate | Date | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

set_purge_batch_size

This API sets the batch size that is used during purge of data.

When purging a large number of records (10 million or higher), a large batch size setting (500k to 1 million) is the most effective way to purge. Using a smaller batch size or NULL causes the purge to take hours longer. Smaller purges finish quickly, so a large batch size setting is only relevant for large purges. You might need to make a tradeoff in performance and disk space usage. Setting the batch to a larger number increases the speed of the purge but consumes more disk space. Using a low batch size decreases the speed of the purge but does not consume as much disk space.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
set_purge_batch_size parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| batchSize | Long | Required. Number of records. Default = 200000. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To increase the purge batch size from the default (200000) to 300000:

```
grdapi set_purge_batch_size batchSize=300000
```

set_stap_debug

This command configures the level of detail written to the S-TAP® debug log.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stap_debug
```

GuardAPI syntax

```
set_stap_debug parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|---|
| stapDebugInterval | Integer | Required. |
| stapDebugLevel | Integer | Required. Level of debug log.
Unix: Logs are stderr.txt, guard_stap.fam.txt located in the directory specified in tap_log_dir parameter (by default: /tmp/guard_stap). Valid values: <ul style="list-style-type: none">• 0: Disable• 1: Basic debug• 4: Verbose debug• 6: Appserver debug• 10: Exit engine debug. Debug information is logged in both S-TAP log and db2_exit log (db2diag.log).• 11: exit engine debug. Debug information is only logged in db2_exit log (db2diag.log). Windows:Leave at 0 unless directed by IBM® Technical Support. <ul style="list-style-type: none">• 0: Only critical error information. Two start-up debug logs, containing only messages that are related to S-TAP startup, are always generated and saved in bin..\logs. Filename syntax: startup_hostname_timestamp.new and startup_hostname_timestamp.old. Files from bin..\logs get uploaded automatically if upload_feature is on.• 1: All previous messages plus repeatable critical error information. Two "normal" debug logs are saved in bin\StapBuffer. Filename syntax: stap_hostname_timestamp.new and stap_hostname_timestamp.old (from the previous S-TAP session, if it exists). Files from bin\StapBuffer are not uploaded.• 2: Not used.• 3: All messages from level 1, plus brief information about packets sent to a Guardium® system• 4: All messages from level 3, plus local sniffing log.• 5: All messages from level 4, plus network sniffing log.• 6: All messages from level 5, plus heartbeat receiving log.• 7: All messages from level 6, plus miscellaneous debugging information. |
| stapDebugOn | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| stapHost | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

```
grdapi set_stap_debug stapDebugInterval= stapDebugLevel=1 stapDebugOn=1 stapHost=9.12.56.158
```

set_universal_connector_data_timeout

12.1 and later

This API defined the time duration for which the Universal Connector connection status remains active on the S-TAP Status page if data is not detected.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/setUniversalConnectorDataTimeout
```

GuardAPI syntax

```
set_universal_connector_data_timeout parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|---|
| noDataThresholdInMins | Integer | Number of minutes until the Universal Connector gets disconnected if data is not detected.. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

The following command defines the time duration as 50 minutes after which the Universal Connection gets disconnected.

```
set_universal_connector_data_timeout noDataThresholdInMins=50
```

set_universal_connector_log_level

Run this API to change log level of a running Universal Connector instance (no reload or restart is needed).

This debug level is for the Universal connector, and not the log level of the API itself.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/setUniversalConnectorLogLevel
```

GuardAPI syntax

```
set_universal_connector_log_level parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|--|
| uc_debug_level | String | Required. Valid values: <ul style="list-style-type: none">• <code>all</code>• <code>debug</code>• <code>info</code>• <code>warn</code>• <code>error</code>• <code>fatal</code>• <code>off</code>• <code>trace</code> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode</p> |

Examples

Set the debug level to warning:

```
grdapi set_universal_connector_log_level uc_debug_level=warn  
Guardium Universal Connector command has been executed.
```

set_user_roles

This API adds or updates the allowed roles for a Guardium user.

Note: Running `set_user_roles` clears all of the current roles for the specified user. Include any existing roles that you want to keep for that user.
This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/user_roles
```

GuardAPI syntax

```
set_user_roles parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| roles | String | Required. The role or roles to assign to this user. To add more than one role, use a comma to separate the roles (but no spaces). |
| userName | String | Required. The name of the user to whom to assign or update roles. |

Example

Set the roles for the user named FredMcDerf (who was created with the [create_user](#) API).

```
grdapi set_user_roles userName="Fred McDerf" roles="admin,dba,diag,cli"
```

Sample output:

```
ID=20001  
Added role (admin).  
Added role (dba).  
Added role (diag).  
Added role (cli).
```

set_ztap_logging_config

This command controls the logging parameters described below.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/ztap_logging_config
```

GuardAPI syntax

```
set_ztap_logging_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| parameter | String | Required. Valid values: <ul style="list-style-type: none">• log_db2z_target: When enabled, targets in db2z protobuf message are logged to GDM_OBJECT in addition to objects from the parser.<ul style="list-style-type: none">◦ 0=off◦ 1=onDefault=0• log_zkey_to_full_sql: When enabled, VSAM or IMS Key values are logged in the full SQL statement for policies using "Log full details."<ul style="list-style-type: none">◦ 0=off◦ 1=onDefault=0• |
| value | String | Required. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To enable logging to GDM_OBJECT:

```
grdapi set_ztap_logging_config parameter=log_db2z_target value=1
```

show_alerter_settings

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/alerter_settings
```

GuardAPI syntax

```
show_alerter_settings parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

show_alerter_smtp_settings

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/alerter_smtp
```

GuardAPI syntax

```
show_alerter_smtp_settings parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. show_alerter_snmp_settings

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/alerter_snmp
```

GuardAPI syntax

```
show_alerter_snmp_settings parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

show_alerter_status

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/alerter
```

GuardAPI syntax

```
show_alerter_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

show_autodetect_process_status

Use this command to output the auto-discovery process status and the progress summary.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/autodetect_process_status
```

GuardAPI syntax

```
show_autodetect_process_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| process_name | String | Required. Name of the auto-discovery process |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To see the status and progress of all tasks associated with the auto-discovery process myProcess::

```
grdapi show_autodetect_process_status process_name=myProcess
```

Related concepts

- [Database auto-discovery](#)

show_backup_cm_ip

Run this command on a central manager to list the IP of the backup central manager for each of its managed units.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/show_backup_cm_ip
```

GuardAPI syntax

```
show_backup_cm_ip parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To show the backup central manager IP for this central manager:

```
grdapi show_backup_cm_ip
```

Related concepts

show_expiring_certificates

12.1 and later This API command shows all the certificates that expire on the system within the specified expiration threshold.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/show_expiring_certificates
```

GuardAPI syntax

```
show_expiring_certificates parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| expirationThreshold | Integer | Required. The value must be greater than or equal to 1. |

Example

The following command shows all the certificates that expire on the system within 40 days.

```
grdapi show_expiring_certificates expirationThreshold=40
```

Sample response:

The following example shows a sample output of an expiring certificate from keystore.

```
[  
{  
  "file_name": "/opt/IBM/Guardium/tomcat/.keystore",  
  "file_type": "KEYSTORE",  
  "certs": [  
    {  
      "expiration_date": "Sun Nov 09 19:00:00 EST 2031",  
      "subject_cn": "DigiCert Global Root CA",  
      "serial_number": XXXXXXXXXXXXXXXXXXXXXXX4346,  
      "alias": "digicertglobalrootca",  
      "fingerprint": "43:48:A0:E9:44:4C:78:CB:26:5E:05:8D:5E:89:44:B4:D8:4F:96:62:BD:26:DB:25:7F:89:34:A4:43:C7:01:61"  
    }  
  ]  
}  
]
```

The following example shows a sample output of an expiring certificate from a PEM file.

```
[  
{  
  "file_name": "/opt/IBM/Guardium/etc/pki/certs/system.cert.pem",  
  "file_type": "PEM",  
  "certs": [  
    {  
      "expiration_date": "Sun Mar 02 19:00:00 EST 2025",  
      "subject_cn": "Guardium",  
      "serial_number": 4,  
      "fingerprint": "CC:D4:B1:A5:FA:DB:E8:69:27:22:E5:23:AB:3B:29:37:B0:90:27:5E:34:1A:60:EF:84:40:CA:BD:21:D7:6D:5C"  
    }  
  ]  
}  
]
```

show_maximum_query_duration

This API displays the current value of the timeout for reports.

You can change the timeout value with `store_maximum_query_duration`.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/show_maximum_query_duration
```

GuardAPI syntax

```
show_maximum_query_duration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

The following GuardAPI example shows the current timeout value:

```
grdapi show_maximum_query_duration --source-host=localhost --username=admin
```

This command provides the following output:

```
timeout = "200"  
END
```

The following REST API displays the timeout value, which is set to 200 seconds:

```
curl -k --header "Authorization: Bearer deaf8d32-f334-4a9b-976f-163a98afa32a" \  
-i -H "Content-Type:application/json" \  
-X GET https://localhost:8443/restAPI/show_maximum_query_duration
```

This command provides the following JSON output:

```
HTTP/1.1 200 OK  
Cache-Control: private  
Expires: Wed, 31 Dec 1969 19:00:00 EST  
X-FRAME-OPTIONS: SAMEORIGIN  
X-Permitted-Cross-Domain-Policies: none  
X-Content-Type-Options: nosniff  
X-XSS-Protection: 1; mode=block  
...  
Date: Mon, 04 Feb 2019 16:53:20 GMT  
Server: SQL Guard  
{ "timeout": "200" }
```

show_universal_connector_plugins

Run this API to print the Logstash plugin list to output.

This API is relevant for collectors and standalone Guardium systems. The last output to the API is also saved in \$GUARD_VAR/uc/universal-connector-plugins-list.txt.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/showLogstashPlugins
```

GuardAPI syntax

```
show_universal_connector_plugins parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Typical output is:

```
grdapi show_universal_connector_plugins
ID=1
Universal-Connector command has been executed.
Universal-Connector plugins list:
logstash-codec-avro (3.2.3)
logstash-codec-cef (6.0.1)
logstash-codec-collectd (3.0.8)
logstash-codec-dots (3.0.6)
logstash-codec-edn (3.0.6)
logstash-codec-edn_lines (3.0.6)
logstash-codec-es_bulk (3.0.8)
logstash-codec-fluent (3.2.0)
ok
```

solr_repair_analysis

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
solr_repair_analysis parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| checkDatamartStatus | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

start_istap_monitor

This command starts the S-TAP® audit process on IBM i.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/start_istap_monitor
```

GuardAPI syntax

```
start_istap_monitor parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| datasourceName | String | Required. The name of the Db2 for i datasource. |

Examples

To start the S-TAP audit process on the IBM i server named db21nn:

```
grdapi start_istap_monitor datasourcename=db21nn
```

Related concepts

stop_audit_process

Stop an audit process.

You can also stop an audit process from the GUI. Select the **stop_audit_process** command from the Actions menu on the Comply > Tools and Views > Audit Process Log report.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stop_audit_process
```

GuardAPI syntax

```
stop_audit_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| process | Integer | Required. The name of the audit process to stop. |
| run | Integer | Required. The audit process runID. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

stop_autodetect_process

This command stops the run of the tasks associated with the specified process.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stop_autodetect_process
```

GuardAPI syntax

```
stop_autodetect_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| process_name | String | Required. Name of the auto-discovery process |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To stop all tasks associated with the auto-discovery process myProcess:

```
grdapic stop_autodetect_process myProcess
```

Related concepts

stop_restart_alerter

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/alerter
```

GuardAPI syntax

```
stop_restart_alerter parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| action | String | Required. Valid values: <ul style="list-style-type: none"><code>stop</code><code>restart</code> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"><code>all_managed</code>: execute on all managed units but not the central manager<code>all</code>: execute on all managed units and the central manager<code>group:<group name></code>: execute on all managed units identified by <code><group name></code>host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

stop_solr

This command stops the solr process on the specified Guardium® system(s).

This command can be run on all types of Guardium systems.

This API is available in Guardium V10.6 and later.

GuardAPI syntax

```
stop_solr parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| stop_all | Boolean | <p>Valid values:</p> <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi stop_solr stop_all=true
```

Related reference

- [Solr APIs](#)

stop_universal_connector

Run this command to stop the Guardium universal connector on the local or the specified collectors.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/stopUniversalConnector
```

GuardAPI syntax

```
stop_universal_connector parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To stop the Guardium universal connector on your local system:

```
grdap> stop_universal_connector  
ID=0  
Universal-Connector was disabled.  
ok
```

Related concepts

- [Guardium universal connector](#)

store_maximum_query_duration

Use this API to change the timeout value for queries and reports.

Use store_maximum_query_duration in cases where you have very large or long-running reports to increase the length of time before the report times out. You can also set this value from the Running Status Monitor pane on the administrator portal.

Note: If you set this value greater than the default, you can overload the system with query processing.

If a report (or query) continues to run past the designated timeout period, you can stop the report by using the [kill_running_process](#) API.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/store_maximum_query_duration
```

GuardAPI syntax

```
store_maximum_query_duration parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| durationSeconds | Integer | Required. Default = 180 (seconds). |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

The following GuardAPI example sets the timeout value to 200 seconds.

```
>grdap> store_maximum_query_duration durationSeconds="200"  
ID=0
```

This command provides the following output:

```
"Query Timeout SuccessFully Updated"  
ok
```

The following REST API sets the timeout value to 200 seconds:

```
curl -k --header "Authorization:Beaf8d32-f334-4a9b-976f-163a98afa32a" -i -H "Content-Type:application/json"  
-X PUT -d '{"durationSeconds":"200"}' https://localhost:8443/restAPI/store_maximum_query_duration
```

This command provides the following JSON output:

```
HTTP/1.1 200 OK  
Cache-Control: private  
Expires: Wed, 31 Dec 1969 19:00:00 EST  
X-FRAME-OPTIONS: SAMEORIGIN  
X-Permitted-Cross-Domain-Policies: none  
X-Content-Type-Options: nosniff
```

```
X-XSS-Protection: 1; mode=block
.
.
Date: Mon, 04 Feb 2019 17:08:54 GMT
Server: SQL Guard
{ "ID": 0, "Message": "Query Timeout SuccessFully Updated" }
```

store_sql_credentials

This command defines the credentials of the connection between an S-TAP® and an Oracle server that is used for Oracle Unified Auditing.

Note: The password can also be defined in the S-TAP Control page, with Send Command.
This API is available in Guardium V11.1 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/stap
```

GuardAPI syntax

```
store_sql_credentials parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| password | String | Required. Password for logging in to the Oracle DB. |
| stapHost | String | Required. The hostname of the S-TAP that connects to this Oracle DB instance. For valid values, call store_sql_credentials from the command line with --help=true . |
| username | String | Required. User name for logging in to the Oracle DB. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

store_stap_approval

This command controls the S-TAP® certification feature; when enabled only approved S-TAPs can access the Guardium® system.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/stap_approval
```

GuardAPI syntax

```
store_stap_approval parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| isNeeded | Boolean | Required. Valid values: <ul style="list-style-type: none">• 0: feature is disabled• 1: feature is enabled |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To enable S-TAP certification on the system on which you enter the command:

```
grdapic store_stap_approval
```

The hostname is independent of IP mode and can be used with any mode.</p> |

test_hashicorp_connection

Use this command to test the connection for a HashiCorp configuration.

This API is available in Guardium® v11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/test_hashicorp_connection
```

GuardAPI syntax

```
test_hashicorp_connection parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| name | String | The name of the HashiCorp configuration. |

Example

```
grdapi test_hashicorp_connection name="No SSL User and password API"
ID=1
Test Connection was successful for hashicorp config.
ok
```

test_solr

This command runs diagnostics on the solr internal database on your system. The output indicates if there are any problems, and gives detailed instructions on resolving them.

This API is available in Guardium V11.0 and later.

GuardAPI syntax

```
test_solr parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| details | Boolean | <p>Can be used on managed units, central managers, and stand-alone systems. On managed units run with details=true only. On the central manager, both options are valid. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| logToFile | Boolean | <p>Outputs results to file. Can be used on managed units, central managers, and stand-alone systems. Log file location: /var/IBM/Guardium/log/solr_test.json. Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 1 (true)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi test_solr
```

Sample response:

```
Look at the following file for results; if the target host was specified, look on the target host
machine:/var/IBM/Guardium/log/solr_test.json
ok
```

test_solr_cluster_status

This API is available in Guardium v12.0 and later.

GuardAPI syntax

```
test_solr_cluster_status parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

test_solr_connectivity

This command checks bi-directional communication between the central manager and its managed units on port 8983; and it checks communication from the managed units to the central manager on port 9983 (this port is open only on the central manager).

This API is available in Guardium V11.0 and later.

GuardAPI syntax

```
test_solr_connectivity parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| logToFile | Boolean | Outputs results to file. Log file location: /var/IBM/Guardium/log/solr_connection_test.json. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. test_solr_hardware_requirements

This command checks if the system hardware meets the Solr hardware requirements.

This API is available in Guardium V11.0 and later.

GuardAPI syntax

```
test_solr_hardware_requirements parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| logToFile | Boolean | Outputs results to file. Log file location: /var/IBM/Guardium/log/solr_test_hardware_requirements.json. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. unassign_load_balancer_groups

This API removes the assignment of a managed unit group from an application or S-TAP® group.

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
unassign_load_balancer_groups parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|--|
| appGroupName | String | Required. The application or S-TAP group name. |
| muGroupName | String | Required. The managed unit group name. |

Related reference

- [assign_load_balancer_groups](#)

unassign_qr_condition_from_action

This command removes the specified query condition from the specified action.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/qr_condition_to_action
```

GuardAPI syntax

```
unassign_qr_condition_from_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | Required. The unique name of the query rewrite action. |
| conditionName | String | Required. The condition that is getting removed from the action. |
| definitionName | String | Required. The query rewrite definition that is associated with this action. |

Examples

```
grdapi unassign_qr_condition_to_action definitionName="case 15" actionName="qr action15_2" conditionName="qr cond15_2"
```

uninstall_policy_rule

This command uninstalls one or more rules from a specified policy.

Specify multiple rules by using a pipe (|) character as a delimiter between rule names.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/uninstall_policy_rule
```

GuardAPI syntax

```
uninstall_policy_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policy | String | Required. The name of the policy. |
| ruleName | String | Required. The name of the rule or rules to uninstall. Use a pipe () character as a delimiter between rule names. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI examples

Uninstall a single policy rule:

```
grdapiclnt uninstall_policy_rule policy="Hadoop Policy" ruleName="Low interest Objects: Allow"
```

Uninstall multiple policy rules:

```
grdapiclnt uninstall_policy_rule policy="Hadoop Policy" ruleName="Low interest Objects: Allow|Low Interest Commands: Allow"
```

universal_connector_cleanup

This API is available in Guardium v11.4 and later.

The API uninstalls all the Universal Connector connections in the Managed Unit, and cleans the relevant data. By using this api UC is in freshly installed state.

REST API syntax

This API is available as a REST service with the **POST** method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/ucCleanUp
```

GuardAPI syntax

```
universal_connector_cleanup parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_disable_metrics

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/updateMetricsSetting
```

GuardAPI syntax

```
universal_connector_disable_metrics parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| enable_metrics | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_enable_metrics

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/updateMetricsSetting
```

GuardAPI syntax

```
universal_connector_enable_metrics parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| | | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| enable_metrics | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 1 (true)</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_keystore_add

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/universalConnectorKeystore
```

GuardAPI syntax

```
universal_connector_keystore_add parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| key | String | Required. |
| override | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) <p>Default = 0 (false)</p> |
| password | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_keystore_list

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/universalConnectorKeystore
```

GuardAPI syntax

```
universal_connector_keystore_list parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_keystore_remove

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **DELETE** method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/universalConnectorKeystore
```

GuardAPI syntax

```
universal_connector_keystore_remove parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| key | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_troubleshooting

This API is available in Guardium v11.5 and later.

REST API syntax

This API is available as a REST service with the **GET** method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/troubleshooting
```

GuardAPI syntax

```
universal_connector_troubleshooting parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

universal_connector_update_proxy

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/ucUpdateProxy
```

GuardAPI syntax

```
universal_connector_update_proxy parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| httpProxyIP | String | Required. |
| httpProxyPort | String | Required. |
| httpsProxyIP | String | Required. |
| httpsProxyPort | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

unregister_unit

REST API syntax

12.1 and later This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/unregister_unit
```

GuardAPI syntax

```
unregister_unit parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|-------------|
| unitIpList | String | Required. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

unschedule_datamart

This command stops extraction of the specified datamart.

This API is available in Guardium V10.5 and later.

REST API syntax

This API is available as a REST service with the `DELETE` method. Call this API as follows:

```
DELETE https://[Guardium hostname or IP address]:8443/restAPI/datamartSchedule
```

GuardAPI syntax

```
unschedule_datamart parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| datamart_name | String | Required. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To unschedule the data mart Export:Full SQL

```
unschedule_datamart datamart_name="Export:Full SQL"
```

update_alias

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/alias
```

GuardAPI syntax

```
update_alias parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|---|
| dbValue | String | Required. |
| groupTypeDesc | String | Required. For valid values, call update_alias from the command line with --help=true. |
| newAliasValue | String | Required. |
| oldAliasValue | String | Required. |

update_assessment

This command updates a security assessment.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/assessment
```

GuardAPI syntax

```
update_assessment parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| assessmentDescription | String | Required. The value for this parameter must match an existing record in a security assessment. |
| newDescription | String | |
| processName | String | |

Example

```
grdapi update_assessment assessmentDescription=Assess1 filterClientIP=192.168.1.1.
```

update_assessment_test

This command updates a test in a security assessment.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/assessment_test
```

GuardAPI syntax

```
update_assessment_test parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|---|
| assessmentDescription | String | Required. |
| datasourceType | String | For valid values, call update_assessment_test from the command line with --help=true. |
| exceptionsGroup | String | |
| explanation | String | |
| ExternalReference | String | |
| fromDate | String | |

| Parameter | Value type | Description |
|-----------------|------------|--|
| severity | String | Valid values: <ul style="list-style-type: none">• <i>Critical</i>• <i>Major</i>• <i>Minor</i>• <i>Caution</i>• <i>Info</i> |
| testDescription | String | Required. |
| threshold | String | |
| toDate | String | |

update_aws_secrets_manager_config

Use this command to edit an AWS secrets configuration.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/aws_secrets_manager
```

GuardAPI syntax

```
update_aws_secrets_manager_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|---|
| access_key_id | String | |
| auth_type | String | Required. Valid values: <ul style="list-style-type: none">• <i>Security-Credentials</i>• <i>IAM-Role</i>• <i>IAM-Instance-Profile</i> |
| name | String | Required. For valid values, call update_aws_secrets_manager_config from the command line with <code>--help=true</code> . |
| role_arn | String | The Role Amazon Resource Name (ARN) |
| secret_access_key | String | |
| secret_key_password | String | The Secret key label for the password |
| secret_key_username | String | The Secret key label for the username |

Examples

```
grdapic update_aws_secrets_manager_config name="GRDAPI Security-Credentials"
access_key_id="home_markdown_jenkins_workspace_Transform_in_SSMPHH_12.x_com.ibm.guardium.doc.reference_grdapic_update_aws_secrets_manager_config_AABBCC123" secret_access_key="XXYYZZ321" secret_key_password="password" secret_key_username="username"

grdapic update_aws_secrets_manager_config name="GRDAPI IAM-Role" auth_type="IAM-Role"
role_arn="arn:aws:iam::123456789:role/AWS_Secret_ManagerReadWrite_role"
access_key_id="home_markdown_jenkins_workspace_Transform_in_SSMPHH_12.x_com.ibm.guardium.doc.reference_grdapic_update_aws_secrets_manager_config_aabbcc123" secret_access_key="abcdefg" secret_key_password="password" secret_key_username="username"

grdapic update_aws_secrets_manager_config name="GRDAPI IAM-Instance-Profile2" auth_type="IAM-Instance-Profile2"
secret_key_password="password" secret_key_username="username"
```

update_cas_host_instance

This command enables or disables a Configuration Auditing System (CAS) template.

Use this command to enable or disable a CAS host instance by setting the enabled parameter to 1 (enabled) or 0 (disabled). Use the [list_cas_host_instances](#) API to find the dataSourceName and templateSetLabel parameter values.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/cas_host_instance
```

GuardAPI syntax

```
update_cas_host_instance parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| datasourceName | String | Required. The data source used for this host instance. |
| enabled | Boolean | Required. Enables or disables the host instance. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| templateSetLabel | String | Required. The name of the template set that is associated with the host instance. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following example shows how to find and update information within a CAS host instance:

1. Call `list_cas_host_instances` to find the `datasourceName` and `templateSetLabel`.

```
grdapi list_cas_host_instances hostName=9.70.150.111
Id, datasourceName(#), datasourceName, templateSetLabel(#), templateSetLabel, hostName, osType, dbType
c0d2327c8dd550549f2579ab44819a54c3db5e6a, 20002, System (9.70.150.111), 16, Default Unix Template Set, 9.70.150.129, UNX, N_A
ok
```

2. Call `update_cas_host_instance`, and enable the host instance

```
grdapi update_cas_host_instance datasourceName=20002 templateSetLabel=16 enabled=1
ID=c0d2327c8dd550549f2579ab44819a54c3db5e6a
ok
```

update_cas_template

This command modifies specified parameters in a Configuration Auditing System (CAS) template.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/cas_template
```

GuardAPI syntax

```
update_cas_template parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| enabled | Boolean | Enable or disable the template. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| isEditable | Boolean | Set the ability for users to modify to the template. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| period | Integer | Change the number of minutes to wait between tests. |
| saveData | Boolean | Enable or disable whether to save previous versions of the template item. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| template | String | A new name for this template. |
| templateId | Long | Required. The internal ID for this template. If needed you can find the template ID by using the list_cas_templates API. |
| useMD5 | Boolean | Enables or disable using the uses the MD5 algorithm. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following example shows how to find and update information within a CAS template:

1. Call `list_cas_templates` to find the template ID and other information about a template to update.

```
grdapi list_cas_templates templatesetLabel=testSet
ID=20001
Id, auditType, template, enabled, period, useMD5, saveData, isEditable
20000, FILE, tempTest, true, 3600, false, false, true
ok
```

2. Call `update_cas_template` to change the name and time period.

```
grdapi update_cas_template templateId=20000 template=newName period=5
ID=20000
ok
```

3. Call `list_cas_templates` again to show the changes/

```
grdapi list_cas_templates templatesetLabel=testSet
ID=20001
Id, auditType, template, enabled, period, useMD5, saveData, isEditable
20000, FILE, newName, true, 5, false, false, true
ok
```

update_classifier_action

This command updates classifier actions.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_action
```

GuardAPI syntax

```
update_classifier_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| accessPolicy | String | |
| accessRuleAction | String | |
| actionName | String | Required. |
| actionType | String | Required. |
| actualMemberContent | String | |
| commandsGroup | String | |
| description | String | |
| excludeObjectGroup | String | |
| includeField | Boolean | Valid values:
<ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| includeServerIP | Boolean | Valid values:
<ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| notificationType | String | |
| objectFieldGroup | String | |
| objectGroup | String | |
| policyName | String | Required. |
| privacySet | String | |
| receiver | String | |
| replaceGroupContent | Boolean | Valid values:
<ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 0 (false) |
| ruleDescription | String | |
| ruleName | String | Required. |
| SchemaGroup | String | |
| severity | String | |

update_classifier_document_rule

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_document_rule
```

GuardAPI syntax

```
update_classifier_document_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|------------|---|
| calculateConfidenceScore | Boolean | Valid values:
<ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 1 (true) |
| category | String | For valid values, call update_classifier_document_rule from the command line with <code>--help=true</code> . |
| classification | String | |
| collectionNameLike | String | |
| collectionTypeCollection | Boolean | Valid values:
<ul style="list-style-type: none"> • 0 (false) • 1 (true) Default = 1 (true) |

| Parameter | Value type | Description |
|--------------------------------|------------|---|
| collectionTypeView | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| compareToValuesInGroup | String | |
| compareToValuesInSQL | String | |
| continueOnMatch | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| continueWithUnmatchedFieldOnly | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| dataTypes | String | |
| description | String | |
| evaluationName | String | |
| excludeCollection | String | |
| excludeCollectionField | String | |
| excludeDatabaseName | String | |
| fieldNameLike | String | |
| fireOnlyWithMarker | String | |
| hitPercentage | Integer | |
| policyName | String | Required. |
| ruleName | String | Required. |
| ruleType | String | Required. |
| searchExpression | String | |
| searchLike | String | |
| showUniqueValues | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| skipEmptyNull | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| uniqueValueMask | String | |

update_classifier_log_level

This command updates the classifier log level.

This API is available in Guardium V10.6 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_log_level
```

GuardAPI syntax

```
update_classifier_log_level parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| logLevel | String | <p>Required.
Valid values:</p> <ul style="list-style-type: none"> • DEBUG • ERROR • FATAL • INFO • WARN • TRACE <p>The DEBUG value logs details about the classification scan. For example, metadata from the scanned database such as table and column names is logged, but actual data from the database is not logged.</p> <p>Important: Restart the job queue using the <code>restart_job_queue_listener</code> API after changing the log level.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

```
grdapi update_classifier_log_level logLevel=INFO
```

update_classifier_policy

This command updates classification policies.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_policy
```

GuardAPI syntax

```
update_classifier_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| category | String | Required. For valid values, call <code>update_classifier_policy</code> from the command line with <code>--help=true</code> . |
| classification | String | Required. |
| description | String | |
| newName | String | |
| policyName | String | Required. |

Examples

```
grdapi update_classifier_policy policyName=access_policy classification=class_01 category=Access
```

update_classifier_process

This command updates classification processes.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_process
```

GuardAPI syntax

```
update_classifier_process parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| comprehensive | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| datasourceGroups | String | |
| datasourceNames | String | |
| datasourceType | String | Valid values: <ul style="list-style-type: none">• DOCUMENT• RELATIONAL Default = RELATIONAL |
| includeInternalTables | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false)

Enabling includeInternalTables indicates that you want to scan internal system databases and schema used by the database software provider. Internal system databases and schema are unlikely to contain sensitive data and are not scanned by default. When including internal tables, verify that the classifier datasource user has sufficient privileges to scan the internal databases and schema. Insufficient privileges may result in unexpected classification policy errors.

To view and edit the databases and schema impacted by the includeInternalTables parameter, use the Group Builder to edit one of the predefined Excluded Classification groups. |
| newName | String | |
| policyName | String | |
| processName | String | Required. |
| sampleSize | Integer | |

Examples

```
grdapi update_classifier_process datasourceNames=datasource_01,datasource_02 policyName=access_policy  
processName=APITEST_Clps_10001_1 comprehensive=0 sampleSize=3000
```

update_classifier_rule

This command updates classification rules.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/classifier_rule
```

GuardAPI syntax

```
update_classifier_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|------------|--|
| calculateConfidenceScore | Boolean | Calculate a confidence score. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| category | String | Required. For valid values, call <code>create_classifier_rule</code> from the command line with <code>--help=true</code> . |
| classification | String | Required. |

| Parameter | Value type | Description |
|----------------------------------|------------|---|
| columnNameLike | String | |
| compareToValuesInGroup | String | |
| compareToValuesInSQL | String | |
| continueOnMatch | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| continueWithUnmatchedColumnsOnly | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| dataTypes | String | |
| description | String | |
| evaluationName | String | |
| excludeSchemaName | String | |
| excludeTable | String | |
| exclude TableColumn | String | |
| fireOnlyWithMarker | String | |
| hitPercentage | Integer | |
| maxLength | Integer | |
| minLength | Integer | |
| policyName | String | Required. |
| ruleName | String | Required. |
| ruleType | String | Required. |
| searchExpression | String | |
| searchLike | String | |
| showUniqueValues | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 0 (false) |
| skipEmptyNull | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 0 (false) |
| tableNameLike | String | |
| tableTypeSynonym | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 0 (false) |
| tableTypeSystemTable | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 0 (false) |
| tableTypeTable | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 1 (true) |
| tableTypeView | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 0 (false) |
| uniqueValueMask | String | |

update_cloud_datasource

Updates the cloud datasource configuration (cloud database service protection).

This API is available in Guardium V10.1 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/cloud_datasource
```

GuardAPI syntax

```
update_cloud_datasource parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------------|------------|--|
| cloudTitle | String | Required. Name of cloud account already defined in Guardium. Required. For valid values, call update_cloud_datasource from the command line with --help=true .
For more information, see create_cloudTitle . |
| conProperty | String | Use only if additional connection properties must be included on the JDBC URL to establish a JDBC connection with this datasource. The required format is property=value, where each property and value pair is separated from the next by a comma. |
| customURL | String | Connection string to the datasource; otherwise connection is made using host, port, instance, properties, etc. of the previously entered fields. This is useful, for example, when creating Oracle Internet Directory (OID) connections. |
| cyberarkConfigName | String | The name of the CyberArk configuration on your Guardium system. For valid values, call update_cloud_datasource from the command line with --help=true . |
| cyberarkObjectName | String | The CyberArk object name for the Guardium datasource. |
| dbInstanceAccount | String | Database Account Login Name that is used by CAS. |
| dbInstanceDirectory | String | Directory where database software was installed that is used by CAS. |
| dbName | String | For a Db2® or Oracle datasource, enter the schema name. For others, enter the database name. |
| description | String | A longer description of the datasource. |
| externalPasswordType | String | For valid values, call update_cloud_datasource from the command line with --help=true . |
| host | String | Required. The host name or the IP address of the server hosting the DB you are monitoring. |
| importServerSSLcert | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| KerberosConfigName | String | Name of Kerberos configuration already defined in Guardium system. |
| name | String | Required. A unique name for the datasource in the Guardium system. |
| new name | string | Specifies a new name for the datasource. |
| objectLimit | Integer | Required. The maximum number of sensitive objects found in the classification process that are added automatically to the list of audited objects. Default = 20. |
| password | String | Password for user. |
| port | Integer | Port number. |
| primaryCollector | Integer | The collector that extracts the audit data from the cloud database. |
| region | String | Required for AWS only. For valid values, call update_cloud_datasource from the command line with --help=true . |
| savePassword | Boolean | Saves and encrypts your authentication credentials on the Guardium appliance. Required if you are defining a datasource with an application that runs as a scheduled task (as opposed to on-demand). When set to yes, login name and password are required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true)
Default = 1 (true) |
| serviceName | String | Required for Oracle, Informix®, Db2, and IBM® i. For a Db2 datasource enter the database name, for others enter the service name. |
| severity | String | Severity Classification (or impact level) for the datasource. For valid values, call update_cloud_datasource from the command line with --help=true . |
| shared | String | Set to true or Shared to share with other applications. To share the datasource with other users, you need to assign roles from the GUI. Valid values: <ul style="list-style-type: none">• Shared• Not Shared• true• false |
| useExternalPassword | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useKerberos | Boolean | Set to 1 (true) to use Kerberos authentication. If true, KerberosConfigName is required. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|---|
| useLDAP | Boolean | Set to 1 (true) to use LDAP. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| user | String | User for the datasource. If used, password must also be specified. |
| useSSL | Boolean | Set to 1 (true) to use SSL authentication. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Say something about the example

```
grdapi update_cloud_datasource
```

update_computed_attribute

This API updates an existing custom attribute that is calculated based on a specified expression.

To help prevent an SQL injection attack, the following words and characters are not allowed in computed attributes:

ALTER, CREATE, DELETE, DROP, INSERT, TRUNCATE, UPDATE, semicolon (;), double-dash (--), or slash-asterisk /*)

For more information, see [create_computed_attribute](#).

This API is available in Guardium V9.5 and later.

The REST API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/computed_attribute
```

GuardAPI syntax

```
update_computed_attribute parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| attributeLabel | String | Required. The name of the computed attribute to update. |
| entityLabel | String | Required. The name of the main entity with which the attribute is associated. |
| newexpression | String | Required. The updated expression for this attribute. |
| oldexpression | String | Required. The original expression for this attribute. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

update_custom_table_ldap_import

This command updates the configuration of a custom table to import data from LDAP.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/custom_data_ldap
```

GuardAPI syntax

```
update_custom_table_ldap_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------------------------|---|
| activateSchedule | Boolean-Constant values list | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| attributeMapping | String | |
| baseDN | String | |
| clearTable | Boolean-Constant values list | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| cronString | String | |
| filter | String | |
| filterScope | String | Valid values: <ul style="list-style-type: none">• <i>one-level</i>• <i>sub-tree</i> |
| hostName | String | |
| importId | Integer | Required. |
| importLimit | Integer | |
| password | String | |
| port | Integer | |
| serverType | String | Valid values: <ul style="list-style-type: none">• <i>Active Directory</i>• <i>Novell Directory</i>• <i>Open LDAP</i>• <i>Sun ONE Directory</i>• <i>z/OS Security Server</i>• <i>Tivoli Directory</i> |
| startDate | Date | |
| userName | String | |
| useSSL | Boolean-Constant values list | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <i>api_target_host=10.0.1.123</i>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

update_cyberark_config

This command updates the CyberArk configuration on your Guardium system. Obtain the application IDs, corresponding safe names, and folder names from your CyberArk administrator.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/cyberark
```

GuardAPI syntax

```
update_cyberark_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| applicationId | String | This is a unique variable that is created on CyberArk. |
| folderName | String | The name of the folder where the CyberArk safe is located. |
| name | String | Required. The name that is used to configure the Guardium datasource to access the CyberArk vault. |
| safeName | String | The name of the CyberArk safe that is assigned to the applicationId. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

update_datamart

This command updates the start time or adds a comment to a user-defined or predefined data mart export.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_datamart
```

GuardAPI syntax

```
update_datamart parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|----------------|--|
| Comment | String | Comment about the change you make. |
| initial_start | Date | Valid values: <ul style="list-style-type: none">• <>: current time• YYYY-MM-DD hh:mm:ss |
| extracted_date_max_limit | java.util.Date | |
| linesPerFile | Integer | |
| Name | String | Required. Data mart name. |

Examples

To set the start time of data mart Export:Full SQL to midnight on 1 September 2019:

```
update_datamart name="Export:Full SQL" initial_start 2019-09-01 00:00:00
```

update_datamart_copy_file_threadpool_params

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_datamart_copy_file_threadpool_params
```

GuardAPI syntax

```
update_datamart_copy_file_threadpool_params parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------------|------------|---|
| corePoolSize | Integer | |
| keepAliveSec | Integer | |
| maxPoolSize | Integer | |
| maxTasksWaitin
gSize | Integer | |
| shouldRestart | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

update_datasource_by_id

This command updates a datasource definition identified by an identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_datasource_by_id
```

GuardAPI syntax

```
update_datasource_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------------|------------|---|
| awsSecretsManagerConfigName | String | For valid values, call update_datasource_by_id from the command line with <code>--help=true</code> . |
| conProperty | String | Use only if additional connection properties must be included on the JDBC URL to establish a JDBC connection with the datasource. Note: For a Sybase database with a default character set of Roman8, enter the following property: <code>CHARSET=utf8</code> . |
| customProps | String | |
| customURL | String | Defines the connection string to the datasource. By default, the connection is made using the host, port, instance, and other properties defined by the API parameters. This is useful, for example, when creating Oracle Internet Directory (OID) connections. |
| cyberarkConfigName | String | The name of the CyberArk configuration on your Guardium system. For valid values, call update_datasource_by_id from the command line with <code>--help=true</code> . |
| cyberarkObjectName | String | The CyberArk object name for the Guardium datasource. |
| dbInstanceAccount | String | The database account login name to be used by CAS. |
| dbInstanceDirectory | String | The database installation directory to be used by CAS. |

| Parameter | Value type | Description |
|-------------------------|------------|---|
| dbName | String | For a DB2® datasource, the database name. |
| description | String | A description of the datasource. |
| externalPassword | String | For valid values, call update_datasource_by_id from the command line with --help=true. |
| hashicorpChildNameSpace | String | |
| hashicorpConfigName | String | |
| hashicorpPath | String | |
| hashicorpRole | String | |
| host | String | The host name or the IP address of the datasource. |
| id | Integer | Required. The identification key of the datasource to be updated. |
| importServerSSLcert | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| KerberosConfigName | String | |
| newName | String | Defines a new name for the datasource. The new name must be unique for a datasource on the system.x |
| password | String | The password for the account identified by the user parameter. If defined, the user parameter must also be used. |
| port | Integer | The port number of the datasource. |
| region | String | For AWS only. For valid values, call update_datasource_by_id from the command line with --help=true. |
| savePassword | Boolean | If enabled, savePassword saves and encrypts authentication credentials on the Guardium system. This is required when defining a datasource with an application that runs as a scheduled task (as opposed to on demand). When set to 1, the user and password parameters are required.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| secretName | String | |
| serviceName | String | For an Oracle datasource, the service name. |
| severity | String | Severity classification (or impact level) for the datasource.
For valid values, call update_datasource_by_id from the command line with --help=true. |
| shared | String | If set to true, share the datasource with other applications. To share the datasource with other users, assign roles from the GUI.
Valid values: <ul style="list-style-type: none">• Shared• Not Shared• true• false |
| useExternalPassword | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useKerberos | Boolean | If set to 1, use Kerberos authentication. When set to 1, the KerberosConfigName is required.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useLDAP | Boolean | If set to 1, use LDAP.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| user | String | The user name for the datasource. If defined, the password parameter must also be used. |
| useSSL | Boolean | If set to 1, use SSL authentication.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| walletZip | String | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

Use this command to change the name of the database with identification key 2 to chicken DB2:

```
grdapi update_datasource_by_id id=2 newName="chicken DB2"
```

update_datasource_by_name

This command updates a datasource definition identified by name.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_datasource_by_name
```

GuardAPI syntax

```
update_datasource_by_name parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------------|------------|---|
| awsSecretsManagerConfigName | String | For valid values, call <code>update_datasource_by_name</code> from the command line with <code>--help=true</code> . |
| conProperty | String | Use only if additional connection properties must be included on the JDBC URL to establish a JDBC connection with the datasource. Note: For a Sybase database with a default character set of Roman8, enter the following property: <code>CHARSET=utf8</code> . |
| customProps | String | |
| customURL | String | Defines the connection string to the datasource. By default, the connection is made using the host, port, instance, and other properties defined by the API parameters. This is useful, for example, when creating Oracle Internet Directory (OID) connections. |
| cyberarkConfigName | String | The name of the CyberArk configuration on your Guardium system. For valid values, call <code>update_datasource_by_name</code> from the command line with <code>--help=true</code> . |
| cyberarkObjectName | String | The CyberArk object name for the Guardium datasource. |
| dbInstanceAccount | String | The database account login name to be used by CAS. |
| dbInstanceDirectory | String | The database installation directory to be used by CAS. |
| dbName | String | For a DB2® datasource, the database name. |
| description | String | A description of the datasource. |
| externalPasswordType | String | For valid values, call <code>update_datasource_by_name</code> from the command line with <code>--help=true</code> . |
| hashicorpChildNamespace | String | |
| hashicorpConfigName | String | |
| hashicorpPath | String | |
| hashicorpRole | String | |
| host | String | The host name or the IP address of the datasource. |
| importServerSSLcert | Boolean | Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |

| Parameter | Value type | Description |
|---------------------|------------|--|
| KerberosConfigName | String | |
| name | String | Required. The datasource to be updated. |
| newName | String | Defines a new name for the datasource. The new name must be unique for a datasource on the system. |
| password | String | The password for the account identified by the user parameter. If defined, the user parameter must also be used. |
| port | Integer | The port number of the datasource. |
| region | String | For AWS only. For valid values, call update_datasource_by_name from the command line with --help=true. |
| savePassword | Boolean | If enabled, savePassword saves and encrypts authentication credentials on the Guardium system. This is required when defining a datasource with an application that runs as a scheduled task (as opposed to on demand). When set to 1, the user and password parameters are required.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

| severity | String | Severity classification (or impact level) for the datasource.
For valid values, call update_datasource_by_name from the command line with --help=true. |
| shared | String | If set to true, share the datasource with other applications. To share the datasource with other users, assign roles from the GUI.
Valid values: <ul style="list-style-type: none">• Shared• Not Shared• true• false |
| useExternalPassword | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useKerberos | Boolean | If set to 1, use Kerberos authentication. When set to 1, the KerberosConfigName is required.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| useLDAP | Boolean | If set to 1, use LDAP.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| user | String | The user name for the datasource. If defined, the password parameter must also be used. |
| useSSL | Boolean | If set to 1, use SSL authentication.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| walletZip | String | |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>.
IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to change the datasource name from chickenDB2 to chicken_DB2:

```
grdapi update_datasource_by_name name=chickenDB2 newName="chicken_DB2"
```

update_datasource_credentials_in_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
update_datasource_credentials_in_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
| groupName | String | Required. |
| password | String | Required. |
| userName | String | |

update_datasource_custom_property

Use this command to update the associated values of a datasource custom property.

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datasource_custom_prop
```

GuardAPI syntax

```
update_datasource_custom_property parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| addValues | String | The values that are to be added to the custom property. |
| deleteValues | String | The values that are to be deleted from the custom property. |
| name | String | Required. The name of the custom property. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following example deletes the value "Retail" from the custom property "Business Unit":

```
grdapi update_datasource_custom_property name="Business Unit" deleteValues="Retail"
```

The following example adds the value "Trading" to the custom property "Business Unit":

```
grdapi update_datasource_custom_property name="Business Unit" addValues="Trading"
```

update_datasource_group

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/datasource_group
```

GuardAPI syntax

```
update_datasource_group parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| appTypeCriteria | String | For valid values, call <code>update_datasource_group</code> from the command line with <code>--help=true</code> . |
| customPropsCriteria | String | A list of datasource custom properties on which to filter datasources that belong to the group. |
| dbTypeCriteria | String | For valid values, call <code>update_datasource_group</code> from the command line with <code>--help=true</code> . |
| groupName | String | Required. |
| groupType | String | Valid values: <ul style="list-style-type: none">• <i>DYNAMIC</i>• <i>STATIC</i> |
| hostCriteria | String | Host name criteria on which to filter datasources for this group. |
| newGroupName | String | |
| severityCriteria | String | Valid values: <ul style="list-style-type: none">• <i>ALL</i>• <i>INFO</i>• <i>NONE</i>• <i>LOW</i>• <i>MED</i>• <i>HIGH</i> |
| userCriteria | String | User name criteria on which to filter datasources for this group. |

update_engine_config

Use the `update_engine_config` command to change inspection engine settings.

An inspection engine monitors the traffic between servers and clients by using a specific database protocol (such as Oracle or Sybase). Configure an inspection engine from the Inspection Engine Configuration page. After the inspection engine is configured, you can use the `update_engine_config` command to change the parameters. For more information, see [Configuring inspection engines](#).

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/engine_config
```

GuardAPI syntax

```
update_engine_config parameter=value
```

Parameters

See [Inspection Engine Configuration](#) for details about each parameter.

| Parameter | Value type | Description |
|-------------------|------------|--|
| computeAverage | Boolean | When enabled, for each SQL construct logged, the average response time is computed. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| defaultAutoCommit | Boolean | Due to various auto-commit models for different databases, this value is used by Replay function to explicitly mark up the transactions and auto commit after each command. When enabled, commits and rollbacks are ignored. Databases currently supported include DB2®, Informix®, and Oracle. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |

| Parameter | Value type | Description |
|-----------------|------------|--|
| defaultCapture | Boolean | Used by Replay function to distinguish between transactions and capture values, meaning that if you have a prepared statement, assigned values are captured and replayed. Enable this if you want to replay your captured prepared statements as prepared statements. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| excludePorts | String | A list of ports to be ignored. Add values to this list if you know your database servers are processing non-database protocols, and you don't want Guardium® to waste cycles analyzing non-database traffic. For example, if you know the host on which your database resides also runs an HTTP server on port 80, you can add 80 to the ignored ports list, ensuring that Guardium does not process these streams. Separate multiple values with commas, and use a hyphen to specify an inclusive range of ports. For example: 101,105,110-223 |
| granularity | Integer | The number of minutes in a logging unit. If requested in a report, Guardium summarizes request data at this granularity. For example, if the logging granularity is 60, and a certain request occurred "n" times in a given hour. If disabled, the exact time when the command occurred within the hour is not recorded. But, if a rule in a policy is triggered by a request, a real time alert can indicate the exact time. When you define exception rules for a policy, those rules can also apply to the logging unit. For example, you might want to ignore 5 login failures per hour, but send an alert on the sixth login failure. Valid values: <ul style="list-style-type: none">• 1• 2• 5• 10• 15• 30• 60 |
| inspectData | Boolean | When enabled, data returned by SQL requests are inspected, and the ingress and egress counts are updated. If rules are used in the security policy, this parameter must be enabled. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| logExceptionSql | Boolean | If enabled, when exceptions are logged, the entire SQL statement is logged. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| logRecords | Boolean | When enabled, the number of records affected is recorded for each SQL statement (when applicable). Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) <p>Default = 0</p> <p>The records affected option is a sniffer operation which requires sniffer to process additional response packets and postpone logging of impacted data. This increases the buffer size and might potentially have an adverse effect on overall sniffer performance. Significant impact comes from really large responses. To prevent large amount of overhead associated with this operation, Guardium uses a set of default thresholds that allows sniffer to decide to skip processing operation when exceeded.</p> <p>Refer to Configuration and Control CLI Commands store max_results_set_size, store max_result_set_packet_size and store max_tds_response_packets, to set levels of granularity.</p> <p>Records Affected feature is not supported for:</p> <ul style="list-style-type: none">• DB2 when streaming is used to send the results.• AWS• Couchbase• Hadoop integration <p>Example of result set values:</p> <ul style="list-style-type: none">• Case 1, record affected value, positive number. This represents correct size of the result set.• Case 2, record affected value, -2. This means number of records exceeded configurable limit (This can be tuned through CLI commands).• Case 3, record affected value, -1. This shows any unsupported cases of packets configurations by Guardium.• Case 4, record affected value, -2. If the result set is sent by streaming mode.• Case 5, record affected value, less than -2. Intermediate result during record count to update user about current value, ends up with positive number of total records. For example, the server returns 1000 records in 4 packets:<ul style="list-style-type: none">◦ Packet #1 250◦ Packet #2 200◦ Packet #3 250◦ Packet #4 200 <p>Then records affected are reported as</p> <ul style="list-style-type: none">◦ Packet #1 -250◦ Packet #2 -500◦ Packet #3 -750◦ Packet #4 1000 |

| Parameter | Value type | Description |
|-----------------|------------|---|
| logSequencing | Boolean | When enabled, a record is made of the immediately previous SQL statement, as well as the current SQL statement, provided that the previous construct occurs within a short enough time period. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| maxHits | Integer | When returned data is being inspected, indicate how many hits (policy rule violations) are to be recorded. |
| parseXml | Boolean | The Inspection Engine does not normally parse XML traffic. Enable to parse XML traffic. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| recordEmpty | Boolean | When enabled, sessions containing no SQL statements are logged. When disabled, these sessions are ignored. Valid values: <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following GuardAPI example changes three inspection engine parameters.

```
grdapi update_engine_config defaultCapture=true logExceptionSql=false maxHits=32
```

If successful, the command returns the following information:

```
ID=0
ok
```

update_entry_location

This command updates the specified catalog entry if you specify a file name. If you do not specify a file name, this command updates the archive locations for the specified path and hostname.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/entry_location
```

GuardAPI syntax

```
update_entry_location parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| fileName | String | Identifies a single catalog entry to update. If omitted, all catalog entries on the specified hostname and path are updated. |
| hostName | String | Required. The hostname or IP address. |
| newHostName | String | A new hostname or IP address for the catalog entries. |
| newPath | String | A new path for the catalog entries. |
| password | String | The user's password. |

| Parameter | Value type | Description |
|-----------------|------------|---|
| path | String | Required. The path to the archive directory. <ul style="list-style-type: none"> Amazon S3: bucket name IBM COS: bucket name EMC Centera: Centera clipID FTP: Specify the directory relative to the FTP account home directory. SCP: Specify the directory as an absolute path. IBM Cloud: Container TSM: path |
| retention | Integer | The number of days to keep the entry in the catalog.
Default = 365 |
| storageSystem | String | Required. The type of archive storage system.
For valid values, call update_entry_location from the command line with --help=true. |
| user | String | The user account to access the host. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> all_managed: execute on all managed units but not the central manager all: execute on all managed units and the central manager group:<group name>: execute on all managed units identified by <group name> host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapi update_entry_location
fileName=a1.corp.com-1_4_2008-01-10_10:27:24.res.70.tar.gz.enc path=/mnt/nfs/ogazit/archive_results/ hostName=qaserver
storageSystem=SCP newPath=/var/dump/mojgan newHostName=192.168.1.18
```

update_external_stap_config

Use this API to modify External S-TAPs on a specified Guardium® host.

External S-TAPs are supported on UNIX or Linux machines only.

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/external_stap_config
```

GuardAPI syntax

```
update_external_stap_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------|------------|--|
| stapHost | String | Required. One of the following: <ul style="list-style-type: none"> The UUID of the External S-TAP®. <code>all_active</code>: All External S-TAPs that are configured to report to this Guardium system. For valid values, call update_external_stap_config from the command line with --help=true. |
| updateValue | String | Required. Modifiable parameters in the <code>guard_tap.ini</code> configuration file. For valid values of each parameter refer to the parameter descriptions in the Windows and UNIX-Linux S-TAP configuration. |

| Parameter | Value type | Description |
|-----------|------------|--|
| | | <p>TAP section:</p> <ul style="list-style-type: none"> • <i>add_to_verification_schedule</i> • <i>all_can_control</i> • <i>alternate_ips</i> • <i>appserver_installed</i> • <i>appserver_login_pattern</i> • <i>appserver_ports</i> • <i>appserver_session_pattern</i> • <i>appserver_session_postfix</i> • <i>appserver_session_prefix</i> • <i>appserver_username_postfix</i> • <i>appserver_username_prefix</i> • <i>appserver_usersess_pattern</i> • <i>appserver_usersess_postfix</i> • <i>appserver_usersess_prefix</i> • <i>bad_alloc_counter_max</i> • <i>buf_msg_time_interval</i> • <i>buffer_file_size</i> • <i>buffer_mmap_file</i> • <i>checksum</i> • <i>checksum_configuration</i> • <i>compression_level</i> • <i>connection_timeout_sec</i> • <i>db_exit_list</i> • <i>db_ignore_response</i> • <i>db_ignore_response_bypass_bytes</i> • <i>db_ignore_response_filter</i> • <i>db_ignore_response_resets_per_request</i> • <i>db_request_handler_enable</i> • <i>enable_dynamic_ring_buffers</i> • <i>extra_info</i> • <i>failover_tls</i> • <i>firewall_default_state</i> • <i>firewall_fail_close</i> • <i>firewall_force_unwatch</i> • <i>firewall_force_watch</i> • <i>firewall_installed</i> • <i>firewall_timeout</i> • <i>force_server_ip</i> • <i>guardium_ca_path</i> • <i>guardium_crl_path</i> • <i>kerberos_plugin_dir</i> • <i>load_balancer_ip</i> • <i>load_balancer_load_affinity</i> • <i>max_server_write_size</i> • <i>min_bytes_to_compress</i> • <i>modification_count</i> • <i>modification_host</i> • <i>modification_microsec</i> • <i>msg_aggregate_timeout</i> • <i>msg_count_watermark</i> • <i>participate_in_load_balancing</i> • <i>private_tap_ip</i> • <i>qrw_default_state</i> • <i>qrw_force_unwatch</i> • <i>qrw_force_watch</i> • <i>qrw_installed</i> • <i>remote_messages</i> • <i>sqlguard_cert_cn</i> • <i>stap_statistic</i> • <i>stap_statistic_version</i> • <i>syslog_messages</i> • <i>tap_buf_dir</i> • <i>tap_debug_output_level</i> • <i>tap_failover_session_quiesce</i> • <i>tap_failover_session_size</i> • <i>tap_identifier</i> • <i>tap_ip</i> • <i>tap_log_dir</i> • <i>upload_feature</i> <p>DB section:</p> <ul style="list-style-type: none"> • <i>connect_to_ip</i> • <i>db_user</i> • <i>db_version</i> • <i>exclude_networks</i> • <i>networks</i> |

update_group_by_desc

This command updates the configuration of a group identified by its description.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_group_by_desc
```

GuardAPI syntax

```
update_group_by_desc parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| category | String | Update the category. A category is an optional label that is used to group policy violations and groups for reporting. |
| desc | String | Required. Identifies the group by its description. |
| GroupType | String | Update the group type. For a list of valid group types, see the type parameter of the create_group API. |

| Parameter | Value type | Description |
|------------------|------------|---|
| tuple_parameters | String | Required. Valid values: <ul style="list-style-type: none">• <i>client_ip</i>• <i>client_host_name</i>• <i>server_ip</i>• <i>server_host_name</i>• <i>source_program</i>• <i>db_name</i>• <i>db_user</i>• <i>os_user</i>• <i>db_type</i>• <i>net_protocol</i>• <i>server_port</i>• <i>sender_ip</i>• <i>analyzed_client_ip</i>• <i>incident</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to update the group named *A group* to use the group type *OBJECTS* and the category *New category*:

```
grdapic update_group_by_desc desc="A group" GroupType=OBJECTS category="New category"
```

Related reference

update_group_by_id

This command updates the configuration of a group identified by its identification key.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_group_by_id
```

GuardAPI syntax

```
update_group_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|---|
| category | String | Update the category. A category is an optional label that is used to group policy violations and groups for reporting. |
| GroupType | String | Update the group type. For a list of valid group types, see the type parameter of the create_group API. |
| id | Integer | Required. Identifies the group by its identification key. |

| Parameter | Value type | Description |
|------------------|------------|---|
| tuple_parameters | String | Required. Valid values: <ul style="list-style-type: none">• <i>client_ip</i>• <i>client_host_name</i>• <i>server_ip</i>• <i>server_host_name</i>• <i>source_program</i>• <i>db_name</i>• <i>db_user</i>• <i>os_user</i>• <i>db_type</i>• <i>net_protocol</i>• <i>server_port</i>• <i>sender_ip</i>• <i>analyzed_client_ip</i>• <i>incident</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• <i>all_managed</i>: execute on all managed units but not the central manager• <i>all</i>: execute on all managed units and the central manager• <i>group:<group name></i>: execute on all managed units identified by <i><group name></i>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

Use this command to update the group with identification key *100003* to use the group type *OBJECTS* and the category *New category*:

```
grdapi update_group_by_desc id=100003 GroupType=OBJECTS category="New category"
```

update_hashicorp_config

This command updates the HashiCorp configuration.

This API is available in Guardium v11.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/hashicorp
```

GuardAPI syntax

```
update_hashicorp_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------|------------|---|
| AuthType | String | For valid values, call <code>update_hashicorp_config</code> from the command line with <code>--help=true</code> . |
| name | String | Required. For valid values, call <code>update_hashicorp_config</code> from the command line with <code>--help=true</code> . |
| namespace | String | |
| password | String | The password. |
| username | String | The username. |
| useTLS | Boolean | Transport Layer Security (TLS) with server-side or client-side authentication.
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| vaultHostName | String | The vault hostname. |

| Parameter | Value type | Description |
|-----------------|------------|------------------|
| vaultPortNumber | Integer | The port number. |

Example

The following example updates the username, authentication method, and port number.

```
grdapi update_hashicorp_config name="No TLS User and password API" username="newname" useTLS="true" vaultPortNumber="9999"
ID=1
ok
```

update_insights_agent_config

Update individual task manager parameters for Guardium® Insights.

Important: Do not change any of these parameters unless you are working with Guardium support. Some parameters are for informational purposes only and cannot be changed.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/insights_agent_config
```

GuardAPI syntax

```
update_insights_agent_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|--|
| paramName | String | <p>Required. You can update the following parameters:</p> <ul style="list-style-type: none"> • ALLOW_ACTIVITY_INSIGHTS_POLICY_INSTALLATION - When set to 1 (on), creates a dedicated GuardiumInsightPolicy and supports blocking users from Guardium Insights. Default = 0 (off). • FORCE_SYNC - When set to 1 (on), forces the Insights agent to verify that the Insights-related setup is synced between the central manager and managed units. Default = 0 (off). Guardium Insights and Guardium Data Protection. • MAX_BLOCKING_TASK_WAIT_TIME - The maximum time (in seconds) that the task manager waits for "blocking tasks" to complete before moving on to process the next queued tasks. Default = 300 (seconds). Value is any integer 0 or greater. • MAX_CONSECUTIVE_ERROR_HANDLING – The number of error messages to send to Guardium Insights upon recurring failure executing the same task. Default = 1. Value is any integer 1 or greater. • MAX_CONCURRENT_TASK_THREADS - Number of concurrent tasks that the task manager can run. Default = 30. Value is any integer 1 or greater. • TASK_GENERATOR_EXECUTION_INTERVAL - The interval by which the internal task generator task is checking tasks to process when agent is not registered. Default = 10 (seconds). Value is any integer 5 or greater. • TASK_MANAGER_PARAM_LOAD_INTERVAL - The interval by which the task manager looks for parameter changes. Default = 10 (seconds). Value is any integer 5 or greater. • TASK_QUEUE_EXECUTION_INTERVAL - The interval by which the task manager checks the task queue. Default = 10 (seconds). Value is any integer 5 or greater. <p>Note: The following parameters display in get_insights_agent_config, but cannot be changed,</p> <ul style="list-style-type: none"> • EXCLUDED_GI_DATAMARTS - The list of data marts to exclude from the extraction profile. • MAX_GI_DATAMART_EXTRACTION_PROFILE_SUPPORTED - The name of the supported data mart extraction profile. |
| paramValue | String | Required. The new value for the paramName. |

update_insights_registration_config

This API allows you to update the Guardium® Insights registration information.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/insights_registration
```

GuardAPI syntax

```
update_insights_registration_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| insights_apikey_token | String | Required. An API token that is generated from Guardium Insights to allow external sources to execute RESTAPI calls on Guardium Insights. The token includes the encrypted Guardium Insights tenant ID. |
| insights_ca_cert_cn | String | The Insights certificate common name that is generated when the certificate is created. During the registration process, you can specify the certificate common name to verify the CN field as part of the standard certificate exchange authentication. |

update_ip_restriction_allowlist

This command adds or removes IP addresses from an IP restriction allowlist.

You can create allowlists either from the GUI or by using the [enable_disable_ip_restriction](#) API. For more information, see [Managing access by IP address](#).

This API is available in Guardium V11.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/ip_restriction
```

GuardAPI syntax

```
update_ip_restriction_allowlist parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| action | String | Required. Specify whether to add or remove an IP address. Valid values: <ul style="list-style-type: none">• ADD• REMOVE |
| ips | String | Required. A list of one or more comma-separated IP addresses to add or remove. |
| type | String | Required. Specify whether to update the IP address allowlist for the GUI, for SSH, or both (ALL). Valid values: <ul style="list-style-type: none">• ALL - Both GUI and SSH• GUI• SSH |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group_name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

This example adds an IP address to the GUI allowlist.

```
>grdapi update_ip_restriction_allowlist action="ADD" ips="9.160.142.63" type="GUI"
```

update_istap_config

Use this command to update the filtering settings on IBM i.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/istap_config
```

GuardAPI syntax

```
update_istap_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------------|------------|--|
| check_server_hb | Boolean | Network connection check. Valid values: <ul style="list-style-type: none"> • 0 (false): Do not use failover. • 1 (true): Use failover. |
| connection_timeout_sec | String | Number of seconds after which theS-TAP® considers a Guardium® server to be unavailable. It can have any integer value. |
| datasourceName | String | Required. IP or name of the IBM i server. |
| filter_audit_entry_types | String | The specified QAUDJRN audit entry filter, if any. Specifies which audit journal entry types should be processed. The default is 'AD AF CA CO DO GD OM OR OW PG PW RA RO RZ SV ZC ZR' |
| filter_client_acct | String | The specified client accounting filter, if any. Only one client accounting filter can be specified. |
| filter_client_app | String | The specified client application filter, if any. Only one client application filter can be specified. |
| filter_client_program | String | The specified client program filter, if any. Only one client program filter can be specified. |
| filter_client_user | String | The specified client user filter, if any. Only one client user filter can be specified. |
| filter_client_wkstn | String | The specified client workstation filter, if any. Only one client workstation filter can be specified. |
| filter_job | String | The specified job filter, if any. Only one job name or generic job name can be specified. |
| filter_port | String | The specified port filter, if any. Only one port filter can be specified. Filtering by port is only supported in release 7.1 and later. |
| filter_rdb | String | The specified relational database filter, if any. Up to 10 relational database names can be specified. Filter_RDB is a case sensitive filter. Execute this command on your target database and enter the name exactly as it is returned. |
| filter_system_sql | String | The specified system SQL statement filter. Specifies whether system SQL statements should be audited (Y or N). The default is Y. |
| filter_table | String | The specified table filter, if any. Up to ten file names or generic file names can be specified. The specified library name must be the system schema name (10 character name). The file name can be either the system table name or table name (long or short name). |
| filter_tcpip | String | The specified TCP/IP filter, if any. Only one TCP/IP address can be specified. |
| filter_user | String | The specified user or group user profile filter, if any. Up to 10 usernames or generic usernames can be used.
Important: If you want to set the filter_user parameter value to null, then enter null in lowercase. If you enter NULL in uppercase, the system apply DBUser=NULL filter. |
| guardium_host | String | IP address or hostname of the Guardium system that acts as the host for the S-TAP. |
| prevent_skipped_entries | String | Directs the SQL auditing to handle the case where the audit server job is overwhelmed with detail. Valid values: <ul style="list-style-type: none"> • N • Y: The audit server is given preference over the performance of the work stream. Default = N |
| remote_messages | String | Send messages to the active Guardium host. Valid values: <ul style="list-style-type: none"> • 0: Do not send messages • 1: Send messages to the active Guardium system. |

| Parameter | Value type | Description |
|---------------|------------|---|
| start_monitor | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true): The auditing process starts (or restarts) on the i server after the configuration table is updated. When the auditing process is started, stored procedures on DB2 for i are invoked that: <ul style="list-style-type: none"> ◦ Create the message queue that will be used to send entries to the InfoSphere Guardium collector and starts a global database monitor using a view with an INSTEAD OF trigger (which sends the entries to the message queue) ◦ Start PASE and S-TAP. ◦ Receive journal entries from QAUDJRN and add them to the message queue. <p>Default = 1 (true)</p> |
| start_user | String | |

Examples

To start monitoring in the server named db21nn:

```
grdapi datasourceName=db21nn update_istap_config start_monitor=1
```

update_managed_units_ping_time

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_managed_units_ping_time
```

GuardAPI syntax

```
update_managed_units_ping_time parameter=value
```

update_policy

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/policy
```

GuardAPI syntax

```
update_policy parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------|------------|---|
| baselineDesc | String | |
| categoryName | String | For valid values, call <code>update_policy</code> from the command line with <code>--help=true</code> . |
| logFlat | Boolean | <p>Valid values:</p> <ul style="list-style-type: none"> • 0 (false) • 1 (true) |
| pattern | String | |
| policyDesc | String | Required. |
| policyLevel | String | |

| Parameter | Value type | Description |
|-----------------|------------|---|
| rulesOnFlat | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| securityPolicy | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

update_policy_analyzer_interval

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_policy_analyzer_interval
```

GuardAPI syntax

```
update_policy_analyzer_interval parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| interval | String | Valid interval values are 2 - 60. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

update_qr_action

This command updates an existing query rewrite action with a new name and optional description.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/qr_action
```

GuardAPI syntax

```
update_qr_action parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|---|
| actionName | String | Required. The unique name of the query rewrite action. |
| definitionName | String | Required. The query rewrite definition that is associated with this action. |
| description | String | Textual description of the action. |
| newName | String | The new name for this action. |

Examples

To rename qr action2 to new qr action2:

```
grdapi update_qr_action definitionName="case 2" actionName="qr action2" newName="new qr action2"
```

update_qr_add_where_by_id

This command updates an existing "add where" function with new text.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_qr_add_where_by_id
```

GuardAPI syntax

```
update_qr_add_where_by_id parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------|------------|---|
| addQualifierFlag | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| qrAddWhereId | Long | Required. The unique identifier for the query rewrite "add where" function. |
| whereText | String | The replacement text for the specified where clause. |

Examples

```
grdapi update_qr_add_where_by_id qrAddWhereId=22222 whereText="1=2"
```

Related concepts

update_qr_condition

This command creates a query rewrite condition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/qr_condition
```

GuardAPI syntax

```
update_qr_condition parameter=value
```

Parameters

| Parameter | Value type | Description |
|---------------------|------------|--|
| conditionName | String | Required. The unique name of this query rewrite condition. |
| definitionName | String | Required. The query rewrite definition that is associated with this condition. |
| depth | Integer | The depth of the parsed SQL that this condition applies to (1 and higher). The value 1 means that the query rewrite condition applies to any matching SQL at any depth. Default = 1 |
| isForAllRuleObjects | Boolean | Indicates that the specified condition applies to all objects for the fired rule. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| isForAllRuleVerbs | Boolean | Whether or not the specified condition applies to all verbs for the fired rule. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| isObjectRegex | Boolean | Whether or not the specified object is specified by using a regular expression. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| isVerbRegex | Boolean | Whether or not the specified verb is specified by using a regular expression. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| newName | String | The new name for the query rewrite condition. |
| object | String | An object (table or view). The default "*" means all objects. This can also be specified as a regular expression, in which case set the isVerbRegex to True. |
| order | Integer | Specifies the order in which to assemble multiple related query rewrite conditions for complex SQL. Default = 1. |
| verb | String | A verb (select, insert, update, delete). The default "*" means all verbs. |

Examples

```
grdapi update_qr_condition definitionName="case 16" conditionName="qr_cond15_3" newName="qr_cond16_3" verb=select object=* dept=2 order=3
```

Related concepts

update_qr_definition

This command updates an existing query rewrite definition.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/qr_definition
```

GuardAPI syntax

```
update_qr_definition parameter=value
```

Parameters

| Parameter | Value type | Description |
|----------------|------------|--|
| dataBaseType | String | Required. The type of database this query rewrite definition is associated with. For valid values, call update_qr_definition from the command line with --help=true. |
| definitionName | String | Required. A unique name for this query rewrite definition condition. |
| description | String | Textual description |
| isNegateQrCond | Boolean | Specify if there is a NOT flag on the set of query rewrite conditions that are associated with this definition. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| newName | String | Specifies a new unique name. |
| sampleSql | String | Specifies a sample SQL statement. In most cases, you will not use this unless you want to use the inputted sample SQL later in the UI. |

Examples

```
grdapi update_qr_definition DataBaseType="DB2" definitionName="case 15" sampleSql="select EMPNO from EMP where ENAME = (select ENAME from EMP where SAL = (select SAL from EMP where HIREDATE = to_date('06/09/1981 00:00:00', 'MM/DD/YYYY HH24:MI:SS')))" newName="DB2_case 15"
```

update_qr_replace_element_byId

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_qr_replace_elementById
```

GuardAPI syntax

```
update_qr_replace_elementById parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------------|------------|--|
| columnAlias | String | Specify an alias for a column name. For more information, see Starting the IBM Knowledge Catalog and Guardium Data Protection integration . |
| isFromAllRuleElements | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| isFromRegex | Boolean | Whether or not the "from" element is specified by using a regular expression. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 |
| isReplaceToFunction | Boolean | Whether or not the "replace to" is the name of a function, such as user-defined function. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) |
| qrReplaceElementId | Long | Required. The unique ID of the query rewrite action. |
| replaceFrom | String | The incoming string for a matching rule that is to be replaced. Use replaceType to indicate specifically which element of the incoming query to examine. |

| Parameter | Value type | Description |
|-----------|------------|--|
| replaceTo | String | The replacement string for the matching element. |

Examples

```
grdapi update_qr_replace_element_byId qrReplaceElementId=1 isFromAllRuleElements=false isFromRegex=false
isReplaceToFunction=false replaceFrom=emp replaceTo=NEW_EMP_UPDATED
```

update_quarantine_allowed_until

This command updates parameters to prevent a user from logging in after a specified length of time passes.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/quarantine_allowed_until
```

GuardAPI syntax

```
update_quarantine_allowed_until parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| allowedUntil | String | Required. The date and time to begin the quarantine in one of the following formats: <ul style="list-style-type: none"> • YYYY-MM-DD hh:mm:ss • A relative time (such as NOW +1 HOUR) For more information about relative time, see Relative to NOW . |
| dbUser | String | Required. The name of the database user to quarantine. |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |
| type | String | Required. If the database is not IBM Z® or IMS, specify <i>normal</i> . Valid values: <ul style="list-style-type: none"> • <i>normal</i> • <i>DB2Z</i> • <i>IMS</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <i>api_target_host=10.0.1.123</i>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

The following command updates the time to start the quarantine for this user:

```
grdapi update_quarantine_allowed_until allowedUntil="NOW +2 HOUR" dbUser="Hadrian.Swall" serverIp="9.32.0.255"
serviceName="company.ibm.com" type="normal"
```

update_quarantine_until

This command updates the parameters that prevent a user from logging for a specified length of time.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/quarantine_until
```

GuardAPI syntax

```
update_quarantine_until parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| dbUser | String | Required. The name of the database user to quarantine. |
| quarantineUntil | String | Required. The date and time to end the quarantine in one of the following formats: <ul style="list-style-type: none"> • YYYY-MM-DD hh:mm:ss • A relative time (such as NOW +1 HOUR) For more information about relative time, see Relative to NOW . |
| serverIp | String | Required. The server IP address. |
| serviceName | String | Required. The server name. |
| type | String | Required. If the database is not IBM Z® or IMS, specify <i>normal</i> . Valid values: <ul style="list-style-type: none"> • <i>normal</i> • <i>DB2Z</i> • <i>IMS</i> |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

The following command changes the quarantine for this user from 1 hour to 2 hours after the command is called:

```
grdapi create_quarantine_until quarantineUntil="NOW +2 HOUR" dbUser="Hadrian.Swall" serverIp="9.32.0.255"
serviceName="company.ibm.com" type="normal"
```

update_ranger_config

This API updates the configuration parameters for the Ranger integration.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_ranger_config
```

GuardAPI syntax

```
update_ranger_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| hostname | String | Required. Hostname or IP address of the Ambari server. |
| newClusterName | String | New cluster name for this ranger configuration. |
| password | String | Required. Password for the admin user specified by <code>user_name</code> |
| port | Integer | Port on the Ambari server for the user interface. |
| sslEnabled | Boolean | Sets whether SSL is enabled for communication with this Ranger. Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false) |
| user_name | String | Required. Ambari server username; must be an admin or service admin user. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To change the cluster name of this ranger configuration to Cluster4:

```
grdapi update_ranger_config hostname=hw-cl4-05 user_name=admin port=8080 password=xxxxxx clusterName=Cluster4
```

Sample output:

```
ID=0
Configuration for Cluster: Cluster4
Updated.
admin@hw-cl4-05:8080 Cluster4
```

update_ranger_hdfs_config

Use this command to update a Hadoop integration with Ranger HDFS that send data to the specified S-TAP.

This API is available in Guardium V11.3 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/update_ranger_hdfs_config
```

GuardAPI syntax

```
update_ranger_hdfs_config parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------------|------------|---|
| ldLibraryPath | String | Locate libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server/libjvm.so) and set <code>ld_library_paths</code> to the directory that contains libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server). |
| principal | String | Required for Kerberos. The value of Ranger HDFS user. |
| rangerHDFSAuditHistoryLength | Integer | Required. |
| rangerHdfsAuditDirs | String | Comma-separated list of directories where Ranger logs the service audits. Include one directory that contains the daily log directories, for each service you want to monitor. Usually the paths are located under /ranger/audit.

Example service directories for CDP 7: /ranger/audit/hive/hiveServer2,/ranger/audit/kafka/kafka,/ranger/audit/hbase/hbaseMaster,/ranger/audit/hbase/hbaseRegional,/ranger/audit/atlas/atlas,/ranger/audit/hdfs/hdfs

Example service directories for HW 3: /ranger/audit/hbaseMaster,/ranger/audit/hbaseRegional,/ranger/audit/hdfs,/ranger/audit/hiveServer2,/ranger/audit/kafka,/ranger/audit/solr,/ranger/audit/storm |
| rangerHdfsKeytab | String | Required for Kerberos. Location of the Kerberos keytab that contains the principal used to connect to HDFS. |
| rangerHdfsLibLocation | String | Locate libhdfs.so provided by Hadoop cluster (for example, /usr/hdp/3.1.0.141-1/usr/lib/libhdfs.so) and set <code>ranger_hdfs_lib_location</code> to the directory that contains libhdfs.so (for example, /usr/hdp/3.1.0.141-1/usr/lib). |
| rangerHdfsNameNode | String | IP or hostname of the HDFS NameNode. |
| rangerHdfsPollMs | Integer | Time interval, in milliseconds, the S-TAP® waits between checking for new Ranger audits in HDFS. |
| rangerHdfsPort | Integer | The HDFS NameNode port the S-TAP connects to. |
| rangerHdfsUser | String | The user with which S-TAP connects to HDFS. If the HDFS setup is using Kerberos, set the parameter to the Kerberos principal. |
| sTapHostName | String | Required. Host name or IP of the S-TAP that receives the Ranger audit messages from the Ranger. |
| useKerberos | Boolean | Enables Kerberos authentication for this connection. When enabled, requires values for Principal and Ranger HDFS keytab. Valid values: <ul style="list-style-type: none">• 0: Disabled• 1: Enabled Default = 0 |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

update_ranger_service

Use this command to update the Ranger service that is mapped to an S-TAP®.

This command requires valid administrative authority on the Ambari server such as an admin or service administrator account. After running the command, the Ambari administrator must restart the affected Hadoop components so that the changes take effect.

This API is available in Guardium V10.1.4 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_ranger_service
```

GuardAPI syntax

```
update_ranger_service parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| clusterName | String | Required. Ambari cluster name. |
| port | Integer | Port on the Ambari server for monitoring. |
| serviceName | String | Required. Name of the service. Valid values: <ul style="list-style-type: none">• hdfs• hive• hbase• kafka• solr• storm |
| stapHostName | String | Required. Host name or IP of the S-TAP that receives the log4j audit messages from the Ranger. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

To change the port for this ranger to 5534:

```
grdapi update_ranger_service clusterName=Cluster4 serviceName=HDFS stapHostName=<Guardium host> port=5534
```

Sample output:

```
ID=0
The Hadoop service configuration has been changed. Ask the Hadoop administrator to restart the Hadoop service to activate the changes.
HDFS Monitoring Enabled on <Guardium host>:5534
Note: Only one port can be configured per S-TAP host. Changing the port here will update it automatically for all Hadoop services configured to this S-TAP.
```

update_rule

This command updates a policy rule.

This command updates the parameters that you specify for an existing rule in a specified policy. Only the rule name (*ruleDesc*) and policy name (*fromPolicy*) are required. If you do not specify a rule field, the field is ignored and not changed.

For more information about rule fields, see [Rule definition fields](#).

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_rule
```

GuardAPI syntax

```
update_rule parameter=value

| xmlPattern | String | A regular expression (regex) to match. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

GuardAPI example

```
grdapic update_rule ruleDesc="Rule Description" fromPolicy="policy1" serviceName="ANY"
```

Related reference

- [Rule definition fields](#)

update_shared_secret

Use this API to update the shared secret for a central manager and its associated managed units. This API is only available as a grdapi.

Be sure to run **update_shared_secret** from a central manager.

Set the shared secret before you register the central manager and managed units. For more information, see [Registering units](#).

When you update the shared secret from the central manager, the secret is propagated from the central managed to all associated managed units that are available. An error message is returned if a managed unit is offline or not available.

Note: The central manager and all managed units must be on the same Guardium version.

This API is available in Guardium v11.4 and later.

GuardAPI syntax

```
update_shared_secret parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| enable | Boolean | Required. When <i>enable</i> is set to 1, Guardium® follows strong password rules for the shared secret. That is, the value of <i>SharedSecret</i> must be a minimum of 15 characters, and follow the rules that are described in store_password_validation .
Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 0 (false)
Note: While SharedSecret uses the strong password rules, the shared secret is not related to passwords. |
| SharedSecret | String | A shared secret that allows communication between the central manager and associated managed units. |
| api_target_host | String | Specifies the target hosts where the API executes. Valid values: <ul style="list-style-type: none">• all_managed: execute on all managed units but not the central manager• all: execute on all managed units and the central manager• group:<group name>: execute on all managed units identified by <group name>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, api_target_host=10.0.1.123.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, api_target_host=10.0.1.123. IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode. |

Examples

The following example shows the shared secret with strong password rules enabled. In addition, only the available managed units are updated.

```
grdapi update_shared_secret SharedSecret="!QertyqUerty!1029" enable=true  
ID=0  
The following managed unit was offline: sys-vm01.my.company.com.  
The offline unit(s) will not be updated  
Updating managed unit : sys-vm03.my.company.com.  
Updating managed unit : sys-vm04.my.company.com.
```

update_stap_config

Modifies the configuration of the S-TAPs reporting to the specified Guardium® systems.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/stap_config
```

GuardAPI syntax

Use the *updateValue* parameter to modify the listed parameters in the file *guard_tap.ini*. Each listed parameter indicates if it is relevant for Windows or Unix. You can specify any combination of parameters in this command.

```
update_stap_config parameter=value updateValue=<guard_tap.ini section name>.〈parameter〉:value
```

To modify multiple parameters:

```
update_stap_config parameter=value updateValue=<guard_tap.ini section name>.<parameter>:value&<guard_tap.ini section name>.<parameter>:value...
```

Parameters

CAUTION:

Many of these parameters are advanced and are usually only modified by IBM Technical Support.

| Parameter | Value type | Description |
|----------------|------------|---|
| stapHost | String | <p>Required. The host name or IP address of a database server on which Guardium system, or a comma-separated list of host names or IP addresses, or one of:</p> <ul style="list-style-type: none">• 9.70.147.80• all_active: All S-TAPs that are configured to report to this Guardium system• all_unix_active: All S-TAPs that are configured to report to this Guardium system and are running on UNIX servers.• all_windows_active: All S-TAPs that are configured to report to this Guardium system and are running on Windows servers. <p>For valid values, call update_stap_config from the command line with --help=true.</p> |
| tap_identifier | NULL | Used to distinguish inspection engines from one another. If unspecified, Guardium auto-populates the field with a unique name using the database type and sequence number. |
| updateValue | String | <p>Required. Modifiable parameters in the guard_tap.ini configuration file. For valid values of each parameter refer to the parameter descriptions in the Windows and UNIX-Linux S-TAP® configuration.</p> <p>TAP section:</p> <ul style="list-style-type: none">• add_to_verification_schedule (UNIX, Windows)• alert_on_shared_memory_enabling (Windows)• all_can_control (UNIX, Windows)• alternate_ips (UNIX, Windows)• appserver_installed (UNIX, Windows)• appserver_login_pattern (UNIX, Windows)• appserver_ports (UNIX, Windows)• appserver_session_pattern (UNIX, Windows)• appserver_session_postfix (UNIX, Windows)• appserver_session_prefix (UNIX, Windows)• appserver_username_postfix (UNIX, Windows)• appserver_username_prefix (UNIX, Windows)• appserver_usersess_pattern (UNIX, Windows)• appserver_usersess_postfix (UNIX, Windows)• appserver_usersess_prefix (UNIX, Windows)• atap_exec_location (UNIX)• auto_discovery (Windows)• bad_alloc_counter_max (UNIX)• buf_msg_time_interval (UNIX, Windows)• buffer_file_size (UNIX, Windows)• buffer_mmap_file (UNIX, Windows)• buffer_percentage_for_priority_packet (UNIX)• cas_checkpoint_period (UNIX, Windows)• cas_client_baseline (UNIX, Windows)• cas_client_checkpoint (UNIX, Windows)• cas_fail_over_file (UNIX, Windows)• cas_fail_over_file_size_limit (Windows)• cas_max_reconnect_attempts (UNIX, Windows)• cas_md5_size_limit (UNIX, Windows)• cas_raw_data_limit (UNIX, Windows)• cas_reconnect_interval (UNIX, Windows)• cas_task_baseline (UNIX, Windows)• cas_task_checkpoint (UNIX, Windows)• cassandra_audit_delimiter (UNIX)• cassandra_audit_enabled (UNIX)• checksum (UNIX, Windows)• checksum_configuration (UNIX, Windows)• compression_level (UNIX, Windows)• connection_timeout_sec (UNIX, Windows, i)• correlation_timeout (Windows)• db_exit_list (UNIX)• db2_shmem_driver_installed (Windows)• db2_tap_installed (Windows)• db_ignore_response (UNIX, Windows)• db_ignore_response_bypass_bytes (UNIX, Windows)• db_ignore_response_filter (UNIX, Windows)• db_ignore_response_local (UNIX, Windows)• db_ignore_response_resets_per_request (UNIX, Windows)• db_request_handler_enable (UNIX)• devices (UNIX, Windows)• disable_shared_memory_if_turned_on (Windows)• discovery_debug (UNIX)• discovery_interval (UNIX, Windows). | waitForResponse | String | <p>Specifies whether the API waits for a response from the S-TAP. Valid values:</p> <ul style="list-style-type: none"> • 0: do not wait • 1: wait for a response <p>The default is 1 when <i>stapHost</i> is a single host name or IP address, and 0 in all other cases.</p> |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <i>all_managed</i>: execute on all managed units but not the central manager • <i>all</i>: execute on all managed units and the central manager • <i>group:<group name></i>: execute on all managed units identified by <i><group name></i> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <i>api_target_host=10.0.1.123</i>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <i>api_target_host=10.0.1.123</i>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

For all active UNIX S-TAPs: in the [TAP] section, set *all_can_control* to 1; set *qrw_default_state* to 0; in the [SQLGUARD] section, set *num_main_thread* to 4:

```
> grdapic update_stap_config stapHost=all_unix_active
updateValue=tap.all_can_control:1&tap.qrw_default_state:0&sqlguard.num_main_thread:4
```

or

```
> grdapic update_stap_config stapHost=all_unix_active updateValue=tap.all_can_control:1
update_stap_config stapHost=all_unix_active updateValue=tap.qrw_default_state:0
update_stap_config stapHost=all_unix_active updateValue=sqlguard.num_main_thread:4
```

For Windows, use this GRDAPIC to turn on the firewall. For example:

```
> grdapic update_stap_config stapHost=MyHost updateValue=TAP.FIREWALL_INSTALLED:1 waitForResponse=1
ID=77039
```

update_test_detail_exception

This command updates test detail exceptions.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/test_detail_exception
```

GuardAPI syntax

```
update_test_detail_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------------------|------------|--|
| assessmentDesc | String | |
| assessmentScope | String | |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | |
| datasourceType | String | |
| detailExceptionValue | String | |
| exceptionType | String | Valid values: <ul style="list-style-type: none">• <code>text</code>• <code>regex</code>• <code>0</code>• <code>1</code> |
| explanation | String | |
| fromDate | String | |
| testDescription | String | |
| testDetailExceptionsId | String | Required. |
| toDate | String | |

update_test_exception

This command updates test exceptions.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/test_exception
```

GuardAPI syntax

```
update_test_exception parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|--|
| assessmentDesc | String | |
| assessmentScope | String | Valid values: <ul style="list-style-type: none">• CURRENT• ALL• 0• 1 |
| datasourceGroup | String | |
| datasourceName | String | |
| datasourceScope | String | Valid values: <ul style="list-style-type: none">• SINGLE• GROUP• ALL• 0• 1• 2 |
| datasourceType | String | For valid values, call update_test_exception from the command line with --help=true. |
| explanation | String | |

| testDescription | String | |
| testExceptionId | Long | Required. |
| toDate | String | |

update_threshold_in_rule

Use this API to change the threshold on a specific violation policy rule that is used to create an active threat analytics case type.

Changes to installed policies are applied according to the policy schedule. When adding a threshold to a rule in an installed policy, cases are created for violations (according to the threshold) only after the policy is reinstalled.

This API is available in Guardium V11.2 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/update_threshold_in_rule
```

GuardAPI syntax

```
update_threshold_in_rule parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| policy_name | String | The policy that has the rule whose threshold you want to change. Use the API list_policy to view policies. |
| rule_name | String | The rule whose threshold you want to change. Use the API list_policy_rules to view rules. |
| threshold_value | Integer | The threshold at which a case is created. |

Examples

To change the threshold to 50 in the ruleNNN in policyAAA:

```
grdapic update_threshold_in_rule policy_name=policyAAA rule_name=ruleNNN threshold=50
```

update_user

Update information for a Guardium user.

To make changes to roles for this user, use the [set_user_roles](#) API.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/user
```

GuardAPI syntax

```
update_user parameter=value
```

Parameters

| Parameter | Value type | Description |
|-------------------|------------|--|
| confirmPassword | String | Required. Confirm the password. The confirmPassword must match the value of Password. |
| country | String | The ISO 3166 2-letter country code for this user, such as US or ES. For valid values, call update_user from the command line with --help=true . |
| disabled | Boolean | Enables or disables this user. Valid values: <ul style="list-style-type: none">• 0 (false): The user is enabled.• 1 (true): The user is disabled. Default = 0 |
| disablePwdExpiry | Boolean | Valid values: <ul style="list-style-type: none">• 0 (false)• 1 (true) Default = 1 (true) |
| email | String | The user's email address |
| firstName | String | The user's given name. |
| lastName | String | The user's family name. |
| password | String | Required. The password must be at least 8 characters long and include at least one of each: <ul style="list-style-type: none">• An uppercase letter (A-Z)• A lowercase letter (a-z)• A number (0-9)• A special character, which can be: at sign (@), hashtag (#), dollar sign (\$), percent sign (%), caret (^), ampersand (&), asterisk (*), exclamation (!), hyphen (-), underscore (_), plus (+), or equals (=). |
| smartCardUserName | String | Common name in the certificate.
Enter the smart card user name when smart card authentication is turned on. |
| userName | String | Required. A user name for this user.
The following characters are not allowed in user names: semicolon (;), forward slash (/), dollar sign (\$), and percent sign (%). |

Examples

After using the [create_user](#) API to create a new user named Fred McDerf, you realize that you forgot to add his email address. Use [update_user](#) to add the email address as follows:

```
grdapi update_user userName="Fred McDerf" email=fredmcd@company.com
```

Related concepts

update_user_db

This command applies all recent changes to the active User-DB association map.

After you run some commands, you also need to run [update_user_db](#) to apply the changes.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the **PUT** method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/user_db
```

GuardAPI syntax

```
update_user_db parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">all_managed: execute on all managed units but not the central managerall: execute on all managed units and the central managergroup:<group name>: execute on all managed units identified by <group name>host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

After you run some commands, such as `create_allowed_db`, you must run `update_user_db`.

```
grdapi create_allowed_db userName=Fred serverIp=192.168.1.1 instanceName=test
```

Sample output

```
ID=1
When complete, in order for synchronization to take effect, run update_user_db
ok

grdapi update_user_db
ID=0
A background process updates the database. The results are not immediate.
ok
```

update_utilization_thresholds

This API is available in Guardium V9.5 and later.

GuardAPI syntax

```
update_utilization_thresholds parameter=value
```

Parameters

| Parameter | Value type | Description |
|------------|------------|---|
| paramName | String | Required. For valid values, call <code>update_utilization_thresholds</code> from the command line with <code>--help=true</code> . |
| threshold1 | Integer | Required. |
| threshold2 | Integer | Required. |

upload_custom_data

This command uploads data to a pre-configured custom table.

Before you run this command, you need to configure a custom table from the Custom Table Builder in the GUI (Reports > Report Configuration Tools > Custom Table Builder). Select a Custom Table, click Upload Data, and add or select a datasource.

This API is available in Guardium V9.5 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/custom_data
```

GuardAPI syntax

```
upload_custom_data parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| tableName | String | Required. The name of the custom table to which to upload data. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none">• <code>all_managed</code>: execute on all managed units but not the central manager• <code>all</code>: execute on all managed units and the central manager• <code>group:<group name></code>: execute on all managed units identified by <code><group name></code>• host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>.• host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

GuardAPI example

```
grdapi upload_custom_data tableName="MY_TABLE"
```

Related concepts

- [External Data Correlation](#)

venafi_import

Use this command to import a Venafi certificate.

This API is available in Guardium v11.3 and later.

REST API syntax

This API is available as a REST service with the `PUT` method. Call this API as follows:

```
PUT https://[Guardium hostname or IP address]:8443/restAPI/venafi_import
```

GuardAPI syntax

```
venafi_import parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|--|
| variant | String | Required. Valid values: <ul style="list-style-type: none">• <code>sniffer</code>• <code>gui</code>• <code>gim</code> |

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Example

```
grdapi venafi_import variant=gui force=true api_target_host=all
```

Related tasks

verify_cyberark_access

This command tests the connection to the CyberArk server.

This API is available in Guardium V11.0 and later.

REST API syntax

This API is available as a REST service with the `GET` method. Call this API as follows:

```
GET https://[Guardium hostname or IP address]:8443/restAPI/cyberark
```

GuardAPI syntax

```
verify_cyberark_access parameter=value
```

Parameters

| Parameter | Value type | Description |
|--------------------|------------|-------------|
| vaultPassword | String | Required. |
| vaultUserName | String | Required. |
| vaultWebServerName | String | Required. |

Example

```
grdapi verify_cyberark_access vaultUserName=username vaultPassword=passwprd vaultWebServerName=servername.com
```

verify_stap_inspection_engine_with_sequence

Use this command to perform verification of the specified S-TAP® inspection engine..

This GuardAPI is available in Guardium V9.5 and later.

The REST API is available in V11.1 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/verify_stap_inspection_engine_with_sequence
```

GuardAPI syntax

```
verify_stap_inspection_engine_with_sequence parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------------|------------|---|
| addToSchedule | String | Whether or not to add this inspection engine to the scheduled verification. Valid values: <ul style="list-style-type: none">• Yes• No |
| datasourceName | String | If this parameter is specified, advanced verification is performed against the specified datasource. If this parameter is omitted, standard verification is performed. |
| protocol | String | Required. The database protocol. |
| sequence | Integer | The sequence number of the inspection engine to be removed within the set of inspection engines of the specified type. Use the <code>grdapi list_inspection_engines</code> command with the type option first to verify the sequence number. |
| stapHost | String | Required. The host name or IP address of the database server on which the S-TAP is installed. |
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • <code>all_managed</code>: execute on all managed units but not the central manager • <code>all</code>: execute on all managed units and the central manager • <code>group:<group name></code>: execute on all managed units identified by <code><group name></code> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Examples

To initiate standard verification of the S-TAP with the sequence number of 4, on an MYSQL database, with the IP address 12.12.12.12:

```
grdapi verify_stap_inspection_engine_with_sequence stapHost=12.12.12.12 protocol=mysql sequence=4
```

wkc_refresh_external_pwd

If you use an external configuration manager to connect to IBM® Knowledge Catalog, this API updates the configuration manager password.

For more information, see [Starting the IBM Knowledge Catalog and Guardium Data Protection integration](#).

This API is available in Guardium v12.0 and later.

REST API syntax

This API is available as a REST service with the `POST` method. Call this API as follows:

```
POST https://[Guardium hostname or IP address]:8443/restAPI/wkc_refresh_external_pwd
```

GuardAPI syntax

```
wkc_refresh_external_pwd parameter=value
```

Parameters

| Parameter | Value type | Description |
|-----------|------------|-------------|
|-----------|------------|-------------|

| Parameter | Value type | Description |
|-----------------|------------|---|
| api_target_host | String | <p>Specifies the target hosts where the API executes. Valid values:</p> <ul style="list-style-type: none"> • all_managed: execute on all managed units but not the central manager • all: execute on all managed units and the central manager • group:<group name>: execute on all managed units identified by <group name> • host name or IP address of a managed unit: specified from the central manager to execute on a managed unit. For example, <code>api_target_host=10.0.1.123</code>. • host name or IP address of the central manager: specified from a managed unit to execute on the central manager. For example, <code>api_target_host=10.0.1.123</code>. <p>IP addresses must conform to the IP mode of your network. For dual IP mode, use the same IP protocol with which the managed unit is registered with the central manager. For example, if the registration uses IPv6, specify an IPv6 address. The hostname is independent of IP mode and can be used with any mode.</p> |

Access management APIs

Use these commands to manage access to the Guardium system. Many of these commands require the accessmgr role.

CLI password APIs

Use the following APIs to manage CLI passwords:

- [change_cli_password](#)
- [enable_strong_cli_password](#)

Custom LDAP table APIs

- [create_custom_table_ldap_import](#)
- [delete_custom_table_ldap_import](#)
- [list_custom_table_ldap_imports](#)
- [run_custom_table_ldap_import](#)
- [update_custom_table_ldap_import](#)

Multi-factor authentication APIs

The following APIs help manage multi-factor (two-factor) authentication. For more information, see [Multi-factor \(two-factor\) authentication](#).

- [add_mfa_exempt_users](#)
- [configure_mfa](#)
- [get_mfa_configuration](#)
- [remove_mfa_exempt_users](#)

Oauth APIs

The following APIs manage OAuth functions.

- [delete_oauth_clients](#)
- [getOAuthTokenExpirationTime](#)
- [list_oauth_clients](#)
- [modify_oauth_validity](#)
- [register_oauth_client](#)
- [register_oauth_internal_client](#)
- [revokeOAuthClient](#)
- [revokeOAuthToken](#)
- [setOAuthTokenExpirationTime](#)

Role and user APIs

The following APIs manage users, roles, and role relationships. For more information about setting roles, see [Security Roles](#).

Note: In a central management environment, the object to which you want to add a role might reside on either the central manager or on a managed unit.

- [create_role](#)
- [create_user](#)
- [delete_user](#)
- [grant_role_to_object_by_id](#)
- [grant_role_to_object_by_Name](#)
- [list_roles](#)

Big Data Intelligence APIs

Run these commands, on your central manager, to manage extraction of datamarts to the Big Data datasource (GBDI), and to pull big data into Guardium for monitoring, reports, and so on.

Big Data Intelligence functions are:

- [add_dm_to_profile](#)
- [clone_extraction_profile](#)
- [disable_big_data_interface](#)
- [enable_big_data_interface](#)
- [get_extraction_profile_info](#)
- [local_disable_big_data_intelligence](#)
- [local_enable_big_data_interface](#)
- [remove_dm_from_profile](#)
- [remove_extraction_profile](#)
- [replace_active_profile](#)

Catalog entry APIs

Use these commands to manage catalog entries. Catalogs are used to track data archive files and result archive files that were created on the servers.

The catalog entry functions are:

- [create_entry_location](#)
 - [delete_entry_location](#)
 - [list_entry_location](#)
 - [update_entry_location](#)
-

Central management APIs

Use these APIs to view and set load balancing parameters, view the current load map, manage S-TAP® and managed unit group associations, and manage backup central managers.

Load balancing APIs

- [assign_load_balancer_groups](#)
- [get_load_balancer_load_map](#)
- [get_load_balancer_params](#)
- [set_load_balancer_param](#)
- [unassign_load_balancer_groups](#)

Other APIs

- [get_unit_data](#)
- [get_unit_pinger](#)
- [update_managed_units_ping_time](#)

Central manager APIs

- [backup_cm_list_candidates](#)
- [backup_cm_set](#)
- [list_managed_units](#)
- [make_primary_cm](#)
- [restart_all_managed_units](#)
- [restore_units_after_bad_shift](#)
- [set_certificate_host_validation](#)
- [show_backup_cm_ip](#)

Classification APIs

Use the following GuardAPI commands for Classification policy configuration, for test automation and, for scripting of prerequisite data preparation.

Note: Some discovery and classification settings are configured using the [modify_guard_param](#) command. For more information, see [modify_guard_param](#).

- [add_classifier_datasource](#)
- [add_classifier_datasource_group](#)
- [create_classifier_action](#)
- [create_classifier_policy](#)
- [create_classifier_process](#)
- [create_classifier_rule](#)
- [delete_classifier_action](#)
- [delete_classifier_policy](#)
- [delete_classifier_process](#)
- [delete_classifier_rule](#)
- [execute_cls_process](#)
- [get_job_process_concurrency_limit](#)
- [list_classifier_policy](#)
- [list_classifier_process](#)
- [set_job_process_concurrency_limit](#)
- [remove_classifier_datasource](#)
- [remove_classifier_datasource_group](#)
- [update_classifier_action](#)
- [update_classifier_log_level](#)
- [update_classifier_policy](#)
- [update_classifier_process](#)
- [update_classifier_rule](#)

Cloud datasource APIs

Use these commands to define, manage, update, and delete cloud datasources.

The cloud datasource APIs are

- [add_stream](#)
- [assign_collectors](#)
- [configure_data_streaming](#)
- [create_cloudTitle](#)
- [create_cloud_datasource](#)
- [delete_stream](#)
- [disable_datastream](#)
- [discover_streams](#)
- [enable_datastream](#)
- [enable_disable_monitoring_streams](#)
- [get_streams](#)
- [list_cloud_datasource_by_name](#)
- [restart_cloud_instance](#)
- [update_cloud_datasource](#)

Configuration Auditing System (CAS) APIs

Use these commands to configure and manage Configuration Auditing System (CAS) hosts, templates, and template sets.

The CAS functions are:

- [clear cas template set](#)
- [clone cas template set](#)
- [create cas host instance](#)
- [create cas template](#)
- [create cas template set](#)
- [delete cas host](#)
- [delete cas host instance](#)
- [delete cas template](#)
- [delete cas template set](#)
- [list cas hosts](#)
- [list cas host instances](#)
- [list cas templates](#)
- [list cas template sets](#)
- [update cas host instance](#)
- [update cas template](#)

Related concepts

- [list_datasourceRef_by_id](#)
- [list_datasourceRef_by_name](#)

Mongo DB datasource APIs

- [load_mongodb](#)
- [load_mongodb_by_datasource](#)

Datasource credential management APIs

Use these commands to manage datasource credentials.

AWS Secrets Manager APIs

- [create_aws_secrets_manager_config](#)
- [delete_aws_secrets_manager_config](#)
- [list_aws_secrets_manager_config](#)
- [update_aws_secrets_manager_config](#)

For more information about the AWS secrets manager, see [Managing datasource credentials with AWS Secrets Manager](#).

CyberArk APIs

- [create_cyberark_config](#)
- [delete_cyberark_config](#)

- [list_cyberark_config](#)
- [update_cyberark_config](#)
- [verify_cyberark_access](#)

For more information about CyberArk, see [Managing datasource credentials with CyberArk](#).

HashiCorp APIs

- [create_hashicorp_config](#)
- [delete_hashicorp_config](#)
- [list_hashicorp_config](#)
- [test_hashicorp_connection](#)
- [update_hashicorp_config](#)

For more information about HashiCorp, see [Managing datasource credentials with HashiCorp](#).

Entitlement optimization APIs

Use these API commands to enable and configure the Entitlement optimization datasources and reporting.

- [add_datasource_to_entitlement_optimization](#)
- [disable_entitlement_optimization](#)
- [enable_entitlement_optimization](#)
- [get_entitlement_optimization_info](#)
- [remove_datasource_from_entitlement_optimization](#)
- [set_entitlement_datasource_parameter](#)

Related concepts

External feed APIs

Use these commands to create mappings for external feeds.

- [create_ef_mapping](#)
- [delete_ef_mapping](#)
- [list_ef_mapping](#)
- [list_ef_report](#)
- [modify_ef_mapping](#)
- [modify_ef_sql_mode](#)

File Activity Monitor APIs

Use the following GuardAPI commands to enable and disable the file activity monitor, configure the file Investigation Dashboard activity and entitlement extractions schedule, and get information on the file activity monitor.

The File Activity Monitoring functions are:

- [add_action_to_fam_rule](#)
- [create_fam_rule](#)
- [create_policy](#)
- [delete_policy](#)
- [disable_fam_crawler](#)
- [enable_fam_crawler](#)
- [get_fam_crawler_info](#)
- [list_policy_fam_rule](#)
- [policy_fam_rule_delete](#)

Related concepts

- [update_alias](#)
- [update_group_by_desc](#)
- [update_group_by_id](#)

Related concepts

- [Groups](#)

Health analyzer APIs

Use these commands to configure the disk and database health analyzer.

Note: Some disk and database health analyzer settings are configured using the `modify_guard_param` command. For more information, see [modify_guard_param](#).

- [disable_health_analyzer](#)
- [enable_health_analyzer](#)
- [enable_health_traffic_job](#)
- [get_health_traffic_status](#)
- [set_health_traffic_job_interval](#)

Hadoop monitoring APIs

Use these APIs to add, update, delete, and view the clusters and services on the clusters for all types monitoring on Hadoop.

Hadoop integration using Ranger HDFS for Hortonworks and Cloudera 7

The commands for Cloudera 7 HDFS configuration are:

- [add_ranger_hdfs_config](#)
- [delete_ranger_hdfs_config](#)
- [get_ranger_hdfs_config](#)
- [update_ranger_hdfs_config](#)

Hadoop integration using Hortonworks and Apache Ranger Log4J

The commands for Apache Ranger configuration are:

- [add_ranger_config](#)
- [add_ranger_service](#)
- [disable_monitoring_ranger_service](#)
- [enable_monitoring_ranger_service](#)
- [get.hadoop_cluster_status](#)
- [get_ranger_config](#)
- [get_ranger_services_status](#)
- [list_ranger_configs](#)

- [list_ranger_staps](#)
- [remove_ranger_config](#)
- [remove_ranger_service](#)
- [update_ranger_config](#)
- [update_ranger_service](#)

Miscellaneous APIs

Use these commands for various tasks that do not fall into other categories.

Other miscellaneous APIs

- [change_to_opensource](#)
- [export_certificate](#)
- [export_config](#)
- [encrypt_value](#)
- [nscd](#)
- [pause_or_resume_scenarios](#)
- [venafi_import](#)
- [wkc refresh_external_pwd](#)

Change tracker APIs

- [change_tracker_get_events](#)
- [change_tracker_get_params](#)
- [change_tracker_get_tasks](#)
- [change_tracker_reset](#)
- [change_tracker_set_params](#)

Custom table distribution APIs

- [delete_cust_table_distribution_schedule](#)
- [sched_cust_table_distribution](#)

Discovered instances APIs

- [apply_rules_on_discoveredinstances](#)
- [run_database_instance_discovery](#)

Eastern font APIs

- [disable_embed_eastern_font](#)
- [enable_embed_eastern_font](#)

F5 integration APIs

- [f5_add_apps_config](#)
- [f5_add_data_params](#)
- [f5_delete_apps_config](#)
- [f5_delete_data_params](#)
- [f5_list_apps_config](#)
- [f5_list_data_params](#)
- [f5_update_data_params](#)

FIPS mode APIs

- [clevus_bind](#)
- [enable_fips_tls](#)
- [fipsmode](#)

IP Aliasing APIs

- [disable_ip_to_host_aliases](#)
- [enable_ip_to_host_aliases](#)
- [get_ip_to_alias_overwrites](#)
- [get_ip_to_alias_selected](#)
- [set_ip_to_alias_overwrites](#)
- [set_ip_to_alias_selected](#)

Keystore APIs

- [copy_key_file](#)
- [pull_external_stap_keystore](#)

Modifiable guard_param APIs

- [get_all_modifiable_guard_params](#)
- [get_guard_param](#)
- [modify_guard_param](#)
- [push_parameter_to_mu](#)

Patch APIs

- [patch_cleanup](#)
- [patch_install](#)

REST APIs

The following APIs are only available as REST APIs and are generally used to find and manage other REST APIs.

- [create_online_report](#)
- [get_definitions_data_sets](#)
- [get_definitions_items](#)
- [import_definitions](#)
- [rest_export_definition](#)
- [retrieveAPIs](#)
- [retrieveApiParameters](#)

Session inference APIs

- [session_inference_control](#)
- [session_inference_setup](#)

TLS protocol APIs

- [enable_all_tls](#)
- [enable_fips_tls](#)
- [enable_latest_tls](#)
- [get_secured_protocols_info](#)

Unit pinger APIs

- [get_unit_pinger](#)
- [restart_unit_pinger](#)

Unit utilization APIs

- [list_utilization_thresholds](#)
- [reset_unit_utilization_data](#)
- [update_utilization_thresholds](#)

z/OS IMS checkpoint APIs

- [delete_imscheckpoint_record](#)
- [list_imscheckpoint_records](#)

Native audit APIs

Use these commands to enable or disable DB Audit (native audit) on a cloud database, add and remove objects from the Object Audit (audit trail), and get configuration, collectors, and objects details.

The Native Audit functions are:

- [add_ip_to_sg](#)
- [add_objects_native_audit](#)
- [disable_native_audit](#)
- [enable_native_audit](#)
- [get_native_audit_collectors](#)
- [get_native_audit_configurations](#)
- [get_native_audit_objects](#)
- [remove_objects_native_audit](#)

Related tasks

- [Cloud database service protection with native audit](#)

Outliers detection APIs

Use these API commands to enable, disable, and configure the Outliers Detection function.

- [disable_outliers_detection](#)
- [disable_outliers_detection_agg](#)
- [disable_outliers_detection_cross_cm_agg](#)
- [disable_outliers_detection_cross_cm_collector](#)
- [enable_outliers_detection](#)
- [enable_outliers_detection_agg](#)
- [enable_outliers_detection_cross_cm_agg](#)
- [enable_outliers_detection_cross_cm_collector](#)
- [get_outliers_detection_info](#)
- [reregister_agg_collector](#)
- [set_outliers_detection_demo_mode](#)
- [set_outliers_detection_parameter](#)
- [set_outliers_detection_to_factory_settings](#)
- [set_outliers_user_detection_mode](#)
- [switch_outliers_user_mode](#)

Related concepts

Policy and rule APIs

Use these commands to manage policies and policy rules.

Policy APIs

- [clone_policy](#)
- [create_policy](#)
- [delete_policy](#)
- [list_installed_policies](#)
- [list_policy](#)
- [list_policy_rules](#)
- [policy_install](#)
- [policy_uninstall](#)

- [reinstall_policy](#)
- [reinstall_policy_rule](#)
- [rule_info_from_policy](#)
- [uninstall_policy_rule](#)
- [update_policy](#)

Policy Analyzer APIs

- [create_adhoc_policy_analyzer](#)
- [delete_adhoc_policy_analyzer](#)
- [disable_policy_analyzer](#)
- [enable_policy_analyzer](#)
- [get_policy_analyzer_status](#)
- [list_adhoc_policy_analyzer](#)
- [update_policy_analyzer_interval](#)

Rule APIs

- [add_receiver_to_rule_action](#)
- [change_rule_order](#)
- [copy_rule](#)
- [copy_rules](#)
- [create_rule](#)
- [create_rule_action](#)
- [delete_rule](#)
- [update_rule](#)

Process Control APIs

Use these commands to manage various process control functions.

- [close_default_events](#)
- [execute_appUserTranslation](#)
- [execute_assessment](#)
- [execute_incidentGenProcess](#)
- [execute_incidentGenProcess_byDetails](#)
- [execute_flatLogProcess](#)
- [execute_ldap_user_import](#)
- [export_log_files](#)
- [execute_populateGroupFromQuery](#)
- [get_flatLogProcessType](#)
- [get_ztap_logging_config](#)
- [kill_running_process](#)
- [list_health_node](#)
- [list_running_processes](#)
- [must_gather](#)
- [restart_job_queue_listener](#)
- [set_flatLogProcessType](#)
- [set_ztap_logging_config](#)
- [upload_custom_data](#)

Audit process APIs

- [audit_process_run_status](#)
- [delete_audit_process](#)
- [delete_audit_process_result](#)
- [execute_auditProcess](#)
- [list_audit_processes](#)
- [stop_audit_process](#)

Quarantine APIs

Use these APIs to manage quarantines for specified users. A user under quarantine cannot log in to the specified database.

- [create_quarantine_allowed_until](#)
- [create_quarantine_until](#)
- [delete_quarantine](#)
- [update_quarantine_allowed_until](#)
- [update_quarantine_until](#)

Query rewrite APIs

Use these commands to automate testing or create definitions for certain complex queries that cannot be done from the user interface.

Note: If you create query rewrite definitions by using APIs, you can still use the UI to retrieve those definitions for testing with the Query Rewrite Builder.

- [assign_gr_condition_to_action](#)
- [create_gr_action](#)
- [create_gr_add_where](#)
- [create_gr_add_where_by_id](#)
- [create_gr_condition](#)
- [create_gr_definition](#)
- [create_gr_replace_element](#)
- [create_gr_replace_element_byId](#)
- [list_gr_action](#)
- [list_gr_add_where](#)
- [list_gr_add_where_by_id](#)
- [list_gr_condition](#)
- [list_gr_condition_to_action](#)
- [list_gr_definitions](#)
- [list_gr_replace_element](#)
- [list_gr_replace_element_byId](#)
- [remove_all_gr_replace_elements](#)
- [remove_all_gr_replace_elements_byId](#)
- [remove_gr_action](#)
- [remove_gr_add_where_by_id](#)
- [remove_gr_condition](#)
- [remove_gr_definition](#)
- [remove_gr_replace_element_byId](#)
- [unassign_gr_condition_from_action](#)
- [update_gr_action](#)
- [update_gr_add_where_by_id](#)
- [update_gr_condition](#)
- [update_gr_definition](#)
- [update_gr_replace_element_byId](#)

Reports and report generation APIs

Use report generation APIs to manage reports and distributed reports, and to take the output from one Guardium® report or entity and feed it as the input for another Guardium entity.

Report APIs

Use these APIs to see the reports on a Guardium system, and to set or view parameters used in reports:

- [list_all_reports](#)
- [list_parameter_names_by_report_name](#)
- [show_maximum_query_duration](#)
- [store_maximum_query_duration](#)

Distributed report APIs

Use these APIs to manage distributed reports:

- [cancel_distributed_report_target](#)
- [delete_distributed_report_result_for_period](#)
- [get_distributed_report_target_info](#)
- [rerun_distributed_report](#)
- [set_distributed_report_target](#)

Ad hoc audit APIs

You can invoke the ad hoc audit APIs automatically from any report.

- [create_ad_hoc_audit_and_run_once](#)
- [create_ad_hoc_audit_and_run_with_name](#)
- [create_ad_hoc_audit_for_security_assessment](#)

Attribute and mapping APIs for reports

Use the following APIs to map API parameters to domain entities and attributes for reporting.

- [create_api_parameter_mapping](#)
- [create_computed_attribute](#)
- [create_constant_attribute](#)
- [delete_api_parameter_mapping](#)
- [delete_computed_attribute](#)
- [delete_constant_attribute](#)
- [disable_special_attributes](#)
- [enable_special_attributes](#)
- [list_param_mapping_for_function](#)
- [update_computed_attribute](#)
- [update_constant_attribute](#)

Related tasks

- [Working with API calls and reports](#)

Schedule and job dependencies APIs

Use these APIs to set schedules for and dependencies between jobs.

Job dependencies APIs

- [auto_execute_suggested_dependencies](#)
- [disable_auto_execute_suggested_dependencies](#)
- [list_existing_job_dependencies](#)
- [modify_job_dependency](#)
- [populate_from_dependencies](#)

Schedule APIs

- [add_all_to_schedule](#)
- [add_time_period](#)
- [delete_schedule](#)
- [list_schedules](#)
- [list_scheduler_jobs](#)
- [modify_schedule](#)
- [pause_or_resume_job](#)
- [remove_all_from_schedule](#)
- [schedule_job](#)

Related concepts

- [Scheduling](#)
- [Job dependencies](#)

Solr APIs

Run these commands on your central manager and managed units to manage their (internal Guardium) Solr database.

The Solr commands are:

- [get_solr_cluster_info](#)
- [getFieldsTitles](#)
- [get_solr_errors](#)
- [get_solr_status](#)
- [get_solr_status_extended](#)
- [restart_solr](#)
- [search](#)
- [stop_solr](#)
- [test_solr](#)
- [test_solr_connectivity](#)
- [test_solr_hardware_requirements](#)

Related information

- [Troubleshooting the investigation dashboard and enterprise search](#)

S-TAP and inspection engine APIs

Use these commands to manage your S-TAPs and their inspection engines.

- [add_approved_stap_client](#)
- [create_stap_inspection_engine](#)
- [delete_approved_stap_client](#)
- [delete_inactive_stap](#)
- [delete_invalid_stap](#)
- [delete_stap_inspection_engine](#)
- [display_stap_config](#)
- [list_approved_stap_client](#)

- [verify_stap_inspection_engine_with_sequence](#)

S-TAP and Oracle Unified Auditing APIs

- [create_sql_configuration](#)
- [delete_sql_configuration](#)
- [store_sql_credentials](#)

S-TAP for IBM i APIs

Use these commands to create, list, delete, restart, and set i-S-TAP® functions.

The S-TAP for IBM i functions are:

- [get_istap_config](#)
- [get_istap_status](#)
- [start_istap_monitor](#)
- [stop_istap_monitor](#)
- [update_istap_config](#)

For more information, see [Db2 for IBM i S-TAP](#).

Threat detection analytics APIs

Use these GuardAPI commands to configure threat detection analytics.

The threat detection analytics commands are:

- [assign_analytic_case](#)
- [delete_analytic_user_feedback](#)
- [disable_advanced_threat_scanning](#)
- [disable_threat_detection_use_case](#)
- [enable_advanced_threat_scanning](#)
- [enable_threat_detection_use_case](#)
- [get_threat_detection_use_case_info](#)

Related concepts

- [Threat detection analytics](#)
