| workload-replay-user  | A user that is specified by this role can run the workload-replay functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| tam                   | A user that is specified by this role can define and modify the File Activity Monitor functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BaselII               | Accelerator - Basel II. This role can not be deleted.<br><br>Basel II Part 2 Sections 4 and 5 require that banking institutions must define a Securitization Framework around financial information and estimate the associated operational risk.                                                                                                                                                                                                                                                                                                         |
| DataPrivacy           | Accelerator - DataPrivacy. This role can not be deleted.<br><br>The Data Privacy Accelerator delivers a portfolio of pre-configured policies, real-time alerts, and audit reports that are specifically tailored to the challenges of identify theft and based on industry best practices. With the Data Privacy Accelerator, security managers, privacy officers, and database administrators begin by defining combinations of data elements – called "privacy sets" – whose access may indicate hacking or inappropriate activities by internal users. |
| GDPR                  | Accelerator - GDPR. This role can not be deleted.<br><br>The Guardium GDPR accelerator provides the GDPR workflow for data ,and predefined reports based on GDPR groups and policies. To begin working with the GDPR accelerator, assign the GDPR role to a Guardium user, then navigate to Accelerators > GDPR with that user account.                                                                                                                                                                                                                   |
| GDPR FAM              | Accelerator - GDPR FAM. This role can not be deleted.<br><br>The Guardium GDPR FAM accelerator provides the GDPR workflow for file servers, and predefined reports based on GDPR groups and policies. To begin working with the GDPR FAM accelerator, assign the GDPR FAM role to a Guardium user, then navigate to Accelerators > GDPR with that user account.                                                                                                                                                                                           |

| Sample Role | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pci         | Accelerator - PCI. This role can not be deleted.<br>The PCI DSS is a set of technical and operational requirements designed to protect cardholder data and applies to all organizations who store, process, use, or transmit cardholder data. Failure to comply can mean loss of privileges, stiff fines, and, in the case of a data breach, severe loss of consumer confidence in your brand or services. The IBM® Guardium accelerator helps guide you through the process of complying with parts of the standard using predefined policies, reports, group definitions, and more. |
| sox         | Accelerator - SOX. This role can not be deleted.<br>SOX Section 404 requires that companies must establish and maintain an adequate internal control structure and procedures for financial reporting.                                                                                                                                                                                                                                                                                                                                                                                |

## Roles in a Central Manager Environment

In Central Manager environments, all User Accounts, Roles, and Permissions are controlled by the Central Manager. To administer any of these definitions, you must be logged in to the Central Manager (and not to a managed unit).

### Create a Role

1. Login as accessmgr, and open the User Role Browser by clicking Access > Access Management > Role Browser.
2. Click Add Role to open the Role Form panel.
3. Enter a unique name for Role Name and click Add Role.

### Remove a Role

1. Open the User Role Browser by clicking Access > Access Management > Role Browser.
2. Click Delete for any role (some roles cannot be removed, and do not have the Delete option). This opens the Role Form for the role.
3. Click Confirm Deletion. A message displays informing you that all references to the role are removed, and you will be asked to confirm the action.
4. Click OK to confirm the deletion, or Cancel to abort the operation.

## Access for default roles and applications

This topic lists user interfaces and other tools associated with the default roles and applications used for access management.

Use this information for auditing the Guardium functionality users can access when they are assigned specific roles.

Important:

- Not all functionality is available on all systems. The specific functions available on a system are determined by several factors including the Guardium version, the system configuration (standalone, central manager, etc.), and the installed licenses.
- Not all accessible user interfaces are displayed in the navigation by default, but a user can configure their navigation to display any user interface that is accessible to their roles. For more information, see [Customizing the user interface](#).

| Access management application             | Default Roles | Access                                                                                                                                                                                                                                                                                                                               |

## Managing roles and permissions

Roles and permissions provide different levels of access to users based on their job duties.

Examples of roles include user, admin, and audit. Using roles allows you to easily define permissions for an entire group of users. Only access managers can create new roles and assign users to that role. As part of role creation, access managers can also customize the navigation menu and permissions for that role.

Creating customized roles involves several processes:

- Creating a new role
- Managing permissions for the role to limit what users can access
- Optionally customizing the navigation menu for the role to further limit what users can see
- Adding users to the role

There are two ways to limit access to specific applications:

Limit access from the application

Limit access from the application by deselecting the All Roles check box on the Role Permissions > Edit Application Role Permissions screen. Next, select the individual roles that should have access to the application.

The process is the same if you find that the All Roles check box is already deselected: simply select or deselect the individual roles to grant or revoke access to the application.

When All Roles is selected for a particular application, every currently-defined role will have access to that application.

Limit access from the role

Limit access from the role by navigating to the Role Browser > Manage Permissions screen and move individual applications from the Accessible applications list to the Inaccessible applications list.

When managing permissions or customizing the navigation menu for a new role, the defaults shown in the Accessible applications list reflects any application with the All Roles check box selected on the Role Permissions > Edit Application Role Permissions screen.

When working with roles and permissions, removing permissions for an application also changes the default permissions for new roles. That is, removing permissions for an application means that any subsequent roles you create will also lack permissions for that application. If you want a new role to have permissions for an application that no longer appears in the Accessible applications list by default, you will need to move the desired application from the Inaccessible applications list to the Accessible applications list for the new role.

It is also possible to restrict access to specific tools by hiding menu items using the Role Browser.[Customize Navigation Menu](#) tool. This approach limits access without altering the default application permissions, but it may be less secure than a permissions-based approach.

#### Best Practices:

- After editing permissions for a role, review the navigation layout for that role as shown on the Role Browser.[Customize Navigation Menu](#) screen. Add or remove items from the Navigation Menu list as needed to create a layout appropriate for the role.
- Copy and edit predefined roles to establish the desired permissions and navigation menu. This approach allows you to revert to the original role if needed.
- Be aware that when copying existing roles, whether predefined or customized, all permissions from the existing role are copied to the new role.

## How to create a role with minimal access

This topic explains how to create a new role with minimal access permissions, for example an auditor role that can only access the Audit Process To-Do List and view specific reports.

## Procedure

---

1. Create a new role.
  - a. Log in as *accessmgr*, navigate to Access.[Access Management](#), and select the Role Browser.
  - b. Click the Add Role button, give the role a name, and click the Add Role button to create the new role.
2. Manage permissions so the new role can only access the Audit Process To-Do List and the Report Builder (which is required for viewing reports).
  - a. From the Role Browser, click the Manage Permissions link for the new role.
  - b. Select the checkbox in the header of the Accessible Items list and use the arrow to move all items to the Inaccessible Items list.  
When creating a highly restricted role, it is easier to begin by removing permissions.
  - c. In the Inaccessible Items list, select the Audit Process To-Do List and the Report Builder, and use the arrow to move them back to the Accessible items list.  
The new role now has access to only these two specific applications.
  - d. Click the OK button to commit your changes.
3. Customize the menus and navigation by defining which reports and applications are available to the new role.
  - a. From the Role Browser, click the Customize Navigation Menu link for the new role.
  - b. In the Navigation Menu list, select the Reports group so it is highlighted.  
The selected group acts as the destination for menu items added in subsequent steps.
  - c. In the Available Tools and Reports list, expand the Reports section or use the Filter to identify specific reports, select the check box next to each item that should be available to the new role, and use the arrow to add the items to the Navigation Menu list.  
Items moved into the Navigation Menu list will become visible to users assigned to this role.
  - d. In the Navigation Menu list, remove access to the Report Builder by clicking the icons next to the Reports.[Report Configuration Tools](#) and Investigate groups.  
This further simplifies the menu structure for this role and removes access to the Report Builder tool without also removing application permissions that are required to access reports.
  - e. Click the OK button to commit your changes.  
You have now created a new role with very minimal privileges that can be assigned to users.
4. Optionally specify a custom home page for the new role.
  - a. From the Role Browser, click the Customize Navigation Menu link for the new role.
  - b. In the Navigation Menu list, specify a new default home page by selecting Comply.[Tools and Views](#).[Audit Process To-Do List](#) and clicking the icon in the toolbar.  
Users assigned to this role will now see the Audit Process To-Do List as the default screen after logging in.
  - c. Click the OK button to commit your changes.
5. Create a new user and add that user to the new role.
  - a. Navigate to Access.[Access Management](#) and select User Browser.
  - b. Click Add User, provide the required information, and click Add User to create the new user.  
You will now see the user you created listed in the User Browser.  
When a new user is created, the account is disabled by default. Deselect the Disabled check box if you want the user to have immediate access to their account.
  - c. From the User Browser, click the Roles link for the new user to view a list of available roles.
  - d. Select the Assign check box next to the custom role you created earlier.  
This will assign the user to the new role.
  - e. Deselect the Assign check box next to the *user* role.  
Deselecting the *user* role prevents the new user from inheriting the default *user* access and permissions.
  - f. Click Save to commit your changes.

- [Managing roles and permissions](#)

## Managing users

Use the Access Manager, assigned the username accessmgr to add user accounts, enable or disable user accounts, import members from LDAP, or edit user permissions. Open the User Browser and browse the user accounts by clicking **Access > Access Management > User Browser**.

Defining and modifying users involves deciding both who can use the Guardium® system and in which roles. A group of users can all have the same role and the same access privileges if you so choose. For more information about roles, see [Understanding Roles](#).

You can import user definitions from an LDAP server, on demand, or on a schedule.

Regardless of how users are defined to the Guardium system, the Guardium administrator can configure the system to authenticate users by using Guardium, LDAP, or Radius.

When you get started with your Guardium system, an important early task is to identify which groups of users will use the system, along with each set of user's functions. For example, an information security group might use Guardium for alerting and troubleshooting purposes while a database administrator group might use Guardium for reporting and monitoring. As you decide who can access the Guardium system, keep in mind that sensitive company data can be picked up by the system. Therefore, you need to be aware of who can access that data.

After you decide which groups of users will use the Guardium system (and for what purpose), collect the following information for each user:

- User's first and last name
- User account name (the name they use to log in)
- User's email address
- User's country or location
- User's function or role with Guardium

## User account security

Guardium provides a number of default settings to simplify the user creation process. Several settings can be changed to provide extra security for user accounts. You can enable or disable these settings by using the show and store password CLI commands. For more information, see [User Account, Password and Authentication CLI Commands](#). Defaults are set for the following settings:

- Password validation is enabled, which means that a minimum of 8 characters is required, and the password must contain at least one character from each of the following categories:
  - Uppercase letters - A-Z
  - Lowercase letters - a-z
  - Digits - 0-9
  - Special characters, as described in [Special characters for Guardium passwords](#)
- Note: If password validation is disabled, any characters are allowed.
- Password expiration is enabled. Passwords can be configured to expire after a designated number of days.
- Account lockout that follows a specified number of failed login attempts is enabled. You can configure lockouts to occur after a fixed number of attempts in a specified time, or after a total number of attempts for the life of the account.

## Unlocking locked accounts

1. From the User Browser, click Edit for the user you want to unlock.
2. Clear the Disabled checkbox.
3. Click Update User to save changes.

If an admin or accessmgr user account is locked, an admin can unlock it with the **unlock admin** or **unlock accessmgr** CLI command. For more information, see [User account, password, and authentication CLI commands](#).

## Creating a user account

1. From the User Browser click Add User to open the User Form page.
2. Enter a unique name for User name. Do not include apostrophe characters in the name. User names are not case-sensitive.  
Note: When you add a user manually, from either the Add User page or User LDAP Import, if no first name or last name is specified, the login name is used. Non-Latin characters, such as Chinese or Japanese, are not supported in the username.
3. If smart card authentication is enabled, enter the Smart card user name.  
Tip: The smart card user name is the Common Name (CN) in the Guardium system's certificate.
4. Enter a password and confirm it again in the Password (confirm) box. The password that you assign is temporary, and the user must change it following their first login.  
Passwords are case-sensitive. When password validation is enabled (the default), the password must be 8 or more characters in length, and must include at least one character from each of the following categories:
  - Uppercase letters - A-Z
  - Lowercase letters - a-z
  - Digits - 0-9
  - Special characters, as described in [Special characters for Guardium passwords](#)
5. Enter the user's first and last name in the respective fields.  
Note: To assign a user the investigator role, the last name must be INV\_1, INV\_2, or INV\_3. While the UI does not stop you from entering a different last name, the application works properly only with these names. Furthermore, you cannot assign an investigator to any additional roles; they can be only *inv*. The *inv* role is the only case where a user or admin role is not required.
6. Optionally, enter the following information:
  - The user's email address.
  - Select the user's country or region from the menu.
  - Select Password never expires to remove password expiration. The default expiration is 90 days. Keep in mind that forcing users to change their passwords is a security feature.

7. When ready, clear the Disabled checkbox to enable access to Guardium for this user.

Note: Disabled is selected by default. Guardium suggests that you do not clear the checkbox and enable the account until after you assign the correct set of roles for the user.

8. Click Add User to save the new user account definition and close the page.

Guardium suggests that you assign all roles before you enable users so that the user has all components in their layout the first time they log in. When a user logs in for the first time, their layout is built by using all of the roles that are currently assigned. If roles are added later, the user has access to everything available to that role, but must add reports or applications particular to that role manually.

The user definition is now complete. Guardium suggests that you add the appropriate roles for the user before you inform them of their password for the initial login. For more information, see [Understanding Roles](#).

For more information on adding a user by using an API command, see [Create user](#).

## Enabling or disabling multiple users

---

Open the User Browser and click Search Users to filter users by role. When you select a user, you can enable or disable the user. Because users are disabled by default, this menu can be useful to change the status of multiple users.

Note: Guardium includes the default Guardium CLI accounts, guardcli1 through guardcli9, that are enabled by default. You can disable one or more of the default users from the User Browser or by using the `store guarduser state` CLI command.

Be sure to leave at least one guardcli account enabled to allow users to log in to the GuardAPI.

For more information about using the guardcln accounts, see [Authenticating GuardAPI commands with set guisuer](#).

## Updating a user account

---

1. From the User Browser, click Edit for the user you want to modify.

2. Replace any values in the User Form page.

3. Click Update User to save changes.

Note: If you change a user's password, the user must change it again after their next login.

## Enabling a disabled user account

---

1. From the User Browser, click Edit for the user you want to enable.

2. Clear the Disabled checkbox.

3. If the user forgets their password, enter a new password in both the Password and Password (confirm) boxes.

4. Click Update User.

## Removing a user account

---

1. From the User Browser, click Delete for the user you want to remove.

2. Click Confirm Deletion.

Note: Alerts that were sent to the deleted user are now sent to the admin; however, this change does not take effect until the access policy is reinstalled.

## Defining the data security user hierarchy

---

1. Browse to Data Security > User Hierarchy.

2. Select a user from the User menu to refresh the screen and display the selected user's current hierarchy in the user page.

3. Right-click a user node for the following options:

- Click Add User to display the Add User dialog. Search or filter by role, and add a user as a descendant of the selected user.

Defining a hierarchy can create a measure of data-level security, by allowing the parent in a hierarchy to look at specified servers and databases, but not the children in the hierarchy. Depending on the configuration, inheritance can also take place in that the parent inherits the data-level security of the child.

Note: Many-to-many relationships are allowed where a user might have more than one parent and a parent might have more than one user.

- Unlink User from parent - Sever the descendant's relationship from the parent
- Remove all descendants - Sever the relationship for all descendants from the parent

4. Click Refresh Cached Hierarchy to apply the recent changes to the user hierarchy map.

5. Click Update Active User-DB Map to apply all recent changes to the active User-DB association map.

Note: Guardium suggests that you run Update Active User-DB Map after you change the User Hierarchy.

When you change a hierarchy or to a database association, this change does not take effect automatically. The Periodic Update does not pick up the change, unless it is the first time the Periodic Update runs. For the changes to take effect, run Update Active User-DB Map.

The user hierarchy is not automatically updated. To update it, run Update Active User-DB Map. The update compares all IP addresses or Service Names to the existing hierarchy and associations to determine who has access to what.

A periodic update of the user hierarchy runs automatically every 10 minutes and cannot be run manually. The periodic update is incremental, meaning that it looks only at server IP addresses or Service Names that were added since the last time the periodic update ran. It compares the existing hierarchy and associations against the new IP addresses or Service Names and determines which users can access these IP addresses or Service Names.

## Defining the data security user-database association

---

Use the Data Security User-DB Association to find, assign, or remove users from available servers and service names (databases).

1. Open the User-DB Association window by browsing to Data Security > User-DB Association.

2. Select the checkboxes of the Server & Service Name Suggestion to find databases and service names to associate to users. Choices include:

- Observed Accesses - Observed traffic from Guardium internal database table GDM\_Access

- Datasource Definitions - Existing datasource definition information such as name, database type, authentication information, and location of datasource.
  - S-TAP Definitions - Existing S-TAP definition information such as the IP address of the database server and the IP address of the Guardium host that receives data from S-TAP.
  - Auto-Discovered Hosts - Hosts discovered by the Guardium Auto-discovery process that were not previously known. You can configure the Guardium Auto-discovery application to probe the network, searching for and reporting on all databases discovered.
  - Guardium Install Manager (GIM)-Discovered Systems - Hosts that are discovered by the GIM that are not previously known.
3. Click Go to find and display available servers, service names, and currently associated users.
- Note: When Guardium traverses the node tree, numerical indicators are displayed next to each server and service name to provide a count of direct and descendant associated users. The indicators take the format of [nn] for direct association and (mm) for descendant association (for example, when a server or service name within the current server has an associated user). Likewise, when you view users that are associated to a server or service name, if a user is associated to a larger level node in the tree, that user displays.
4. Click a server or service name node to display associated users. With any node selected, you can do one of the following tasks:
- Click Add User to add a user-DB association, click any users that you want to add, and then click Add.
  - Click Add Group to add a group-DB association. When Add Group is selected, groups that are created by using the Group Builder for group type Guardium Users display. Select the group you'd like to add and click Add.
5. Right-click any server or service name node to select one of the following tasks:
- Highlight the server.
  - Expand or collapse the server.
  - Find a server.
  - Add server, service name, or unnamed service.
  - Delete the server.
6. Add an IP address or IP/Service Name pair in the IP and Service Name fields.

Note: Use Find to search the IP/Service Name tree structure. You can enter partial IP strings or include the asterisk wildcard (\*) so that, for example, 192.168 and 192.168.\* are both valid. Numeric values cannot trail the use of any wildcard or be used with the wildcard to form an octet. Service Name names can include the wildcard % anywhere within their name.

7. Click Update Active User-DB Map to apply all recent changes to the active User-DB association map.

Note: Guardium suggests that you run Update Active User-DB Map after you change the User-DB Association.

The user hierarchy is not automatically updated. To update it, run Update Active User-DB Map. The update compares all IP addresses or Service Names to the existing hierarchy and associations to determine who has access to what.

A periodic update of the user hierarchy runs automatically every 10 minutes and cannot be run manually. The periodic update is incremental, meaning that it looks only at new server IP addresses or Service Names that were added since the last time the periodic update ran. The periodic update compares the existing hierarchy and associations against the new IP addresses or Service Names and determines which users can access these IP addresses or Service Names.

When you change a database association, this change does not take effect automatically. The periodic update does not pick up the change, unless it is the first time the periodic update runs. Otherwise, for the change to take effect, click Update Active User-DB Map.

## Managing smart card authentication

---

When smart card authentication is enabled, admin and access managers can log into the Guardium system without using a smart card. For more information, see [store system admin-only](#).

The Smart card user name is an editable field in the Guardium Portal UI that is manually populated by admins or access managers when new users are created. To authenticate a user, the Guardium system attempts to match the information on the smart card with either the User name field or the Smart card user name field.

If you upgraded your Guardium system from a previous version that did not include the Smart card user name field, the system authenticates by using the User name.

In the event that the Smart card user name is not populated but the User name is matched, the system automatically copies the value in the User name field to the Smart card user name field.

If the common name on the Guardium system's certificate is changed, the admin or access manager can manually edit the Smart card user name to match the common name. The system can then authenticate by using the Smart card user name even if the User name no longer matches.

During LDAP import, all users are imported with their existing user names. Admins or access managers can then manually add the valid common name in the certificate as the Smart card user name for authenticating by using smart cards without losing any related settings.

## Managing Guardium credentials with CyberArk

---

You can use CyberArk to manage your Guardium credentials. For more information on this application, access the CyberArk Marketplace web page and search for Guardium.

## Creating a user who can run GuardAPI commands

---

Create a user who has the proper roles and entitlements to run GuardAPI commands from the command-line interface (CLI).

### About this task

---

You can use the Guardium CLI to run both CLI commands and GuardAPI functions. This task describes how to create a user with access to the GuardAPI functions.

Note: Only the cli and guardcli1 to guardcli9 users can log in to the CLI and view or run CLI commands.

### Procedure

---

1. Log in as accessmgr to create a user who can use GuardAPI commands. Select Access > Access Management > User Browser to open the User Browser.

2. From the User Browser pane, click Add User.
3. Complete the User Form. To enable the user immediately, clear the Disabled checkbox. Click Add User to create the user. The first time the new user logs in, they must change the password.
4. From the User Browser, click Roles for the new user to display the User Role Form pane.
5. Select CLI, along with any additional roles that the user requires.  
Note: Many GuardAPI commands are associated with specific applications and their roles. That is, only a user with the accessmgr role can view and run access management commands (such as `create_user`).
6. Click Save to grant the specified roles to this user.

## What to do next

---

After you create a user with the CLI role (along with any other roles they need), that user can log in and use the CLI as follows:

1. From the CLI, log in as one of the `guardcli` users (that is, `guardcli1` to `guardcli9`). For example:

```
ssh guardcli2@company.com
```

2. Run the `set guouser` CLI command to associate the new user with the `guardcli` user. The first time the user logs in, they are prompted to change their password. For example, if you created a user with CLI privileges for Hadrian Swall:

```
company.com> set guouser Hadrian.Swall
Enter current password:
First login as Hadrian.Swall. Please change the default password.
Enter new password:
Re-enter new password:
ok
```

For more information about `set guouser`, see [User Account, Password, and Authentication CLI Commands](#).

3. The user, Hadrian Swall, can now access to any GuardAPI commands that are available for the associated roles.

## Importing users from LDAP

---

You can import Guardium® user definitions from one or more LDAP servers by configuring an operation that imports the set of users who need Guardium access.

You can run the import operation on demand, or schedule it to run on a periodic basis. You can elect to import only new users, or replace existing user definitions. In either case, LDAP groups can be imported as Guardium roles.

When you import LDAP users,

- The Guardium admin user definition is not changed in any way.
- Existing users are not deleted unless you select the Delete user if not on the import list option.
- Guardium passwords are not changed.
- New users who are added to Guardium:
  - Are marked inactive by default.
  - Have blank passwords.
  - Are assigned the user role.

Notes:

- You cannot use special characters in usernames.
- When you add a user manually via access management (either from Add User or LDAP user import), if no given name or surname is provided, the login name is used.

## Configuring the LDAP server connection

---

To open the LDAP User Import page, browse to Access > LDAP User Import from the Guardium access manager.

Note: To configure LDAP user import, the accessmgr user must have privileges to run the group builder. In certain situations, when changes are made to the role privileges, accessmgr's privilege to group builder can be removed. In this case, you cannot save or run LDAP user import. From the access management portal, select Role Permissions. From Group Builder, select Roles. Make sure that either All Roles or accessmgr is selected.

1. To configure an LDAP server for user import, click  to open the Create LDAP Configuration window. In the LDAP Config tab, enter the following information:

- LDAP host name - The IP address or host name for the LDAP server to access.
- Port - The port number for connecting to the LDAP server.
- Server type - The LDAP server type.
- Use SSL connection - Select if Guardium connects to your LDAP server using an SSL (secure socket layer) connection.
- Base DN - The node in the tree at which to begin searching for the LDAP server. The following example shows a Base DN entry for a company tree,

```
DC=encore,DC=corp,DC=root
```

- Log in as and Password The user account information that is needed to connect to the LDAP server.
- Search Filter Scope - Defines the search level. Select One-Level to apply the search to the base level only, or select Sub-Tree to include levels underneath the base level.
- Import Limit - The maximum number of items to return. Guardium recommends that you use this field only to test new queries or modifications to existing queries so that you do not inadvertently load an excessive number of members.
- Search Filter - Defines a base DN, scope, and search filter. Typically, imports are based on membership in an LDAP group, so you want to use the memberOf keyword. For example,

```
memberOf=CN=syyTestGroup,DC=encore,DC=corp,DC=root
```

- Disable user if not on the import list - Allows you to automatically disable users who are not explicitly added to Guardium.

2. Click Test Connection to test the connection to the LDAP server, and then Save to save your changes.

## Configuring the import process

---

After you configure the connection to the LDAP server, select the Import Config tab to configure the process of importing users and roles from LDAP.

In the Import Config tab, enter the following information to import users:

- LDAP host name - The IP address or host name of the LDAP server (from the LDAP Config tab).
- Domain - A unique identifier for this LDAP server. The same user ID (sAMAccountName) might exist in more than one domain, so Guardium needs a way to distinguish between the users in separate domains. If an existing user is already loaded from another domain, the current LDAP domain is appended to the username from LDAP to create the Guardium user: <user>@<domain>. In general, do not update the LDAP server domain after you import users because the domain might be part of the username. If you do update the LDAP server domain, Guardium updates any usernames from the old domain to the new domain (that is, from user@old\_domain to <user@new\_domain>).

Note: If your site is upgrading to Guardium 11.4 or later, you must populate the domain field after the upgrade.

- Import mode - If you choose to import existing users, then select whether to keep or override the existing attributes for those users.
- Delete user if not on the import list - Delete existing Guardium users who were previously imported from the same LDAP server, but are no longer in LDAP. Use this option to help keep Guardium users in sync with the LDAP server.
- Enable new imported users - Enable users as soon as they are imported. If you do not select this option, then enable new users from the access manager User Browser.
- User RDN Type - LDAP users are identified by the User RDN Type. The default User RDN type is *uid*. However, work with your Guardium administrator to determine what value to use.

Note: The following RDN values require special processing:

- For *uid* - Always specify the RDN type as *uid=search*. For example,

```
uid=search
```

- For *sAMAccountName* - Specify the RDN type as either *=search* or *=[domain name]* in the users' full names. For example,

```
sAMAccountName=search, sAMAccountName=dom
```

- Object class for user - Search filter for object class of user DN in LDAP. For example,

```
(objectClass=organizationalPerson) (objectClass=inetOrgPerson) (objectClass=person)
```

For more information, see [Configuring authentication](#).

Note: For any option that includes the  icon, click  to enter the default values.

To also import LDAP roles, select Import roles and then enter the information that you need:

- Overwrite existing user roles - Synchronize user roles in Guardium with the role assignments in LDAP. Guardium internal roles are not updated or changed.
- Attribute to import as role - The attribute to use for importing roles, such as CN. Each attribute has a name and belongs to an objectClass.
- Role Search Base DN - The node in the tree at which to begin searching for roles. For example,

```
OU=groups,DC=encore,DC=corp,DC=root
```

- Role Search filter - The search filter for roles.
- Object class for role - The search filter for the object class of role DN in LDAP. For example,

```
(objectClass=groupOfNames) (objectClass=group) (objectClass=groupOfUniqueNames)
```

- Attribute in user to associate role - The attribute of user DN in LDAP that contains the user's role entries. For example, `memberOf`.
- Attribute in role to associate user - The attribute of role DN in LDAP that contains the member entries. For example, `member`.

When you are done, click Test Connection and then click Save.

## Running an LDAP Query

---

After you configure LDAP or the import process, click Query LDAP to run a query against the selected LDAP server with any selected filters. The results display in the LDAP Query Result tab.

From LDAP Query Result, you can select one or more users to import into Guardium.

To import users from LDAP Query Result:

1. Run an LDAP query from either the LDAP Config or Import Config tabs.
2. From LDAP Query Result, select one or more users (or all users), and click  to import the selected users.

## Scheduling LDAP user import

---

After you configure the LDAP user import, you can create an import schedule.

1. From LDAP User Import, click Schedule to open the LDAP user import schedule window.
2. Create a schedule for importing LDAP users and roles. For more information about creating a schedule, see [Scheduling](#). Select Run Once Now to import LDAP users immediately.

## Deleting an LDAP connection

To delete an LDAP server connection, select the connection that you want to delete, and click .

**CAUTION:**

If you delete an LDAP server connection, you also delete all of the users who are imported from that server.

Guardium suggests that instead of deleting a server, you update the configuration. Select the server that you want to update and click .

## Data Security - User Hierarchy and Database Associations

You can use data security features to create a hierarchy of users and associate users to specific databases and servers. Guardium® data security features report on which users accessed what information, and ensure that only specific users see information that they are responsible for.

Follow these steps to enable and use Guardium data security features:

1. Enable Data Security
2. Create a User Hierarchy
3. Create a User to Database Association
4. Filter Results

When data security features are used with the Classification feature (which discovers and classifies sensitive data found in multiple places of the database), the Data Level Security prevents a specified user from seeing classifier results from a specified datasource (datasource definition). Using Data Level Security can also prevent a specified user from seeing Audit Task results when the task type is Classifier.

## Enable Data Security

Restriction: Data Level Security and the Investigation Dashboard cannot be enabled concurrently.

1. Log in as the admin user and open the Global Profile by clicking [Setup > Global Profile](#).
2. Click Enable for Data level security filtering.

Note: The status indicator icon for Data level security filtering will now appear as .

You can verify that Data level security filtering is enabled by referencing the Services Status panel ([Setup > Services Status](#)).

- With data level security filtering enabled, log in as the accessmgr to use the User Hierarchy and User-DB Association features.

## Create a User Hierarchy

The User Hierarchy shows you the parent-child relationships between all users. User hierarchies permit the parent of the relationship to look at specified servers and databases, but not the children.

Log in as accessmgr and open the User Hierarchy by clicking [Data Security > User Hierarchy](#).

Do one of the following:

- Click Update Active User-DB Map to view the full hierarchy of users.
- Use the Roles and Users filters to view the hierarchy for a specific user or role. Right-click a node in the hierarchy to expand or collapse the tree, or add a user to a specific hierarchy.
- Click Refresh Cached Hierarchy to update the hierarchy.

Note: Depending on the configuration, inheritance can also take place where the parent inherits the data-level security of the child.

## Create a User to Database Association

The User-DB Association feature maps users to specific databases to ensure that users see only data that they are permitted to view.

Log in as accessmgr and open the User-DB Association by clicking [Data Security > User-DB Association](#).

Do one of the following:

1. View the current mapping of users to databases by clicking Update Active User-DB Map.
2. Create a new User-DB association map by selecting options from the Server & Service Name Suggestion list and clicking Go.

Note: Once the map is updated, you will see a tree listing all your servers. Click any node in the tree to view which users are currently associated with that node. If you are using dual-stack configuration, there is a root node, and two trees of addresses to choose from. One tree is for the IPV4 address, and the longer tree is for the IPV6 address.

Add a user or group to a node by selecting the node and clicking Add user or Add group.

## Central Management

On a Central Management appliance, there is also a box on the User-Database Associations screen that allows a user to create database associations based on data from a managed node. Select a remote source from only a box that appears for Central Management appliances. Also, there is a check box to get data from ALL managed nodes.

## Filter Results

Data level security at the observed data level requires the filtering of data for specific users and the specific databases they are responsible for.

Filtering at the system level is based on the User Hierarchy and User-DB Association so that users will see only information from their assigned databases for the various reports, audit processes, security assessments, and so on, within the Guardium system.

Log in as the admin user and use the Global Profile to filter results. Open the Global Profile by clicking [Setup > Global Profile](#).

- Default filtering:
  - Show all - This option is available only if the user logged in has the special role *datasec-exempt* defined, which allows the user to see all data as if there was no data level security.
  - Include indirect records - This check box shows the viewer not only the rows that belong to the user logged in, but also all the rows that belong to other users within that hierarchy.
- Audit Process Escalation: Escalation is allowed for tasks on this type only to users who have the *datasec-exempt* role. Users without the *datasec-exempt* role are not shown in the escalation list.  
Escalate results to all users - A check mark in this check box escalates audit process results (and PDF versions) to all users, even if data level security at the observed data level is enabled. The default setting is enabled. If the check box is disabled (no check mark in the check box), then audit process escalation only will be allowed to users at a higher level in the user hierarchy and to users with the *datasec-exempt* role. If the check box is disabled, and there is no user hierarchy, then no escalation is permitted.
- PDF and CSV generation for results (attached to email) distribution will use the default global profile values set in Administration Console parameters.
- PDF and CSV generated from the viewer will use the same filtering as in the screen.

Note:

The Data Security User to Database Association filters reports only from the following domains: Access; Exception; and, Policy Violations (as well as custom domains using these domains or tables from these domains). All other domains (reports) are not filtered by the Data Security User to Database Association.

Users with admin role will be able to see event types on all roles (the information will still be filtered based on observed data level security parameters).

If Data Level Security is turned on, predefined entities added to a custom domain need to be in the same domain(s) for the data level security filtering to work properly.

If Data Level Security is on, and two predefined entity subjects are trying to send data from two domains (not Custom Domains) that are using a filtering policy, then the sending of the two predefined entity subjects will not be permitted. Data Level Security can only enforce one kind of filtering policy (for example, there can be only one policy depending on server\_ip/service\_name and one policy depending on datasource).

## How to define User Hierarchies

Use the UI from an access manager account to easily define user hierarchies.

### About this task

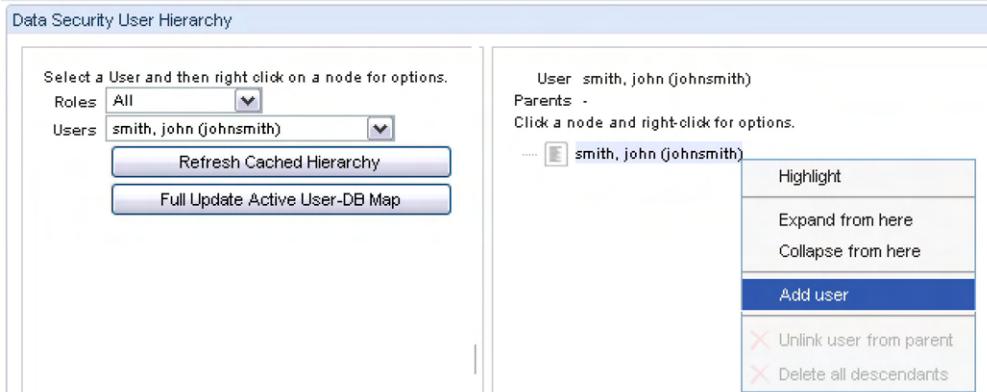

The Data Security User Hierarchy represents the parent-child relationships between users; allowing for the creation and enforcement of a data-level security by permitting the parent of a hierarchy to look at specified servers and databases, but not the children. Depending on the configuration, inheritance can also take place in that the parent inherits the data-level security of the child.

### Procedure

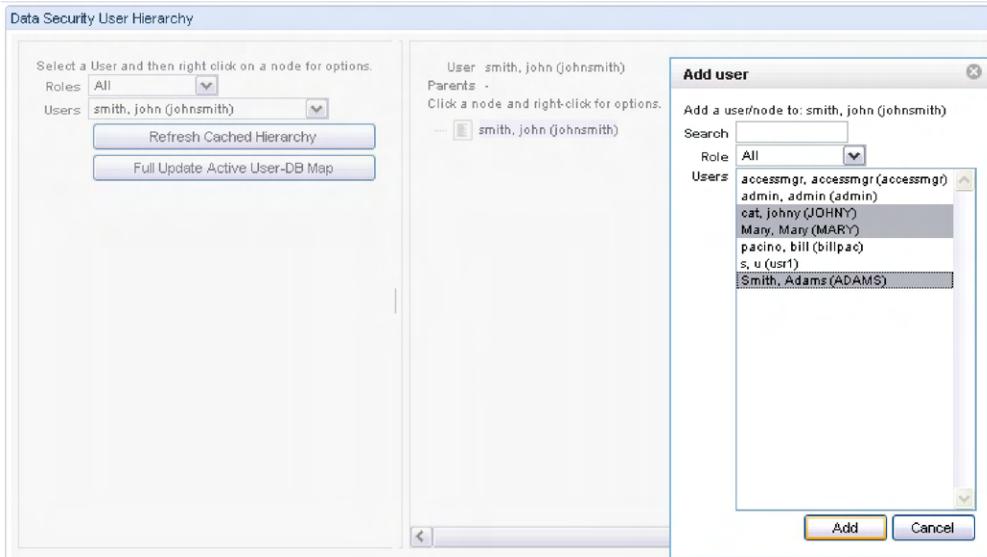

1. Login as accessmgr and click [Data Security > User Hierarchy](#).
2. Select a user from the Users drop-down menu to display it in the Data Security User Hierarchy pane. This example uses john smith as a user.

The screenshot shows the 'Data Security User Hierarchy' interface. On the left, there's a search bar with the placeholder 'Select a User and then right click on a node for options.' Below it are dropdown menus for 'Roles' (set to 'All') and 'Users' (set to 'smith, john (johnsmith)'). There are two buttons at the bottom of this panel: 'Refresh Cached Hierarchy' and 'Full Update Active User-DB Map'. On the right, the user 'smith, john (johnsmith)' is listed under 'User'. Below it, it says 'Parents - Click a node and right-click for options.' followed by a tree structure starting with '... smith, john (johnsmith)'.

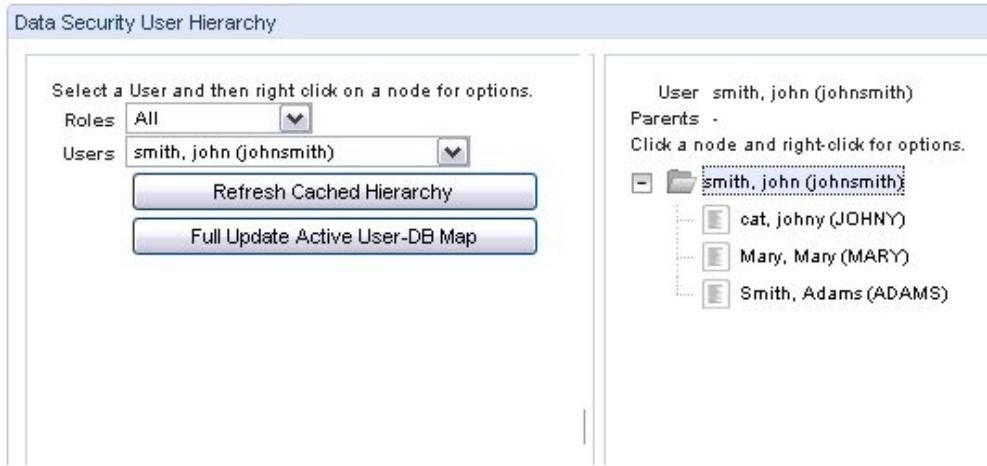

3. To add a user to john smith's hierarchy, right-click on the user in the Data Security User Hierarchy pane, and select Add user from the drop-down menu.

4. After clicking Add user from the drop down list, the Add user dialog appears. Select one or more users that you would like to add to the user's hierarchy, and then click Add.

5. After adding the users to a hierarchy, the Data Security User Hierarchy panel will be refreshed; allowing the user to drill down and see the new hierarchy.

6. Repeat the steps until all required users are defined to the data security user hierarchy.

## Central Management

In a central management configuration, one Guardium® unit is designated as the Central Manager. That unit can be used to monitor and control other Guardium units, which are referred to as managed units. Unmanaged units are referred to as stand-alone units.

The concept of a local Guardium system can refer to any Guardium system in the Central Management paradigm. Some applications (Audit Processes, Queries, Portlets, etc.) can be run on both the managed units and the central manager. In both cases, the definitions come from the Central Manager, and the data comes from the local Guardium system (which might also be the central manager).

After a Central Management system is set up, you can use either the central manager or a managed unit to create or modify most definitions. Keep in mind that most of the definitions are stored on the central manager, regardless of the system that does the actual editing.

Note:

- With the Remote Source function, a user on the manager can: run any report on the managed unit (the user must have the correct role privileges); and view data and information of that managed unit.
  - CAS template definitions are shared between all units of a federated environment just like all other definitions (reports, policies, alerts, and so on).
  - It is recommended that a user run CAS Reports on a manager, especially CAS Reports relating to CAS configurations, hosts, and templates.
  - If you create a report with the Custom Domain Builder, and some or all of the tables are remote (they are stored on the manager, such as Datasource or Comments), this report does not work on a managed node. No data is returned.
  - The Central Management page of a manager does not automatically refresh itself based on a specific interval. It times out based on the GUI timeout of the system.
  - After some time of inactivity, the system logs you out automatically and displays a sign-in dialog. The length of the GUI timeout can be set with the CLI command **store session timeout** (default is 900 seconds). View the timeout with the CLI command **show session timeout**. Status lights refresh every 5 minutes when the session is active.
  - To synchronize or upload any data from the Central Manager to managed nodes, all nodes that are involved in this type of activity MUST be on the SAME version of Guardium.
  - During the Central Management Redundancy Transition, it can take up to 5 minutes for the Unit type sync to occur depending on how many units are defined in the central management environment.
  - IPMODE information is shared with the central manager at registration. A managed unit that registered with the central manager in a pre-V11.2 release is not aware of its IP mode and cannot share that information with the central manager. Even if a managed unit was upgraded to V11.2 and later, it does not share its IP mode with the central manager, unless you unregister and reregister it. To rectify: In the Central Manager page, select individual managed units, or all managed units, and click Refresh Unit info.
- Guardium Component Services**
- Identify Guardium components and the locations from which they are taken in a central management environment.
- That unit can be used to monitor and control other Guardium units, which are referred to as managed units. Unmanaged units are referred to as stand-alone units.

Table 1. Guardium Component Services

| Component                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Users, Roles and Permissions | <p>Central Manager controls the definition of users, roles, groups and datamart tables for all managed systems. The Central Manager exports the complete set of user, security role, group, and datamart tables definitions on a scheduled basis or on demand. The managed units update their internal databases on an hourly basis. As a result, there might be a delay of up to an hour between the time users, roles, permissions or datamart tables are added or modified on the Central manager and the time that the managed unit applies those updates.</p> <p>Note: If you have Guardium® users or security roles that are defined on an existing stand-alone unit that is about to be registered for central management, those definitions will not be available after the system is registered, unless those users and security roles have also been defined on the Central Manager. You cannot administer users or security roles on a managed unit. Those definitions can be administered only when logged on to the Central Manager. When a unit is unregistered for central management, all added users and security roles are removed leaving only the default users (admin, accessmgr). When installing an Accelerator add-in product (PCI, SOX, etc.), in a Central Manager environment, install it first on the Central Manager and then on the managed unit. Add any roles and users as required for the Accelerator on the Central Manager (and those will be synchronized with the managed unit from there). Accelerator documentation is contained within the Accelerator module. See an overview of PCI Accelerator at the end of this Component Services table.</p> |
| Aliases and Groups           | On all processes that automatically generate aliases or groups, for example: import user groups from LDAP, group generation from queries, alias generation from queries, classifier, etc. if the same group or alias is automatically generated on more than one managed machine (managed by the same manager), then it might conflict with an existing group or alias, which will not be replaced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Audit Processes              | The definitions of the Audit Process itself and all of its corresponding tasks are saved to the Central Manager and available to all managed units. However, Schedules, Results, and To-Do lists are saved on the local machine. This means that the same Audit Process tasks can be run on all Managed Units, plus the Central Manager. But it can be run at different times on different machines, which can be useful if the Managed Units have different peak load periods. Each machine has its own set of results, which are based on the data that the machine has collected; and each machine has its own set of To-Do lists for all users. Audit Process definitions are exported from the Central Manager to the managed units as part of the user synchronization process (see Synchronizing Portal User Accounts). When audit process results have been produced, the results are available to users, but on managed units, there might be a delay of up to an hour before reports or monitors such as Outstanding Audit Process Reviews are updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Queries                      | Each query can get only database information from a single machine. Queries that require access information including both Central Manager definitions and Managed Unit data show no data, or missing data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Policies                     | Policy definitions are saved on the Central Manager. However, when you install a policy on a Managed Unit, a local copy is made and saved on the Managed Unit. The reason for that is that the Managed Unit is needed to keep on monitoring the database activity and using the policy even when the Central Manager is not available for any reason.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                              | <p>Note: Installing a policy on a managed node will not upload this policy to the Central Manager until the Refresh on the Central Manager is clicked. Versions must be the same between Central Manager and Managed Unit when installing policies else policies will not install and errors are generated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Component                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reports                        | <p>Report definitions are saved on the Central Manager.</p> <p>When regenerate portlet is called on a Central Manager, it also sends a management (https) request to all managed units to regenerate the portlet (with the report ID). When regenerate is called on a managed unit - if it is called from the screen (not the management request), then it should send a management request to the manager to refresh the portlet (this would also send it to all units). There is a persistence mechanism for management requests for the case a unit is down - see sections within this topic on registration and policy installation.</p> <p>From the Central Manager, reports and audit processes can use data from a managed unit but not managed aggregators. The managed unit is selected as a run-time parameter, is referred to as a remote datasource, and presented as a filtered drop-down selection list containing only managed units. When an audit process references a remote datasource, that audit process can be run from the Central Manager only, so it will not appear in a list of audit processes that are displayed on a managed unit.</p> <p>Note: Certain reports, on a Central Manager, of domain Sniffer Buffer Usage (for example, Request Rate, CPU Usage, Buffer Usage Monitor) will NOT display any data. The reports will be empty.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Security Assessment            | Like the Audit Process, the definition of the Security Assessment itself is saved to the Central Manager. But the results are saved on the local machine. This means that the same Security Assessment can be run on all Managed Units, plus the Central Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Comments                       | Comments can be saved on either the local machine or the Central Manager, depending on what the comment is associated with. If the Comment is associated with a definition that resides on the Central Manager, then it is also saved on the Central Manager. If the Comment is associated with a Result on the local machine, OR something specific to a Managed Unit (like an Inspection Engine), the Comment is also saved on the local machine.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Schedules                      | Schedules are always saved on the local machine, even when the definition is saved on the Central Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Non-Central Manager Tasks      | When a server is configured as a Central Manager, you must be aware of the tasks that cannot be performed on that unit, but rather must be performed on other (non-Central Manager) units. Inspection engines cannot be defined on the Central Manager and can be created only on the Managed Units. But Inspection engines can be viewed from the Central Manager.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Upgrade Considerations         | It is recommended to have your Central Manager and managed units on the same version. The Central Manager should be upgraded first and then the managed units should follow. Having a manager in a different version than its managed units should be a temporary thing and it is highly recommended to upgrade all managed units to the same version as the manager. Run Sync (Refresh) on all managed nodes after upgrading, in order for these managed nodes to recognize the proper software version that they are.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| PCI Accelerator for Compliance | <p>The PCI Data Security Standard consists of twelve basic requirements. Much of the requirements are focused on protecting physical infrastructure (for instance, Requirement 1: Install and maintain a firewall configuration to protect data) or implementing procedural best practices (for instance, Requirement 5: Use and regularly update anti-virus software). However, an extra emphasis is placed on real-time monitoring and tracking of access to cardholder data and continuous assessment of database security health status (for instance, Requirement 10: Track and monitor all access to network resources and cardholder data).</p> <p>Guardium's PCI Accelerator for Database Compliance is tailored to simplify organizational processes that are needed to support these monitoring and tracking mandates and to allow for cardholder data security. The Accelerator report templates can be customized to directly reflect specific organizational and regulatory requirements. You can access these templates using the tabs that are provided:</p> <ul style="list-style-type: none"> <li>• PCI Data Security Standard overview</li> <li>• Plan and Organize</li> <li>• PCI Req. 10: Track and Monitor Access</li> <li>• PCI Req. 11: Regularly Test and Validate</li> <li>• PCI Policy Violations Monitoring</li> </ul> <p>Other tools in the Guardium family of solutions are available to help meeting regulations include the following:</p> <ul style="list-style-type: none"> <li>• PCI Compliance Report Card - A detailed view of cardholder databases access security health that is used to automate the compliance processes with continuous real-time snapshots customized for user-defined tests, weights, and assessments. The Report Card can be generated using security assessment.</li> <li>• Full Audit Trail - The non-intrusive generation of a full audit trail for data usage and modifications that are required by regulatory compliance.</li> <li>• Automated Scheduling - Automated scheduling of PCI work flows, audit tasks, and dissemination of information to responsible parties across the organization.</li> </ul> |

The following table can help identify which components are taken from which location in a central management environment.

Table 2. Components and Location in Central Manager Environment

| Central Manager              | Managed Unit                     |
|------------------------------|----------------------------------|
| Users                        | System Configuration             |
| Security Roles               | Inspection Engines               |
| Application Role Permissions | Alerter (configuration)          |
| Queries                      | Anomaly Detection                |
| Reports                      | Session Inference                |
| Time Periods                 | IP-to-Hostname Aliasing          |
| Alerts                       | System Backup                    |
| Security Assessments         | Aggregation / Archiving          |
| Audit Process Definitions    | Custom Alerting                  |
| Privacy Sets                 | Custom Identification Procedures |
|                              | Exported csv Output              |
| Policies                     | Schedules                        |
| Groups                       | DB Auto-discovery Configurations |
| Aliases                      | Audit Process Results            |

Users, Security Roles, Audit Process Definitions, and Groups are exported from the Central Manager to all managed units on a scheduled basis, as described later.

From the Central Manager, the administrator can:

- Register Guardium units for management
- Monitor managed units (unit availability, inspection engine status, etc.)

- View system log files (syslogs) of managed units
- View reports using data on managed units
- View main statistics for managed units
- Install Guardium security policies on managed units
- Restart managed units
- Manage Guardium inspection engines on managed units
- Maintain the complete set of Users, Security Roles, Groups, and Application Role Permissions that are used on all managed systems
- Patch distribution
- Distribute Uploaded JAR files
- Distribute Patch Backup Settings
- Distribute Authentication Config
- Distribute Configurations

Note: Application Role Permissions can also be changed by the administrator from any managed unit. When this happens, the permissions are changed for all managed units.

---

## Implementing Central Management

Make one machine into a Central Manager, connect the other machines into a Central Management system, and register the Managed Units to communicate with the Central Manager.

- Implementing Central Management in a New Installation
- Implementing Central Management in an Existing Installation
- If the Central Management Unit is unavailable
- **Implementing Central Management in a New Installation**  
Make one Machine the Central Manager, use the same shared secret, register units, and group managed units.
- **Implementing Central Management in an Existing Installation**  
Implement Central Management in an existing Guardium environment and migrate a CAS collector with active instances to be managed.

---

## Implementing Central Management in a New Installation

Make one Machine the Central Manager, use the same shared secret, register units, and group managed units.

### Make one machine the Central Manager

The first thing is to make one machine into a Central Manager. Select a machine. Then, complete the following steps.

1. Log in to the CLI of the Machine that you want to make the Central Manager.
2. Enter store unit type manager. This step makes the machine a Central Manager; however, it is not yet managing anything.

### Use the Same Shared Secret

After you have a Central Manager, you must connect the other machines into a Central Management system. For security reasons, it is a requirement that the communications between the machines be encrypted by using the same shared secret. To do this step, do the following action items.

1. Click Setup> Tools and Views> System to open System.
  2. Set the shared secret to the same string on all systems.
- **Registering Units**  
Register managed units to communicate with the Central Manager.
  - **Unregistering a Managed Unit**  
When a unit is unregistered, always unregister from the Central Manager. This method is the only way that the Central Manager decrements its count of managed units.
  - **Synchronizing Portal User Accounts**  
Manage portal user synchronization by using the Central Manager.

---

## Registering Units

Register managed units to communicate with the Central Manager.

You can register Guardium units for central management either from the Central Manager or from the unit itself. Regardless of how the registration is done, the Central Manager and all managed units must have the same system shared secret. If the unit to be managed is already registered for central management with another manager, unregister the unit from that central manager before you register it with the new manager. Be sure to understand exactly what happens to that unit when it is registered and unregistered for central management.

Note: If the user that is logged in to a managed unit does not exist on the Central Manager, the session is invalidated. It remains invalidated until the unit is registered with a Central Manager.

### What Happens during Registration

The following actions happen on registration.

- The unit type is set to managed and manager IP is stored.
- Product key of manager is applied. (License key is not propagated with Ping or User sync. It is sent on registration or when the system refreshes.)
- All job scheduling is reset to default.
- All psml files (portal GUI customizations) are removed.
- All local users and roles are removed.
- List of threshold alerts that is not be evaluated is reset.
- Users roles, permissions from manager are loaded.
- Custom classes, user uploaded JARs, LDAP truststore from manager are uploaded.
- Database connection from managed to manager is enabled.
- Database connection from manager to managed is enabled.
- CAS listener is started if needed.

After registration all definitions of reports, queries, groups, policies, audits, and more are retrieved from the Central manager.

Attention: When registering a standalone system that was previously used for data-access monitoring or vulnerability assessment, export any content from that system that you want to preserve and then import that content after completing registration with the central manager. This may include any of the following definitions:

- Policies and groups
- Queries and reports
- Security assessments
- Datasources
- Data marts
- Dashboards

For more information, see [Exporting and importing definitions](#).

## If the Registered Unit Status Remains Offline

---

If you know the unit that is registered is online and accessible from the Central Manager, but its status remains offline, then complete the following steps.

- Verify that the unit to be managed is online, accessible, and operational by using a browser window to log in to the Guardium system on that unit.
- Click Refresh for the unit.
- Check that you entered the correct IP address for the unit.
- Check that the unit has the same shared secret as the Central Manager.

Note: If the registration of a unit is offline, the registration request persists. It is resent to the IP/port specified on a set interval until the unit registers. A registration request that does not succeed expires after seven days.

## Registering from a Managed Unit

---

On a managed unit, you can use the GUI to register the unit with the Central Manager. Otherwise, you can use the CLI register command as described in Registering a Managed Unit with the CLI.

1. Click Setup > Central Management > Registration and Load Balance to open Central Management Registration.
2. For Host IP, enter the IP address of the Central Manager.
3. For Port, enter the https port for the Central Manager (usually 8443).
4. Click Register.

After you register on the managed unit, it initiates communication with the Central Manager, and nothing more needs to be done.

Note: The central management unit must be online and accessible by this unit when you register for central management. In contrast, when you register units for management from the central management unit, you can register units that are not currently accessible.

## Registering a Managed Unit with the CLI

---

1. On the managed unit, log in to the CLI.
2. Type register management <Manager IP> <Manager Port>

After you register on the managed unit, it initiates communication with the Central Manager, and nothing more needs to be done.

## Registering units from the Central Manager

---

You can register units that are not currently accessible.

1. Navigate to Manage > Central Management > Central Management to open Central Management.
2. Click Register New. The unit Registration page opens.
3. Enter the Unit IP and port, and click Save. The Central Management page refreshes with the new unit.

## Unregistering a Managed Unit

---

When a unit is unregistered, always unregister from the Central Manager. This method is the only way that the Central Manager decrements its count of managed units.

Unregistering from the managed unit does NOT unregister the unit on the Central Manager. The Central Manager still counts that unit as a managed unit for licensing purposes and treats the unit as managed. It might not allow another unit to be registered with the Central Manager. The unregister function on the managed unit is included for emergency use ONLY. If a manager is no longer in service, then you must unregister the unit before you can register it to another manager.

If you unregister a unit from the managed unit, it still shows on the Central Manager screen. Pressing refresh for that unit reregisters it. Pressing any other operation for that unit gives out a message that the unit is no longer managed and removes it from the manager.

On a managed unit, you can use the GUI to unregister the unit with the Central Manager. Also, you can use the CLI unregister command as described in Unregistering a Managed Unit with the CLI.

1. Log in as admin to the Guardium UI of the unit to be managed.
2. Click Set > Central Management > Registration and Load Balance to open Central Management Registration.
3. Click Unregister.

## What Happens during Unregistration

---

The following actions take place upon unregistration.

- The unit type is set to standalone.
- The manager IP is cleared.
- The product key is cleared (license is null until registration to new manager or a license is loaded manually).
- The list of threshold alerts that is not evaluated is reset.
- All job scheduling is reset to default.
- Psml files are removed.
- All users but the default users (admin, accessmgr) are removed.
- The database connection from managed to manager is disabled.
- The GUI is restarted.

After unregistration all definitions of reports, queries, groups, policies, audits, and more are retrieved from the local database, the definitions that are stored on Central Manager are no longer accessible.

If you are unsure about how to verify, contact Guardium Support before you unregister the unit.

## Unregistering a Unit from the Central Manager

---

1. Log in, as admin, to the Central Manager.
2. Click Manage > Central Management > Central Management to open Registration.
3. Mark the check box for the managed unit you want to unregister.
4. Click Unregister.

Unregistering a managed unit from the Central Manager screen removes it from the managed unit list and sets the unit to be a stand-alone unit.

Note: The product key of the unit is removed and unless the unit is registered to another manager the product key is placed in manually.

## Unregistering from a Managed Unit

---

On a managed unit, you can use the UI to unregister the unit with the Central Manager. Also, you can use the CLI unregister command as described in Unregistering a Managed Unit with the CLI.

1. Log in, as admin, to the managed unit.
2. Click Setup > Central Management > Registration and Load Balance to open Registration.
3. Click Unregister.

To unregister a Managed Unit by using the CLI, complete the following steps.

1. On the Managed Unit, log in to the CLI.
2. Enter `unregister management`.

After you have unregistered from the Managed Unit, it severs communication with the Central Manager, and nothing more needs to be done.

## Synchronizing Portal User Accounts

---

Manage portal user synchronization by using the Central Manager.

### About this task

---

As mentioned earlier, the Central Manager controls the definition of Users, Security Roles, Groups, and datamart tables for all managed units. The Central Manager makes an encrypted and signed copy of its complete set of User and Security Roles. In addition, the Central Manager transmits that information to all managed units. Furthermore, some other definitions that are required for local processing (Groups and Group members, Audit processes, Aliases, and more) are also copied. The managed units then update their internal databases on an hourly basis. This process means that there might be a delay of up to an hour before using these roles or datamart tables.

A full user synchronization cycle occurs on registration or by pressing Refresh from the Central management screen. In both cases, the synchronized information is sent from the manager and loaded on the managed units immediately.

Note: Use caution when setting the schedule so that it does not interfere with other scheduled jobs like Import which can fail to start.

### Procedure

---

Click Manage > Central Management > Portal User Sync to manage portal user synchronization.

- a. Click Modify Schedule to change the user synchronization task schedule by using the standard task scheduler.
- b. If the task is actively scheduled, click Pause to stop further scheduled executions.
- c. If the task is paused, click Resume to start running the task again (according to the defined schedule).

d. Click Run Once Now to run the synchronization task immediately.

Note: The task that is scheduled or Run Once Now refers to the collection of data and its transmission to the managed units only. The managed units might not use that data to update their user tables until up to 1 hour after it is received.

Restriction: The Central Manager and managed units must have the same SSH port for Portal User Sync to work. Use this CLI command to get the SSH port: `show ssh port`.

## Implementing Central Management in an Existing Installation

Implement Central Management in an existing Guardium environment and migrate a CAS collector with active instances to be managed.

In an existing Guardium environment, refer to the procedure outlined to develop a plan for implementing central management. If you are converting an existing Guardium unit to a Central Manager, keep in mind that a Central Manager cannot monitor network traffic. For example, inspection engines cannot be defined on a Central Manager.

1. Select a system shared secret to be used by the Central Manager and all managed units. For more information, see the system shared secret in System Configuration.
2. Install the Central Manager unit or designate one of the existing systems as the Central Manager. In either case, use the store unit type command to set the manager attribute for the Central Manager.
3. Any definitions from the stand-alone unit that you want to have available in the central management environment must be exported before the stand-alone unit is registered for management. Later, those definitions are imported on the Central Manager. BEFORE exporting or importing any definitions, follow the procedure that is outlined for each stand-alone unit that is to become a managed unit. Read through the introductory information under Export/Import Definitions.
  - Decide which definitions from the standalone system you want to have available after the system becomes a managed unit. Ignore any components on the stand-alone system you do not want to have available.
  - Compare the security roles and groups that are defined on the stand-alone unit with those defined on the Central Manager. Under central management, a single version of these definitions applies to all units. If a security role with the same name exists on both systems and it is used for different purposes, add a new role on the Central Manager and assign the new role to the appropriate definitions after they are imported.
  - If the same group name exists on the stand-alone unit and the Central Manager but it has different members, create a new duplicate group on the stand-alone system, taking care to select a group name that does not exist on the Central Manager. In all of the definitions to be exported, change the old group name references to new group name references.
  - All security roles that are assigned to all definitions that are exported from the stand-alone system. When definitions are imported, they are imported WITHOUT roles, so you must add them manually.
  - Check the application role permissions on each system. If any security roles assigned to an application on the stand-alone unit are missing from the Central Manager, add them to the Central Manager.
  - Export all definitions from the stand-alone system that you want to have available after the system becomes a managed unit. (See Export/Import Definitions) Do not export users or security roles. If you are unsure about a definition, export it in a separate export operation so that you can decide in the future whether to import that definition to the Central Manager. After you register for central management, none of the old definitions from the stand-alone unit are available.
  - On the stand-alone unit, create PDF versions audit process results and store them in an appropriate location. Under central management, only the audit results produced under central management are available.
  - On the stand-alone unit, instruct all users to remove all portlets that contain custom report, and to not create any new reports until the conversion to central management is complete.
  - On the Central Manager, manually add all users from the stand-alone unit.
  - On the stand-alone unit, delete all user definitions except for the admin user (which cannot be deleted).
  - Register the stand-alone unit for central management. See Registering Units for Central Management.
  - On the Central Manager, import all definitions that are exported from the stand-alone system. Check to make sure that references to included items (receivers in alert notifications, for example) are correct. Reassign security roles, as necessary, to all imported definitions.
  - Inform users of the managed unit that they must use the Report Builder application to regenerate the portlets for any custom reports they want to display in their layouts.

## Migrating a stand-alone CAS collector to managed

Use the following steps when you migrate a CAS collector with active instances to managed.

1. Export the CAS host definitions from the stand-alone collector.
2. Manage the stand-alone collector.
3. Restart the CAS host from the GUI of the now managed collector.
4. Import the CAS host definition to the manager.
5. Restart the CAS host from the GUI of the managed collector again.

After these steps are performed, the CAS collector has the same instances and monitor the same files that it did when it was a stand-alone.

Note: The CAS data that was collected when it was a standalone is deleted. There is no collected CAS data unless a file changes.

## Using Central Management Functions

Use Central Management functions to synchronize portal user accounts, monitor managed units, and install security policies on managed units.

- **[Managing expiring certificates](#)**  
12.1 and later You can view, manage, update, and distribute certificates from Guardium Data Protection central manager to the central manager and the managed units.
- **[Deployment health views](#)**  
The deployment health views gather and display information about your entire Guardium environment in powerful, easily consumed graphical views.
- **[Creating a cross-CM health view](#)**  
The cross-central manager health view (cross-CM health view) is a Guardium unit type that provides aggregated health views for an entire Guardium deployment.

These views include health information for all available central managers, aggregators, collectors, and S-TAPs in your environment. After you build a cross-CM health view unit, you can manage patches for all the central managers that are associated with that unit.

- **S-TAP and GIM dashboard**

This dashboard presents S-TAP and GIM health, status, version, and other information through several easy-to-use charts.

- **Create and manage S-TAP clusters**

Learn how to define S-TAP clusters in Guardium that are useful for managing active-passive S-TAP cluster arrangements on your data servers.

- **Enterprise load balancing**

The enterprise load balancer dynamically allocates managed units to S-TAP agents based on system load and availability.

- **Deployment inventory**

The inventory view provides centralized view of all database servers and any installed S-TAPs or GIM clients.

- **Resource deployment view**

The resource deployment view shows the GIM clients and S-TAPs installed on the database servers in a Guardium environment.

- **Monitoring managed units**

Monitor managed units from the Guardium Central Management page.

- **Creating managed unit groups**

Organize managed units into groups and then take actions on those groups.

- **Installing security policies on managed units**

Install a security policy on a manage unit.

- **Central patch management**

Provide visibility and control over patch installation, status, and history.

- **Distributing authentication configuration**

Instead of configuring authentication on each appliance separately, central management authentication (Configure Authentication) can be configured once on the central manager and then distributed to all managed units. This way, information is entered once and it applies to some or all units; some of the units may have a different type of authentication.

- **Distributing configurations**

Configurations and their schedules, can be distributed, either all or individually, between the central manager and the managed units.

- **Working with configuration profiles**

Configuration profiles allow you to define configuration and scheduling settings from a central manager and distribute those settings to managed unit groups without altering the configuration of the central manager itself.

- **Distribute custom tables**

Distribute custom tables and their data from a central manager to managed units.

- **Central manager redundancy**

Use Central Manager Redundancy or Backup Central Manager (CM) to configure a secondary or backup CM in case the Primary CM becomes unavailable.

---

## Managing expiring certificates

12.1 and later You can view, manage, update, and distribute certificates from Guardium® Data Protection central manager to the central manager and the managed units.

### About this task

For nontrusted certificates, you can distribute only the certificates that are issued from externally generated certificate signing requests (CSRs); these certificates need a private key and server certificate.

Note: You cannot distribute MySQL and GIM certificates from Guardium Data Protection central manager to the managed units.

You can distribute certificates from the central manager to managed units that are 12.1 or later only.

### Procedure

1. From the Manage menu, browse to System View > Certificate Management.

2. From the list, select the certificate that you want to update.

The different colors indicate the time period of expiry. For example, red color indicates that the certificate has expired and orange color indicates that the certificate expires in less than 180 days.

Note: You cannot update the self-signed certificates such as `keystore_default`, and patch certificates such as `patch-signing.cert.pem`.

3. Click Update certificate. The Update certificate window is displayed.

4. Paste the newly signed certificate.

- If you are using public certificates, paste the newly signed certificate.
- If you are using server certificates like Tomcat, paste the private key, server certificate, intermediate key, and the root certificate.

Note: Make sure to paste the correct certificate information in the text box.

5. All the units to which the updated certificate is applicable are selected by default. If you do not want the certificate to be distributed to a unit, clear the checkbox.

Note: If a managed unit is not accessible from the central manager, the updated certificates are not distributed to that managed unit.

6. Select the Restart Tomcat on the units after update checkbox if you want to restart Tomcat on the managed units after the certificates are updated.

7. Click Update. A window displays the success message, and the location of the log file to view the update.

### Results

The certificate distribution occurs in the background. You can monitor the progress of the certificate update in the log file `dist_certificate.log`.

Note: You cannot view the progress of the certificate distribution in the GUI.

You can also monitor the progress by using the `distribute_certificate showlog` CLI command.

---

## Deployment health views

The deployment health views gather and display information about your entire Guardium® environment in powerful, easily consumed graphical views.

The deployment health views help you investigate system-utilization trends and quickly identify ailing or down systems. These views decrease reaction times and reduce risks from problems in your Guardium deployment. The deployment health views are designed to work together by consolidating several different sources of information into unique but related views.

#### Deployment health topology and table views

The deployment health topology and table views show the data flow relationships between systems in your environment. These views make it easy to identify problematic systems and investigate the underlying issues.

- To access the topology view, browse to [Manage > System View > Deployment Health Topology](#).
- To access the table view, browse to [Manage > System View > Deployment Health Table](#).

#### Deployment health dashboard

The deployment health dashboard provides an at-a-glance summary of issues that are found across a Guardium deployment. The dashboard is especially useful for identifying patterns and trends in the health data before investigating individual systems where problems are identified.

To access the dashboard, browse to [Manage > System View > Deployment Health Dashboard](#).

The following table summarizes the types of data available to each of the deployment health views.

Table 1. Summary of deployment health views

|                                              | Dashboard | Topology | Table |
|----------------------------------------------|-----------|----------|-------|
| Unit utilization                             | ✓         | ✓        | ✓     |
| Correlation alerts                           | ✓         |          |       |
| Self-monitoring                              | ✓         |          |       |
| System requirements                          | ✓         |          |       |
| Aggregation                                  |           | ✓        | ✓     |
| Inspection engines (S-TAP verification data) |           | ✓        |       |
| Connectivity                                 |           | ✓        | ✓     |
| S-TAP connectivity                           |           | ✓        |       |

Attention: The deployment health views present data gathered from an entire Guardium environment and are only available from a central manager.

## Configuring a central manager for the deployment health views

To use the deployment health views, enable the collection of unit utilization data, configure correlation alerts, and configure data import and export for your environment.

### About this task

From a central manager, the deployment health views display data from across a Guardium® environment. The ability to display data about an entire deployment requires the collection of unit utilization data, the configuration of correlation alerts, and that data import, export, and S-TAP verification is correctly configured. For a summary of data that is displayed on the deployment health views, see [Deployment health views](#).

It is likely that your deployment is already configured to support the deployment health views. Verify the configuration steps that are described in this procedure if you notice any of the following issues on any of the deployment health views:

- CM buffer usage report not scheduled
- Unit utilization report not scheduled
- Export not scheduled
- Import not scheduled
- No issues found
- Status unavailable

The S-TAP details include the inspection engines and their database versions if the auto-discovery feature is enabled. On Unix-Linux databases, auto-discovery is enabled by default and runs once daily. For more details, see [Linux-Unix: Discover database instances](#). On Windows databases, auto-discovery is not enabled by default because it would overwrite user modifications to the inspection engine configurations. For more details, see [Windows: Discover database instances](#)

### Procedure

1. Configure the collection and processing of unit utilization data from the central manager.

For more information, see [Configuring unit utilization data processing](#).

2. Enable correlation alerts for inclusion on the deployment health dashboard.

a. Open [Protect > Database Intrusion Protection > Alert Builder](#).

b. Select an existing alert and click the icon, or create a new alert by clicking the icon.

c. Provide a Category for the alert.

Alerts without a specified category are displayed as Uncategorized.

d. Select the View in deployment health dashboard checkbox to include the alert on the dashboard.

Attention: Alerts must have the Severity set to LOW, MED, or HIGH to be included on the deployment health dashboard.

For more information about defining alerts, see [Building alerts](#).

### 3. Configure data import and export from the central manager.

For more information, see [Data aggregation](#).

Tip: Use the distribute configuration profiles tool to simplify the process of configuring data import and export for a Guardium deployment. For more information, see [Working with configuration profiles](#).

### 4. Configure S-TAP verification for all supported S-TAPs.

For more information, see [Windows Inspection engine verification](#) and [Linux-UNIX Inspection engine verification](#).

## Results

---

After you complete the configuration procedures and allow the data to update, the deployment health topology and deployment health table views predominately show  status except for systems with preexisting health issues. The deployment health dashboard includes any preexisting unit utilization issues and begins showing new correlation alert conditions.

After altering the unit utilization or data import and export schedules, wait up to 1 hour to allow the deployment health views to update with new information. The availability of new correlation alert data depends on the notification frequency that is specified for an alert.

## Deployment health topology and table views

---

Learn more about how the deployment health topology and table views present the configuration of your Guardium® environment and its data.

The deployment health topology view is accessible from any central manager and provides an at-a-glance visualization of the entire Guardium environment that is connected to that central manager. In addition to showing relationships between nodes in the environment, the deployment health topology view also provides health information about all connected aggregators, collectors, and S-TAPs. Several investigation and resolution actions are available directly from the deployment health topology view to help quickly address health issues that are discovered in your environment.

Tip: It is also possible to view aggregated health data from across multiple central managers by establishing a cross-CM *health* view system in your environment. For more information, see [Viewing cross-CM health view deployment health data](#).

The default deployment health topology view is a data flow view that shows the data import and export relationships between aggregators and managed units. Browse to the deployment health topology view at [Manage > System View > Deployment Health Topology](#).

A sortable table view of the deployment health data is also available at [Manage > System View > Deployment Health Table](#). In the table view, the Guardium systems tab provides overall deployment health information while the S-TAPs tab provides detailed health information about S-TAPs and databases.

## Data availability

---

Several factors influence that availability of system data and how that data is displayed on the deployment health topology and table views. For information about configuring your system to use the deployment health views, see [Configuring a central manager for the deployment health views](#).

The backup central manager only shows its connectivity status.

### Types of data

When correctly configured, the deployment health topology and table views display data that is collected from several different sources. The specific types of data that are displayed depend on the unit type, as summarized in the following sections.

#### Overall Status

The overall status gives the status of the unit:

- Overall status.
- Guardium version for Guardium systems and S-TAPs.
- OS version, databases, and database status for S-TAPs, including S-TAP type, version, and verification status. For more information, see [Windows: Inspection engine verification / Linux-UNIX: Inspection engine verification](#).

#### Connectivity

The connectivity category indicates whether systems in a Guardium environment are able to communicate.

- Applies to central managers, aggregators, collectors, and S-TAPs.
- Examples include unit not responding and S-TAP not responding, and incorrect S-TAP configuration.

#### Investigation dashboard

The investigation dashboard category indicates whether there are open issues with the investigation dashboard environment.

- Applies to central managers, aggregators, and collectors.
- For more information see [Investigation dashboard issues](#).

#### 12.1 and later Monitored processes

This report provides combined information about the Investigation dashboard and Threshold alerter.

- **Investigation dashboard**

The investigation dashboard category indicates whether there are open issues with the investigation dashboard environment.

- Applies to central managers, aggregators, and collectors.
- For more information see [Investigation dashboard issues](#).

- **Threshold alerter**

The threshold alerter category indicates whether the alerter service is down.

- Applies to central managers, aggregators and collector.

#### View Unit utilization report

This report provides information about how heavily Guardium systems are loaded.

- Applies to central managers, aggregators, and collectors.
- Examples include CPU load, free buffer space, and MySQL disk usage.
- For more information, see [Unit utilization and inspection core performance](#).

#### View Aggregation/Archive Log

This log provides information about data import and export flow between Guardium systems.

- Applies to central managers (if configured as aggregators), aggregators, and collectors.
- Examples include import failed, export failed, and export not scheduled.
- For more information, see [Predefined admin reports](#) and [Data aggregation](#).

#### S-TAP only

##### K-TAP status

The K-TAP status indicates whether K-TAP is successfully loaded. Use the View S-TAP events link for more information.

##### Traffic status

If Traffic is selected from the Customize settings menu, then Guardium checks the status of traffic between S-TAPs and Guardium.

- Applies to central managers, aggregators, and collectors.
- For topology views, traffic status displays on the S-TAP roll-up.
- By default, traffic is queried every five minutes on the collector, but you can modify this interval (to between 5 and 30 minutes) with the `set_health_traffic_job_interval` API. If the status changes, the data is pushed to the central manager every 5 minutes. In most cases, traffic data is less than 10 minutes old (but can be as much as 20 minutes old in some worst-case scenarios).

##### Data latency

Several preset and user-defined schedules determine the latency of data that is displayed on the deployment health topology view. These schedules are summarized in the following table.

Table 1. Deployment health topology view data latency

| Health category         | Node type                                  | Latency                                                                                                                                       |
|-------------------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Connectivity            | Aggregator or collector                    | Less than 15 minutes                                                                                                                          |
| Connectivity            | S-TAP, data stream, or universal connector | Less than 15 minutes if enterprise load balancing is enabled<br>Less than 1 hour if enterprise load balancing is not enabled                  |
| Aggregation             | Central manager, aggregator, or collector  | Less than 1 hour                                                                                                                              |
| Verification            | S-TAP                                      | Less than 1 hour                                                                                                                              |
| Unit utilization        | Central manager, aggregator, or collector  | 1 - 2 hours, based on the recommended configuration. For more information, see <a href="#">Configuring unit utilization data processing</a> . |
| Investigation dashboard | Central manager, aggregator, or collector  | Less than 1 hour                                                                                                                              |

Observe the following latencies for specific environment and configuration changes:

- Newly registered aggregators or collectors become available to the deployment health views within 15 minutes.
- Deleting the data export schedule or data export configuration from a collector are reflected on the deployment health views within 2 hours.

## Data presentation

##### Health status

The deployment health topology view displays three categories of health information for Guardium systems: connectivity, unit utilization, and aggregation. Metrics under these categories are assigned one of the following health statuses: status unavailable (least severe), no health issues, low severity, medium severity, and high severity (most severe). The overall status is determined by the most severe status of any individual metric included under any of the health categories being displayed. Data that has been excluded using the Customize Settings dialog is not used for determining the overall status of a system.

For example, if the Restarts metric under the Unit utilization category is assigned a High severity status, but no health issues exist under another category, the Overall status for that system is High severity. This behavior ensures that the most severe condition is always visible at-a-glance as the overall status of a system.

At the Manage > System View > Deployment Health Topology view, detailed statuses for the available health categories are only displayed when at least one low, medium, or high severity issue is found.

At the Manage > System View > Deployment Health Table view, detailed statuses for the available health categories are always displayed.

##### Health status roll-up

The deployment health topology view implements a health status roll-up strategy to efficiently display health information for an entire Guardium environment. Using this strategy, child nodes are collapsed under their parent nodes, and the child's health status is rolled-up to the parent. The rolled-up status is expressed as a small icon attached to the parent node.

Attention: Health status roll-up is only supported for S-TAP nodes rolling-up status to their parent collector.

For example,  indicates a collector with no health issues, but the small red circle indicates that one or more S-TAPs that are associated with that collector has high severity issues. Clicking the collector expands the node and reveals the associated S-TAPs and their health status. For example,

indicates four S-TAPs that are associated with the collector: two S-TAPs have high severity health issues, and two S-TAPs have low severity health issues. Only the most severe status is rolled-up from the child to the parent node when the child nodes are collapsed. In the previous example, the parent node shows a small red circle because one or more of its children has high severity issues. However, if one or more child nodes contain low severity issues but all the other child nodes have no health issues, the parent node would display a small yellow circle.

#### Filtering

The topology view provides Active filters for several metrics, such as database type, host name, and health severity. Use the filter-type fields to select and apply filters to the topology.

The table view provides quick filtering by health status using the Filter overall status by check boxes in the table header. In addition to quick filtering, the table view also provides Advanced filter controls that can be configured and saved.

1. Use the icon to open the Advanced filter pane.
2. To use an existing filter, select one from the Saved filters menu and click Apply Filter.
3. To create a new filter:
  - a. Leave the Saved filter field blank.
  - b. Use the menus and fields to define filtering criteria.
  - c. Click Save.
  - d. On the Save Filter dialog, use the Filter name field to name the filter.
  - e. Click Save and Apply or Save Filter.
4. Use the Remove link in the table header to disable an advance filter that has been applied.

#### Customizing the settings

Click the icon to open the Customize Settings dialog and define the following properties:

- From the Health Settings tab:
  - The health status categories to display, such as connectivity, traffic, and unit utilization.
  - Display settings for the topology view, such as default zoom settings, and whether to exclude healthy nodes or expand S-TAPs by default.
  - Column-display settings for the table view.
  - Other settings, such as whether to show S-TAP aliases.
- From the Traffic ignore list tab, you can select one or more databases to ignore for traffic monitoring. If you do not select Traffic from the Health Settings tab, traffic is not monitored.
  1. From the Traffic ignore list tab, click the icon to display a list of all available databases.
  2. Select the databases to ignore. You might, for example, want to ignore test databases.
  3. Click Add to ignore list.

## Deployment presentation

Some deployment configurations display unexpectedly on the deployment health topology view. Several of these configuration scenarios are described in the following sections.

#### Unsupported S-TAPs

The deployment health topology view displays any S-TAPs that are configured for S-TAP verification or that participate in enterprise load balancing. If an S-TAP cannot be configured for S-TAP verification or to participate in enterprise load balancing, it is not displayed.

#### S-TAP load balancing

If S-TAP load balancing is configured with the `participate_in_load_balancing` parameter and an S-TAP is configured to balance traffic across multiple collectors, the deployment health topology view displays that S-TAP as a child node of each collector. For example, if S-TAP 1 is load balancing with *Collector A* and *Collector B*, both *Collector A* and *Collector B* display S-TAP 1 as a child in the deployment health topology view.

#### Invalid S-TAPs

Invalid S-TAPs are similar to inactive S-TAPs, but they only appear in topology views. Use the API [delete\\_invalid\\_stap](#) to remove invalid S-TAPs from the topology views.

#### Unmanaged units

If a collector exports data to a central manager or to an aggregator that is configured as a central manager, but that collector is not designated as a managed unit of that central management cluster, the Overall status of the collector in the deployment health topology view is shown as Health status unavailable. No additional information about the collector is made available through the deployment health topology view unless the collector is designated as a managed unit of the central manager.

#### Collector exporting data to primary and secondary hosts

When a collector is configured to export data to both primary and secondary hosts, only the primary host is used for the deployment health topology view.

For more information, see <a href="#">Correlation Alerts</a> .                                                                                                                                                                                                                                                                           | Data is purged after 7 days                                                                            |
| System resources       | System configuration, such as CPU cores, system memory, /var disk capacity             | System does not meet minimum requirements                                                    | Updated whenever the user-interface server is started or restarted                                                                                                                                                                                                                                                                                                                          | Not applicable                                                                                         |
| System self-monitoring | MySQL disk usage and system disk usage                                                 | Usage meets or exceeds default thresholds (75% for high severity, 90% for critical severity) | Updated every 5 - 10 minutes.<br><br>For high-severity, if the same event occurs multiple times in a 15 minute period, the timestamp is updated to reflect the most recent instance. If the same event occurs after a 15 minute interval, a new entry is created with the most recent timestamp.<br><br>For critical issues, every instance of an event is created with a unique timestamp. | High-severity issues are purged after 7 days<br><br>Critical issues are never purged                   |
| Unit utilization       | Unit utilization data such as sniffer restarts, MySQL disk usage, and CPU load.        | Value exceeds unit utilization thresholds                                                    | Updated within 1 - 2 hours, based on the recommended configuration. For more information, see <a href="#">Configuring unit utilization data processing</a> .                                                                                                                                                                                                                                | Unit utilization data is purged after 60 days<br><br>Sniffer buffer usage data is purged after 14 days |

Important:

- Only data from systems that are running Guardium V10.1.2 and later are included on the deployment health dashboard.
- When you change the host name of a system, preexisting data that is associated with the original host name is no longer displayed on the deployment health dashboard.
- When a primary central manager transfers data to a backup central manager during a failover scenario, up to 30 minutes of data is unavailable to the deployment health dashboard.

## Data presentation

The deployment health dashboard formats and presents data through various tiles or small window-like containers. The following table summarizes the data that is presented on each dashboard tile.

Table 2. Summary of deployment health dashboard tiles

| Data source            | Tile name                                               |                        |                         |                             |                                                 |        |                                               |                                               |
|------------------------|---------------------------------------------------------|------------------------|-------------------------|-----------------------------|-------------------------------------------------|--------|-----------------------------------------------|-----------------------------------------------|
|                        | Resource requirements                                   | Central manager limits | Unit utilization issues | Unit utilization timecharts | Alerts (by category, name, severity, or system) | Events | High severity                                 | Critical                                      |
| Analyze data           | ✓ (values are a percentage of user-configurable limits) |                        |                         |                             |                                                 |        |                                               |                                               |
| Correlation alerts     |                                                         |                        |                         |                             | ✓                                               | ✓      | ✓                                             |                                               |
| System resources       | ✓                                                       |                        |                         |                             |                                                 |        | ✓                                             |                                               |
| System self-monitoring |                                                         |                        |                         |                             |                                                 | ✓      | ✓ (When usage meets or exceeds 75% threshold) | ✓ (When usage meets or exceeds 90% threshold) |
| Unit utilization       |                                                         |                        | ✓                       | ✓                           |                                                 | ✓      | ✓                                             |                                               |

The following tiles are displayed by default: *alerts by name*, *central manager limits*, *critical issues*, *events timeline*, *high severity issues*, and *unit utilization issues*.

## Dashboard filter

The dashboard filter allows quick filtering of the data based on Guardium systems, issue severity, and time period. Filter settings affect the data displayed on the entire dashboard unless noted otherwise.

The Guardium systems filter allows filtering the dashboard by unit type or by groups defined at [Manage > Central Management > Managed Unit Groups](#).

By default, the dashboard displays all available issues: low, medium, high, and critical. Use the Severity menu to filter data on the dashboard by severity. Selecting high filters the entire dashboard to display only high-severity issues. Selecting critical filters the entire dashboard to display only critical issues. It is possible to select both high and critical issues to filter out all lower-severity data.

Notes:

- Outstanding or unresolved critical issues are displayed on the dashboard regardless of the Severity filter setting.
- For the *unit utilization issues* tile, the dashboard Severity filter is based on the overall unit utilization severity. For more information about how unit utilization severity is assigned, see [Unit utilization issues](#).

The time filter determines the range of data that is displayed on the dashboard. Default settings allow time periods from 1 hour to 3 weeks, but custom time periods are also supported. The time filter does not apply to critical issues: critical issues are always displayed, regardless of the time filter setting.

Use the Add chart menu to add tiles to the dashboard or replace default tiles that you previously removed.

## Dashboard summary

The dashboard summary provides overall counts of health issues that are detected in your Guardium deployment. The Collectors with issues and Aggregators with issues counts indicate the number of systems--collectors and aggregators--that are detected with health issues. The Critical and High counts indicate the number of issues detected from all systems that are included on the dashboard.

Note:

- The Critical and High counts are not affected by adding or removing tiles from the dashboard.
- The counts on the dashboard summary bar reflect the dashboard filter settings.

## Alerts by category, name, severity, or system

The deployment health dashboard supports several tiles based on Guardium correlation alerts: *Alerts by category*, *Alerts by name*, *Alerts by severity*, and *Alerts by system*. Add correlation alert tiles to the dashboard by using the Add chart menu.

Correlation alerts must be explicitly configured for inclusion on the deployment health dashboard. For information about configuring alerts for the dashboard, see [Configuring a central manager for the deployment health views](#).

## Central manager limits

The *central manager limits* tile displays information to help assess central manager activity over time. For example, *MySQL connections*, *HTTP GUI connections*, *Tomcat open handlers*, and other related metrics are tracked on the tile.

All values are expressed as a percentage of a defined *analyze limit* threshold. For example, if a threshold is set at 80%, the tile indicates 100% when that 80% threshold is reached. The thresholds are configurable using the **modify\_guard\_param** API command. For more information, see the *analyze limits parameters* section of [modify.guard.param](#).

Customize the tile to include or exclude specific metrics and show or hide the legend.

## Resource requirements

The *resource requirements* tile indicates whether systems in a Guardium deployment meet the minimum hardware requirements for CPU, memory, and /var disk capacity. Any system resource that does not meet the minimum requirement is designated as a high-severity issue and displayed on both the *resource requirements* tile and the *high severity issues* tile.

Use the Include healthy systems check box on the details view of the tile to include all available data for the systems and time frame that are indicated on the dashboard filter bar. By including all available data, the Include healthy systems check box overrides the Severity setting of the overall dashboard filter. Systems without any detected health issues are excluded by default.

A table that displays all met and unmet resource requirements in your Guardium deployment is also available at Manage > Central Management > System Resources. Note:

- System resource issues are not displayed in the *Events* timeline because they are not associated with a specific time stamp

## Unit utilization issues

The *unit utilization issues* tile displays issues based on unit utilization thresholds. The issues that are displayed on the tile represent individual metrics that exceed their respective thresholds. The overall severity is assigned based on the highest severity issue that is found in all available metrics for an individual system in a specified time period. For more information about unit utilization thresholds, see [Unit utilization and inspection core performance](#).

The details view of the *unit utilization issues* tile includes both a Period start time and a Timestamp:

- The Period start time indicates that the *CM buffer usage monitor* data is rolled-up into hourly periods, for example periods starting at 13:00, 12:00, and 11:00.
- The Timestamp indicates when the unit utilization levels data is added to the deployment health dashboard, either based on the unit utilization levels schedule or by using *run once now*.

For more information, see [Configuring unit utilization data processing](#).

The first time that unit utilization data is brought into the deployment health dashboard, all the unit utilization data has the same *timestamp* but different *period start* times. Over time, the time stamps will appear at intervals based on the unit utilization levels schedule. For example, if the unit utilization levels data is collected every hour at 40 minutes after the hour, you will see *period start time* and *timestamp* values as follows:

Table 3. Example unit utilization period start time and timestamp values

| Period start | Timestamp |
|--------------|-----------|
| 13:00        | 14:40     |
| 12:00        | 13:40     |
| 11:00        | 12:40     |

Use the Include healthy systems check box on the details view of the tile to include all available data for the systems and time frame that are indicated on the dashboard filter bar. By including all available data, the Include healthy systems check box overrides the Severity setting of the overall dashboard filter. Systems without any detected

health issues are excluded by default.

## Unit utilization timecharts

*Unit utilization timecharts* allow the observation of trends in unit utilization data over time. *Unit utilization timecharts* can be configured to show multiple unit utilization metrics for a single Guardium system or to show a single unit utilization metric for multiple Guardium systems.

*Unit utilization timecharts* are structured based on the following criteria:

- The x-axis represents the *period start* time
- When multiple metrics are being charted and the values for the metrics are in the same range, one y-axis is drawn. For example, both *MySQL disk usage* and */var disk usage* are expressed as percentages and are drawn with the same y-axis.
- When multiple metrics are being charted and the values of the metrics are not similar, two y-axes are drawn. For example, *MySQL disk usage* is expressed as a percentage and *flat log requests* is expressed as an integer, so two y-axes are drawn: one displaying percentages and one displaying integers.
- If the value of a metric falls outside the range of a y-axis, that value is displayed at the bottom of the chart. This behavior accommodates scenarios where different metrics are expressed with similar units but significantly different values: for example, integers in the range of thousands versus millions.

Tip: Create multiple time charts when values are in significantly different ranges.

Note: Systems are not included on Timechart settings Host name menu when unit utilization data does not exist for that system in the time frame that is specified on the dashboard filter bar.

## Scenario: Troubleshooting overloaded systems using the deployment health topology view

This topic describes using the deployment health topology view to identify and fix an overloaded system in your environment.

## About this task

This scenario involves identifying health issues from the deployment health topology view, assessing the root cause, and correlating that assessment with additional data before resolving the problem and verifying the fix. The example described here involves an overloaded collector, but the process is applicable for other cases.

## Procedure

1. On a central manager, navigate to Manage System View Deployment Health Topology.
2. Review the deployment topology and assess the overall health of systems in the environment.  
At a high level, icons indicate healthy systems while and icons indicate systems with some health issues.
3. If you notice systems with or status icons, click the node to view an overlay with additional health information.
4. Use the information presented on the node overlay to begin diagnosing any health problems. For example, a collector with high or medium severity statuses for */var disk usage*, *Restarts*, *Analyzer queue*, and *Logger queue* indicates that the collector is overloaded.
5. After initially assessing health issues from the deployment health topology view, try to correlate your findings with additional data. For example, if you suspect that a system is overloaded, begin monitoring the traffic for that system.
6. When you are confident that you have diagnosed the underlying health issues, take corrective actions. In the example of an overloaded system, you could establish [Enterprise load balancing](#) or reassign S-TAPs to another collector.  
Typically, this set of symptoms would not occur if enterprise load balancing was already configured and in use.
7. After taking corrective actions, the status of the node on the deployment health topology view will be updated following the next refresh of unit utilization and central manager buffer usage monitor data. This refresh interval depends on your [schedule for processing unit utilization data](#).

## Creating a cross-CM health view

The cross-central manager health view (cross-CM health view) is a Guardium unit type that provides aggregated health views for an entire Guardium deployment. These views include health information for all available central managers, aggregators, collectors, and S-TAPs in your environment. After you build a cross-CM health view unit, you can manage patches for all the central managers that are associated with that unit.

## Before you begin

Important: Build your cross-CM health view system as a new Guardium unit that is dedicated to viewing deployment health across your entire environment. Unlike a standard central manager, a cross-CM health view system is not intended for providing other types of data or managed functionality.

- Central managers registered to the cross-CM health view system must be at version 11.5p530 or later
- Communication over port 8443 between the cross-CM health view system and connected central managers

Note:

- If you have access to deployment health views on the cross-CM health view system, you can view health information for all Guardium units that are connected to the cross-CM health view system. However, you do not have any additional access to those connected systems beyond the access that their role provides.
- For user access and roles management, treat the cross-CM health view system as a stand-alone unit.
- When you upgrade Guardium systems in your environment, treat the cross-CM health view system as a stand-alone unit.

## About this task

---

### Procedure

---

1. Deploy a new Guardium aggregator. For more information, see [Installing your Guardium Data Protection system](#).
2. Change the system type to cross-CM health view by running the following CLI command:

```
store unit type cmhealthview
```

3. Register central managers to the cross-CM health view system by running the following API command:  
12.0 Syntax

```
grdapic modify_guard_param paramName=CM_HEALTH_VIEW_HOSTNAME paramValue=<host name of cross-CM health view system>
```

The preceding command registers 12.0 and earlier versions of central manager to the cross-CM health view system.

12.1 and later Syntax

```
grdapic register_unit unitIp="" unitPort="" secretKey=""
```

The preceding command registers 12.1 central manager to the cross-CM health view system.

- Run the command from each central manager that you are registering to the cross-CM health view system.
- The health data is forwarded from the central manager to the cross-CM health view system. No other types of data or managed functionality is provided.

Note:

12.0 You can unregister central managers from the cross-CM health view system by providing an empty `paramValue` for `CM_HEALTH_VIEW_HOSTNAME`.

Unregistered systems still appear on the aggregated health views of the cross-CM health view system, but their data is no longer updated and their status may not be listed accurately.

```
grdapic modify_guard_param paramName=CM_HEALTH_VIEW_HOSTNAME paramValue=
```

12.1 and later You can unregister 12.1 central manager from the cross-CM health view system by providing the central manager name.

```
grdapic unregister_unit unitIpList=""
```

### What to do next

---

After central managers are registered to the cross-CM health view system, you will begin seeing aggregated health data on the cross-CM health view system after a short delay. While the health data is being updated, the registered systems can indicate an *unknown* status and a *status updated* date from sometime in the past.

12.0 You cannot view the registered central managers in the Patch Management page.

12.1 and later You can manage patches and register and unregister central managers from the Patch Management page. You can also view the registered central managers in the Patch Management page. For more information, see [Managing patches on a cross-CM health view system](#).

- [Viewing cross-CM health view deployment health data](#)

After you create cross-central manager health view (cross-CM health view) Guardium unit, you can view aggregated health views for an entire Guardium deployment. These views include health information for all available central managers, aggregators, collectors, and S-TAPs in your environment.

- [Managing patches on a cross-CM health view system](#)

12.1 and later From the Patch Management UI on a cross-central manager health view (cross-CM health view) Guardium unit, you can view and update patches for multiple Guardium Data Protection central managers and their associated managed units.

## Viewing cross-CM health view deployment health data

---

After you create cross-central manager health view (cross-CM health view) Guardium unit, you can view aggregated health views for an entire Guardium deployment. These views include health information for all available central managers, aggregators, collectors, and S-TAPs in your environment.

The cross-CM health view system supports the following aggregated health views:

- Manage > System View > Deployment health topology
- Manage > System View > Deployment health table
- Manage > System View > S-TAP and GIM dashboard

These health views on a cross-CM health view system function as they do on a standard central manager but provide health data from multiple central managers. For more information about the deployment health views, see [Deployment health views](#). However, the following features (available on standard central managers) are not supported for a cross-CM health view system:

- Configuring the traffic ignore list
- The investigation dashboard status type

## Managing patches on a cross-CM health view system

12.1 and later From the Patch Management UI on a cross-central manager health view (cross-CM health view) Guardium unit, you can view and update patches for multiple Guardium® Data Protection central managers and their associated managed units.

### Before you begin

Before you can view and manage available patches from the Patch Management page, you need to make them available to Guardium. For more information, see [Getting fixes from Fix Central](#) or [How to install patches](#).

To install patches on a central manager and its associated managed units, you must register the central manager on Patch Management. For more information, see [What to do next](#).

Note: Register (or reregister) all central managers that you want available for the deployment health view.

This feature is available on cross-CM health view systems only. You can install patches only on Guardium 12.1 and later central managers.

### Procedure

1. From a cross-CM health view unit, browse to System View > Patch Management.
2. From the CLI, run the following command to populate the Available patches table.

```
show system patch available
```

3. From Available patches, select the patch that you want to apply.

Note: You can select and install one patch at a time from the list.

4. From Registered units, select one or more units for which you want to apply the selected patch.

From the Registered units table, you can sort on any table column or filter on the following elements:

- Central manager name
- Managed unit group
- A search string

An admin user can assign roles to the central manager; only users with those assigned roles can access the central manager and their associated managed units and install the patch.

Note: Only the admin user that has access to the central manager can assign roles to the central manager.

5. Click Install to install the patch on all selected central managers.

6. In the Install Patch window, select a date if you want to schedule the patch installation, and then click Install

### What to do next

In addition to managing patches for your central managers, you can also register (and unregister) central manager units from the Patch Management window. To register a new unit, take the following steps:

1. From the Registered units table, click Register to open the Register New Unit window.
2. Enter the following information:
  - Unit IP - IP address (not the hostname) for the unit you want to register.
  - Unit port - The port for this unit. In general, use port 8443.
  - Secret access key - The system shared secret. For more information, see [Use the Same Shared Secret](#).
3. Click Register. After a few minutes, the unit is registered and is available in the Registered units table.

To unregister a unit, select the unit to unregister and click Unregister.

## S-TAP and GIM dashboard

This dashboard presents S-TAP and GIM health, status, version, and other information through several easy-to-use charts.

Data for the S-TAP and GIM dashboard is derived from the deployment health topology and table views. For more information, see [Deployment health views](#).

Open the dashboard at Manage > System View > S-TAP and GIM Dashboard.

The dashboard is divided into three sections:

#### S-TAP charts

Charts in this section support dynamic filtering: click on a chart element to filter the other charts by that element. For example, clicking Db2 on the Databases by inspection engine chart filters the other S-TAP charts so they only display information for S-TAPs with Db2 inspection engines. Use the Remove link to clear dynamic filters.

- S-TAP health summarizes S-TAP health status.
- S-TAPs by version shows how many S-TAPs are operating at specific version levels.
- Databases by inspection engine shows the different database types that are known in the environment.
- S-TAPs by operating system shows the different operating systems that are known in the environment. For Linux-UNIX operating systems, each distribution is represented by a vertical bar and the bars are segmented by version. For example, with two different versions of Red Hat Enterprise Linux (RHEL), the chart shows a single rhel bar divided into two segments (one for each version of RHEL). Similarly, one bar is used for Windows and the bar is segmented by version.
- S-TAPs with recent traffic. Use the Configure traffic metric link or use the icon and select the Traffic ignore list tab to create a list of hosts to exclude for the traffic metric. To exclude all traffic metrics for all hosts, use the icon and clear the Traffic check box on the Health settings tab.

Important: The list of hosts ignored for the traffic metric is shared between the S-TAP and GIM dashboard, the Deployment health topology, and the Deployment health table.

#### Historical charts

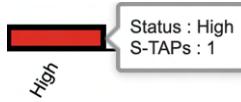

- S-TAP count shows the number of S-TAP that have detected traffic during the specified time period. Use the icon to set the time period.
- Inspection engine count shows the number of inspection engines that have detected traffic at 1-hour intervals for the past 3 hours. Use the icon to set the time period.

#### GIM charts

- GIM status summarizes the GIM client status information.
- GIM clients by version.
- S-TAP vs. GIM

Note: For S-TAPs or Guardium systems before V11.1, the operating system is listed only by the categories Linux-UNIX or Windows.

All charts are interactive such that hovering over a chart element shows details and tallies for that element. For example, hovering over a specific status bar in the S-TAP health chart shows the total number of S-TAPs with that status:

For each chart, use the icon to view a detailed table of the underlying data. The table views provide several troubleshooting features:

- Column sorting.
- Filtering using the Filter overall status by check boxes and the Filter text field.
- For S-TAP charts, view underlying inspection engines by expanding individual S-TAP rows.
- For S-TAP charts, investigate problems by selecting an individual S-TAP and using the Reports > S-TAP events report. If the S-TAP is associated with multiple collectors, each collector is shown in its own tab in the report.

This view can show invalid S-TAPs. Invalid S-TAPs are similar to inactive S-TAPs, but they only appear in some deployment health and deployment dashboard views. Use the **delete\_invalid\_stap** API command to remove invalid S-TAPs.

## Create and manage S-TAP clusters

Learn how to define S-TAP clusters in Guardium that are useful for managing active-passive S-TAP cluster arrangements on your data servers.

## About this task

S-TAP clusters and the Manage S-TAP clusters page are only available on Guardium central managers.

## Procedure

1. Open Manage > System View > Manage S-TAP Clusters.  
The page displays a table of S-TAP clusters with standard , , and controls.
2. Create a new S-TAP cluster by clicking the icon to open the Add cluster dialog.
3. From the Cluster details tab of the Add cluster dialog:
  - a. Use the provided fields to enter a Cluster name, Cluster description, and Cluster IP.
  - b. Optional: Enable Remove inactive S-TAP connections by cluster.  
When enabled, this option automatically removes S-TAPs from Guardium when S-TAPs are not connected and the S-TAPs are part of an S-TAP cluster with one (and only one) connected S-TAP. If there are no active S-TAPs or multiple active S-TAPs in a cluster, no S-TAPs are removed from Guardium. Clusters are checked at a predefined interval.  
Important: When S-TAPs are removed using Remove inactive S-TAP connections by cluster, they are not merely removed from the S-TAP cluster: they are entirely removed from the Guardium system.
  - c. Optional: Enable Monitor S-TAP traffic by cluster.  
When enabled, this option changes how S-TAP traffic status is reported on the Deployment Health views: if one or more S-TAPs in the cluster has traffic, all S-TAPs in the cluster are reported as having traffic.
4. From the Cluster members tab of the Add cluster dialog, use the icon to add S-TAPs to the cluster.  
Manually enter an S-TAP IP address or host name, or use type-ahead functionality to select from existing S-TAPs.  
Note: S-TAPs may not be assigned to more than one S-TAP cluster.
5. Click Save to create the new S-TAP cluster.  
If Remove inactive S-TAP connections by cluster is enabled (see step 3.b), you are required to provide additional confirmation before continuing.

## Results

After creating S-TAP clusters, the Manage S-TAP Clusters table shows configuration summary for all S-TAP clusters. In addition:

- The Deployment health table includes an S-TAPs by cluster tab where you can review health information organized by S-TAP cluster.

- The Deployment health topology features S-TAP Cluster filters.
- The S-TAP and GIM Dashboard displays an S-TAP clusters with recent traffic tile.

## Enterprise load balancing

The enterprise load balancer dynamically allocates managed units to S-TAP agents based on system load and availability.

### Overview

Enterprise load balancing automates several tasks:

- It dynamically rebalances loaded or busy managed units by relocating S-TAP agents to managed units with lower loads. It balances the load of a group of S-TAPs among a group of managed units.
- It dynamically manages failover and unavailable managed unit scenarios, relocating S-TAP agents to another managed unit, or units, in its associated group.
- It evaluates the load of managed units before it assigns those managed units to an S-TAP agent.

See the Load Balancer Events report to review all load balancing activity.

Enterprise load balancing is disabled by default on Guardium® systems.

Enterprise load balancer does not balance the number of S-TAPs, sessions, or traffic. It allocates and moves S-TAPs between managed units to avoid overloading the sniffer process on those Guardium systems. The result is that some managed units have more S-TAPs pointing to them than others.

Note: S-TAP load balancing can be used simultaneously with enterprise load balancing, except for the grid model. For more details on S-TAP load balancing, see [Linux-UNIX: S-TAP load balancing models and configuration guidelines](#) and [Windows: S-TAP load balancing models and configuration guidelines](#).

### How it works

The enterprise load balancing application works by collecting and maintaining up-to-date load information from all its managed units. This process is called load collection.

It uses the load information to create a load map. This load map provides the data that directs load balancing and managed unit allocation activities. For more information, see [Viewing the enterprise load balancing load map](#).

Load collection errors from specific managed units are recorded in the Load Balancer Events report but do not interfere with the overall load collection and load balancing processes. However, failure to collect load information from a managed unit excludes that managed unit from participation in load balancing processes.

### Failover groups

If an S-TAP is requesting a new managed unit to fail over to, the load balancer searches in the associated managed unit group for an available managed unit. If it cannot find a managed unit, it continues its search in the failover groups until it finds one. You can define multiple failover groups.

You can prioritize the failover groups, for a controlled disaster recovery strategy. The load balancer searches for an available managed unit in the failover groups, starting with the group, or groups, whose priority is 1. Priority rule guidelines:

- The priority list must be sequential starting with 1.
- Multiple groups can have the same priority.
- The priorities cannot skip a level. For example, 1,1,2,3 is valid. However, 1,2,4,5 is invalid.

You must specify at least one associated managed unit group before you can specify a failover group association.

Attention: Make sure that all failover groups send their data to the same aggregator to simplify aggregation. (An exception is if you are using a data mart.) Load is not rebalanced within any one failover group.

- [Enabling enterprise load balancing and associating an S-TAP with a central manager](#)

First, enable enterprise load balancing on the central manager. Then, configure S-TAPs to point to the central manager. Then the central manager allocates managed units to the S-TAP.

- [Associating an S-TAP group with a managed units group for enterprise load balancing](#)

Learn how to use enterprise load balancing by creating and associating S-TAP groups with managed unit groups. If a managed group unit becomes unavailable, the S-TAPs sending data to that managed unit group are reassigned to the managed unit in the associated group with the lowest load. Optionally, define failover groups. You can specify multiple failover groups, with priorities, for disaster recovery.

- [Restarting \(resynchronizing\) S-TAPs for enterprise load balancing](#)

S-TAPs can become unsynchronized for a few reasons, for example, after you modify the S-TAP groups or the managed user groups in your centrally managed environment.

- [Viewing the enterprise load balancing load map](#)

Learn how to view the current enterprise load balancer load map.

- [Viewing an enterprise load balancing activity report](#)

View a report of enterprise load balancing events and activities.

- [Enterprise load balancing configuration parameters](#)

Use the load balancer configuration parameters to manage enterprise load balancing. To access the load balancing properties in a central manager, go to Manage > Central Management > Enterprise Load Balance > Enterprise Load Balance Properties. In a managed unit, go to Setup > Central Management > Registration and Load Balance.

## Enabling enterprise load balancing and associating an S-TAP with a central manager

First, enable enterprise load balancing on the central manager. Then, configure S-TAPs to point to the central manager. Then the central manager allocates managed units to the S-TAP.

## Before you begin

- The enterprise load balancer runs on a central manager or managed unit, listens to port 8443, and uses Transport Layer Security (TLS).
- No new firewall or extra system setup is required.
- Load information is only collected from managed units that are online and configured with the central management parameter LOAD\_BALANCER\_ENABLED=1. Setting LOAD\_BALANCER\_ENABLED=0 disables load balancing and prevents that managed unit from being dynamically allocated to S-TAP agents during load balancing activities.

## Procedure

1. Enable enterprise load balancing on the central manager. Go to [Manage > Central Management > Enterprise Load Balance > Enterprise Load Balance Properties](#) and set LOAD\_BALANCER\_ENABLED=1.
2. Point one or more S-TAPs to the central manager by modifying the S-TAP parameter in the S-TAP Control page:
  - Load balancer host name or IP address
  - load\_balancer\_port
3. Modify the S-TAP configuration parameters in the S-TAP Control page:
  - Managed Units: The number of managed units the enterprise load balancer allocates for this S-TAP.
  - Load balancing: Defines how the load is split between the assigned managed units. For example,
    - Managed Units=2, and Load balancing=1 (load balancing). The Enterprise Load Balancer assigns two managed units to the S-TAP, and traffic is split between the managed units.
    - Managed Units=2, and Load balancing=2 (mirroring). The Enterprise Load Balancer assigns two managed units to the S-TAP, and traffic is mirrored to both of the managed units.
  - For Unix-Linux databases only. Load balancer node affinity: Whether the S-TAP connects to more than one managed unit, for enterprise load balancing. Some scenarios need all traffic to go to the same collector. With Oracle ATAP, for example, the analyzed client IP only shows if both the encrypted and unencrypted sessions go to the same managed unit. For more information, see [Load balancer node affinity](#).

## What to do next

## Associating an S-TAP group with a managed units group for enterprise load balancing

Learn how to use enterprise load balancing by creating and associating S-TAP groups with managed unit groups. If a managed group unit becomes unavailable, the S-TAPs sending data to that managed unit group are reassigned to the managed unit in the associated group with the lowest load. Optionally, define failover groups. You can specify multiple failover groups, with priorities, for disaster recovery.

## About this task

When you specify multiple failover groups, each one has a priority. When the load balancer searches for an available managed unit in a failover group, it starts with the group, or groups, whose priority is 1.

## Procedure

1. On a central manager, go to [Manage > Central Management > Enterprise Load Balancer > Associate S-TAPs and Managed Units](#).
2. If you need to create an S-TAP group:
  - a. Click  to open the Create New S-TAP Group dialog.
  - b. Type a name in the Group Name field.  
For example, North\_American\_S-TAPS.  
Recommendation: To ensure compatibility with other Guardium components, do not use spaces or special characters in group names.
  - c. Add group members by selecting from existing host names, or add new members using the Group Member field. S-TAPs indicated with a  are included with the new S-TAP group.
  - d. Click Create New Group to create the S-TAP group.
3. Associate the S-TAP group with a managed units group.
  - a. Select the S-TAP group that you want to associate.  
For example, North\_American\_S-TAPS.
  - b. Click Associate Managed Units to open the Associate Managed Unit Group dialog.
  - c. If necessary, create a new group of managed units.
    - i. Go to [Manage > Central Management > Managed Unit Groups](#).

- ii. Click  to open the Create New Managed Unit Group dialog.
  - iii. Type a name in the Group Name field. For example, `North_American_MUs`.  
Recommendation: To ensure compatibility with other Guardium components, do not use spaces or special characters in group names.
  - iv. Add group members by selecting from existing Managed Unit IP addresses.
  - v. Click Create New Group to create the new group of managed units. The Managed Unit Groups page refreshes, showing the new group.
  - d. Select one or more managed units groups to associate with the S-TAP group.  
For example, `North_American_MUs`.
  - e. Click Apply.
  - f. Click Save to complete the association between an S-TAP group and a managed units group.
4. Optional: Associate the S-TAP group with a managed unit group for failover.
- a. Select the S-TAP group. For example, `North_American_S-TAPs`.
  - b. Click Associate Failover Groups to open the Associate Failover Group dialog. All groups appear in both the associated group and failover group lists. After a group is designated as either an associated group or a failover group, it no longer appears in the other group list.
  - c. If necessary, create a new group of managed units (described in step 3.c).
  - d. Select one or more target managed unit failover groups. For example, `North_American_MUs_failover`.
  - e. Modify the failover priorities of the groups, as relevant.
    - The priority list must be sequential starting with 1.
    - Multiple groups can have the same priority.
    - The priorities cannot skip a level. For example, 1,1,2,3 is valid. However, 1,2,4,5 is invalid.
  - f. Click Apply.
  - g. Click Save to complete the association between an S-TAP group and a failover managed units group.

## Restarting (resynchronizing) S-TAPs for enterprise load balancing

S-TAPs can become unsynchronized for a few reasons, for example, after you modify the S-TAP groups or the managed user groups in your centrally managed environment.

### About this task

S-TAPs can become unsynchronized due to modifications in the Associate S-TAPs and Managed Units page, changes to the S-TAP groups or managed unit groups in other UI pages, scheduler events, and GRD API commands. You can view all unsynchronized S-TAPs in one dialog, and select S-TAPs for restart, which resynchronizes them.

### Procedure

1. Go to `Manage > Central Management > Enterprise Load Balance > Associate S-TAPs and Managed Units`
2. Click Find non-sync S-TAPs.  
The Restart STAPs dialog opens, with a list of all S-TAPs that are not synchronized.
3. Select the S-TAPs that you want to resynchronize and click Restart S-TAPs.

## Viewing the enterprise load balancing load map

Learn how to view the current enterprise load balancer load map.

### About this task

The enterprise load balancing application uses the load information from managed units to create a load map. This load map provides the data that directs load balancing and managed unit allocation activities.

### Procedure

1. To view the current load map as a report in the Guardium® UI, navigate to `Manage > Reports > Unit Utilization > Load Balancer`.
2. It is also possible to view the current load map using the Guardium API. Issue the following GuardAPI command: `grdapic get_load_balancer_load_map`.  
The load map should look like the following example:

```
ID=0

```

## Viewing an enterprise load balancing activity report

View a report of enterprise load balancing events and activities.

### About this task

The Enterprise Load Balancer Events report shows all load balancing events and activities, including successful associations between S-TAP agents and managed units, changes in managed unit load, and failed associations. This report can be copied and modified.

### Procedure

To view the report, navigate to **Manage** > **Reports** > **Activity Monitoring** > **Enterprise Load Balancer Events**.

## Enterprise load balancing configuration parameters

Use the load balancer configuration parameters to manage enterprise load balancing. To access the load balancing properties in a central manager, go to **Manage** > **Central Management** > **Enterprise Load Balance** > **Enterprise Load Balance Properties**. In a managed unit, go to **Setup** > **Central Management** > **Registration and Load Balance**.

| Parameter                                        | Default value                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Related reference

- [Central management APIs](#)

## Deployment inventory

The inventory view provides centralized view of all database servers and any installed S-TAPs or GIM clients.

Note: S-TAP points to a single primary collector and possibly multiple secondary collectors for load balancing. If you change the primary collector from the Central Manager, it reflects in the Deployment inventory table within 5 minutes. The table displays primary collector label in the Collector column to indicate the primary collector.

## Resource deployment view

The resource deployment view shows the GIM clients and S-TAPs installed on the database servers in a Guardium environment.

## Monitoring managed units

Monitor managed units from the Guardium Central Management page.

To monitor and manage managed units,

1. Log in as an admin user to the Guardium® GUI of the central manager for the units you want to view or manage.
2. Click [Manage > Central Management > Central Management](#) to open Central Management page.

The Central Management page is divided into two sections, the Central Management table, and the Selected Units section. From the Selected Units section, you can select several management tasks that you can perform on selected units. The information and tasks are described in the following tables.

Click any column in the Central Management table to sort the table in ascending order. Click again to sort in descending order.

Table 1. Central Management table. View information about all the managed units for this central manager and select and manage the managed units.

| Select all checkbox       | <input type="checkbox"/>                                                            | Select the checkbox in the heading to select all managed units (and clear the checkbox to deselect all managed units).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Checkbox                  | <input type="checkbox"/>                                                            | Select a specific unit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Refresh unit information. |  | Refreshes all information that is displayed in the expanded view of that unit and issues new requests to that unit. This action also causes a full user synchronization cycle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Reboot unit               |  | Reboots the unit at the operating system level. By default, the Guardium portal is started at startup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Restart unit portal       |  | Restarts the Guardium application portal on the selected managed unit. You can then log in to that unit to perform Guardium tasks (defining or removing inspection engines, for example).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Shortcut to unit portal   |  | Opens the Guardium login page for the managed unit, in a separate browser window.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Unit                      |                                                                                     | <p>The hostname of the managed unit.</p> <p>If the hostname changes on the unit, the central manager no longer sees that unit when the online status is automatically refreshed. If you suspect the hostname was changed, click Refresh on the toolbar. Guardium updates the hostname and online status as needed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Install Policy                                 | Opens the Install Security Policy page. Select a policy to apply to all selected units. For more information, see <a href="#">Installing security policies on managed units</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Patch Distribution                             | Patch Distribution opens the Patch Distribution page, which displays a list of available patches with dependencies. You can select a patch and install it on all selected units. You can also schedule patches up to one year in the future. For more information, see <a href="#">Central patch management</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Distribute Uploaded Jar Files                  | <p>Click Harden &gt; Vulnerability Assessment &gt; Customer Uploads. Then, enter the name of the file to be uploaded. Otherwise, click the Browse to locate and select that file. Upload one driver at a time.</p> <p>Click Upload. You are notified when the operation completes, and the file that is uploaded is displayed. This action brings the uploaded file to the central manager.</p> <p>Select the managed unit or units where you want to distribute the JAR files. Click Distribute Uploaded JAR files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Distribute Patch Backup Settings               | This setting distributes the following to selected units:<br><br>PATCH_BACKUP_FLAG; PATCH_AUTOMATIC_RECOVERY_FLAG; PATCH_BACKUP_DEST_HOST; PATCH_BACKUP_DEST_DIR;<br>PATCH_BACKUP_DEST_USER; PATCH_BACKUP_DEST_PASS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Distribute Authentication Config               | Distribute the authentication configuration to all managed units selected. For more information, see <a href="#">Distributing authentication configuration</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Distribute Configurations                      | <p>The following configurations are distributed to sync parameters between the central manager and the managed units:</p> <ul style="list-style-type: none"> <li>• Anomaly Detection - Active on startup, Polling interval</li> <li>• Alerter - all fields</li> <li>• Data Archive - all fields</li> <li>• Global profile - Concurrent Logins, Data Level Security, all fields except Named Templates (which are already synced), PDF footer text, and logo image.</li> <li>• IP-to-Hostname Aliasing - both check boxes</li> <li>• Results Archive - all fields</li> <li>• Results export - all fields</li> <li>• Session Inference - all fields</li> <li>• System Backup - all fields</li> <li>• Data export - all fields</li> </ul> <p>Some of these configurations do not take effect until the portal is restarted (Anomaly Detection, Session Inference). Other processes, such as the Alerter, need to be restarted, either directly through the admin portal of the managed unit, or by rebooting all relevant managed units from the manager. For more information, see <a href="#">Distributing configurations</a>.</p> <p>Distribute Configurations does not restart the managed units. To restart the managed units, either select the restart unit icon ( for a single unit or select Restart Portal to restart all the selected units.</p> <p>For any configuration that includes scheduling , you can select the Include Schedule checkbox. When Include Schedule is selected, Distribute Configurations also includes the configuration's scheduling.</p> |
| Distribute GIM bundles                         | Distributes GIM bundles to the selected managed units. A message displays when the GIM bundles are distributed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Register New                                   | Opens the Unit Registration page to register a new unit for management.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Patch Installation Status                      | Opens the Patch Installation Status window, which displays failed installations and discrepancies for each unit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Designate Backup CM                            | Displays the Designate Backup CM window. Select a backup central manager IP address or select a unit that can serve as the backup central manager and click Apply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 12.1 and later Run database instance discovery | <p>Runs the database instance discovery from the central manager on all the active Unix or Windows S-TAP units for all the managed units, a group of managed units, or a single managed unit.</p> <p>Opens the Run database instance discovery page, where you can select all managed units, a group of managed units or an individual managed unit, all active S-TAP hosts, and the Replace Inspection Engines checkbox.</p> <p>Important: Do not check <b>Replace Inspection Engines</b> unless you want to overwrite the existing inspection engine configurations. You can view the discovered instances under Discover &gt; Reports &gt; Discovered Instances.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Assigning correlation alerts from the central manager to individual managed units or managed unit groups

You can assign correlation alerts to individual managed units or managed unit groups from the central manager. You can assign or exclude alerts to a unit or to a managed unit group. You can also specify whether to run the alerts on the central manager itself. For more information, see [Managing correlation alerts](#).

Notes:

- On the individual managed units, the alert builder does not show any section on managed units. Only the central manager can assign alerts to units and groups.
- For any entries in the alert table that exclude a given managed unit, a system-generated group is created to exclude that unit for each excluded alert. The group is created when the alerts are started on that managed unit.
- The alert windows on the anomaly detection page under admin console were used to locally enable or disable alerts. For this feature, the alert windows appear only on the central manager.
- On the managed units, a table shows active alerts and whether they are enabled.

## Creating managed unit groups

Organize managed units into groups and then take actions on those groups.

### About this task

Managed unit groups allow you to organize managed units into meaningful groups and then take actions on those groups. For example, you might create managed unit groups for specific unit types, geographies, or lines of business. Actions you might take include installing policies or distributing patches or configurations to a group of managed units.

Guardium® has two predefined groups that account for all managed units: All Aggregators, and All Collectors. When you add a managed unit to your system, it is automatically added to one of these groups. These two groups are mutually exclusive.

When you restore a unit from the backup taken from the different environment that contains appliances that are not registered to the new restored system, go to the Managed Unit Groups page in the new environment and modify the groups accordingly. If there are distributed reports based on these groups, they are corrected automatically when you save the changes in the Managed Unit groups page.

### Procedure

1. Go to [Manage > Central Management > Managed Unit Groups](#).
2. Click to create a new managed unit group or to edit an existing group.
3. In the Create new managed unit group dialog, type a name for the group in the Group name field.  
Recommendation: To ensure compatibility with other Guardium components, do not use spaces or special characters in group names.
4. Use the icons to select managed units to include in the group.
5. When you have finished selecting managed units to include in the group, click Save.  
The new managed unit group is saved and appears on the Managed Unit Groups page.
6. Optionally, from the Managed Unit Groups page, click the icon to expand a group and view its managed units.

### Results

Once defined, a managed unit group is available from the [Manage > Central Management > Central Management](#) page, the [Manage > Central Management > Distribute Configuration Profiles](#) page, as a managed unit group within the [Manage > Central Management > Enterprise Load Balance > Associate S-TAPs and Managed Units](#) tool, and in other locations where managed unit groups are used.

## Installing security policies on managed units

Install a security policy on a manage unit.

### About this task

To install a security policy on a managed unit:

### Procedure

1. Click [Setup > Tools and Views > Policy Installation](#) to open Currently Installed Policies and the Policy Installer.
2. From the Policy list, select the policy that you want to install.
3. From the list, select an installation action. After you select an installation action, you are informed of the success (or failure) of each policy installation. If a selected unit is not available (it might be offline or a link might be down), the Central Manager informs you of that fact. It continues attempting to install the new policy for a maximum of seven days (on the condition that unit remains registered for central management).
4. From the Policy list, select the policy that you want to install.
5. The available installation actions include the following items:
  - a. Install and Override - delete all installed policies and install the selected one instead
  - b. Install last - installing the selected policy as the last one in the sequence; installing the policy after all currently installed policies and having the lowest priority
  - c. Install first - installing the selected policy as the first one in the sequence; installing the policy before all currently installed policies.

Note: If you install a policy from the Central Manager, the selection of Run Once Now (and scheduler) updates existing groups within the installed policies.

To load changes to rules, including addition and subtraction of groups, you must either:

- a. Initially install policies from the Collector, or
- b. Reinstall policies from the Collector or Central Manager.

## Central patch management

Provide visibility and control over patch installation, status, and history.

### About this task

The central manager provides the interface to install patches on all managed units in your environment and also view the patch installation status and history for each unit. After your central manager is upgraded, you can use its interface to also view the detailed patch status log for each managed unit even if the units are running on an older version.

When you install a patch, a date and time request can be specified to indicate when the patch is installed. If no date and time is entered or if now is entered, the installation request time is immediate.

Note: A patch that is installed successfully can be installed again. This fact is important for batched patches. A warning informs you if the patch is already installed. Log in to the Guardium® GUI of the unit to be managed as the admin user:

### Procedure

1. Click **Manage > Central Management > Central Management**.
2. Select the units that need the patch, and click **Patch Distribution**.
3. From the Patch Distribution screen select the patch you want to distribute and click **Install Patch Now** or **Schedule Patch**.
4. To see the summary of the installation status, click **Manage > Central Management > Central Management** and then select the units and click **Patch Installation Status**. The summary lists all the patches for each managed unit in the order that the installation was requested. The Patch Installation Status screen also displays, for each unit, failed installations and discrepancies. For example, having one patch installed on part of the units only, regardless if it failed on other units or was not installed. To remove patches from the Patch Distribution screen, click the delete icon (red x) next to the patch. This does not delete the patch from the patch distribution directory on the appliance, but will remove it from the display.  
Attention: Removing a patch from the patch distribution display also removes that patch from dependency-checking and can prevent the installation of newer patches.
5. To see detailed information about the patch installation, click on a managed unit that is listed under the Unit name column. This action opens the **Patch Status Details** window, where you can view the last five lines of the patch status log for the managed unit. The patch status log reflects the last patch that was installed. If a patch installation is in progress, the latest patch log is displayed. If you'd like to see more details from the log, click **Fetch More**.
6. When you click on a different managed unit, the log in the **Patch Status Details** window is appended. You also have the ability to **Clear** or **Close** the log, as needed.  
Important: To view the patch status details, the root passkey must be installed on the managed unit. If the root passkey is not installed, you will receive an error message. For more information, see [Resetting the root password](#).

## Distributing authentication configuration

Instead of configuring authentication on each appliance separately, central management authentication (Configure Authentication) can be configured once on the central manager and then distributed to all managed units. This way, information is entered once and it applies to some or all units; some of the units may have a different type of authentication.

### Procedure

1. Ensure authentication (Configure Authentication) on both the central manager and the managed unit. So if LDAP authentication is being used, ensure that LDAP is configured on the central manager and the managed unit.
2. Select the managed units to receive the distribution of the central management authentication.
3. Click **Distribute Authentication Config** to distribute the authentication configuration to all managed units selected.

## Distributing configurations

Configurations and their schedules, can be distributed, either all or individually, between the central manager and the managed units.

### Procedure

1. Select the managed units that receive the configurations.
2. Click **Distribute Configurations** to display the **Distribute Configurations** window.
3. Check the appropriate boxes for the configurations that you want to distribute. Use the check box in the header to select all configurations.
4. Check the appropriate boxes for any schedules that you want to distribute. Use the check box in the header to select all schedules. If a configuration is not scheduled, the check box is not available.
5. Click **Distribute** to distribute the configurations and schedules.

## What to do next

After you distribute the configuration, you might need to either reboot or restart any managed units that you have updated.

#### Alerter

Restart managed units.

If Active on Startup is selected, the alerter starts each time the appliance restarts.

GUI restart does not take the Active on Startup value.

The alerter must be manually restarted on the managed units through the admin portal (Admin Console > Alerter). Since you cannot restart the alerter from the central manager, restart the managed units from the Admin Console for the same effect.

#### Anomaly Detection

Restart managed units.

If Active on Startup is selected, anomaly detection starts each time the appliance restarts.

GUI restart takes the Active on Startup value.

#### Session Inference

Restart managed units

If Active on Startup is selected, session inference starts each time the appliance restarts.

GUI restart takes the Active on Startup value.

#### Results Export, System Backup, Data Archive, Result Archive, and Data export

No restart or reboot needed. The configuration is distributed automatically.

#### Global profile

No restart needed. However, using a different named template applies only when policy is installed.

Note: When you distribute the configuration for the global profile, the following values are distributed:

- ACTIVATE\_ALIASES
- CUSTOM\_DB\_MAX\_SIZE
- CHECK\_CONCURRENT\_LOGIN
- HTML\_BOTTOM\_RIGHT
- HTML\_BOTTOM\_LEFT
- DISPLAY\_LOGIN\_MESSAGE
- LOGIN\_MESSAGE
- CSV\_DELIMETER
- FILTERING\_ENABLED
- INCLUDE\_CHILDREN\_ON\_FILTER
- SHOW\_ALL\_RECORDS
- ACCORDION\_DISABLED
- SCHEDULER\_RESTART\_INTERVAL
- SCHEDULER\_RESTART\_WAIT\_SHUTDOWN
- ESCALATE\_TO\_ALL
- MESSAGE\_TEMPLATE

---

## Working with configuration profiles

Configuration profiles allow you to define configuration and scheduling settings from a central manager and distribute those settings to managed unit groups without altering the configuration of the central manager itself.

### Before you begin

Before creating and distributing configuration profiles, verify the following prerequisites:

- Allow communication over port 8447 between the central manager and its managed units
- The central manager and the managed units that will receive configurations must be at or above Guardium® V10.1

### About this task

Configuration profiles contain two types of information: configuration type (one or more sets of configuration and scheduling settings), and a list of managed unit groups to be updated with the configuration and scheduling settings. Once defined, configuration profiles can be stored, modified, and reused to distribute specific sets of configuration and scheduling settings to specific groups of managed units.

The configuration types you can add to a configuration profile are:

- Alerter
- Audit process schedules
- CyberArk upgrade configuration
- Data archive
- Data export
- Data import schedule
- Data streaming configuration
- Database discover instances rules schedule
- Flat log process
- Ip-to-hostname aliasing
- Kerberos
- PIM data correlation
- Policy installation schedule
- Results archive (Audit)
- Results export (Files)
- Session Inference
- System backup
- Unit utilization schedule
- Unit utilization thresholds

Configuration profiles are defined independently of the local settings on the central manager. This allows you to quickly define configuration settings and deploy those settings to managed unit groups without disrupting the configuration of your central manager or configuring each managed unit individually.

This task describes how to create, distribute, and save a configuration profile.

## Procedure

---

1. Navigate to [Manage > Central Management > Distribute Configuration Profiles](#).
2. Click or select an existing profile to begin working with a configuration profile.
3. From the Name and description panel, provide a name and optionally provide a description for the profile. Click Next to continue.
4. Optionally, click Roles to specify security roles that can use the configuration profile.
5. From the What to distribute panel, click to define a new configuration, or select an existing configuration and click to edit.
  - a. From the Configuration type menu, select a configuration type to add to the profile.
  - b. Specify configuration and scheduling details for the selected configuration type.  
Restriction: Distributing data export configuration settings to an aggregator do not distribute any purge settings. The existing purge settings on an aggregator are retained. On collectors, purge settings, including retention periods, are distributed to and replace existing purge settings.
  - c. Click Save to finish editing the configuration profile.
  - d. Optionally, add additional Configuration Types/schedules by clicking , and repeating steps [5.a](#) through [5.c](#).
  - e. Click Next to continue.
6. From the Where to distribute panel, select groups from the Managed unit groups table and use the icon to add the groups to the Selected groups table. Click Next to continue.  
Note: Click to create a new managed unit group or to edit an existing group. Managed unit groups can also be defined and edited at [Manage > Central Management > Managed Unit Groups](#).
7. Optionally, from the Distribute configurations panel, click Run Now to distribute the configuration profile to the selected groups. When the status indicates that distribution is complete, click Next to continue.
8. From the Review results panel, review a summary of the distribution process and its results.  
Optional: click Run Log to view a detailed log of the distribution process.
9. Click Save to save the configuration profile for reuse.

## What to do next

---

If you need to move configuration profiles between central managers, use [Manage > Data Management > Definitions Export](#) and [Manage > Data Management > Definitions Import](#) and select Configuration profile from the Type menu.

## Distribute custom tables

---

Distribute custom tables and their data from a central manager to managed units.

## Before you begin

---

Distributing custom tables from a central manager to managed units requires that the table structure on the managed units match the table structure on the central manager. Distribution fails if the tables are altered only on the managed units.

## Procedure

---

1. Navigate to [Comply > Custom Reporting > Custom Table Distribution](#).
2. Use the check boxes to select tables for distribution.  
The list includes all custom tables available on the central manager. The tables you select are distributed to all managed units that report to the central manager.
3. In the Scheduling section, define a recurring schedule for distributing custom tables.
4. Click Save.
5. Optional: Click Run Once Now to submit an ad hoc job for custom table distribution.

## Results

---

The selected tables and their data are distributed from the central manager to its managed units according to the defined schedule.

Attention: When distributing tables, if a table with the same name exists on a managed unit, the table and all of its data are replaced on the managed unit.

## Central manager redundancy

---

Use Central Manager Redundancy or Backup Central Manager (CM) to configure a secondary or backup CM in case the Primary CM becomes unavailable.

Central Manager redundancy supports the following:

- Backup Central Manager - Make Primary CM link is available after the primary central manager loses connection.
- User Layouts are retained.
- User and roles are in the sync backup and do not rely on Portal User Sync.
- User Group Roles Data are retained.
- An API function `make_primary_cm` allows you to switch the central manager from the CLI.
- Data is retained from Audit Process Builder processes after switching Primary Central Manager to Backup Central Manager.
- Central Management backup includes all the definitions (reports, queries, alerts, policies, audit processes etc.), users and roles as it did before.
- It includes the schedules for enterprise reports, distributed reports and LDAP.
- It includes schedules for all audit processes; schedules and settings for data management processes such as archive, export, backup, and import; populate group members from query.
- It includes settings for Alerter and Sender.
- User's GUI customization's, custom classes and uploaded JDBC drivers are included.

Note:

- Data, either collected data, audit results and custom tables data, is not included.
- The Top risky users list and threat cases are not copied to the backup central manager.
- To list status of `cm_sync_file`(s) on Backup CM, use the CLI command, `show local_cm_sync_file`. To list the value of Backup CM IP for each managed unit, use the GuardAPI command, `grdapic show_backup_cm_ip` (this API command can only run on a central manager).
- Failover with Central Manager load balancing - After failover, if the new managed units connect and then disconnect right away, the correct DB\_USER is not sent until the failover message is received.
- Switching to a backup central manager interrupts communication with collectors and may generate the following message: "Central manager experienced failed data transfer from collector." The issue is visible in the Scheduled Jobs Exceptions report and should clear within 24-hours.

Perform these steps on your development or secondary servers and test. If successful, then perform these steps on your Primary or live Guardium Servers.

Install Patches on Central Manager

1. From the now Primary CM, login as CLI.
2. Install patches with the following CLI command, `store system patch install scp`
3. This CLI command will copy the files over to your Guardium Server and give you the ability to install them.
4. Watch these patches being installed with the following CLI command, `show system patch install`
5. Wait until the patch status shows "DONE: Patch installation Succeeded." for both patches.

Install Patches on Backup CM

1. Login into the now Primary CM GUI as admin.
2. Navigate to `Manage > Central Management > Central Management`.
3. Click check box for the Backup CM managed unit ONLY on the Central Manager.
4. Click Patch Distribution and install all of the patches that you just installed onto the Primary CM.

Example to install a patch:

1. Click Patch Distribution.
2. Click Install Patch Now.
3. Wait approximately 15 minutes to be sure the patch is installed on all managed servers.
4. To verify, login as CLI on the Backup CM and run CLI command, `show system patch install`, from Backup CM server.

Install Patches on all other managed servers (optional steps)

1. Repeat the previous steps to install patches on all managed servers.
2. Verify that all patches have been installed before going to the next procedure.

After all Patches have been installed on the CM and managed servers

1. Login as admin onto the now Primary CM.
2. Navigate to `Manage > Central Management > Central Management` and click Designate Backup CM.
3. Select Backup CM server from the returned list of eligible Backup CM candidates.
4. Click Apply.
5. Wait approximate two minutes for the Backup CM to sync and the NEW Backup CM file to be created and copied to the Backup CM.
6. Wait for two complete rounds of backups to complete (approximate 1 hour) for two Backup CM sync files that will be copied to the Backup CM and can be viewed from the Guardium Monitor tab - Aggregation Archive Log Report.
7. Select Guardium Monitor and select Aggregation/Archive Log Report to view the progress of the creation of the Backup CM sync file.
8. Verify the Activity Backup has started and the `cm_sync_file.tgz` file has been created from the Aggregation/Archive Log Report.
  - a. Login as Admin from the GUI.
  - b. Select Guardium Monitor tab.
  - c. Select Aggregation/Archive Report.
  - d. Look for Backup Types.
9. When complete:
  10. The patches have been installed on the CM.
  11. The patches have been installed on the Backup CM.
  12. Option: The patches have been installed on all other managed units.
  13. Two Backup CM Sync files have been completed (see Aggregation/Archive Log file under Guardium Monitor Tab).
  14. The following steps outline the process to convert the now Primary CM and its managed nodes to the Backup CM.
    - IMPORTANT: Wait approximately one hour to be sure at least TWO of the Backup CM sync files supporting Backup CM have completed.
    - The backups schedule for Backup CM sync files is approximately every 30 minutes.
    - The process will run on the CM to create a backup CM file and copy that file to the directory on the Backup CM.

Start the Backup CM Process after two sync file process have completed

## Shutdown the Primary CM Guardium Server

If you have no access to shutdown the Primary CM, then go directly to the Backup CM and login as Admin. Navigate to [Manage > Central Management > Central Management](#) and click Make Primary CM. Skip to the section "Steps to start the Backup CM configuration to become the Primary CM" in this document.

1. Wait approximate five minutes and login again as admin in the GUI of the Backup CM.
2. Once the Primary CM is shutdown completely, you can continue onto the next step

If you are logged into the Primary CM and it goes down, you get a message indicating that the connection has timed out.

## Steps to start the Backup CM configuration to become the Primary CM

The secondary CM will not be responsive for approximately five minutes. Login after five minutes and the Make Primary CM link will be available. The link is available under the admin login at [Manage > Central Management > Central Management](#).

1. When the Primary Server goes down, you will get a message on the Backup CM "Unable to connect to Remote Manager, consider switching to (the name of the backup CM)".
2. If you decide to switch:
  - a. Login as admin
  - b. Navigate to [Manage > Central Management > Central Management](#).
  - c. Click Make Primary CM (do not click the "Make Primary CM" link more than once. Also stay on this screen and do not select anything else during the running of this process. A log file will be created that you can view to see the progress and completion of this process.) Be patient as this process will take awhile to complete. There is a safeguard that if you do click this button more than once nothing will change with the current running process.
  - d. Within seconds you should get a message "Are you sure you want to make this unit the primary CM? Click OK."
  - e. Within a few seconds more you will get a message stating "This may take a few minutes". The time it takes for the Backup CM to become the primary CM depends on the amount of data backed up from the Backup CM sync file and the amount of managed nodes that switch to the Backup CM which will become the Primary CM. Click OK. As soon as we click OK a log file will be created called `load_secondary_cm_sync_file.log` that will allow you to view the progress of the switch to the completion of the Backup CM switch process. This file can be viewed from your GUI. The following steps indicate how to view this log file.
  - f. The last message will take a while to be presented to the screen. It will be the last message before the Backup CM switch has completed. The message is "GUI will restart now. Try to login again in a few minutes and the Backup CM will now become the Primary CM". Click OK. Wait a few minutes for the Backup CM to become Primary and for all the managed nodes to complete switching over to the new Primary CM.

While the CM Backup Process is running – viewing the progress log file

From the Backup CM while the Make Primary CM process is running, you can do the following to view the progress of the Backup CM becoming the Primary CM.

Prerequisite: You will need the IP of the server you are connected to in order to view the log files.

1. Login as CLI from your Backup CM server from a Putty.exe session
2. From CLI run Fileserver <IP> "enter your IP number" 3600", for example: fileserver 9.70.32.122 3600
3. From the GUI, enter the value: <http://yourserver.x.x.x.com> (will display in the CLI screen after entering the command, example: <http://joe.server.guardium.com> (the server name will be the Backup CM server).  
Fileserver Window on the UI will open to select file – Select Sqlguard logs
4. Select the file: `load_secondary_cm_sync_file.log`. (The file will display in a list of files from Step #3.) This will allow you to view the progress of the Backup CM becoming the Primary CM. Locate log file for viewing  
CM Backup Process is complete when you see this line in the `load_secondary_cm_sync_file.log`  
Import CM sync info - DONE
5. Wait approximately 10 minutes for all the Managed units to become available to the New Primary CM.

After the Backup CM becomes the Primary and all Managed nodes are now managed by the Backup CM server

You can now bring up the old CM server. Once it is up and running, perform the following steps to add it as the Backup CM server.

1. Reboot Old Primary CM.
2. Once the Server is up, login as CLI.
3. Delete the manager unit type, enter delete unit type manager.
4. After it completes and you get an OK message from CLI.
5. VERY IMPORTANT: Wait approximately five minutes for the GUI to completely restart even after the deleted unit type displays a successful message and the GUI restart message.
6. After five minutes, log into the New Primary CM to register Old CM as a managed unit.
7. Login as admin on New Primary CM.
8. Navigate to [Manage > Central Management > Central Management](#).
9. Click Register New.
10. Enter IP of the Old Primary CM that you just rebooted.
11. Enter 8443 as Port.
12. Click Save. (IMPORTANT: Be patient, do not click this button twice).
13. Wait a minute for the Old Primary CM to become registered.
14. Make the Old Primary CM a New Backup CM.
15. Click Designate Backup CM.
16. Click on Old Primary CM server.
17. Click Apply.
18. Old Primary CM server is NOW the New Backup CM server.
19. Refresh Central Management screen to see the New Unit type Backup CM defined.
20. This task is complete.

Report Data After Backup CM Process is complete

The following data is missing after the Backup CM process is completed. This is related to only the "first" switch from the Primary to the Secondary CM.

Missing Data:

1. Audit Process Results
2. Custom Table Data
3. Custom Report Data
4. VA Results
5. Classifier Results

6. DSD Results
7. CAS results
8. Datamart Data
9. Collected Data
10. Entitlement Data

The reports are populated again once you run these reports again on the New Primary CM. If you switch back to the old Primary CM, the data for these reports will be presented.

## Managing your Guardium system

Management tasks include monitoring your system's health and managing artifacts such as groups, domains, and notifications.

- [\*\*Guardium Administration\*\*](#)  
Guardium® administrators perform various administration and maintenance tasks.
- [\*\*Certificates\*\*](#)  
Install certificates so you can connect to the Guardium GUI, and for Guardium-S-TAP communication. Check certificates regularly, so you can update them before they expire.
- [\*\*Alerts\*\*](#)  
Learn how to work with alerts.
- [\*\*System performance and monitoring\*\*](#)  
Learn to use Guardium tools to maintain system performance: unit utilization reports to identify under- and over-utilized systems; system self-monitoring; and the Services status page.
- [\*\*Scheduling\*\*](#)  
The general-purpose scheduler is used to schedule many different types of tasks (archiving, aggregation, workflow automation, and so on).
- [\*\*Aliases\*\*](#)  
Create synonyms for a data value or object to be used in reports or queries.
- [\*\*Dates and Timestamps\*\*](#)  
Use a calendar tool to select an exact date, and a relative date picker to select a date that is relative to the current time.
- [\*\*Building Time Periods\*\*](#)  
Policy rules and query conditions can test for events that occur (or not) during user-defined time periods.
- [\*\*Cipher suites\*\*](#)  
Cipher suites are combinations of cryptographic parameters that define the security algorithms and key sizes.
- [\*\*Comments\*\*](#)  
Comments apply to definitions and to workflow process results.
- [\*\*Customer Uploads\*\*](#)  
The Database Protection Subscription Service supports the maintenance of predefined assessment tests, SQL based tests, CVEs, APARs, and groups such as database versions and patches.
- [\*\*Stream Guardium data to another application\*\*](#)  
Use the Data Streaming to send traffic collected by Guardium to another tool for analysis.
- [\*\*Big Data Intelligence\*\*](#)  
The Guardium Big Data Intelligence (GBDI) platform stores collected data over longer timeframes, providing direct, near real-time access to data security and compliance reports and insights.
- [\*\*Exporting and importing definitions\*\*](#)  
Use export and import definitions if you have multiple systems with identical or similar requirements and are not using central management. You can define the components that you need on one system and export those definitions to other systems that are on the same software release level.
- [\*\*Remote loggers\*\*](#)  
View the forwarding rules for the remote logging and test the connections.
- [\*\*Manage Custom Classes\*\*](#)  
Upload and maintain custom classes used in alerts or evaluations. Manage custom classes by clicking Setup > Custom Classes.
- [\*\*GDPR readiness: Considerations when configuring Guardium\*\*](#)  
Learn how Personal Identification Information (PII) data gets stored on your Guardium system, and how to manage this.
- [\*\*Groups\*\*](#)  
Using groups makes it easy to create and manage classifier, policy and query definitions, as well as roll out updates to your S-TAP's and GIM clients. Rather than having to repeatedly define a group of data objects for an access policy, put the objects into a group to easily manage them.
- [\*\*Security Roles\*\*](#)  
Security roles are used to grant access to data (groups, queries, reports, etc.) and to grant access to applications (Group Builder, Query-Report Builder, Policy Builder, CAS, Security Assessments, etc.).
- [\*\*How to install patches\*\*](#)  
Install a single patch or multiple patches as a background process.
- [\*\*Support Maintenance\*\*](#)  
The Support Maintenance feature is password protected and can be used only as directed by Technical Support. Contact Technical Support if you require more information.

## Related information

- [IBM Security Guardium product information](#)

## Guardium Administration

Guardium® administrators perform various administration and maintenance tasks.

Any user assigned the admin role is referred to as a Guardium administrator. The admin role is distinct from the admin user account. The Guardium Administrator role is accountable for the usage of the admin and CLI IDs in production systems.

## Admin role privileges

---

The Guardium admin role has privileges that are not explicitly assigned to that role. For example, when a user with the admin role displays a list of privacy set definitions, all privacy sets defined on the Guardium system display. The user with the admin role can view, modify, or delete any of those definitions. When a user without the admin role accesses the list of privacy sets, that user sees only the following privacy sets:

- The privacy sets that they own (that is, that they created).
- Any privacy sets that are assigned a security role that is also assigned to that user.

Note: If you create a new role that is based on the admin role, any user with the new role has access to the same UI as the admin role. However, the role does not automatically grant access to artifacts created by other users.

## CLI diag command access

---

Use of the **diag** CLI command requires an additional password, which can be the password of any user with the admin role.

If automatic account lockout is enabled (where a user account is locked after a specified number of login failures), the admin user account can be locked after a number of failed login attempts. If that happens, use the **unlock admin** CLI command to unlock it.

Note: The access manager (accessmgr) can unlock accounts from the User Browser. Open the User Browser by clicking Access > Access Management > User Browser.

## Admin user privileges

---

The admin user has extra privileges that are not granted to the admin role, as follows:

- Access to all users' to-do lists
- Owner of imported definitions
- Access management functions

## Admin user To-Do List powers

---

The To-do List is a workflow automation feature that controls the distribution of audit process results to users. The admin user has special privileges and responsibilities in this area. If a user account is disabled, all audit process results for that user are automatically reassigned to the admin user. If a user is unavailable for any other reason, audit process results are installed in that user's to-do list; that is, awaiting sign-off before they are released to the next results receiver. The admin user can open any user's to-do list, and take any actions that are available to that user. When the admin user performs any actions on another user's to-do list, that fact is noted in the audit process activity log, for example, User admin signed results on behalf of user x.

## Imported definition ownership

---

When definitions are exported, all roles are removed, and the owner is changed to the admin user. This is the only way to control how the definition will be used on the importing system.

## Access management and the administrator

---

For security purposes, a separation of duties exists between the access manager and admin. Admin users cannot have access manager privileges, and vice versa.

The next time the admin user logs in, access manager functionality will be available to them. This is possible for the admin user only (and not for other users that have the admin role).

Note:

The same user can contain both of these roles through a legacy situation or as a result of an upgrade. However, current use does not allow the two roles to be assigned to the same user.

In the past, when a unit was upgraded, the accessmgr role was assigned to the admin user, and the accessmgr user was disabled.

In this situation, to configure the accessmgr and admin, log in as admin and enable the accessmgr user, then log in as accessmgr (the default initial password is **guardium**), and remove the accessmgr role from the admin user.

## Certificates

---

Install certificates so you can connect to the Guardium® GUI, and for Guardium-S-TAP communication. Check certificates regularly, so you can update them before they expire.

- [Installing an appliance certificate to avoid a browser SSL certificate challenge](#)

Use Guardium CLI commands to create a certificate signing request (CSR), and to install server, certificate authority (CA), or trusted path certificates on your Guardium system. Installing certificates allows your site to connect to the Guardium GUI without security warnings such as *This site is not secure, or Your connection is not private.*

- [Configuring Guardium-S-TAP communication using an SSL certificate](#)

Create and store an SSL certificate for Guardium-S-TAP communication.

- [Identify expired certificates and certificates that will expire within six months](#)

Expired certificates result in a loss of function. Check certificates regularly to identify certificates that are already expired, and certificates that will expire in the next six months.

- [Managing certificates by using Venafi](#)

Use Venafi to generate and manage GUI, Sniffer, and GIM certificates in your stand-alone or central manager environment.

- [Restoring the Guardium Insights certificate](#)

When you install Guardium, the Guardium Insights self-signed certificate is loaded automatically. If you replace or change that certificate, you can revert to the original certificate by taking the following steps.

## Installing an appliance certificate to avoid a browser SSL certificate challenge

Use Guardium® CLI commands to create a certificate signing request (CSR), and to install server, certificate authority (CA), or trusted path certificates on your Guardium system. Installing certificates allows your site to connect to the Guardium GUI without security warnings such as This site is not secure, or Your connection is not private.

### About this task

For more information about certificate CLI commands, see [Certificate CLI Commands](#).

- You must provide a public certificate from a certificate authority (CA) that you can use to sign your certificates. For example, Verisign, Thawte, Geotrust, GoDaddy, Comodo, or in-house).
- Guardium does not provide CA services and does not ship systems with different certificates other than the default certificate. To use your own certificate, certificate you must contact a third-party CA.
- If the certificate is not self-signed, you must obtain the public certificate for each signer up to the lowest level (for example, that is self-signed). You can use the **openssl x509 -in t.pem -text -nout** command to show contents of a x509 certificate.
- You can obtain and store the public certificate of the CA (step 1) either before or after you generate the CSR (step 2).

### Procedure

1. Have the public certificate from the CA that you need to sign your certificates available.
2. Log in to the CLI and enter the following command:

```
create csr gui
```

Enter the requested information. If the CN (common name) of the certificate is not set to the *hostname.domain* of the system, the browser responds with certificate errors.

Note: If the Common Name (CN=) field starts with a number and is used as an identifier, it must have an *ID:* prefix. For example, **ID:1234**.

You are prompted to supply the organizational unit (OU), country code (C), and so forth. Be sure to enter this information correctly. The last prompt is:

```
What encryption algorithm should be used (1=DSA or 2=RSA) ?
```

The default encryption algorithm is RSA (2). DSA (Digital Signature Algorithm) is a federal information processing standard (FIPS) for digital signatures. RSA is a public-key cryptosystem that involves key generation, encryption, and decryption.

After you select a decryption algorithm, the system displays a description of the request, followed by the request itself, and some additional instructions. For example,

```
Certificate Request:
Data:
Version: 0 (0x0)
Subject: C=US, ST=MA, L=Littleton, O=XYZCorp, OU=Accounting, CN=g2.xyz.com

-----BEGIN NEW CERTIFICATE REQUEST-----
MIICWCCAhcAQAwVDELMakGA1UEBhMCVVMxEDAOBgNVBAgTB1dhbHRoYWoXETAPBgNVBAoTCEd1

N1BauyaC9PS4Gz1eYakCF2kcfxfjx1bfy5i228XWMAUON95
-----END NEW CERTIFICATE REQUEST-----
```

```

Copy and paste the Certificate Signing Request (CSR), starting at the
'-----BEGIN NEW CERTIFICATE REQUEST-----' tag and ending at the '-----END
NEW CERTIFICATE REQUEST-----' tag, to a file. The CSR file will need to be
provided to a Certificate Authority (CA) of your choice in order to obtain
a valid certificate. Please note that the certificate will need to be in PEM
format so that it can be imported into the Guardium appliance. Once you receive
the certificate from your CA, use the following CLI command to start the import
process:
```

```
<< store certificate gui >>
```

Note:

- For Common Name, enter the hostname in FQDN format (fully qualified domain name). If you connect to the GUI normally using the short hostname (for example, *system1*) instead of the FDQN (*system1.us.ibm.com*), Guardium returns an Address Mismatch certificate error. Either change the CN to use the FDQN, or connect with *https://system1.us.ibm.com:8443/sqlguard* to use the certificate.
- Country Code must be two letters.
- Keysize can be 1024 or 2048.

3. After the CA signs the CSR and returns a signed key, log in to the CLI and enter the following command:

```
store certificate gui console
```

The system returns with the following output:

Please paste your End-Entity certificate below in PEM encoded format. A certificate in PEM encoded format should include the '-----BEGIN CERTIFICATE-----' and '-----END CERTIFICATE-----' tags. The Certificate Authority (CA) Root and Intermediate certificate(s) (if applicable) will also need to be pasted at this time for validation purposes. Please ensure that all certificates are in PEM format and include the aforementioned tags. When pasting multiple certificates, please make sure that each certificate is pasted on a new line in the following order:

```
-----BEGIN CERTIFICATE-----
(End-Entity certificate)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Intermediate certificate(s) - if applicable)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Root certificate)
-----END CERTIFICATE-----
```

Once done pasting your certificate(s), press ENTER followed by CTRL-D to continue.

4. After you load the certificate, the system asks if the certificate matches the existing CSR request.

If you enter yes, the system responds with the following warning: **WARNING: Alias "tomcat" already exists. Are you sure that you want to replace it [y/n]? Enter "y" for yes.**

The system responds with the success or failure of the store operation.

5. Paste the certificate chain together in order, starting with the appliance certificate first and the root certificate last. The GUI restarts automatically. If needed, restart the GUI manually.

## Results

A certificate for one Guardium unit is installed.

## What to do next

Repeat the steps for every Guardium system onsite.

## Configuring Guardium-S-TAP communication using an SSL certificate

Create and store an SSL certificate for Guardium-S-TAP communication.

### About this task

For Windows systems, if you do not choose to use a value for a parameter, do not include it in the guard\_tap.ini. This is pertinent to the CRL path in particular, or if you want to shut off certificate authentication and go back to TLS.

For UNIX or Linux systems, if you do not choose to use a value for a parameter, set its value equal to NULL. This is pertinent to the CRL path in particular, or if you want to shut off certificate authentication and go back to TLS.

Attention: For z/OS, steps [7](#) and [8](#) are not required, but an AT-TLS policy must be configured. Work with your system admins to configure AT-TLS. For more information, see [AT-TLS policy example](#).

## Procedure

1. Log in to the CLI of your Guardium.
2. Enter: `create csr sniffer`
3. Enter the common name (CN) of the requested system to create the CSR request.
4. Get the CSR signed by a certificate authority (CA) service to get the certificate, as well as the root certificate used by the certificate authority (CA) service.  
If the certificate is not already in PEM format, use OpenSSL or another third-party tool to convert it. For example, to convert from PKCS7 format to PEM, use the following OpenSSL command: `openssl pkcs7 -print_certs -in certificate.p7b -out certificate.pem`
5. Store the certificate on your system by entering the CLI command: `store certificate sniffer`
6. If you don't know the CA and the CN of the certificate, enter: `show certificate sniffer`. Output is similar to the following, though the signature algorithm may use a more recent encryption algorithm:

```
Certificate File system.cert.pem
Certificate:
Data:
Version: 1 (0x0)
Serial Number: 12345678912345678999 (0x8ba99886be3317ab)
Signature Algorithm: sha256WithRSAEncryption
Issuer: C=aa, ST=aa, L=aa, O=aa, OU=aa, CN=CYCLOPS
```

7. On the DB server, store the root certificate from certificate authority (CA) service in a file.
8. In the `guard_tap.ini` file, update the following parameters:
  - `guardium_ca_path=[Location of the Certificate Authority certificate]`
  - `sqlguard_cert_cn=<CN from step 3>`
  - `guardium_crl_path=<the path to the certificate revocation list file or directory (the blocklist)>`
9. Restart the S-TAP, and restart the sniffer with the CLI command: `restart inspection-engines`.
10. Verify that the installed certificate is being used by entering `openssl`, for example: `openssl s_client -connect 9.70.157.113:16018`. The output should be similar to  
`-connect 9.70.157.113:16018`  
You are now connected using OpenSSL.

## Identify expired certificates and certificates that will expire within six months

Expired certificates result in a loss of function. Check certificates regularly to identify certificates that are already expired, and certificates that will expire in the next six months.

### About this task

To see a summary of all certificates, run the CLI command **show certificate summary**.

### Procedure

Log in to the CLI and run the command: **show certificate warn\_expire**.

The output lists certificates that will expire within six months and certificates that have already expired.

## Managing certificates by using Venafi

Use Venafi to generate and manage GUI, Sniffer, and GIM certificates in your stand-alone or central manager environment.

### About this task

Use the following procedure to integrate your Guardium® stand-alone or centrally managed system with the Venafi certificate management system.

### Procedure

1. Create a Venafi instance. For more information, see [Creating a Venafi instance](#).
2. Configure Venafi for GUI, Sniffer, or GIM certificates. For more information, see [Configuring Venafi for GUI and Sniffer certificates](#), and [Configuring Venafi for GIM certificates](#).
  - **Creating a Venafi instance**  
Set up the Venafi portal to generate signed certificates.
  - **Configuring Venafi for GUI and Sniffer certificates**  
Use the Guardium CLI to configure your Guardium system to connect to Venafi as a Service or TPP instance.
  - **Configuring Venafi for GIM certificates**  
Use the Guardium CLI to configure your Guardium system to connect to the Venafi as a Service or TPP instance.

## Creating a Venafi instance

Set up the Venafi portal to generate signed certificates.

### Procedure

Create user credentials on the Venafi portal and populate the fields in your configuration template. You can optionally use a wildcard in your zone configuration. For more information, see the Venafi documentation.

Tip: Make a note of your zone configuration information. If you are not using a wildcard, you must enter the exact zone configuration information on your Guardium® system to establish a successful connection to Venafi.

## Configuring Venafi for GUI and Sniffer certificates

Use the Guardium® CLI to configure your Guardium system to connect to Venafi as a Service or TPP instance.

### Before you begin

Ensure that Venafi as a Service or TPP instance is configured and running.

### About this task

Use the following procedure to configure GUI or Sniffer certificates.

### Procedure

- If you are using the Venafi TPP instance, store the ROOT CA certificate by running the following command on the central manager or stand-alone system: **store certificate keystore trusted-venafi console** and pasting the Venafi certificate. Skip this step if you are using Venafi as a Service.
- Store the Venafi connection credentials on your Guardium Guardium system by running the CLI command **store certificate cms**.
  - Select 1 to **Add Venafi** to your Guardium system.
  - Enter your Venafi instance type.
  - Select GUI or Sniffer as the type of certificate to install.
  - Enter the authentication type: access token or username and password.
  - For the TPP instance, enter the TPP URL, Venafi token, and the exact zone configuration information that you used when you created your Venafi instance. For Venafi as a Service, enter the zone value and API key. If the information does not match, the connection fails.  
Note: vCert prefixes \VED\Policy\ to the zone. When you enter the zone in the Guardium system, you must specify only the child folders under the root Policy folder.
  - Select enroll or pick up for the vcert action.

**Enroll**  
Use the enroll option to create a new certificate on Venafi and add it to the Guardium keystore.

  - After selecting enroll, if you have custom fields configured on Venafi, add up to nine fields using the **name=value** format.  
Attention: If custom fields are configured as mandatory on Venafi, the names and values must be provided accurately and in the correct format otherwise certificate creation fails.
  - After selecting enroll and defining any custom fields, follow the prompts to enter CN, name of your organization, organization unit, city, state, country code, and optional SANs. This completes the creation of a new certificate on Venafi.

**Pick up**  
Use the pick up option to retrieve certificates manually created on Venafi and add them to the Guardium keystore. Use this option if you do not want to create new certificates through Guardium.
- When prompted, enter **y** or **n** to distribute certificates from the central manager to the managed units, if any. If you enter **y**, propagate the Venafi certificates across your deployment by completing steps [4](#) to [6](#). If you enter **n**, complete only step [4](#).
- Import the GUI or Sniffer certificate into the central manager or stand-alone system:
  - From the CLI, run the command **grdapi venafi\_import variant=[gui|sniffer]**.
  - For GUI certificates, you must restart the GUI by running the CLI command **restart gui**. Sniffer certificates do not require a GUI restart.
  - Run the CLI command **show certificate [gui|sniffer]** to check whether the correct certificate is displayed.
- On the central manager, run the following grdapi commands:  
Important: If the root password on the managed unit doesn't match with the root passkey, you must first reset the root password on the managed unit by running the CLI command **support reset-password root**.
  - Distribute the Venafi configuration files to some or all the managed units: **grdapi export\_config type=venafi host=[all\_managed|group:<group-name>|<IP>|<hostname>] force=[true|false]**
  - Propagate the Venafi ROOT CA certificate to some or all the managed units: **grdapi export\_certificate alias=<alias> host=[all\_managed|group:<group-name>|<IP>|<hostname>] force=[true|false]**  
Note: This command restarts the GUI on the managed unit. Wait until the GUI restarts before you proceed to the next step.
  - Install the Venafi GUI or sniffer certificate on the managed unit: **grdapi venafi\_import variant=[gui|sniffer] api\_target\_host=[all|all\_managed|group:<group-name>|<IP>|<hostname>]**
  - For GUI certificates, you must restart the GUI on the managed units by accessing **Manage > Central Management > Central Management**, selecting the managed units, and clicking **Restart Portal**. Sniffer certificates do not require a GUI restart.
- On each managed unit, run the CLI command **show certificate [gui|sniffer]** to check whether the correct certificate is displayed.

## Configuring Venafi for GIM certificates

Use the Guardium® CLI to configure your Guardium system to connect to the Venafi as a Service or TPP instance.

### Before you begin

Ensure that Venafi as a Service or TPP instance is configured and running.

### About this task

Use the following procedure to configure GIM certificates.

### Procedure

- From the Guardium UI, access **Manage > Module Installation > GIM Global Parameters**. Ensure that the global parameter value for **gim\_auto\_certificate\_distribution** is **1**.
- If you are using the Venafi TPP instance, store the ROOT CA certificate by running the following command on your Guardium system: **store certificate keystore trusted-venafi console** and pasting the Venafi certificate. Skip this step if you are using Venafi as a Service.
- Store the Venafi connection credentials on your Guardium system by running the CLI command **store certificate cms**.
  - Select 1 to **Add Venafi** to your Guardium system.
  - Enter your Venafi instance type.
  - Select **GIM client** as the type of certificate to install.
  - Enter the authentication type: access token or username and password.
  - For the TPP instance, enter the TPP URL, Venafi token, and the exact zone configuration information that you used when you created your Venafi instance. For Venafi as a Service, enter the zone value and API key. If the information does not match, the connection fails.  
Note: vCert prefixes \VED\Policy\ to the zone. When you enter the zone in the Guardium system, you must specify only the child folders under the root Policy folder.
  - Select enroll or pick up for the vcert action.

#### Enroll

Use the enroll option to create a new certificate on Venafi and add it to the Guardium keystore.

- After selecting enroll, if you have custom fields configured on Venafi, add up to nine fields using the **name=value** format.

Attention: If custom fields are configured as mandatory on Venafi, the names and values must be provided accurately and in the correct format otherwise certificate creation fails.

- ii. After selecting enroll and defining any custom fields, follow the prompts to enter CN, name of your organization, organization unit, city, state, country code, and optional SANs. This completes the creation of a new certificate on Venafi.

#### Pick up

Use the pick up option to retrieve certificates manually created on Venafi and add them to the Guardium keystore. Use this option if you do not want to create new certificates through Guardium.

4. If prompted, enter **y** or **n** to distribute certificates from the central manager to the managed units that are GIM servers. If you enter **y**, propagate the Venafi certificates across your deployment by completing steps to [5 to 11](#). If you enter **n**, complete steps [5 to 7](#).
5. Stage the GIM clients with the new certificate by running the CLI command **store certificate gim client venafi**.
  - a. Select the GIM client that is registered to your Guardium system.
  - b. Run the CLI command **show certificate gim client**.
  - c. Select the GIM client to check whether the correct certificate is displayed. The status of the certificate can display as pending, processing, or deployed. You must wait until the certificate is deployed.  
CAUTION:  
Ensure that all your GIM clients are updated with the new certificate. When a new GIM server certificate is stored, a GIM client without the new certificate loses connection to the GIM server.
6. After the GIM client certificate is deployed, run the CLI command **store certificate cms**.
  - a. Select [1](#) to **Add Venafi** to your Guardium system.
  - b. Enter your Venafi instance type.
  - c. Select **GIM server** as the type of certificate to install.
  - d. For the TPP instance, enter the TPP URL, Venafi token, and the exact zone configuration information that you used when you created your Venafi instance.  
For Venafi as a Service, enter the zone value and API key. If the information does not match, the connection fails.
  - e. Follow the prompts to enter CN, name of your organization, organization unit, city, state, country code, and optional SANs.
7. Import a new GIM server certificate by completing the following steps:
  - a. From the CLI, run the command **grdapi venafi\_import variant=gim force=true**.
  - b. Restart the GUI by running the CLI command **restart gui**.
  - c. Run the CLI command **show certificate gim server** to check whether the correct certificate is displayed.  
Note: For authentication to succeed, the GIM server and all related GIM clients must have certificates that are signed by the same CA (root and intermediate, if applicable) for both trusted and private certificates.
8. On the central manager, run the following grdapi commands:  
Important: If the root password on the managed unit doesn't match with the root passkey, you must first reset the root password on the managed unit by running the CLI command **support reset-password root**.
  - a. Distribute the Venafi configuration files to some or all the managed units: **grdapi export\_config type=venafi host=[all\_managed|group:<group-name>|<IP>|<hostname>] force=[true|false]**
  - b. Propagate the Venafi ROOT CA certificate to some or all the managed units: **grdapi export\_certificate alias=<alias> host=[all\_managed|group:<group-name>|<IP>|<hostname>] force=[true|false]**  
Note: This command restarts the GUI on the managed unit. Wait until the GUI restarts before you proceed to the next step.
9. Stage the GIM clients with the new certificate by running the CLI command **store certificate gim client venafi**.
  - a. Select the GIM client that is registered to your Guardium system.
  - b. Run the CLI command **show certificate gim client**.
  - c. Select the GIM client to check whether the correct certificate is displayed. The status of the certificate can display as pending, processing, or deployed. You must wait until the certificate is deployed.  
CAUTION:  
Ensure that all your GIM clients are updated with the new certificate. When a new GIM server certificate is stored, a GIM client without the new certificate loses connection to the GIM server.
10. Complete the following steps on the central manager:
  - a. Import the GIM certificate: **grdapi venafi\_import variant=gim force=true api\_target\_host=[all|all\_managed|host name|IP]**.
  - b. For GUI certificates, you must restart the GUI on the managed units by accessing **Manage > Central Management > Central Management**, selecting the managed units, and clicking **Restart Portal**. Sniffer certificates do not require a GUI restart.
11. Complete the following steps on each managed unit:
  - a. Check whether the GIM server and client are active by running the CLI command **show certificate gim client**. The status of the certificate must change from **deployed** to **active**.
  - b. From the Guardium UI, access **Manage > Module Installation > GIM Process Monitor** and ensure that the connection is active.

## Restoring the Guardium Insights certificate

When you install Guardium, the Guardium Insights self-signed certificate is loaded automatically. If you replace or change that certificate, you can revert to the original certificate by taking the following steps.

### About this task

To learn about the **store system domain** and **store system hostname** system CLI commands referenced in this topic, see [System CLI commands](#).

### Procedure

1. Issue the command for restoring the default certificate:

```
restore default
```

2. Set the domain (**store system domain**) and hostname (**store system hostname**), and then restart the network to set the CN and SAN to FQDN.
3. Ensure that the original Guardium Insights certificate is restored. For more information, see [Domain name and TLS certificates](#).

# Alerts

Learn how to work with alerts.

- [How to create a real-time alert](#)

Send a real-time alert to the database administrator whenever there are more than three failed logins for the same user within five minutes.

- [Notifications](#)

Use the Alerter and Alert Builder to create notifications. When email or other notifications are required for alerting actions, follow this procedure for each type of notification to be defined.

- [Predefined alerts](#)

Guardium comes with a set of predefined alerts that can be found in the Alert Builder.

- [Custom Alerting Class Administration](#)

Use a custom alert class to send alerts to a custom recipient. Upload the custom class, then use the Alert Builder to designate the custom class as an alert notification receiver.

## How to create a real-time alert

Send a real-time alert to the database administrator whenever there are more than three failed logins for the same user within five minutes.

### About this task

Generate real-time security alerts whenever suspicious activity is detected or access policies are violated.

Follow these steps:

1. Create a policy
2. Add rules to the policy
3. Add an action when the rule is triggered
4. Install the policy

Prerequisites

Configure SMTP or SNMP in the Alerter. Open the Alerter by navigating to **Setup** > **Tools and Views** > **Alerter**, and then fill out the SMTP or SNMP information.

Note: Policy violations can also be seen in the Incident Management report.

### Procedure

1. Create a policy.

a. Open the policy builder by navigating to **Protect** > **Security Policies** > **Policy Builder for Data**.

b. Click the icon to create a new policy or modify an existing policy by selecting the policy and clicking the icon.  
c. In the Name and properties panel, select the `Data security policy` type and provide a policy name.

2. Add rules to the policy.

a. Click to open the Rules panel for the policy.

b. Click the icon to add a new rule.

c. In the Rule definition panel, use the Rule type menu to select the `Exception` rule type and use the Rule name field to provide a short descriptive name for the rule.

d. Click to open the Rule criteria panel and define the triggering criteria for the rule.

Use the following settings to create a rule that triggers when there are more than three failed logins for the same user within five minutes:

Under Session level criteria:

- Database user = .

Count each individual database user value separately.

Under SQL criteria:

- Exception type = `LOGIN_FAILED`

Under Other criteria:

- Minimum count = 3

Set the minimum number of times the rule is matched before the action is triggered. The count is reset each time the action is triggered or when the reset interval expires.

- Reset interval = 5

Set the number of minutes after which the rule counter is reset. The counter is also reset when the rule action is triggered.

- Record values = 1 - Log full SQL in policy violation

Define what is included in the policy violation report: no SQL, full SQL, or masked SQL.

Select the Continue to next rule option. Continue testing rules once this rule is satisfied and its action is triggered. If this is not selected, no additional rules are tested after this rule is satisfied.

3. Add an action when the rule is triggered.

a. Click to open the Rule action panel and define actions to take when rule conditions are matched.

b. For this example, select > **ALERT** > **ALERT PER MATCH** to get a notification every time the rule is triggered.

c. From the Add new action window, select a Message template, define a Notification type, and then click OK.

For `MAIL` or `SNMP` notification types, you must configure the alerter at **Setup** > **Tools and Views** > **Alerter**.

d. After defining rule actions, click OK to save the rule definition. Click OK again to save the policy.

4. Install the policy.
  - a. From the Policy Builder for Data, select the policy and then select **Install > Install**.
  - b. From the Install policy window, select the Installation action you want and click **OK**.

Your policy is now installed. Your alert receiver will receive real-time notifications when the policy rules are enacted.

## Notifications

Use the Alerter and Alert Builder to create notifications. When email or other notifications are required for alerting actions, follow this procedure for each type of notification to be defined.

### Alerter configuration

1. Before you choose alerting actions, you must be configure the email SMTP settings in theAlerter
2. Open the Alerter by clicking **Protect > Database Intrusion Detection > Alerter**.
3. Fill out the SMTP and/or SNMP information.
4. After filling out each section, click **Test Connection**, and verify that the connection is working. You will receive a message stating the connection is unreachable if the connection is not working.
5. Click **Apply** to save the configuration.
6. At a minimum, IP Address/Host name, port, and return email address must be specified.
7. Select **Mail** from the Notification Type menu. If the Severity of the message is **HIGH**, the Urgent flag is set.
8. Select a user (which can be an individual or group) from the Alert Receiver list. Additional receivers for real-time email notification are **Invoker** (the user that initiated the actual SQL command that caused the trigger of the policy) and **Owner** (the owner/s of the database). The Invoker and Owner are identified by retrieving user IDs (IP-based) configured by using the Guardium® APIs.
9. Click **Add**.

### Build an alert

1. After configuring the Alerter, open the Alert Builder by clicking **Protect > Database Intrusion Detection > Alert Builder**.
2. Fill out the information in the Settings, Alert Definition, Alert Threshold, and Notification sections and click **Apply**.
3. Choose who will receive the notifications by clicking **Add Receiver..** and choosing a user.

### Predefined alerts

Guardium comes with a set of predefined alerts that can be found in the Alert Builder.

Open the Alert Builder by going to **Protect > Database Intrusion Detection > Alert Builder**. When you open the Alert Builder, you are presented with a list of all existing alerts. Select an alert from the finder and click **Modify** to edit it.

In the Modify Alert page, modify any part of the alert, such as receivers or threshold.

You cannot modify the default queries that the alerts are based on. If you want to modify a query, click the **Edit this Query icon**  for any query to open the Query-Report Builder. Once in the builder, clone any query, and then modify the clone to suit your needs.

After making changes to an alert, click **Apply** to save them.

This table describes all predefined alerts.

Table 1. Predefined Alerts

| Alert                                  | Description                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active Risky Users - Risky Users Score |                                                                                                                                                                                                                                                                                                                                                     |
| Active S-TAPs Changed                  | Checks for changes to Active S-TAP inspection engines done during the last accumulation interval. The alert will trigger if at least one inspection engine has been changed during the period. By default the alert checks every 1/2 hour and checks the last hour.                                                                                 |
| Aggregation/Arc hive Errors            | Alert once a day on all aggregation or archive tasks that did not complete successfully.                                                                                                                                                                                                                                                            |
| Connection Profiling Alert             | Alert runs every 60 minutes and sends the list of allowed (trusted) connections that were found during the time interval to the Connection Profiling List predefined group.                                                                                                                                                                         |
| CAS Instance Config Changes            | Alert once a day on any CAS instance configuration changes.                                                                                                                                                                                                                                                                                         |
| CAS Templates Changes                  | Alert once a day on any CAS template configuration changes.                                                                                                                                                                                                                                                                                         |
| Data Source Changes                    | Alert once a day on any data source definition changes.                                                                                                                                                                                                                                                                                             |
| Discovered Instances Rules Alert       | Alert when a discovered instance is added or replaced. Displays in the alert builder list as Discovered Instances Rules Alert: Discovered Instance Add or Replace.                                                                                                                                                                                  |
| Database disk space                    | Alert every 10 minutes if internal database is more than 80% filled. For more information about Disk Space (% full) and the Guardium® Nanny process, see <a href="#">Self Monitoring</a> .                                                                                                                                                          |
| Enterprise No Traffic                  | Alert runs only on central manager systems. It is based on a query similar to the query on the No Traffic alert and retrieves the records with: timestamp between X and Y, when X is a query parameter and Y is query from date generated by the alert mechanism based on the accumulation interval (same way the existing no traffic alert works). |

| <b>Alert</b>                                           | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Enterprise S-TAPs changed                              | Alert runs on central manager systems only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Failed Logins to Guardium                              | Every 10 minutes alert if there have been more than 5 failed login attempts on the Guardium appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Guardium - Add/Remove Users                            | Alert once a day if any Guardium users have been added or removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Guardium - Credential Activity                         | Alert once a day if there have been any Guardium credential changes, including LDAP configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Inactive Managed Unit                                  | Alert runs 30 minutes and sends a notice once a day to the predefined group that is called "Managed Units Alert".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Inactive S-TAPs Since                                  | Alert once an hour on all S-TAPs that have not been heard from.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Inspection Engines and S-TAP                           | Alert once a day on any activity related to inspection engine and S-TAP configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Investigation Dashboard Issues                         | New issue detected and cannot be resolved automatically                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| No Traffic                                             | Alert to indicate whether there is no traffic from specific database servers. This alert will alert when there is no traffic collected from a server from which the Guardium system was collecting traffic at some point during the last 48 hours. The alert will trigger when there is no traffic within the period defined in the accumulation interval.<br>For example if the accumulation interval is 60 minutes the alert will send an email if there was no traffic from a specific database server in the last hour but there was some traffic in the last 48 hours. The alert will send an email (by default) only every 24 hours. Parameters such as accumulation interval, notification interval, run frequency etc. can be customized. Parameters such as Threshold, Per Line, operator, query etc. should not be changed, as changes to these parameters will cause the alert not to work properly. Note the No Traffic query should not be cloned. |
| No Traffic by Server/Protocol                          | Similar to the regular No traffic alert with the following differences: The alert is per service Name/Net Protocol, and will report per line. There is a new additional parameter: Active Traffic Interval that determines when the last request from each server was received. The alert will trigger under the following conditions: There was No traffic during the alert interval from each server/net protocol but there was traffic since: Active Traffic Interval for that combination.<br>Unlike the regular No traffic alert that will trigger if there was no traffic during the alert interval but there was traffic in the previous 48 hours per server IP.                                                                                                                                                                                                                                                                                         |
| Outlier Analysis Failure                               | Triggered by failure of the outlier mining process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 12.1 and later Outlier with anomaly score 90 and above | Alert once an hour if an outlier with anomaly score 90 and above is encountered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Policy Changes Alert                                   | Alert once a day if there have been any security policy changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| QWR Exceptions Alert                                   | Alerts once per session to Syslog if during one hour at least one QWR exception was triggered. The QRW exception occurs when Query Rewrite cannot mask data because the query returns more than 16,000 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Queries Running Long Time                              | Notify if a query takes more than 900 seconds to run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Scheduled Job Exceptions                               | Alert every 10 minutes on any scheduled job exception (including assessment jobs).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| S-TAP Uninstall Alert                                  | Alerts hourly (default) if an S-TAP is uninstalled from a database server. Alert results are also reported in the S-TAP Uninstall Events report in My Dashboard.<br>Tip: Best practice is to leave the alert settings at their defaults. If you need to change the configuration, run the CLI command <b>restart gui</b> so the changes take effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Custom Alerting Class Administration

Use a custom alert class to send alerts to a custom recipient. Upload the custom class, then use the Alert Builder to designate the custom class as an alert notification receiver.

- Before you can use a custom class, you must upload it onto the Guardium system. Click **Setup > Custom Classes > Alerts > Upload Alerting Class** to upload a custom alerting class. Click **Browse** to select a file, then **Apply** to save.
- After uploading the custom class, use it in an alert with the Alert Builder. Open the Alert Builder by clicking **Manage > Database Intrusion Detection > Alert Builder**. Fill out the required information, select **CUSTM** from the Notification Type menu, and click **Save**.

## System performance and monitoring

Learn to use Guardium® tools to maintain system performance: unit utilization reports to identify under- and over-utilized systems; system self-monitoring; and the Services status page.

- [Unit utilization and inspection core performance](#)**

This section presents details about Unit utilization and Buffer usage monitor reports so you can learn to identify problems. It includes troubleshooting tips for queue overflow scenarios, and managing utilization thresholds.

- **Self Monitoring**  
The Guardium solution monitors itself to minimize disruptions and correct problems automatically whenever possible.
- **Services Status panel**  
The Services Status panel is a centralized place to check status of services such as CAS or alerter, and if necessary, investigate each service further. Open the Services Status panel by clicking [Setup > Tools & Views > Services Status](#). Each time the Services Status panel is opened, the status of each service is refreshed.

## Unit utilization and inspection core performance

This section presents details about Unit utilization and Buffer usage monitor reports so you can learn to identify problems. It includes troubleshooting tips for queue overflow scenarios, and managing utilization thresholds.

The Inspection Core (sniffer) is the heart of the Guardium collector. It receives all data that is sent from S-TAPs, Network TAPs, and SPAN ports. It is composed of the following components that perform various tasks of transforming network packets into data that can be stored in the internal MySQL database of the collector:

- Sniffer Engine: The sniffer engine reassembles packets that are coming from a SPAN port or Network TAP, or from S-TAPs that are using the packet capture (pcap) driver to capture data. It is not used to process data that is captured by the native S-TAP drivers, such as KTAP (in the case of UNIX S-TAP).
- Analyzer/Parser: The analyzer determines the database type, protocol, and packet structure that is used for each monitored session. It then passes this information to the Parser, which, as the name implies, parses the SQL statements into their constituent parts (VERB, OBJECT, FIELD, and so on).
- Logger: The parsed data is then passed to the logger, which stores this data into the collector's database.

Each of these inspection core components feature dedicated buffers to cope with temporary spikes in traffic. When these buffers overflow, data loss occurs. When the appliance loses packets, you might notice data missing from Guardium reports or reports with missing fields (such as Database Username). Therefore, managing the performance of the Inspection Core comes down to doing what is necessary to keep the various buffers from overflowing. The most efficient way to do this varies with the size of your Guardium environments.

The sniffer can restart because of logger queue overflow. Any data that is stored in any of the sniffer buffers during a restart is lost.

Open the unit utilization reports by going to [Manage > Reports > Unit Utilization](#), and then selecting one of the reports.

Using aliases is recommended when using unit utilization data in custom and predefined reports. Otherwise, utilization levels display with the values: 1, 2, 3, instead of Low, Medium, High.

- **Buffer usage monitor report**

For environments with up to three collectors, the Buffer usage monitor report is your primary source of information about inspection core performance (although the report is not limited to this information only).

- **Unit utilization and Unit utilization details reports**

The Unit utilization report provides an enterprise-level view of collector usage. It employs a simple Low, Medium, or High indicator that shows which collectors are over or under-used. The analysis is mostly based on Buffer Usage Monitor Data, with a few parameters from the Guardium statistics, collected internally on the collectors. The data is downloaded from the managed collectors. From Unit utilization report, you can click and drill down to see a collector's Unit utilization details report that lists many utilization categories and their levels.

- **Performance issue: buffer usage process not running**

The buffer usage process is running on the system to monitor the sniffer and populate the Buffer usage monitor report. If this process is not running, the report is not populated.

- **Performance issue: analyzer queue overflow**

The logger part of the sniffer has a non-circular buffer that is held in the sniffer memory. If the logger queue increases, the amount of memory used by the sniffer (**mem\_sniffer**) also increases. Once the memory has been used by the sniffer, it is not released until the sniffer restarts. This means that you see the mem\_sniffer value increase as logger queue increases, but never decrease unless the sniffer restarts.

- **Configuring unit utilization data processing**

This procedure describes how to configure Guardium systems for processing and displaying unit utilization data.

## Buffer usage monitor report

For environments with up to three collectors, the Buffer usage monitor report is your primary source of information about inspection core performance (although the report is not limited to this information only).

This report is automatically updated by an internal script every minute, so the information that is contained is the most recent. The script runs on, and populates data for, each appliance individually. By default, the appliance stores two weeks of data.

The Buffer usage monitor report can be used for real-time alerting, correlation alerting, and periodical review for deployment evaluation, trending, and capacity planning for expansion.

The enterprise buffer usage monitor report uses data from the enterprise central manager sniffer buffer usage table.

The Buffer usage monitor report consists of 47 or more columns, most of which you might never use in day-to-day monitoring of the appliance. One of the first things to do is to create a simpler version of this report that contains the following columns:

Table 1. Simplified buffer usage monitor report

| Parameter     | Description                                                                                                                                                    | Interpretation                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp     | The time the data was collected.                                                                                                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| % CPU Sniffer | A normalized representation of sniffer CPU usage. For example, 50% sniffer usage on an 8-core appliance means that the sniffer is using 400% CPU (four cores). | % CPU Sniffer can be used as a proxy to identify other problems, or to see if an appliance isn't at its "normal" values, indicating that something changed. For example, often if the sniffer CPU is high the analyzer queue would be higher, meaning the number of flat log requests is high. The number of flat log requests however is a more direct indicator. Higher sniffer CPU can also indicate a change in traffic volume or type. |

| Parameter                   | Description                                                                                                   | Interpretation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------|---------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| % CPU Mysql                 | A normalized representation of the running MySQL CPU usage.                                                   | % CPU Mysql can be used as a proxy to identify other problems, or to see if an appliance is not at its "normal" values, indicating something changed. For example, when % CPU Mysql is high the logger queue might be higher, meaning more chance of sniffer restarts. But checking for sniffer restarts is a more direct observation. % CPU Mysql can also be higher due to other non-sniffer processes running on the system like aggregation or audit processes.                                                                                                                         |
| % Memory Mysql              | The percentage of total system memory that is used by the MySQL database.                                     | Provides general background information. This value goes up or down depending on usage of the system. The exact value is not important unless a problem was identified.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Free Buffer Space           | The percentage of free buffer space for the sniffer process.                                                  | The sniffer buffer engine is only used in implementations that use SPAN ports, Network TAPs, or S-TAP PCAP. If the native S-TAP drivers are used, this value usually remains at 100%.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Mem Sniffer                 | Sniffer memory usage in kB.                                                                                   | Sniffer memory usage is always greater than 0 when the sniffer is running. The memory usage increases as more data is held in the logger queue. Memory that is allocated to the sniffer is not released until the sniffer restarts.                                                                                                                                                                                                                                                                                                                                                         |
| Sniffer Process ID          | The sniffer process ID.                                                                                       | The PID value in this column changes when the sniffer restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Analyzer Rate               | An approximate representation of the amount of data that is processed by the Analyzer/Parser per minute.      | The unit of data that is represented is an internal structure that is closely analogous to a packet. The maximum analyzer rate that a specific appliance can handle is a function of several variables, such as the appliance hardware, the type of data that is analyzed and parsed, and the type of rules that are used in the policy. Therefore, analyzer rate alone is not a good indicator of sniffer load, but it can be a good way to identify the busiest times of the day. The Analyzer Rate does not have a generic value that is problematic or a generic 'best practice' value. |
| Analyzer Queue Length       | Indicates the amount of data that is in the Analyzer/Parser buffer.                                           | This value is one of the most direct indicators of sniffer performance. Ideally, the value remains at, or close to, zero. The analyzer queue might grow temporarily during temporary periods of high traffic, but should never remain elevated for more than five or six rows (5 - 6 minutes) in the Buffer Usage Monitor report. The Analyzer/Parser buffer is circular. When the analyzer goes over 80% of queue full, it starts to drop data or put it into flat log, depending on the system configuration. For more information, see <a href="#">Flat log process</a> .                |
| Analyzer Lost Packets (ALP) | Deprecated                                                                                                    | Replaced by <a href="#">Flat log requests</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Logger Rate                 | A rough representation of the amount of data that is processed by the logger per minute.                      | The units here represent the parsed components of the SQL traffic that is inserted into the appliance's internal MySQL database. As with analyzer rate, the logger rate an appliance can handle depends on many factors, such as the appliance hardware, size of SQL statements that are logged, type of policy, and overall load on MySQL imposed by reports, and alerts.                                                                                                                                                                                                                  |
| Logger Queue Length         | The amount of SQL data that is in the logger buffer and waiting to be inserted into the collector's database. | Similar to the analyzer queue, a consistently high amount of data in the logger queue indicates that the appliance is unable to cope with the amount of traffic that is monitored. Temporary spikes in buffered data are normal, provided the buffer is flushed within several minutes.                                                                                                                                                                                                                                                                                                     |
| Session Queue Length        | The total number of open sessions that are monitored by the sniffer.                                          | This information is important because sniffer must allocate a certain amount of memory for each session that is monitored, and it cannot monitor more than 4000 simultaneous sessions.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Total               | The overall number of sessions that were opened and closed since the last sniffer restart.                    | Session total can be useful to correlate a spike with other statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Mysql Disk Usage            | The Current MySQL disk usage (percentage).                                                                    | High or increasing Mysql disk usage means that the appliance might be in danger of reaching or exceeding 90% full. At that point the sniffer automatically stops. Not related to Inspection Core performance, but should also be included in your simplified Buffer Usage Monitor report.                                                                                                                                                                                                                                                                                                   |
| System CPU Load             | A normalized representation of total system CPU usage.                                                        | System CPU load is derived from % CPU Sniffer and % CPU Mysql, plus other loads on the CPU. Since CPU load is derived from a few measurements, it does not indicate a specific problem. When higher than normal, it can indicate an underlying problem in many areas. Not related to Inspection Core performance, but should also be included in your simplified Buffer Usage Monitor report.                                                                                                                                                                                               |
| Flat Log Requests           |                                                                                                               | <b>Flat log requests indicate that the sniffer is dropping packets.</b> The sniffer usually drops packets due to an analyzer queue overflow problem caused by high traffic. <b>Flat log requests do not increase in a system that is working correctly.</b> If Flat log requests go over the threshold once it is a concern. Flat Log, when configured, takes the overflow from the buffer and stores it in a flat log, then inputs it later to the sniffer, with full analysis according to the policies. For more information, see <a href="#">Flat log process</a> .                     |

## Unit utilization and Unit utilization details reports

The Unit utilization report provides an enterprise-level view of collector usage. It employs a simple Low, Medium, or High indicator that shows which collectors are over or under-used. The analysis is mostly based on Buffer Usage Monitor Data, with a few parameters from the Guardium statistics, collected internally on the collectors. The data is downloaded from the managed collectors. From Unit utilization report, you can click and drill down to see a collector's Unit utilization details report that lists many utilization categories and their levels.

In the Unit Utilization report, each managed collector is displayed with its corresponding utilization level. The three utilization levels are: Low, Medium, and High. Right-click any Guardium system and select Unit Utilization Details to open the Unit Utilization Details report. It provides the statistics and levels of the individual parameters that are used to calculate the overall collector utilization in 1-hour increments over a 24-hour period.

The summary is always per hour. It summarizes the data, starting from the last time it was extracted for each managed unit, until the latest whole hour reported to the central manager. If data was not extracted for a specific unit at all, it starts at 24 hours previous to the current time. For example, data was never extracted for a specific unit and it is now 14:04 on a Tuesday and the latest reported record for that unit has a timestamp Tuesday (today) 13:05. Data is extracted for all whole hours from yesterday (Monday) at 15:00 (now minus 24 hours from the first whole hour). The latest period that is extracted is the period that starts today (Tuesday) at 12:00 (the last whole hour that is reported is between 12:00 and 13:00, since the last record is from 13:05).

The Low, Medium, and High utilization levels are defined by a predefined but configurable set of thresholds. The predefined thresholds are adequate in most cases. Threshold 1 defines the level at which a particular parameter goes from Low to Medium. Threshold 2 defines the level at which a particular parameter is at High utilization. You might see an overall High Utilization level in the Unit Utilization Details report but it might not necessarily be indicative of an issue. If the Guardium system reaches this level for only 1 hour in an extended period, it is most likely an isolated event that can be ignored. If you are getting "too many" false positives, consider modifying the

default thresholds. The rate of false positives is whatever you decide. It might be one per day, or one per week, for example. To modify the thresholds, go to [Manage > Reports > Unit Utilization > Utilization thresholds](#).

The Deployment Health Dashboard, by default, includes a unit utilization issues pane, which is the same as the Unit Utilization Details report.

The two most important statistics in the Unit utilization levels are:

- Number of flat logs: does not increase in a system that is working correctly.
- Number of sniffer restarts: the sniffer does not restart in a system that is working correctly.

These two statistics indicate that data is definitely being dropped. If they go over the threshold once, investigate the reasons. All other statistics can go over thresholds and come back down without actual data loss.

Each measurement has two columns: the hourly statistic, and the level. For example, Number of restarts and Number of restarts level. The hourly statistics are:

Table 1. Unit utilization report

| Parameter                      | Description                                                                                                   | Interpretation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|---------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hostname                       | Collector or aggregator hostname or IP.                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Period start                   | Hour at which statistics collection started.                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Overall unit utilization level | The highest level from all of the analyzed parameters.                                                        | If the number of sniffer restarts reaches a level of Medium, for example, but all other parameters are Low, the overall Unit utilization level for this period is Medium.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Number of restarts             | Number of times the sniffer restarted.                                                                        | Number of sniffer restarts. <b>Indicates that the sniffer is dropping packets. The sniffer does not restart in a system that is working correctly.</b> If Number of restarts goes over the threshold once, it is of concern. Common causes of sniffer restart: <ul style="list-style-type: none"> <li>• Crash of the sniffer process.</li> <li>• Engine buffers become full.</li> <li>• Logger queues filling up, system out of memory, can be caused by any of:               <ul style="list-style-type: none"> <li>◦ Too much traffic is coming in from the STAPs.</li> <li>◦ High level of traffic is captured by policy rules, for example, Log Full details. (<a href="#">Log full details</a>.)</li> </ul> </li> </ul> |
| Sniffer memory                 | Sniffer memory usage in kB.                                                                                   | Sniffer memory usage is always greater than 0 when the sniffer is running. The memory usage increases as more data is held in the logger queue. Memory that is allocated to the sniffer is not released until the sniffer restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Percent Mysql memory           | The percentage of total system memory that is used by the MySQL database.                                     | Provides general background information. This value goes up or down depending on usage of the system. The exact value is not important unless a problem was identified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Free buffer space              | The percentage of free buffer space for the sniffer process.                                                  | The sniffer buffer engine is only used in implementations that use SPAN ports, Network TAPs, or S-TAP PCAP. If the native S-TAP drivers are used, this value usually remains at 100%.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Analyzer queue                 | Indicates the amount of data that is in the Analyzer/Parser buffer.                                           | This value is one of the most direct indicators of sniffer performance. Ideally, the value remains at, or close to, zero. The analyzer queue might grow temporarily during temporary periods of high traffic, but should never remain elevated for more than five or six rows (5 - 6 minutes) in the Buffer Usage Monitor report. The Analyzer/Parser buffer is circular. When the analyzer goes over 80% of queue full, it starts to drop data or put it into flat log, depending on the system configuration. For more information, see <a href="#">Flat log process</a> .                                                                                                                                                  |
| Logger queue                   | The amount of SQL data that is in the logger buffer and waiting to be inserted into the collector's database. | Similar to the analyzer queue, a consistently high amount of data in the logger queue indicates that the appliance is unable to cope with the amount of traffic that is monitored. Temporary spikes in buffered data are normal, provided the buffer is flushed within several minutes.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Mysql disk usage               | The Current MySQL disk usage (percentage).                                                                    | High or increasing Mysql disk usage means that the appliance might be in danger of reaching or exceeding 90% full. At that point the sniffer automatically stops.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| System CPU load                | A normalized representation of total system CPU usage.                                                        | System CPU load is derived from % CPU Sniffer and % CPU Mysql, plus other loads on the CPU. Since CPU load is derived from a few measurements, it does not indicate a specific problem. When higher than normal, it can indicate an underlying problem in many areas.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| System var disk usage          | The utilization of the /var partition.                                                                        | Most of files that are generated by the appliance are stored in /var.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Number of requests             | Number of SQL requests that were processed during the time period.                                            | From the internal Guardium statistics. This value is indicative of 'normal' traffic level on the system. The threshold needs to be tuned to the specific environment to be useful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Number of full SQLs            | Number of full SQL records logged.                                                                            | From the internal Guardium statistics. This value is indicative of 'normal' traffic level on the system. The threshold needs to be tuned to the specific environment to be useful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Number of exceptions           | Number of exceptions logged.                                                                                  | From the internal Guardium statistics. This value is indicative of 'normal' traffic level on the system. The threshold needs to be tuned to the specific environment to be useful. For example, if there is a massive spike in exceptions on one collector, this might indicate an issue.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Number of policy violations    | Number of policy violations logged.                                                                           | From the internal Guardium statistics. This value is indicative of 'normal' traffic level on the system. The threshold needs to be tuned to the specific environment to be useful. For example, if there is a massive spike in policy violations on one collector, this might indicate an issue.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Number of flat log requests    | Number of requests that were flat logged.                                                                     | <b>Flat log requests indicate that the sniffer is dropping packets.</b> The sniffer usually drops packets due to an analyzer queue overflow problem caused by high traffic. <b>Flat log requests do not increase in a system that is working correctly.</b> If Flat log requests go over the threshold once it is a concern. Flat Log, when configured, takes the overflow from the buffer and stores it in a flat log, then inputs it later to the sniffer, with full analysis according to the policies. For more information, see <a href="#">Flat log process</a> .                                                                                                                                                       |

## Performance issue: buffer usage process not running

The buffer usage process is running on the system to monitor the sniffer and populate the Buffer usage monitor report. If this process is not running, the report is not populated.

## Symptoms

---

Key columns in the Buffer usage monitor report: Timestamp

## Causes

---

A common cause of this is the internal database previously filled up to 90% and the buffer usage process was not restarted afterwards.

## Diagnosing the problem

---

Check the timestamp column of the report and the run time parameters. Does the report have one row every minute up to the current time?

Using the CLI, check if the database is close to full: **support show db-status used %**.

## Resolving the problem

---

If the Buffer usage monitor report does have one row every minute up to the current time, the buffer usage process should be restarted.

If the database is more than 75% full or unusually full for the appliance, consider purging more data. See [Purging data to resolve a full disk when the GUI is down](#).

If the database is at a normal size, restart the buffer usage process.

To restart the buffer usage process, run:

```
restart stopped_services
restart sniffer_buffer_usage
```

Wait 1 minute before checking the reports again.

## Performance issue: analyzer queue overflow

---

## Symptoms

---

Key columns in the Buffer usage monitor report: Analyzer Rate, Analyzer Queue, Flat Log Requests.

You can use **Alerting on Analyzer Queue Overflow** to help identify symptoms.

Analyzer queue is tracked in the [Unit Utilization Level](#) and [Deployment Health View](#). A High status on analyzer queue in these views indicates a likely analyzer queue overflow. You can view the the buffer usage report on the individual collector to confirm.

To alert directly on flat log requests, see [Predefined alerts](#). By default, the alert is set to send to syslog only. Add any receivers that are required. Confirm the alert is active from [Setup > Tools and Views > Anomaly Detection](#).

## Causes

---

There are several reasons for issues with the Analyzer Queue overflowing, but the most common reason is that the sniffer cannot cope with the high rate of traffic that is monitored.

## Diagnosing the problem

---

The analyzer part of the sniffer has a circular buffer. When the queue is full any incoming data is dropped. The amount of dropped data from the last minute is logged in **flat log requests**. If there was data dropped by the analyzer in the last minute, the flat log requests increase. Increasing flat log requests is the key indicator of analyzer queue overflow. For a healthy sniffer it should not be increasing.

## Resolving the problem

---

In the case of high rate of monitored traffic, you must reduce the amount of traffic that is monitored by the appliance by using one of the following strategies:

- Introducing rules to filter more traffic. The most effective rule action to achieve filtering is the Ignore S-TAP Session rule because the sessions are ignored by the S-TAP instead of being sent across the network to the appliance.
- Moving some of the S-TAPs to a less loaded collector
- S-TAP load balancing. Sometimes, a busy database server alone can overwhelm a collector. In these cases, it might help to load balance the traffic from this database to two or more collectors (for more information, see [Linux-UNIX: S-TAP Load Balancing models and configuration guidelines](#) or [Windows: S-TAP Load Balancing models and configuration guidelines](#))
- Consider using a Selective Audit policy. By default, the collector logs all data that is sent to it from S-TAPs or Hardware TAPs. A Selective Audit policy changes this behavior by monitoring only the database traffic that is specified in the policy rules.
- Adding more collectors to the environment.

## Performance issue: logger queue overflow

---

The logger part of the sniffer has a non-circular buffer that is held in the sniffer memory. If the logger queue increases, the amount of memory used by the sniffer (**mem sniffer**) also increases. Once the memory has been used by the sniffer, it is not released until the sniffer restarts. This means that you see the mem sniffer value increase as logger queue increases, but never decrease unless the sniffer restarts.

## Symptoms

---

Key columns in the Buffer usage monitor report: Logger Rate, Logger Queue, Mem Sniffer, Sniffer Process ID.  
When the sniffer restarts the sniffer process ID changes, indicating a new sniffer process has started.

High **logger queue**, and **mem sniffer** reaching its maximum followed by change of **sniffer process ID** means there has been a logger queue overflow problem.

Logger queue overflow is not the only possible cause of sniffer restarts. The sniffer can be restarted from the CLI.

(The logger queue is different from the analyzer queue in that it is not circular and continues to allocate memory until the sniffer reaches 33% of the total system memory.)

You can use **Alerting on Logger Queue Overflow** to help identify symptoms.

Logger queue is tracked in the [Unit Utilization Level](#) and [Deployment Health View](#). A high utilization status on logger queue in these views indicates a likely logger queue overflow. The buffer usage report on the individual collector can then be checked to confirm.

To alert directly on a high number of sniffer restarts, see [Predefined alerts](#). By default, the alert is set to send to syslog only. Add any receivers that are required. Confirm the alert is active from [Setup > Tools and Views > Anomaly Detection](#).

## Causes

---

After the sniffer allocates memory, it does not release it even if the logger queue recovers. Therefore, it is possible to have a high sniffer memory usage even if the logger queues are not holding any data. Sniffer restarts because of logger queue overflow is also shown in the collector's syslog file (/var/log/messages). These messages come in two varieties. The first is a sniffer Memory Allocation Problem, which happens when the logger queues grow quickly. The second type of logger queue overflow restart happens when the Guardium "nanny" process, which monitors sniffer memory usage, detects that the sniffer is dangerously close to the limit and restarts it.

Usually, both types of restarts are caused by the same issues, the only difference being the speed at which the sniffer memory grows. Memory allocation problems happen when the sniffer memory grows quickly before the nanny process can react.

The logger queue can grow for the following reasons:

- Too much traffic or an overly aggressive policy with many heavy rules, such as Log Full Details. Though the solutions for Analyzer Queue issues can also apply here, most times it might be sufficient to reduce the number of Log Full Details or policy violation rules in the policy, or make such rules less inclusive.
- The logger might be competing for MySQL resources if there are an excessive number of reports, correlation alerts, or other internal processes that are running in the background. If your environment includes an Aggregator, consider running daily reports on that appliance instead.

The logger queue is different from the analyzer queue in that it is not circular and continues to allocate memory until the sniffer reaches 33% of the total system memory, by default. This can be configured in the CLI with **support store snif\_memory\_max**.

If the logger queues stay high, the maximum memory is eventually reached. At that point the sniffer automatically restarts and the data in the queues is dropped.

## Resolving the problem

---

Reducing the traffic as for analyzer queue overflow helps to some extent, however the amount of data is not the most common cause of logger queue overflow. Reducing the amount of data logged with intensive logging actions in the policy will have more impact. Sniffer patches are more likely to resolve specific issues leading to high logger queues. Decreasing the workload on the internal database will also improve performance of the logger, for example by running Audit Processes on an aggregator where possible. If the logger queue overflow problem is correlated with a specific scheduled job, that jobs impact on database performance is the likely cause. Suggestions for handling logger queue:

- Install latest sniffer patch from fix central on the appliance
- Reduce amount of traffic logged with 'Log Full Details' or 'Alert per Match' policy actions. See [Configuring your policy to prevent appliance problems](#) for more details.
- Investigate any scheduled jobs that correlate with logger queue overflow.

## Configuring unit utilization data processing

---

This procedure describes how to configure Guardium® systems for processing and displaying unit utilization data.

### About this task

---

For a centrally managed environment, populating the unit utilization information requires scheduling two processes on the central manager: uploading data to the central manager for the buffer usage monitor; and processing the unit utilization data.

For a stand-alone system, you just need to schedule the processing of unit utilization data.

### Procedure

---

1. For a centrally managed environment, define a schedule on the central manager for uploading the central manager buffer usage monitor data.
  - a. Go to Reports > Report Configuration Tools > Custom Table Builder.
  - b. From the Custom Tables screen, select CM Buffer Usage Monitor and click Upload Data to continue.
  - c. From the Upload Data screen, click Modify Schedule to define a schedule for uploading the central manager buffer usage monitor data. Click Save after defining a schedule, then click Back to return to the Upload Data screen.
- Scheduling the process to run once every hour is a reasonable starting point for many deployments, but you may want to adjust the interval around your available resources or data-currency needs.
- Important: To ensure that the most recent data is available for unit utilization reports, define a schedule that processes the buffer usage monitor data before processing the unit utilization data. Additionally, the buffer usage monitor data should not be scheduled to run exactly on the hour.

- Best practice: Define schedules that process the buffer usage monitor data at 10-minutes after the hour and unit utilization data at 40-minutes after the hour.
- From the Upload Data screen, optionally click Run Once Now to immediately upload the data.
2. For a centrally managed environment or for a standalone system, define a schedule for processing unit utilization data.
- In a centrally managed environment, you only need to define the unit utilization schedule on the central manager.
- Go to [Manage > Unit Utilization > Unit Utilization Levels](#).
  - Click Modify Schedule to define a schedule for processing unit utilization data. Click Save after defining a schedule, then click Back to return to the Unit Utilization Levels page.
- Scheduling the process to run once every hour is a reasonable starting point for many deployments, but you may want to adjust the interval around your available resources or data-currency needs.
- Important: To ensure that the most recent data is available for unit utilization reports, define a schedule that processes the unit utilization data after processing the buffer usage monitor data.
- Best practice: Define schedules that process the buffer usage monitor data at 10-minutes after the hour and unit utilization data at 40-minutes after the hour.
- From the Unit Utilization Levels page, optionally click Run Once Now to immediately process the data.

## Results

Go to [Manage > Reports > Unit Utilization](#) to view unit utilization reports. In a centrally managed environment, the data covers the central manager and its managed units. For a standalone system, data is for that individual system. If you did not use the Run Once Now option when defining the schedules, you must wait until those processes run before the unit utilization reports update with the latest data.

## Self Monitoring

The Guardium solution monitors itself to minimize disruptions and correct problems automatically whenever possible.

Guardium uses a three-pronged approach to ensure that it is available, functioning properly, is not been tampered with, and alerts users of problems:

- Reports: Whether textual or graphical, reports are at the core of the Guardium® solution. By using the Guardium Query-Report Builder, a user can effectively report on any of the self-monitoring data that is collected through associated domains and entities. Many of the predefined reports can be enhanced through more detailed effort to provide higher levels of granularity. Use the domain VA Tests to report on tests that are available for security assessments.
- Alerts: In addition to building reports, a user can define an alert against those reports through defined thresholds, indicating an exception or policy rule violation. These alerts can either be real-time or determined through historical analysis. These alerts can then trigger notification to users through SMTP, SNMP, syslog, or a custom Java™ class.
- Self-Monitoring Utility: Guardium has implemented an internal self-monitoring daemon (always running) service utility on collectors and aggregator. This internal self-monitoring daemon wakes up every 5 minutes and does a system scan, checking components for optimal configuration, operational effectiveness, and repairs when necessary. For example, if the utility finds the Web Server down, it first validates a complete shutdown of the service, restarts the service, and then alerts an administrative user.

## Components Monitored

Table 1. Components monitored

| Components                                                                                                                                                                    | How to access                                                                                                                                                                                                                                                                                                                                            |

| S-TAP Info (Central<br>Manager)           | Report: See S-TAP Reports. On a Central Manager, an additional report, S-TAP Info, is available. This report monitors S-TAPs of the entire environment. Upload this data using the Custom Table Builder. This report is the result of uploading data using remote sources on a Central Manager and using that data to see a consolidated view of S-TAPs.<br><br>S-TAP info is a predefined custom domain which contains the S-TAP Info entity and is not modifiable like the entitlement domain. |

## Guardium nanny process

The Guardium nanny is an internal process that monitors key components and critical resources within the Guardium system—guaranteeing their availability and reliability. The nanny alerts when potential problems are emerging. Nanny alerts go to syslog, can be forwarded and sent as emails to the administrator. In some cases the nanny can take remedial actions.

The monitored resources and components include:

- Web service monitoring - service port (default 8443) not responding or tomcat service is not up
  - syslog message
  - mail admin
  - will issue restarts of the web service
- Inspection Engine activity - snif overloaded, not responding, or failure
  - syslog message
  - mail admin
  - mail guardium support (optional)
  - tries to fix by restarting the snif under certain conditions
  - tries to respawn snif if process dies
- Diskspace utilization - alerts when > 75% on the critical partitions
  - syslog message
  - alert admin
  - performs preventive action by cleaning temporary files when over 95%
- Monitor internal database (TURBINE) - verify service is up, status, and capacity utilization monitoring
  - syslog message
  - mail admin
  - restart service
- File System utilization - every five minutes, Nanny.pl checks file system at /var, warning alert when > 75% in the /var directory, critical alert and services stopped when >90% in /var directory
  - syslog message
  - alert admin
  - Admin clean-up required, using CLI commands: show filesystem usage, clear filesystem dir, and restart stopped\_services
- remote syslog. You can send test messages to the rsyslog to verify that it is communicating with Guardium. To enable and configure the rsyslog test, use the API command [modify\\_guard\\_param](#). To run the test, use the CLI command [show remotelog status](#).
  - If the test message is successful, the response is success.

- If the test message is unsuccessful, Guardium restarts the rsyslogd and checks with a test message. If the test message is successful, the response is success.

- **Monitoring with SNMP**

An SNMP agent is installed on Guardium systems, and read-only access is provided using the SNMP community name of **guardiumsnmp**. You can use SNMP commands within Guardium to display SQL Guard SNMP information.

- **Running Query Monitor**

The Running Query Monitor displays the status of active user queries, and enables you to set a timeout value for all Report/Monitor queries.

## Related information

---

## Monitoring with SNMP

---

An SNMP agent is installed on Guardium® systems, and read-only access is provided using the SNMP community name of **guardiumsnmp**. You can use SNMP commands within Guardium to display SQL Guard SNMP information.

When querying, a value of -1 (minus one) indicates a NULL in the database. The table at the end of this section lists the available SNMP OIDs.

## SNMP Examples

---

From a Unix session, you can display SQL Guard SNMP information using the **snmpget** or **snmpwalk** commands. For more information about the **snmpget** and **snmpwalk** commands, call **snmpget -h** or **snmpwalk -h**. Various UI-based software packages are available to display SNMP information. Those alternatives are not described here.

Note: For version 3 SNMP commands, the securitylevel depends on how the SNMP user is created. On the Guardium appliance, you must set securitylevel to *authPriv*. For *authPriv*, you must provide an authentication type, encryption type, authentication password and encryption password.

Table 1. SNMP 3 examples

| SNMP Examples                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>snmpget -v 3 -u SNMPV3USER -a MD5 -A password -x AES -X password -l authPriv 9.42.101.8 UCD-SNMP-MIB::dskAvail.1</code>                                                                                                                                                                                                       |
| <code>snmpget -v 3 -u SNMPV3USER -a MD5 -A password -x AES -X password -l authPriv 9.42.101.8 UCD-SNMP-MIB::dskUsed.1</code>                                                                                                                                                                                                        |
| List total memory and used memory:                                                                                                                                                                                                                                                                                                  |

| .1.3.6.1.2.1.25.2.3.1.6.1<br>HOST-RESOURCES-MIB::hrStorageUsed.1 | Memory in use                                                                                      |
| .1.3.6.1.4.1.2021.8.1.101.1<br>UCD-SNMP-MIB::extOutput.1         | Open monitored session count                                                                       |
| .1.3.6.1.4.1.2021.8.1.101.2<br>UCD-SNMP-MIB::extOutput.2         | Requests logged by the current sniffer process (set to zero for each restart)                      |
| .1.3.6.1.4.1.2021.8.1.101.3<br>UCD-SNMP-MIB::extOutput.3         | Last session timestamp                                                                             |
| .1.3.6.1.4.1.2021.8.1.101.4<br>UCD-SNMP-MIB::extOutput.4         | Last construct timestamp                                                                           |
| .1.3.6.1.4.1.2021.8.1.101.5<br>UCD-SNMP-MIB::extOutput.5         | Memory used by the sniffer process                                                                 |
| .1.3.6.1.4.1.2021.8.1.101.7<br>UCD-SNMP-MIB::extOutput.7         | Packets in on ETH1/ out on ETH2; usually only one number (inbound) when a SPAN port or TAP is used |
| .1.3.6.1.4.1.2021.8.1.101.8<br>UCD-SNMP-MIB::extOutput.8         | Packets in on ETH3/ out on ETH4; usually only one number (inbound) when a SPAN port or TAP is used |
| .1.3.6.1.4.1.2021.8.1.101.9<br>UCD-SNMP-MIB::extOutput.9         | Packets in on ETH5/ out on ETH6; usually only one number (inbound) when a SPAN port or TAP is used |

Other MIBs accessible in the machine are: SNMPv2-MIB, IF-MIB, RFC1213-MIB, and HOST-RESOURCES-MIB.

## Running Query Monitor

The Running Query Monitor displays the status of active user queries, and enables you to set a timeout value for all Report/Monitor queries.

Open the Running Query Monitor by clicking [Manage](#) > [Activity Monitoring](#) > [Running Query Monitor](#).

From the Running Query Monitor, you can:

- Set the query timeout for all reports and monitors that are running in a portlet. Other query processes, such as policy simulations, audit processes, and internal processes are not affected by this timeout value. The default is 180 seconds (3 minutes).
- Kill any currently running user query. Some queries that are listed in this panel—audit processes, for example—can exceed the query timeout specified. That is expected, because the Report/Monitor query timeout applies only to reports and monitors running in a portlet.

We do not recommend setting the Query Timeout higher than the default setting (180 seconds) for an extended time. If you set this limit higher, it increases the chances of overloading the system with ad-hoc reporting activity.

To change the timeout setting, type a number of seconds in the Report/Monitor Query Timeout (seconds), and click Update. You will be informed when the update finishes.

## Services Status panel

The Services Status panel is a centralized place to check status of services such as CAS or alerter, and if necessary, investigate each service further. Open the Services Status panel by clicking **Setup > Tools & Views > Services Status**. Each time the Services Status panel is opened, the status of each service is refreshed.

Say that you set up a policy that sends a real-time alert whenever there are more than three failed log-ins in 5 minutes. To protect against this possible intrusion, you must make sure that the policy was installed, and that the alerter is on.

Use the Services Status panel to verify that both of these services are configured properly.

Clicking any service takes you to its configuration page, where you can, as relevant, turn the service off or on, restart a service, configure a service, etc.

If for some reason the policy didn't install correctly, click **Setup > Tools & Views > Policy Installation** to go to Policy Installer, view the currently installed policies, and make the necessary changes.

Each service displays one of the following icons:

- Service is running/scheduled: 
- Service is paused: 
- Service is off: 

## Scheduling

The general-purpose scheduler is used to schedule many different types of tasks (archiving, aggregation, workflow automation, and so on).

Depending on the type of task being performed, not all of the features described here might be available - for example, the schedules for some types of tasks can be paused, while others cannot be (they can only be stopped or started).

Note: Be aware of scheduling anomalies that might occur when scheduling tasks during Daylight Saving Time.

## Define or Modify a Schedule

1. Access the Scheduling pane from the specific task.
2. Schedule by:
  - Day: select the days.
  - Month: select either the day of the month, or the day of the week; and either every month or specific months.
3. If you want the task to run more than once per day, define the repeat schedule by specifying the interval (in hours) between the tasks. You can also define it to run more than once per hour.  
Note:  
When the schedule is defined to repeat multiple times within an hour, the iteration starts and ends within the hour. The next hour is considered as a new iteration.  
For example, if a job is scheduled to run every 15 minutes starting at 12:15 PM, the job runs at 12:15 PM, 12:30 PM, and then at 12:45 PM. The next iteration begins at 1:15 PM and runs again at 1:30 PM and 1:45 PM.  
To run a job 4 times within an hour, schedule the job to begin before the first quarter of the hour. For example, a job that is scheduled to begin at 12:05 PM repeats at 12:20 PM, 12:35 PM, and 12:50 PM. The next iteration begins at 1:05 PM.
4. Fill in the Start Schedule at. This is the hour at which the schedule starts.
5. In the Begin Schedule, enter the date and time at which the task should first run. If you choose a date earlier than the current date, it reverts to the current date.
6. Select Activate Schedule if activate the schedule.
7. Optionally, select Auto run dependent jobs to automatically find all the job's prerequisite jobs and run them in order, before running this job. This ensures that the job runs with the latest, most accurate data.
8. Click Save. If you selected Auto run dependent jobs, a popup opens with details of the prerequisite jobs that must execute just before this job runs. For more information, see [Job dependencies](#).

## Pause a Schedule

Note: Not all types of scheduled tasks provide a pause option.

1. Clear Activate schedule and save the job.
  - [Job dependencies](#)  
When you create and schedule tasks such as installing policies, updating groups, or running audit processes, you can run the task on a schedule that you define for that process. If that task (the parent) depends on other scheduled jobs (such as jobs that populate groups that are needed by the audit process), then the schedule must ensure that related jobs run and complete in a timely manner before the parent task starts.
  - [Viewing job history](#)  
The job history view provides a Gantt chart that shows when jobs ran and for how long. The chart supports audit, aggregation, and data mart jobs and includes information about start and stop times, duration (current, shortest, longest, and average), and task count.

## Job dependencies

When you create and schedule tasks such as installing policies, updating groups, or running audit processes, you can run the task on a schedule that you define for that process. If that task (the parent) depends on other scheduled jobs (such as jobs that populate groups that are needed by the audit process), then the schedule must ensure that related jobs run and complete in a timely manner before the parent task starts.

Manually defining a schedule that includes these dependent jobs can be complicated or impossible. Therefore, to automate the process, select Auto-complete dependent jobs, which takes the following steps:

1. Guardium checks to see whether the parent task has dependent jobs.

Note: This is a specific check: For example, if the parent task depends on a group, and the group is populated by a query, the query that populates the group must run first to refresh the group (that is, the parent task depends on the group). However, if that group is static or not populated by a query, then the parent task does not have a dependency on the group. In this case, it is your responsibility to ensure that the data in the group is up to date.

- If dependent jobs are found, Guardium checks to see whether the jobs have run in the past 24 hours.
- If the dependent jobs have not run in the past 24 hours, Guardium runs the dependent jobs in the appropriate order. That is, if dependent jobs have dependencies on each other, they are run sequentially and in an order that clears those dependencies.

2. After all of dependent jobs run successfully, the parent job runs.

3. If any of the dependencies fails to run, the job that is currently scheduled does not run. If a failure occurs, an error message is written to the Scheduled Jobs Exception report. The dependent job will retry three times, three minutes apart before failing.

Guardium has defined dependencies for several different job types.

Table 1. Job dependencies. When Auto-complete dependent jobs is selected, Guardium manages job dependencies for the described situations.

| Job type                                                | Dependent jobs                                                                                                                                                                                                                                                                  | Reason                                                                                                                                     |
|---------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Audit process with discover sensitive data task         | Where the task includes a discover sensitive data scenario with a Policy >_Rule_>_Action for Add To Group of Objects, Add To Group of Object/Fields or Add To Access Rule. For more information, see <a href="#">Discovery scenarios</a> and <a href="#">What to discover</a> . | Before installing policy rules that use groups, the group data must be up to date.                                                         |
| Audit Process with report task                          | A custom table upload job where the custom table name is referred to by the report audit task.                                                                                                                                                                                  | Custom table data that is referred to by a report-type audit task must be populated with up-to-date data before the Audit Process can run. |
| Audit Process with report task                          | Groups that are defined in an audit task report condition that are populated by the 'Populate From Query' mechanism.                                                                                                                                                            | Groups that are referred to by a query condition must be populated with up-to-date data before a report-type Audit Task can run.           |
| Audit Process (for aggregators)                         | Import                                                                                                                                                                                                                                                                          | For aggregators only. Ensures that information is imported from all aggregated units before any audit process can run.                     |
| Policy Installation with a discover sensitive data task | Groups that are defined in any policies to be installed that are populated by the 'Populate From Query' mechanism.                                                                                                                                                              | Before installing policy rules that use groups, the group data must be up to date.                                                         |
| Populate From Query                                     | Populating a query that uses an uploaded custom table as an entity.                                                                                                                                                                                                             | For any entity that uses populate from query with custom table data, the custom table must be populated with up-to-date data.              |

To enable job dependencies, select Auto run dependent jobs in the Scheduler of a task. When you save the task, a window opens with details of the prerequisite jobs that must run before this job runs.

To identify job dependencies, run the [auto\\_execute\\_suggested\\_dependencies](#) API with the jobTrigger=<job name> parameter.

To obtain a list of all the scheduled jobs and triggers, run the [list\\_scheduler\\_jobs](#) API.

## Viewing job history

The job history view provides a Gantt chart that shows when jobs ran and for how long. The chart supports audit, aggregation, and data mart jobs and includes information about start and stop times, duration (current, shortest, longest, and average), and task count.

## Before you begin

The job history chart does not show jobs that ran for less than 1 minute and does not show failed or canceled jobs.

## Procedure

1. Open Investigate > Job History.
2. Optional: Define a time period for the chart.  
The default period is two weeks, including the current date.
  - a. Click the  icon to open the Specify time period dialog.
  - b. Use the Period start and Period end controls to define a time period.
  - c. Click OK to apply the settings.
3. Review the job history.  
Jobs are listed vertically on the y-axis while time is shown horizontally on the x-axis. Job duration is indicated by the length of horizontal bars that represent individual jobs.
4. Investigate specific jobs.
  - a. Hover on individual jobs to see details.  
Depending on the specific job, the details can include start and stop times, duration (current, shortest, longest, and average), and task count.
  - b. For jobs with tasks, click the job to see individual tasks and task durations.

# Aliases

Create synonyms for a data value or object to be used in reports or queries.

## Aliases Overview

Aliases display a meaningful or user-friendly name for a data value.

For example, *Financial Server* might be defined as an alias for IP address 192.168.2.18. After you define an alias, users can display report results, formulate queries, and enter parameter values with the alias instead of the data value.

Aliases can be defined in a number of ways:

- Through the IP-to-Hostname Aliasing tool - use this tool to generate aliases for discovered client and server IPs.  
Click **Protect > Database Intrusion Detection > IP-to-Hostname Aliasing** to open the IP-to-Hostname Aliasing tool.
- Through the Alias Builder - use this method to define aliases manually.  
Open the Alias Builder by clicking **Comply > Tools and Views > Alias Builder**.
- Through a GuardAPI or REST API query.
- Through the Alias Quick Definition while using the Group Builder pane.

Note: Alias changes on the Central Manager or managed units are not available on other systems until either GUI is restarted or any alias changes are made through their GUI.

## IP-to-Hostname Aliasing

One of the more common applications of aliases is to use them as synonyms for IP addresses. Use this tool to schedule the discovery of client and server IP's and generate aliases for them.

1. Open the IP-to-Hostname Aliasing tool by clicking **Protect > Database Intrusion Detection > IP-to-Hostname Aliasing**.
2. Check the Generate Hostname Aliases for Client and Server IPs (when available) check box.
3. Check the Update existing Hostname Aliases if rediscovered check box if you want the tool to continually look for and update hostname aliases.
4. Click **Apply** to save your configuration, then schedule the operation.
  - Click **Run Once Now** to start the tool immediately.
  - Click **Define Schedule...** to schedule the tool in the future.
  - Click **Pause** to pause the generation of client and server IPs aliases.

## Alias Builder

Use this method to manually create an alias.

1. Open the Alias Builder by clicking **Setup > Tools and Views > Alias Builder**.
2. Select the attribute type for which you want to define aliases.
3. Filter your search on that attribute type that uses the Value and Alias fields and click **Search**.
4. If any results match your search, they display in the value and alias table. Click **Apply** for the search results, or add a new alias by specifying a Value and Alias name, then clicking **Add**.
5. Add a comment to an alias by clicking the Item Comments icon . Comments can be helpful for quickly referencing what an alias refers to in the future.

## Define Aliases using a Query

Use this method to create aliases from a query. When a custom table is uploaded to Guardium®, that table is available to map aliases to specific values.

Restriction:

- When importing group members from Members tab > Import From query using Run Once Now, the maximum number of imported members is 5,000 rows. This is not configurable.
- When importing group members from Members tab > Import From query using a schedule, the maximum number of imported members is 20,000 rows by default. You can configure this limit with the CLI command **show/store populate\_from\_query\_maxrecs**. For more information, see [Configuration and Control CLI Commands](#).

1. Open the Alias Builder by clicking **Setup > Tools and Views > Alias Builder**.
2. Select the attribute type for which you want to define aliases from the Alias Finder and click **Populate from Query** to open the Builder Alias From Query Set Up pane.
3. Enter the required information and click **Save** to save the alias.
  - Select the query to run from the Query menu.
  - Choose a value for both Choose Column for Value Column and Choose Column for Alias Column.
  - After you select column values, more fields display that require input (From Date, To Date, Remote Source, and any additional parameters for the selected query).
  - Check the Clear existing group members before Importing check box to delete the existing content of the group before you populate from the query.
  - Click **Save** to save.
  - With the query saved, the Scheduling buttons become active. Click **Modify Schedule** to run the query in the future, or click **Run Once Now** to run it immediately.

## Alias Quick Definition from Group Builder

Use this method to create an alias for a group immediately when you create or populate a group.

1. Open the Group Builder by clicking **Setup** > **Group Builder**. Select any group from the list, and click **Modify**.
2. Click **Aliases** to open the Alias Quick Definition window. Type in an alias for any group or groups, and click **Apply** to save the alias.

## Dates and Timestamps

Use a calendar tool to select an exact date, and a relative date picker to select a date that is relative to the current time.

There are two tools that Guardium provides to populate date fields: a calendar tool to select an exact date, and a relative date picker to select a date that is relative to the current time (now -1 day, for example). In addition, you can manually enter exact or relative dates.

Note: When you select or enter dates, the date on the system on which you are running your browser might not be the same as the date on the Guardium® appliance to which you are connected.

### Timestamps in Queries

---

Be careful when you include Timestamps in queries.

First, be aware of the distinction between a timestamp (lowercase t) and a Timestamp (uppercase T).

- A timestamp (lowercase t) is a data type containing a combined date-and-time value, which when printed displays in the format yyyy-mm-dd hh:mm:ss (for example, 2020-07-17 15:40:25). When you create or edit a query, most attributes with a timestamp data type display with a clock icon in the Entity List pane.
- A Timestamp (uppercase T) is an attribute that is defined in many entity types. It usually contains the time that the entity was last updated.

Including a Timestamp attribute value in a query produces a row for every value of the Timestamp, which can produce an excessive amount of output. Instead, use the count aggregator when including the Timestamp in a query, and then drill down on a report row to view the individual Timestamp values for the items included in that row only, in a drill-down report. See **Aggregate Fields in Queries**.

When displaying a Timestamp value in a query that contains Timestamp attributes in multiple entities, be careful to select the Timestamp attribute from the appropriate entity type for the report. For example, if the query displays information from both the client/server and the Session entities, with the Session selected as the main entity, you can display a Timestamp attribute from one or both entities. If you include the client/server Timestamp, you see the same value printed for every Session for a given client/server connection – always the time at which that particular client/server was last updated. If you include the Timestamp attribute from the Session, you see the time that each Session listed was last updated.

Tip: If your report displays the same times when you expect them to be different, the report probably includes a Timestamp attribute from an entity too high in the entity hierarchy for the level of detail you want on the report.

### Select an Exact Date from Calendar

---

To use the Calendar Window to select an exact date:

1. Click **Calendar** for the field where you want to insert a date. The calendar opens in a separate window.
  - Click the arrows to display the previous or next month in the calendar window.
2. Click any date to select that day. The calendar window closes and the selected date is inserted into the date field next to the calendar tool that you clicked.

Note: The default time for a date that is selected from the calendar is always 00:00:00 (midnight). To specify a different time, enter the time that you want in 24-hour format: hh:mm:ss, where hh is the hour (0-23), and mm and ss are minutes and seconds (both 0-59).

### Enter an Exact Date Manually

---

1. Click the field where you want to enter the date and enter the date in YYYY-MM-DD format, where:
  - YYYY is optional and can be any positive integer value. If omitted, YYYY defaults to the current year. If a one- or two-digit year is entered, the century portion of the date defaults to 19.
  - MM is the month (1-12)
  - DD is the day of the month (1 - 28, 29, 30, or 31, depending on the month)
2. The default time for a date that is selected from the calendar is always 00:00:00 (midnight). To specify a different time, enter the time that you want in 24-hour format: hh:mm:ss, where hh is the hour (0-23), and mm and ss are minutes and seconds (both 0-59)..

Note: Some APIs accept dates or timestamps. In these cases, the format is always **yyyy-mm-dd**  
**hh:mm:ss**.

### Select a Relative Date from Date Picker

---

Rather than specify an exact date, it is often more convenient to specify dates relative to either the current date (now) or some other date (the first Monday, for example). For example, to always include information from the previous seven days in a query, it's more convenient to define relative dates (for example, **start = now minus seven days** and **end = now**). The Relative Date Picker tool can be used to select a relative date for many types of tasks.

1. Click the Relative Date Picker next to any field where a relative date is allowed. The Relative Date Picker window opens.
2. Select Now, Start, or End from the list. Depending on your choice, the display changes to provide for additional selections.
3. From the middle list, select this, last, or previous, which is relative to the unit (day, week, month, or day of the week) that is selected in the next list) as follows:

- This is the current unit.
  - Last is the current unit minus one.
  - Previous is current unit minus two.
4. Select the day, week, month, or a specific day: Monday-Friday.
  5. Click Accept when you are done. The relative date is inserted into the field next to the Relative Date Picker button that you clicked.
  - 6.

## Enter a Relative Date Manually

---

To enter a relative date manually, follow one of the procedures. The keywords are not case-sensitive but each component must be separated from the next by one or more spaces.

There are three general formats you can use to enter a relative date:

- NOW plus or minus a specified number of minutes, hours, days, weeks, or months.
- The Start or End of the current, last or previous day, week, or month.
- The Past or Previous day of the week (Sunday, Monday, Tuesday, and so on.).

## Relative to NOW

---

1. Click in the field where you want to enter the relative date. Depending on the application, you can either search for data in the past (such as from a report) or schedule an action in the future (to start a service).
2. Enter the keyword NOW.
3. To search for existing data, enter a minus sign and an integer to specify the relative time. To specify a future action, specify a plus sign and an integer.
4. Specify one of the following keywords: HOUR, DAY, WEEK, or MONTH. Plurals (hours, days, etc.) are not allowed.

Examples:

- To query data from a report for the last 12 hours, enter NOW -12 HOUR.
- To start an S-TAP installation via GIM in exactly one day, enter NOW +1 DAY.

Note: Some APIs also accept relative dates. Enter the relative date as, for example, NOW +3 DAY or NOW -12 HOUR. For APIs, the text is case-sensitive.

## Relative to a Day, Week or Month

---

1. Click in the field where you want to enter the relative date.
2. Enter the keywords START OF or END OF.
3. Enter THIS or LAST, followed by DAY, WEEK, or MONTH. Example: end of last week

## Relative to a Day of the Week

---

1. Click in the field where you want to enter the relative date.
2. Enter the keywords START OF or END OF.
3. Enter LAST or PREVIOUS, followed by SUNDAY, MONDAY, TUESDAY, WEDNESDAY, THURSDAY, FRIDAY, or SATURDAY. Example: start of previous Tuesday

## Building Time Periods

---

Policy rules and query conditions can test for events that occur (or not) during user-defined time periods.

When you open the Time Period Builder, a set of pre-defined time periods is available. You can edit the available time periods to meet your needs or you can define your own.

## Adding a time period

---

1. Browse to the Time Period Builder by clicking Setup > Tools and Views > Time Period Builder.
2. Click  to open the Add Time Period page.
3. You can create either contiguous or repeating block time period. For example, the following two custom time periods both begin at 09:00 (9 AM) Monday and end on 17:00 (5 PM) Friday:
  - Workweek is contiguous and defines a single 164-hour period beginning at 9 AM on Monday and ending at 5 PM on Friday.
  - Workday is a repeating block (that is, noncontiguous) and defines five separate eight-hour time periods (9 AM – 5 PM), on five consecutive days (Monday – Friday).
4. In the Name box, enter a name for this time period. For this example, enter either Workweek or Workday.  
Note: Do not use apostrophes (') in the description.
  - For Workweek, select Contiguous.
  - For Workday, select Repeating block.
5. Enter a beginning time in hours (00-24) and minutes (00-59) in the Hour From box. For this example, enter 09:00.
6. Enter an ending time in hours (00-24) and minutes (00-59) in the Hour To box. For this example, enter 17:00.
7. Select a beginning day of the week in Weekday From.
8. Select an ending day of the week in Weekday To.
9. Click OK to save the new time period.

Note: When you define a time period, Sunday is always assumed to be the first day of the week. Therefore, if you define a full week, you must start with Sunday. That is, you can set DAY FROM to Sunday and DAY TO to Saturday, but setting DAY FROM to Monday and DAY TO to Sunday returns unexpected results.

## Editing a Time Period

---

1. From the Time Period Builder, select an existing time period and click  to open the Edit time period page.
2. Change any fields as needed in the Edit time period page for the selected time period.
3. Click OK to save your changes.

## Removing a Time Period

---

From the Time Period Builder, select the time period that you want to remove, and click  to delete the selected time period.  
Note: You cannot delete a time period that is used by an existing policy rule.

---

## Cipher suites

---

Cipher suites are combinations of cryptographic parameters that define the security algorithms and key sizes.

Guardium® uses operating system level ciphers for many different purposes, such as,

- GIM agent
- SSH
- S-TAP agents (both Windows and Linux®)
- Guardium inspection core (that is, the Guardium sniffer)

Use the **show ssl\_configuration** CLI command to view the ciphers configured for the sniffer. For example,

```
my.example.com> show ssl_configuration
```

Sample output

```
TLS 1.2/ OpenSSL 1.x Ciphers
(1) [X] AES128-SHA
(2) [X] AES256-SHA
(3) [] AES256-SHA256

TLS 1.3/ OpenSSL 3.x Cipher Suites
(4) [X] TLS_AES_128_GCM_SHA256
(5) [X] TLS_AES_256_GCM_SHA384
(6) [X] TLS_CHACHA20_POLY1305_SHA256
(7) [] TLS_AES_128_CCM_SHA256
(8) [] TLS_AES_128_CCM_8_SHA256
```

ok

To change the SSL ciphers, use the **store ssl\_configuration** CLI command.

For more information, see the [store ssl\\_configuration](#) command in [Configuration and control CLI commands](#).

Note: If you run Linux or UNIX, use the **nmap -sV --script ssl-enum-ciphers -p <port\_number> <appliance>** command to list all of the ciphers available on the Guardium appliance.

For a list of the ports that Guardium uses, see [Guardium port requirements](#).

## Hashing user passwords

---

Guardium uses the following cipher to hash user passwords:

PBKDF2-SHA512 cipher

## GUI encryption ciphers

---

To view and manage the ciphers that are used between clients and servers in the Guardium GUI, use the **show ssl\_gui\_ciphers** CLI command. For example,

```
my.example.com> show ssl_gui_ciphers
1. SSL_ECDHE_RSA_WITH_AES_256_GCM_SHA384
2. SSL_ECDHE_RSA_WITH_AES_256_GCM_SHA256
3. SSL_ECDHE_RSA_WITH_AES_128_GCM_SHA384
4. SSL_ECDHE_RSA_WITH_AES_128_GCM_SHA256
5. SSL_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
6. SSL_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
7. SSL_ECDHE_RSA_WITH_AES_256_CBC_SHA384
8. SSL_ECDH_ECDSA_WITH_AES_256_CBC_SHA384
9. SSL_ECDH_RSA_WITH_AES_256_CBC_SHA384
10. SSL_ECDHE_ECDSA_WITH_AES_256_CBC_SHA

ok

For more information about the **ssl\_gui\_ciphers** commands, see [delete ssl\\_gui\\_ciphers and restore ssl\\_gui\\_ciphers](#) in [Configuration and control CLI commands](#).

## File backup cipher

Guardium uses the following cipher to encrypt and decrypt files and backups:

- aes256

## MySQL encryption ciphers

MySQL encrypts data at rest by using AES\_ENCRYPT() and AES\_DECRYPT(), which are considered to be the most cryptographically secure encryption functions that are currently available in MySQL. SHA-2, DES, and AES functions require MySQL to be configured with SSL support.

## Comments

Comments apply to definitions and to workflow process results.

Comments can be added or viewed in several places throughout the UI. You can add a comment to a group or alias for reference purposes, or add a comment to report to ease auditing requirements. For example, an auditor may want to know why a configuration change was made on a certain date. Use a comment to easily reference the reason why the change was made.

Comments apply to definitions (groups, aliases, reports, policies), and to workflow process results. You can add multiple comments to a component, and you can add comments to comments, but you cannot modify or delete existing comments.

There are two different kinds of comments:

- **Comments Entities** are stored on the Central Manager, and will be available within that Central management environment, given the usual constraints regarding roles and permissions.
- **Local Comments Entities** are defined on a single unit, and remain local to that unit. Local Comments from the standalone or managed unit are not stored on the Central Manager.

## Add or View Comments

1. To view comments, open the User Comments window by clicking Comply > Reports > User Comments.
2. Throughout the UI, there are different ways to add a comment to an entity or report.
  - Add a comment to a group by modifying the group, and clicking Add Comments from the Manage Members for Selected Group screen.
  - Add a comment to an alias by opening the Alias Builder and clicking the Comment icon  . Open the Alias Builder by clicking Setup > Tools and Views > Alias Builder

## Report Comments

View a report of all user comments by clicking Comply > Reports > User Comments.

- The Local Comments entity is used in a Central Manager environment only. Local comments remain local to the system on which they were defined, and are not stored on the Central Manager.
- The Comments entity contains comments that are stored on the Central Manager.

## Customer Uploads

The Database Protection Subscription Service supports the maintenance of predefined assessment tests, SQL based tests, CVEs, APARs, and groups such as database versions and patches.

Uploads are used to keep information current and within industry best practices to protect against newly discovered vulnerabilities. Updates are distributed quarterly.

Use Customer Uploads to upload the following types of files: DPS update files; Oracle JDBC drivers; MS SQL Server JDBC drivers; and, DB2 for z/OS license jar files.

Note: If a custom group exists with the same name as a predefined Guardium® group, the upload process adds Guardium in front of the name for the predefined group.

1. Open Customer Uploads by clicking Harden > Vulnerability Assessment > Customer Uploads.
2. For DPS Upload, click Browse to locate and select the file to be uploaded.
  - a. Navigate to Harden > Vulnerability Assessment > Customer Uploads.
  - b. In the DPS Upload section, click Browse and choose the latest DPS update file, then click Upload.
  - c. In the Import DPS section, click  to import the DPS update.

Note: The DPS file can take a long time to install. If you restart the browser, the install stops. Either keep the Customer Upload window open until you see a status message, or use the CLI command `show dps` to check install status. Reference the Import DPS pane to see what files have been uploaded.

3. For Upload DB2 z/OS License jar, click Browse to locate and select the file.

4. Use Upload Oracle JDBC driver or Upload MS SQL Server JDBC driver to upload open source drivers. After the upload finishes, you will see the databases that are added to the Select datasource window. Upload one driver at a time.

Note: There are two instances where open source drivers are recommended over Oracle Data Direct drivers or MS SQL Data Direct drivers.

a. To support Windows Authentication for MS SQL Server. In all other uses, the Data Direct driver pre-loaded in the Guardium appliance is sufficient.

b. When you use the Value Change Tracking application for Oracle version 10 or higher, the open-source driver is recommended in order to support the use of streams instead of triggers.

Use keywords to search and download open source JDBC drivers (for example: *open source JDBC driver for MS SQL*).

5. Use the Central Manager to distribute the .jar file to managed units. After the file is successfully uploaded, the GUI needs to be restarted on the Central Manager and the managed units.

Note: If you will be exporting and importing definitions from one unit to another, be aware that subscribed groups are not exported. When you export definitions that reference subscribed groups, ensure that all referenced subscribed groups are installed on the importing unit (or central manager in a federated environment). When uploading DB2® z/OS® license jar files, the license will take effect after restart of the GUI.

Note: If the DPS stops for any reason (for example, a server restart or a GUI restart), it is recommended to wait 30 minutes before starting the DPS upload process again.

Enable ASO on the Oracle server using latest Oracle DataDirect driver

Refer to the following information when you enable ASO on the Oracle server that uses the latest Oracle DataDirect driver.

SQLNET.CRYPTO\_CHECKSUM\_SERVER = required

SQLNET.ENCRYPTION\_SERVER = required

SQLNET.ENCRYPTION\_TYPES\_SERVER = (AES256, AES192, AES128)

#SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER = (SHA256)

SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER = (SHA1)

The Oracle JDBC driver will work and does not require specifying a connection property. Download the latest Oracle JDBC driver that is compatible with your database version, then upload that driver to the system using the Guardium Customer Uploads function.

If you continue to use Oracle DataDirect driver, then you need to specify a connection property to the datasource.

Use the following when defining the Oracle DataDirect driver connection property:

DataIntegrityLevel=required;EncryptionLevel=required;DataIntegrityTypes=(MD5,SHA1)

Note: The current Oracle DataDirect driver does not support SHA-256. So SHA-1 has to be used. That is why sqlnet.ora reference (#SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER = (SHA256)) had to be commented out. However, if a Guardium customer must connect using SHA-256, they need to use the Oracle JDBC driver instead.

Download the Oracle database JDBC User' Guide PDF for a list of command references.

Use a tab-delimited file (.TXT) when creating and saving a Datasource Upload file from the Customer Upload functionality

If you choose to use a comma-delimited file structure (.CSV), it will not behave as intended if any column value contains a comma.

Follow these steps:

1. If using EXCEL, save file as a tab-delimited (.TXT) file.
2. If using OpenOffice or Libre Office then save a (.CSV) file with TAB Delimiters.
3. Log in as admin and open Customer Uploads by clicking Harden->Configuration Change Control (CAS Application)->Customer Uploads.
4. For Upload CSV to Create/Update Datasources, click Browse..., and select the tab-delimited file.

## Upload CSV file to create or update datasources

Follow the proceeding steps to create a tab-delimited .TXT formatted file containing datasource information. This tab-delimited .TXT file can then be used with the Customer Upload function in the Guardium application to many datasource types.

Use the function to import datasources was not always compatible with each Guardium Software Release. This procedure will enable the uploading of any datasource.

The following is a list of Header Columns that should be added to an Excel spreadsheet when creating the .TXT tab-delimited datasource upload file:

Column Values (accepted for .CSV datasource upload file)

Table 1. create\_datasource

| Parameter | Description |
|-----------|-------------|
|-----------|-------------|

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| application         | Required. Identifies the application for which the datasource is being defined. It must be one of the following:<br><br>ChangeAuditSystem<br>Access_policy<br>MonitorValues<br>DatabaseAnalyzer<br>AuditDatabase<br>CustomDomain<br>Classifier<br><br>AuditTask<br>SecurityAssessment<br>Replay<br>Stap_Verification                                                          |
| compatibilityMode   | Compatibility Mode: Choices are Default or MSSQL 2000. The processor is told what compatibility mode to use when monitoring a table.                                                                                                                                                                                                                                          |
| conProperty         | Optional. Use only if additional connection properties must be included on the JDBC URL to establish a JDBC connection with this datasource. The required format is property=value, where each property and value pair is separated from the next by a comma.<br><br>For a Sybase database with a default character set of Roman8, enter the following property: charSet=utf8 |
| customURL           | Optional. Connection string to the datasource; otherwise connection is made using host, port, instance, properties, etc. of the previously entered fields. As an example this is useful for creating Oracle Internet Directory (OID) connections.                                                                                                                             |
| dbInstanceAccount   | Optional. Database Account Login Name (software owner) that will be used by CAS                                                                                                                                                                                                                                                                                               |
| dbInstanceDirectory | Optional. Directory where database software was installed that will be used by CAS                                                                                                                                                                                                                                                                                            |
| dbName              | Optional. For a DB2 or Oracle datasource, enter the schema name. For others, enter the database name.                                                                                                                                                                                                                                                                         |
| description         | Optional. Longer description of the datasource.                                                                                                                                                                                                                                                                                                                               |
| host                | Required. Can be the host name or the IP address.                                                                                                                                                                                                                                                                                                                             |
| name                | Required. Provides a unique name for the datasource on the system.                                                                                                                                                                                                                                                                                                            |
| owner               | Required. Identifies the Guardium user account that owns the datasource.                                                                                                                                                                                                                                                                                                      |
| password            | Optional. Password for owner. If used, user must also be used.                                                                                                                                                                                                                                                                                                                |
| port                | Optional (integer). Port number.                                                                                                                                                                                                                                                                                                                                              |
| serviceName         | Required for Oracle, Informix®, DB2, and IBM® iSeries. For a DB2 datasource, enter the database name. For others, enter the service name.                                                                                                                                                                                                                                     |
| severity            | Optional. Severity Classification (or impact level) for the datasource.                                                                                                                                                                                                                                                                                                       |
| shared              | Optional (boolean). Set to <b>true</b> to share with other applications. To share the datasource with other users, you will have to assign roles from the GUI.                                                                                                                                                                                                                |
| type                | Required. Identifies the datasource type. For a list of supported datasource types, use the <code>list_db_drivers</code> API command:<br><br><code>grdapi list_db_drivers</code><br><br>For more information, see <a href="#">list_db_drivers</a> .                                                                                                                           |
| user                | Optional. User for the datasource. If used, password must also be used.                                                                                                                                                                                                                                                                                                       |
| role                | Optional. One or more user roles that can access the datasource. Separate roles by using a semicolon.                                                                                                                                                                                                                                                                         |
| environmentTitle    | Required for cloud database service protection. Account name.                                                                                                                                                                                                                                                                                                                 |
| region              | Required for cloud database service protection. The AWS region.                                                                                                                                                                                                                                                                                                               |
| objectLimit         | Required for cloud database service protection with native audit. The maximum number of objects found in the classification process that are added automatically to the list of audited objects. See <a href="#">Cloud database service protection</a> .                                                                                                                      |
| primaryCollector    | Relevant for cloud database service protection. The collector that extracts the audit data from the cloud database.                                                                                                                                                                                                                                                           |

Notes:

1. Each of the column names must be included in the Excel spreadsheet SAVED as a tab-delimited (.TXT) file.
2. The Created Datasource name (what is shown when looking for the datasource) is made up of both the name column and the type column.
3. Upload file MUST be saved as a Column Tab Delimited file type.

Steps to create and upload txt file in a Text CSV format file and add Datasource Data

1. Create the Excel spreadsheet file save as a tab-delimited .TXT file with the following headers and datasource data to support the datasource import capability.
2. Create and save your .txt file to your PC or UNIX/Linux device for uploading into the Guardium application.
3. Log in as admin and open Customer Uploads by clicking Harden > Configuration Change Control (CAS Application) > Customer Uploads
4. From Upload CSV to Create/Update Datasources, click Browse and select the .txt file containing the tab-delimited datasource information.
5. Click Upload.

A message displays showing which values from the .txt file were uploaded:

1. **New:** Per file upload (if save file and added New Datasource member(s), these members returns the status of NEW.
2. **Update:** Uploading the same datasource on which you made changes returns an Update status.
3. **Fail:** Displayed failed datasource or errors

# Stream Guardium data to another application

Use the Data Streaming to send traffic collected by Guardium to another tool for analysis.

## About this task

### Procedure

1. Open the Data Streaming configuration page.
  - To configure a standalone system or a single managed unit in an environment with a central manager, navigate to **Setup > Tools and Views > Data Streaming**.
  - To configure multiple managed units from a central manager, navigate to **Manage > Central Management > Distribute Configuration Profiles** and work with a configuration profile where the Configuration type is Data streaming configuration. For more information about configuration profiles, see [Working with configuration profiles](#).
2. Use the Stream to menu to select a destination for Guardium Data Activity Monitoring traffic.
  - IBM Security Guardium is the default behavior: Guardium data is stored locally.
  - IBM Security Guardium Big Data Intelligence sends traffic to Guardium Big Data Intelligence. Data is not stored locally.
  - Datamart for Guardium Insights stores data locally and periodically syncs with IBM Security Guardium Insights.  
Note: Selecting this setting sends traffic to Guardium Insights. Verify that Guardium Insights is configured to receive and analyze traffic from the Guardium system.
3. Click Save to save the configuration.  
On a standalone system or a single managed unit, the selected settings are immediately enabled. On a central manager, complete the configuration profile and distribute the settings to managed units.

## Big Data Intelligence

The Guardium Big Data Intelligence (GBDI) platform stores collected data over longer timeframes, providing direct, near real-time access to data security and compliance reports and insights.

Note: If your site uses GBDI with data marts, you can reconfigure your site to use data streaming.  
You can provide access to Guardium Big Data Intelligence (GBDI) in two different ways:

- [Big Data Intelligence with data marts](#)  
Guardium® Big Data Intelligence uses data marts to export data to a central storage location.
- [Big Data Intelligence with data streaming](#)  
Use data streaming to Guardium Big Data Intelligence (GBDI) to stream audit data directly from your Guardium system to the GBDI platform.

## Big Data Intelligence with data marts

Guardium® Big Data Intelligence uses data marts to export data to a central storage location.

To deploy and use Guardium Big Data Intelligence:

1. Define the central storage. Use the GuardAPI **create\_datasource** or the GUI ([Creating a datasource definition](#)). Use Big Data Intelligence as the application type.
2. Define your data export profile by using the GuardAPI Big Data Intelligence function **enable\_big\_data\_interface**. The profile defines the datasource, the target host, the units that export data, the data mart extraction profile (made up of one or more data marts), and the export schedule. There are four predefined, non-modifiable profiles. To create your own data export profile, copy and modify the predefined profiles. You must use the data marts specified in the predefined profiles in order to access your data in the Big Data Intelligence domains of the Query-Report Builder.  
The profile is applied to the managed units you specify in the command **enable\_big\_data\_interface**; all the managed units of the central manager, and to the central manager itself, a managed unit group, or specific managed units.
3. After you run **enable\_big\_data\_interface** you'll see Big Data Intelligence domains in the Query-Report Builder. When you define a query, Guardium needs to connect to the GBDI to validate and save the query. This can take up to a minute. Watch the lower left corner of your GUI; you'll see text waiting for server until it connects. If Guardium cannot connect to the GBDI, it responds: *Unable to establish connection...*, and the query is not saved.
4. Use the standard Guardium predefined reports and Investigation Dashboards (Quick Search) to analyze your data. You can also create reports using the Big Data Intelligence domains.

You can enable additional managed units for data extraction at a later date with the command **grdap local\_enable\_big\_data\_interface profile\_name="<profile name>"**. This is useful if a collector was offline or not in the MU group when the interface was enabled; or, for advanced users, if you want to include data from a collector that requires a different profile, or is in another group. For example, two managed units of a central manager run only VA, and the other managed units are tracking other data. You would create a second profile that is a subset of the main profile, and run it only on the specified units. However, the local profile does not have a target for the data; add it using the command: **datamart\_update\_copy\_file\_info**.

## Data handling guidelines

- Data retention on the collector can be reduced to 1 day since the Big Data Intelligence server saves data over a long time period.
- Data backup can be handled on the Big Data Intelligence server.
- Configuration backup should be handled on the Guardium system.

- Archives should be handled according to your regulation requirements. The Big Data Intelligence server keeps data longer than collectors and aggregators, and can be used for archiving.

The Guardium capabilities to read Big Data Intelligence directly using the Guardium Query-Report Builder, or enterprise search, require Guardium Big Data Intelligence Version 3.3. If you already have a data mart extraction to an earlier GBDI version, disable the extractions that are running, and then re-enable by using the following API: **enable\_big\_data\_interface**

## Summary of data marts in each profile

## Configure key pair authentication for GBDI file extraction

---

By default, Guardium® uses a password for GBDI file extraction. Use this procedure to configure a key pair authentication instead of a password. You upload the file to the central manager, and from there distribute it to the relevant managed units.

## About this task

---

Upload the key file to the central manager if you want to distribute it to managed units. You can upload it to an individual managed unit, but cannot distribute it from there to other managed units. When you upload the file to the Guardium system, it is deleted from the file server.

## Procedure

---

1. Upload the key to the file server.
2. On the central manager, upload the key file to all managed units with the GuardAPI command **copy\_key\_file**, for example:

```
grdapi copy_key_file fileName="/opt/IBM/Guardium/log/key-file" all="true"
```

The central manager copies (by SCP) the key file to all managed units, copies the file to the central manager, and deletes it from the file server. At the end it returns a list of all managed units with the status of the grdapi execution for each. If a unit is down, its status is failed.

3. For GBDI using data marts: Update the copy\_file details with the GuardAPI command **datamart\_update\_copy\_file\_info**, for example:

```
grdapi datamart_update_copy_file_info destinationHost=<server name> destinationPassword="file:key-file" destinationPath=<path> destinationUser=<user> Name="<datamart name>" transferMethod="SCP"
```

4. If distribution to a managed unit failed, upload the key to the file server on this unit and run the GuardAPI command **copy\_key\_file** on that unit.

```
grdapi copy_key_file fileName="<keyFile.key>"
```

5. To install a new key file, repeat steps 1, 2, and 3.

## Results

---

The key file is used for file transfer, instead of a password.

## Big Data Intelligence with data streaming

---

Use data streaming to Guardium Big Data Intelligence (GBDI) to stream audit data directly from your Guardium system to the GBDI platform.

With GBDI data streaming, monitored event data from your site is sent to Guardium collectors. From there, it is processed by the Guardium collector and the selected audit data is formatted into JSON documents and streamed to the security data lake on the GBDI platform. From the GBDI platform, you can use GBDI reporting and analytic tools.

When you enable GBDI data streaming, the Guardium collector generates JSON documents for the events you choose to monitor and log. The JSON documents are sent to GBDI for storage and analysis. In addition, other information is stored in a MySQL database on the Guardium database server.

The following information can be collected and streamed to GBDI:

- Session: Contains details about the event session such as DB name, client and server ports, session start, and end, server type, client IP, and other information.
- Instance: For each SQL statement, the streamed data includes the ConstructID, original SQL statement, any objects and verbs included in that statement, and other objects.  
Note: For Instances, the difference between MySQL and data streaming is as follows:
  - For MySQL, detailed SQL construct information is logged in separate GDM tables: GDM\_CONSTRUCT, GDM\_SENTENCE, and GDM\_OBJECT.
  - With data streaming, construct information is part of the instance document, including original\_sql, objects and verbs.
- Full\_SQL: Includes all of the relative information relative to the event. This information includes data (masked or unmasked, depending on the policy rule action), the returned data count, and the total number of records affected.
- Policy\_violations: Includes any policy violation information. Each policy violation message has a unique identifier, which is referenced in the Guardium alert when the alert template variable %ViolationID is configured.
- Exception: Collects sniffer exceptions and errors. Depending on the policy rule action, the SQL string can be either full or masked.
- [Configure GBDI data streaming](#)  
To configure and use Guardium Big Data Intelligence (GBDI) data streaming, install a jProxy connector to initiate and maintain the connection between the Guardium collector and the GBDI platform.

## Configure GBDI data streaming

To configure and use Guardium Big Data Intelligence (GBDI) data streaming, install a jProxy connector to initiate and maintain the connection between the Guardium collector and the GBDI platform.

### About this task

The jProxy connector is available as an RPM package within the Guardium installation package. After jProxy is installed, the Guardium collector sniffer component communicates with jProxy (rather than directly with GBDI).

The jProxy installation includes the following services:

- **sonarjproxyd**: A light-weight MongoDB server with some customized functionality for GBDI.
- **jproxytimer**: Controls service timing configuration, including starting jProxy and managing the intervals for flushing the data.

jProxy includes the following configuration files:

- **jproxy.conf**: sonarjproxyd service settings
- **jproxyforwarder.env**: jproxyforwarder service settings
- **logging.conf** : Log file and log level settings

Use the CLI commands, described in the Procedure section, to update the configuration file settings.

Note: Every CLI **store** command that is described in this section has a matching **show** command that displays the current stored value.

### Procedure

1. From your Guardium collector, call the following CLI command to control the sniffer logger destination.

```
store snif_logger_destination_type [LOCAL | REMOTE]
```

Where:

- LOCAL (default) sets the logger destination to the local database on the Guardium collector.
- REMOTE sets the logger destination to the intermediate database used by GBDI.

2. For security reasons, each GBDI machine provides an authentication key file (SSH key) to secure data communication between the Guardium collector and GBDI.

Use the following CLI commands to upload the GBDI SSH key file (in .pem format) and configure the SSH target host to communicate with GBDI:

- **import jproxy\_files**
- **store jproxy\_config ssh\_key\_file <key\_file\_name>**

Take the following steps to import and store the SSH key file:

- a. Call **import jproxy\_files** to import the jProxy ssh key file from the specified location.
- b. Call **store jproxy\_config ssh\_key\_file <key\_file\_name>** to store the key file in the key store.

3. Then, use the following CLI commands to configure information such as logger destination, Mongo client authentication (username, auth, database, and mechanism).

Note: All of the following configuration commands are optional. You can use these commands to change the defaults, if needed.

- **store logger\_data\_destination\_config type <database type>**  
The default value = "mongodb"
- **store logger\_data\_destination\_config database\_name <db name>**  
The default value = "sonargd"
- **store logger\_data\_destination\_config destination [hostname | port] <value>**
  - The default value for hostname = "localhost"

- The default value for port = "27118"
  - `store logger_data_destination_config [auth_username | auth_database_name | mechanism] <value>`
    - The default value for auth\_username = "enchantedsdg"
    - The default value for auth\_database\_name = "admin"
    - The default value for mechanism = "plain"
4. Optionally, use the following CLI command to specify the collections that you want to stream. The default for all collections is ON.
- ```
store logger_data_destination_config data <collection_type> [on|off]
```

The collection types are:

- session
- instance
- full_sql
- policy_violations
- exception

5. Optionally, use the following CLI commands to configure the streaming interval for transporting the JSON document data from Guardium to GBDI. Whenever Guardium hits either threshold, jProxy sends the data to GBDI.

- `store jproxy_config flush_timeout_sec <seconds>`
The default is 60 seconds.
- `store jproxy_config flush_at_size <bytes>`
The default is 102400000

What to do next

After you set the `store snif_logger_destination_type` to REMOTE and store the jProxy SSH key, the data collections are automatically streamed to the GBDI platform. From there, you can use the GBDI data analytic tools as needed.

In addition, data is also stored in the Guardium MySQL database.

Exporting and importing definitions

Use export and import definitions if you have multiple systems with identical or similar requirements and are not using central management. You can define the components that you need on one system and export those definitions to other systems that are on the same software release level.

You can export one type of definition (reports, for example) at a time. Each element that you export can cause other referenced definitions to be exported as well. For example, a report is always based on a query, and it can also reference other items, such as IP address groups or time periods. All referenced definitions (except for security roles) are exported along with the report definition. However, only one copy of a definition is exported if that definition is referenced in multiple exported items. An export of policies or queries exports only the groups that are referenced by the exported policies or queries.

Using export and import definitions

Use Definitions export and Definitions import to save and then restore functional data from a specific Guardium system. For example, you can create a report on one Guardium system and then import that same report onto another server (of the same Guardium installed version).

Note: The export and import function is not the same as a full backup of the server. Be sure that you still define and run backups on a scheduled or manual basis.

UseDefinitions export to save and share defined functional values such as reports and queries, CAS data, or classifier data. The export types are saved as .sql files.

You can import the exported definitions onto servers that use the same Guardium Software version. In general, if you export definitions from a Guardium V10 system, then you can import those definitions only onto another V10 system.

You can export data marts and reports from an earlier version and import to a later version. For example, you can export definitions from a Guardium V10 system and import the definitions onto a V11 system. However, you cannot export from a later version to an earlier version.

Export definitions rules

When you export definitions, Guardium cannot export the following elements:

- For graphical reports, the presentation parameter settings (such as colors, fonts, or titles) are not exported. When imported, these reports use the default presentation parameter settings for the importing system.
- Subscribed groups are not exported. When you export definitions that reference subscribed groups, make sure that all referenced subscribed groups are installed on the importing appliance (or the central manager in a centrally managed environment).
- Comments are not exported.
- When you export a data source with an open source driver, the open source driver is not included in the export. Upload the open source driver into the new system before you import the data source definition that was created by using it. If the open source driver is not available during the import, Guardium substitutes the data direct driver.
- When you export the definition of classifier policies, any custom evaluation classes that are associated with the policies are not exported with the definition. For the imported policies to work, upload the custom evaluation classes separately.

In addition, be aware of the following rules before you export definitions.

- You cannot import or export definitions between different languages. For example, if you export a file from a Simplified Chinese Guardium® system, you cannot import the file to a system where the language is set to English.
- Definitions export and import logs have the same retention period as the monitored database activity logs.
- When you export audit process definitions of scheduled runs (including schedule time) to another system, the Active checkbox in Audit Process Builder is never checked.
- For Schedule start time of an audit process that is defined on one appliance and exported to another (unrelated) appliance; if the original schedule start time is defined, it is retained. If the original schedule start time is not defined (empty), then the imported schedule start time is set to the time it was imported.

- Large complex imports can take a long time and can exceed the length of the user's session. If the session times out, the import continues to run in the background until it completes.

Import definitions rules

Before you import definitions, make sure you understand the following rules.

- When you import an existing group, members can be added, but members are not deleted.
- When you import aliases, new aliases can be added, but aliases are not deleted.
- When a definition is created, the user who creates it is saved as the owner of that definition. Therefore, if no security roles are assigned to that definition, only the owner and the admin user have access to it.
- When you import a definition, the owner is always changed to admin.
- References to security roles are removed from exported definitions. Therefore, any imported definitions do not have assigned roles.
- A reference to a user in an exported definition causes the user definition to be exported. When definitions are imported, the referenced user definitions are imported only if they do not exist on the importing system. In other words, existing user definitions are never overwritten. The implications are described in [Duplicate Group and User Implications](#).

In addition, imported user definitions are disabled. Imported users can receive email notifications that are sent from the importing system, but they cannot log in to that system, unless and until the administrator enables that account.

Duplicate Group and User Implications

If a group that is referenced by an exported definition exists on the importing system, the definition of the exported group is not imported. If the group is not used for the same purposes on both systems, this might create some confusion.

If a user definition exists on the importing system, it might not be for the same person that is defined on the exporting system. For example, assume that on the exporting system the user jdoe with the email address john_doe@example.com is a recipient of output from an exported alert. Assume also that on the importing system, the jdoe user exists for a person with the email address jane_doe@sample.com. The exported user definition is not imported, and when the imported alert is triggered, email is sent to jdoe at jane_doe@sample.com. In either case, when security roles or user definitions are not imported, check the definitions on both systems to see whether differences exist. If so, make the appropriate adjustments to those definitions.

Definition Types for Exporting

Table 1. Definition Types for Exporting

Can export	Cannot export
Alert	Custom Alerting Class For alerts, you can choose to exclude group members. For more information, see the description under Group .
Alias	Custom Assessment Test
Audit process	Custom Identification Procedure
Auto-discovery process	
AWS Secrets Manager configuration	
CAS hosts	
CAS template Sets	
Classification process	Access Rule
Classifier policy	
Cloud service account	
Compound attribute	
Configuration profile	
Custom class connection permission	
Custom domain	
Custom table	
CyberArk configuration	
Dashboard	
Data classifier	
Datamart	
Datasource	
Datasource custom field	
Datasource group	
Discover sensitive data	
Distributed reports	

Can export	Cannot export
Event type	
External feed	
External ticket configuration	
Group	The Exclude group members option displays for data sets that have groups somewhere in the export hierarchy (for example, exporting an alert includes the alert query, and the query might include groups in the query conditions). If the export does not include groups, the Exclude group members option does not display. When the option is set, the export file includes groups (if groups are linked to the exported definition) but members of the groups are not exported. The option is not set by default. In addition, the state is not persistent and it applies only to the current export.
HashiCorp configuration	
IMS definition	
Investigation dashboard	
Kerberos configuration	
LDAP user import config	Passwords
Named template	
Period (time period)	
Policy (but not an included baseline)	
Privacy set	
Query	
Query rewrite definition	
Replay	
Report	For reports, you can choose to exclude group members. For more information, see the description under Group .
Role	
Security assessment	
Security assessment with no datasources	For security assessments with no datasources, you can choose to exclude group members. For more information, see the description under Group .
User	
Users database mapping	
Users database permission	
Users hierarchy	

Exporting definitions

1. Go to [Manage > Data Management > Definitions Export](#). The Definitions Export page opens.
2. Select an option from the Type menu. The Definitions to Export menu populates with definitions of the selected type.
3. Select all of the definitions of this type to be exported.
4. Click Export. Depending on your browser security settings, you might receive a warning message that asks if you want to save the file or to open it using an editor.
5. Save the exported file in an appropriate location.

Importing definitions

1. Go to [Manage > Data Management > Definitions Import](#). The Definitions Import page opens.
2. Click Browse to locate and select the file.
3. Click Upload. You are notified when the operation completes and the definitions that are contained in the file are displayed. Repeat to upload additional files.
4. Use the Fully synchronize group members checkbox to set the behavior of how to add new group members imported directly or via other data sets such as queries or policies. If not checked, new members that are in the import are added, but members not in the import are not removed. If checked, then group members not in the import are removed. Use the Set as default button next to the checkbox to save the checkbox setting.
5. Click Import this set of Definitions to import a set of definitions, or click Remove this set of Definitions without Importing to remove the uploaded file without importing the definitions.
6. You are prompted to confirm either action.
Note: An import operation does not overwrite an existing definition. If you attempt to import a definition with the same name as an existing definition, you are notified that the item was not replaced. If you want to overwrite an existing definition with an imported one, you must delete the existing definition before performing the import operation.

Exporting to XACML Protocol

Guardium supports export of Policy Rules to a XACML file, and import of XACML files to another Guardium system.

The XACML (eXtensible Access Control Markup Language) is a declarative access control policy language that is implemented in XML and a processing model, describing how to interpret the policies.

Note: XACML imports from previous versions of Guardium are not supported.
To export Guardium policies to XACML, follow these steps:

1. Click **Manage > Data Management > Export**.
2. Select **Policy** from the Type menu.
3. Check the **Export to XACML File** check box.
4. Select **definitions** from the Definitions to Export menu.
5. Click **Export**.

To Import an XACML file from another Guardium system, open the Definitions Import by clicking **Manage > Data Management > Import**.

Remote loggers

View the forwarding rules for the remote logging and test the connections.

Guardium sends system and other messages to syslog. Remote logging allows Guardium to send system and other messages to a remote receiver (such as an SIEM) by using the [store remotelog add](#) CLI.

After you configure remote logging, use the Remote loggers page to view and test the connectivity for existing remote logs.

To open the Remote loggers page, browse to **Setup > Tools and Views > Remote Loggers**. The remote logs that are configured for your current machine display.

- To download a list of all logs as a CSV file, click the  icon.
- To test the connectivity of a log, select the log and click **Test Remote Logger**. Wait a moment for the response.
Note: Guardium cannot verify the response for loggers that are configured as UDP.

In addition, you can use the [export config](#) API command to propagate the configuration from a central manager to its managed units.

Manage Custom Classes

Upload and maintain custom classes used in alerts or evaluations. Manage custom classes by clicking **Setup > Custom Classes**.

After you compile a class, it must be uploaded to the Guardium® system.

Uploading a Custom Class

1. You can upload a custom class for alerts or evaluations. Upload a custom class by clicking **Setup > Custom Classes**, then either **Alerts > Upload** or **Evaluations > Upload**
2. Enter a description for the custom class.
3. Click **Browse** to locate and select the class file that you want to upload.
4. Click **Apply**.

Updating a Custom Class

1. Select **Setup > Custom Classes**, then either **Alerts > Update** or **Evaluations > Update**.
2. Select the description of the class to be updated.
3. Click **Browse** to locate and select the class file that is to be used for the update.
4. Click **Apply**.

Deleting a Custom Class

1. Select **Setup**, then either **Alerts > Delete** or **Evaluations > Delete**
2. Select the description of the class to be deleted.
Note: You cannot remove a class that is in use by some other component (the installed policy, for example).
3. Click **Delete**.

GDPR readiness: Considerations when configuring Guardium

Learn how Personal Identification Information (PII) data gets stored on your Guardium system, and how to manage this.

Policy Builder

If Log full details is selected in your Policy Rule Actions in the Policy Builder, Guardium logs data for each separate request, with unmasked values. Depending on the type of traffic being examined, it could contain PII. For more information, see: [Rule actions](#)

Inspection Engine

If Inspect return data is selected in the Inspection Engine configuration, data from the traffic, including result sets, is returned to the Guardium collector. Depending on the type of traffic being examined, it could contain PII. For more information, see: [Network mirroring methods \(SPAN, N-TAP\) and related inspection engines](#)

Follow these deployment guidelines for GDPR readiness:

Encryption

If you need to configure Policy Rule Actions to *Log full details* or Inspection Engines to *Inspect Return Data*, consider encrypting the disks in the appliances. For more information, see: [How to partition with an encrypted LVM](#).

Purge Intervals

Guardium may capture debug information that could contain PII if the database traffic that triggered the exception contained PII. Guardium admins can purge data by setting the purge interval via the GUI purge panel or the CLI command **store purge objects age**. For more information, see: [Enabling and disabling the Investigation Dashboard](#).

The default for several of these items can be viewed using the CLI complementary command, [show purge objects age](#). Interval is defined as *number of days*.

SQL Masking

Guardium may capture PII if a SQL query that contains PII fails. For more information, see [Logging Exceptions](#).

Groups

Using groups makes it easy to create and manage classifier, policy and query definitions, as well as roll out updates to your S-TAP's and GIM clients. Rather than having to repeatedly define a group of data objects for an access policy, put the objects into a group to easily manage them.

- [Groups overview](#)

Group similar data objects together and use them in creating query, policy, and classification definitions. Use one of the many predefined groups, or create your own group by using the Group Builder.

- [Using the group builder](#)

The group builder provides at-a-glance information about group membership and use and several convenient methods for populating groups.

- [Using groups in queries and policies](#)

Short overview of conditional operators for queries and where to use groups in policies.

- [Example: Using groups to create rules and policies](#)

Use groups to quickly specify rule conditions in a policy.

- [Predefined Groups](#)

This section details the predefined groups in Guardium®.

Groups overview

Group similar data objects together and use them in creating query, policy, and classification definitions. Use one of the many predefined groups, or create your own group by using the Group Builder.

Groups are practical to use in many places. By grouping similar data objects, you can use the whole set of objects in policies, classifications, queries, and reports, rather than having to select multiple data objects individually.

If you need to change a query or policy, rather than applying those changes to each individual object, you can apply those changes to the group.

S-TAPs and GIM also use groups to make it easier to roll out updates across managed servers.

Group Builder

Use the Group Builder to create a new group or modify an existing group from the user interface.

To open the Group Builder, click **Setup > Group Builder**.

Use the Group Filter screen to sort through groups based on application type, group type, description, or category.

Types of groups

The field Group Type refers to the type of data that can be grouped. For example, *Server IP* expects data that is formatted as an IP address and *Users* expects to see names of users on the application.

Note: The contents of group type Managed Units are not validated as being Guardium managed units, and the group type is not used by internal Guardium applications such as enterprise load balancing.

Tuple groups

A tuple group allows multiple attributes to be combined together to form a single composite group member. Tuples can help simplify specifying conditions for reporting and policy rules. Three of an ordered set of values are called 3-tuple. An n-tuple is one with an n-set of value attributes.

Examples of tuple groups include:

- Tuple groups - Object/Command, Object/Field, Client IP/DB User, Server IP/DB User
- 3-tuple groups - Client IP/Source Program/DB User, DB User/Object/Privilege
- 5-tuple group - Client IP/Source Program/DB User/Server IP/Service Instance
- 7-tuple group - Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name

Use a slash (/) to separate values within a tuple. You can specify multiple tuple elements by using a wildcard (%).

Note: In a tuple query, if your data contains a backslash (\), and you specify LIKE GROUP, the result might be wrong. If the data includes a backslash, use IN GROUP instead.

Predefined groups

Guardium includes a number of predefined groups. Use the Group Filter and Group Type menu to browse the list of groups and find the one that best suits your needs.

Group types *DB User* and *DB Password* are by default only available to admin users. Modify the group roles if you want to change this default setting.

Overlapping group memberships

Groups members can be in more than one group.

For example, two predefined groups, *Create Commands* and *DDL Commands*, both have members that are named CREATE TABLE. If you query for either of these groups, all of the CREATE TABLE members from the reporting period are counted in that group.

In some cases, you might want to define a set of groups so that each member belongs to only one group. For example, suppose that for reporting purposes you need to group database users into 1 of two groups: employees or consultants. You can define each of those groups with the same subgroup type (Employee-Status, for example). When subgroups are used, you cannot add a member to a subgroup if that member was already added to another group with the same subgroup type.

Wildcards in members

Group members can include wildcard (%) characters for when the group is used in a query condition or policy rule.

Table 1. Wildcards in members

Member	Matches	Does not match
aaa%	aaa, aaazzz	zzzaaa, aaz
%bbb	bbb, zzzbb	bb, bbbzzz
%ccc%	ccc, ccczz, zzzcccc	cc, zzzcczz

Wildcards for security assessment test exceptions

To create a wildcard search within groups for security assessment test exceptions, preface the member name with (R). You can then create a regular expression search for the group by using period (.) and asterisk (*) operators to match exactly one character (.) or zero or more characters (*).

Note: Search parameters are case-sensitive.

Table 2. Wildcards for security assessment test exceptions

Member	Matches	Does not match
(R)aaa	aaa, zzaaa, aaazz	Aaa, zzaba
(R)aaa*	aaa, aaazzz	zzzaaa, aaz, AAA
(R)*bbb	bbb, zzzbb	bb, bbbzzz, Bbb
(R)*c.c*	cbc, ccc, _c3c123	cc, _CAC123

Managed Unit Groups

Managed unit groups and the groups that are created through the group builder that used for grouping elements are distinct. Groups that are created through the group builder help simplify creating and managing policies and clarifying the presentation of reports. For more information about managed unit groups, see [Creating managed unit groups](#).

Using the group builder

The group builder provides at-a-glance information about group membership and use and several convenient methods for populating groups.

Use the group builder to create and populate groups from a variety of sources including CSV files, external datasources, and existing groupd. In addition, the builder provides at-a-glance information about group membership and where groups are used in security policies, classifier policies, queries, and reports.

The group builder is accessible at Setup > Tools and Views > Group Builder.

- [Creating and editing groups](#)
Learn how to create and edit groups.
- [Viewing group membership and where groups are used](#)
Learn how to view group membership and identify the policies, reports, and queries where groups are used.
- [Populating groups](#)
The group builder supports several methods of adding members to groups.

Creating and editing groups

Learn how to create and edit groups.

Creating a group

Procedure

1. Open the group builder by navigating to Setup > Tools and Views > Group Builder.
2. Click the  icon on the Group Builder table.
3. Use the Create new group dialog to define a new group.
Provide a group description and use the Application type and Group type menus to define the group.
4. After defining the new group, use the Members tab to populate the group.
For information about populating groups, see [Populating groups](#).
5. Click Save to create finish defining the new group.

Editing a group

Procedure

1. Open the group builder by navigating to Setup > Tools and Views > Group Builder.
2. Select a group from the Group Builder table and click the  icon.
3. Use the Edit group dialog to modify group settings.
To add members to the group or modify group membership, use the Members tab. For information about populating groups, see [Populating groups](#).
4. Click Save to finish editing the group.

Viewing group membership and where groups are used

Learn how to view group membership and identify the policies, reports, and queries where groups are used.

Viewing group membership

About this task

The Members and Populated by columns of the Group Builder table summarize how many members are in a group and how the group is populated. The following procedure describes how retrieve detailed information about group membership and the methods used for populating the group.

Procedure

1. Open the group builder by navigating to Setup > Tools and Views > Group Builder.
2. Open the Edit group dialog by selecting a group from the Group Builder table and clicking the  icon.
3. View group membership on the Edit group dialog by clicking the Members tab.

Identify where a group is used

About this task

The Used in classifier, Used in policy, and Used inquiry columns of the Group Builder table provide an overview of where groups are used in Guardium. The following procedure describes how retrieve detailed information about the policies, queries, and reports where a group is used.

Procedure

1. Open the group builder by navigating to Setup > Tools and Views > Group Builder.
2. Open the details panel by selecting a group from the Group Builder table and clicking Actions > View details.
Attention: The View details action is only enabled when the selected group is being used, for example by policies or queries.
3. Use the Policies and Queries tabs on the details panel to view where the selected group is used in security policies, classifier policies, queries, and reports.

Populating groups

The group builder supports several methods of adding members to groups.

Procedure

1. Click the  icon to create a new group or select a group from the Group Builder table and click the  icon to edit an existing group.
2. Select the Members tab of the Create new group or Edit group dialog.
3. Populate the group using one of the following methods:
 - Use the  icon to manually define group members.
 - Use the Import menu to add group members using one of the following methods:
 - From CSV
 - From group
 - From external datasource
 - From query
 - From LDAP

Restriction: The following restrictions apply when importing group members using Members tab > Import > From query or Import > From external datasource:

- When using Run Once Now, the maximum number of imported members is 5,000 rows. This is not configurable.
- When using a schedule, the maximum number of imported members is 20,000 rows by default. You can configure this limit with the CLI command **show/store populate_from_query_maxrecs**. For more information, see [Configuration and Control CLI Commands](#).

Tip: After the group is configured, import actions that can be scheduled appear as tabs on the Create new group or Edit group dialog. One-time actions such as Import from CSV cannot be scheduled and do not introduce a new tab to the dialog.

- Some group types also support advanced methods for populating groups, including the following:

- Using stored procedure analysis on datasources
- Using database dependencies
- Using reverse dependencies
- Using observed procedures
- Generating selected objects

Note: Advanced import actions are invoked on a target group that is populated based on the results of analysis performed on a user-selected input group.

What to do next

Troubleshooting: Managing groups with more than 1 million members consumes significant system memory. If you need to import, load, edit, or save very large (1 million or more members) groups, make sure that the following resources are available:

- Linux/UNIX- 2GB of free memory per million group members.
- Windows - 500MB of free memory per million group members.

If you have insufficient free memory you might experience inexplicable problems such as UI hangs, Chrome crashes, or the following error message Operation could not complete due to database error.

- [Importing from external datasources](#)

Learn how to quickly populate Guardium groups with data from your own databases and keep those groups in sync with your data.

Importing from external datasources

Learn how to quickly populate Guardium groups with data from your own databases and keep those groups in sync with your data.

About this task

Using Import > From external datasource automates the creation of custom tables, domains, and queries to populate Guardium groups from your own datasources. Once created, these artifacts represent a durable connection between Guardium and your data: updates to your data become reflected in the associated Guardium groups.

Restriction: The following restrictions apply when importing group members using Members tab > Import > From external datasource:

- When using Run Once Now, the maximum number of imported members is 5,000 rows. This is not configurable.
- When using a schedule, the maximum number of imported members is 20,000 rows by default. You can configure this limit with the CLI command **show/store populate_from_query_maxrecs**. For more information, see [Configuration and Control CLI Commands](#).

Procedure

1. Select Import > From external datasource to open the Import from external datasource dialog.
2. Use the Datasource menu to import data from a datasource.
Click the icon to define a new datasource or the icon to edit an existing datasource.
3. Use the Table name and Column name fields to identify the location of data to import from your datasource.
4. Click OK to continue.

Results

Completing the Import from external datasource dialog automatically creates or updates the following Guardium artifacts:

- Custom table
- Custom datasource
- Custom domain
- Custom query
- Group

These artifacts are available through standard Guardium tools using naming conventions described in the following table, where [table name] and [column name] are taken from the Table name and Column name fields of the Import from external datasource dialog.

Table 1. Import from external datasource: summary of artifacts created.

Artifact	Guardium tool	Naming convention	Example	Scheduled
Custom table	Custom Table Builder > Edit Data	[table name]_[column name]_[datasource ID]	USERS_ADMIN_12345	
Custom datasource	Custom Table Builder > Upload Data	[datasource name]_[datasource type](Custom Domain)	user_repository(Custom Domain)	
Custom domain	Custom Domain Builder	[group type]_[table name]_[column name]_[datasource ID]	USERS_USERS_ADMIN_12345	
Custom query	Custom Query Builder	[group type]_[table name]_[column name]_[datasource ID]	USERS_USERS_ADMIN_12345	

Artifact	Guardium tool	Naming convention	Example	Scheduled
Group	Group Builder Populate from Query		PCI Admin Users	

Attention: Imported names are truncated after 64 characters.

Using groups in queries and policies

Short overview of conditional operators for queries and where to use groups in policies.

Queries

Queries use conditional operators with groups. Here are examples of each conditional operator:

- IN GROUP - If the value matches any member of the selected group, the condition is true. IN ALIASES GROUP, this operator works on a group of the same type as IN GROUP, however assumes the members of that group are aliases. Note that the IN GROUP/IN ALIASES GROUP operators expect the group to contain actual values or aliases respectively. The Query-Report Builder will look for records with database values matching the aliases value in the group.
- NOT IN GROUP - If the value does not match any member of the selected group, the condition is true. NOT IN ALIASES GROUP, this works on a group of the same type as NOT IN GROUP, however assumes the members of that group as aliases.
- IN DYNAMIC GROUP - If the value matches any member of a group that will named as a run-time parameter, the condition is true. IN DYNAMIC ALIASES GROUP, this works a group of the same type as IN DYNAMIC GROUP, however assumes the members of that group as aliases.
- NOT IN DYNAMIC GROUP - If the value does not match any member of a group that will named as a run-time parameter, the condition is true. NOT IN DYNAMIC ALIASES GROUP, this works a group of the same type as NOT IN DYNAMIC GROUP, however assumes the members of that group as aliases.

Note: The group may contain either aliases or actual values according to the operator used (IN GROUP OR IN ALIASES GROUP) can not be used at the same time.

- LIKE GROUP - If the value is like any member of the selected group, the condition is true. This condition enables wildcard (%) characters in the group member names.

Note: A like member value uses one or more wildcard (%) characters, and matches all or part of the value. For a like comparison, alphabetic characters are not case sensitive. For example, %tea% would match tea, TeA, tEam, or steam.

Policies and rules

When creating a rule as part of a policy, groups simplify the process of specifying the parameters you want.

Anywhere there is a Group drop-down menu on the rule definition pane you can select a group.

Further, if you want to create or modify a group on the fly, click the Groups icon to open a Group Definition window and make your desired changes.

For example: if you want to capture activity occurring on your production servers, rather than typing in full IP addresses each time, you could create a group *Production Servers* and use that.

Example: Using groups to create rules and policies

Use groups to quickly specify rule conditions in a policy.

About this task

Each policy is composed of one or more rules. Specify which conditions will enact a rule, and then choose one or more actions to take when that rule is triggered. This example shows you how to use groups to identify unauthorized users, log details of their access on a group of sensitive objects, and send an alert indicating that the access occurred.

Procedure

1. Login to your Guardium system, and open the Policy Builder by clicking **Setup > Tools and Views > Policy Builder for Data**.
2. Create a new policy by clicking the icon to open the Policy Definition window.
3. Define the policy definition, then click **Apply** to save the policy.
4. Click **Edit Rules** to open the Policy Rules window and begin adding rules to the policy.
5. Click **Add Rules > Add Access Rule** to add a new rule to the policy.
6. Begin by providing a Description for the rule. Optionally provide Category and Classification labels.
7. Specify where to look for data. From the Server IP row, select the (Public) PCI Authorized Server IPs group.
The rule will apply to all activity from all PCI servers.
Note: You can view the members of any group or modify any group by going to the Group Builder.
8. Specify unauthorized users. From the DB User row, mark the Not check box and select the (Public) Authorized Users group.
The rule will apply to all users who are not in the (Public) Authorized Users group.
9. Specify sensitive objects. From the Object row, select the (Public) PCI Cardholder Sensitive Objects group.
The rule will now apply to all unauthorized users on PCI servers looking to access PCI sensitive objects.
10. Add an action to the rule by clicking **Add Action** and selecting **Action > LOG FULL DETAILS** from the menu. Click **Apply** to save the rule.
This action logs details of the access, including an exact timestamp of the access.
11. Add another action to the rule by clicking **Add Action** and selecting **Action > ALERT ONCE PER SESSION** from the menu. Specify an alert destination, then click **Apply** to save the rule.
This action sends or logs an alert indicating that the rule was triggered.
12. Click **Save** to save the rule.
13. Install the policy.
 - a. Find the policy that you created. Click Back twice, or click Policy Builder to get to the Policy Finder and browse the list of policies.

- b. With the policy selected, choose Install & Override from the installation action menu.
 c. Click OK to confirm the policy installation, and then check Latest Logs and Violations to verify the policy was installed.
 The policy is now installed and active. Any person not in the *(Public) Authorized Users* group attempting to access an object in the *(Public) PCI Cardholder Sensitive Objects* groups will have their session logged and will trigger an alert indicating the access.

Predefined Groups

This section details the predefined groups in Guardium®.

The following table describes the predefined groups that are included with your Guardium system. To view the list of all groups, open the Group Builder by clicking [Setup > Group Builder](#). Select **SQL_APP_NAME** from the Applications menu, and click Next. From the next screen, manage members from Selected Groups. The term *Group Type* refers to expectations on the type of data designated by the label. For example, the group type *Server IP* expects data arranged as an IP address (192.168.1.0) and the group type *Users* expects to see names of users of the application.

Additional predefined groups do get added periodically and these additional predefined groups may not be described here. Open the Group Builder to see all existing groups.

Predefined groups of group type DB User/DB Password are allowed only to users with the role of admin. Users can, if preferred, add other roles or even allow the groups to all roles.

Table 1. Predefined Groups

SQL_APP_NAME	GROUP_DESCRIPTION	MEMBERS
DB2® zOS Groups	zOS Audit Dynamic SQL	Group Type for DB2 commands
DB2 zOS Groups	zOS Audit Query	Group Type for DB2 commands
DB2 zOS Groups	zOS Audit Updates	Group Type for DB2 commands
DB2 zOS Groups	zOS Audit Deletes	Group Type for DB2 commands
DB2 zOS Groups	zOS Audit Inserts	Group Type for DB2 commands

SQL_APP_NAME	GROUP_DESCRIPTION	MEMBERS
Security Assessment Builder	DB2 Database Version+Patches Informix® Database Version+Patches MS Sql Server Database Version+Patches MySQL Database Version+Patches Netezza® Version+Patches Oracle Database Version+Patches Postgress Version+Patches Sybase Database Version+Patches Teradata PDE Version+Patches Teradata TDBMS Version+Patches Teradata TDGSS Version+Patches Teradata TGTW Version+Patches	Used for (specific) database version and patch level tests.
Security Assessment Builder	DB2 Allowed Grants to Public Informix Allowed Grants to Publics MS-SQL Allowed Grants to Public MYSQL Allowed Grants to Public Netezza Allowed Grants to Public Oracle Allowed Grants to Public Postgres Allowed Grants to Public Teradata Allowed Grants to Public	TUPLE, Object/Command Application 8 (Security assessment) List of objects/commands for which grants to public are allowed. These objects will be skipped on MS-SQL and Sybase tests that check grants to public. Note: Exceptions group can contain a regular expression or just a member. If regular expression, the group member must start with (R) (case sensitive), and the records in the detail will be checked against the regular expression after the (R). For example if a group member is: (R)SYSTEM.[a-z]+ each detail record will be checked using pattern: SYSTEM.[a-z]+ If the member does not start with (R) the detail record will be considered an exception only if it is equal to the group member. Note a group may contain a mix of regular expressions and specific exceptions.
Security Assessment Builder	MS-SQL Extended Procedures Allowed	Group Type is Objects
Security Assessment Builder	MS-SQL Database Administrators	Group Type is Users
12.1 and later Security Assessment Builder	MS-SQL Exclude Databases	Database names to exclude
Security Assessment Builder	Teradata Profile	Group Type is Objects
Public	Account Management Commands	Commands used to maintain accounts (users, roles, permissions), examples: REVOKE, GRANT, ALTER/CREATE/DROP USER
Public	Account Management Procedures	Account Management Objects, stored Procedures used to maintain accounts (users, roles, permissions)
Public	Active Users	Group Type is Users

SQL_APP_NAME	GROUP_DESCRIPTION	MEMBERS
Public	Admin Users	Default administrative users (DBAs and SysAdmins)
Public	Administration Objects	Privileged Objects, objects that only DBA or Sys Accounts should access. These accounts are locked for "public" by default.
Public	Administrative Commands	Privileged Commands, privileged Commands, should be executed only by DBAs. Examples: GRANT, BACKUP, DDL commands
Public	Administrative Programs	Database utilities (clients) that come with database and usually reside on the database server and could be used by the server itself
Public	ALTER Commands	Examples, alter database, alter procedure, alter profile, alter session, alter user
Public	Application Privileged Commands	Public privileged commands that should be revoked from "public", but not revoked since they are used by the application
Public	Application Privileged Procedures	Application Privileged Objects, public privileged procedures that should be revoked from "public" but not revoked since they are used by the application
Public	Application Schema Users	Application Users, database user used by the application to maintain/user the application tables
Public	Archive Candidates	Group Type is Objects
Public	Authorized Source Programs	Group Type is Source Programs
Public	Authorized Users	Group Type is Users
Public	Connection Profiling List	Group Type is Client IP/Src App/DB User/Server IP/SVC. Name List of allowed connections
Public	CREATE Commands	Examples, create context, create database link, create function, create statistics, create type, create user
Public	Credentials Related Entities	Guardium Audit Types, Self-Monitoring, examples, allowed_role, LDAP_config, Turbine_user_group_role
Public	Data Transfer Commands	Backup Commands, commands dealing with backup/restore of database data
Public	Data Transfer Procedures	Data Transfer Objects, procedures dealing with backup/restore of database data (mostly on MSS and SYB)
Public	DB Predefined Users	Either non-admin predefined users or all predefined users, including administrative ones
Public	DBCC Commands	Group Type is Commands
Public	DDL Commands	Data Definitions Language, schema-privileged commands, examples, ALTER, CREATE, DROP
Public	DML Commands	DML Commands, examples, insert, truncate, update
Public	DROP Commands	Examples, drop_context, drop_event_monitor, drop_procedure, drop_role
Public	DW All Object-Field DW All Objects DW Execute Accessed Objects DW Select Accessed Objects DW Select Accessed Objects/Fields	There are five predefined reports that use monitored data to show object names. These reports all start with the prefix DW (Data Warehouse). See the help topic, How to report on dormant tables/columns, for further information on how to use these predefined reports.
Public	EBS App Servers	Group Type is Client IP
Public	EBS DB Servers	Group Type is Server IP
Public	EXECUTE Commands	Examples, call, execute, execute function
Public	GRANT Commands	Examples, grant, grant objectives, grant system privileges
Public	Guardium Audit Categories for Detailed Reporting	Guardium patches, TURBINE_USER_GROUP_ROLE
Public	ICM App Servers	Group Type is Client IP
Public	ICM DB Servers	Group Type is Server IP
Public	ImportLDAPUser	Group Type is Objects
Public	ImportLDAPUser_bin dValues	Group Type is Objects
Public	Inspection Engine Entities	Examples, adminconsole_sniffer, software_tap_db_client, software_tap_db_server
Public	Java™ Commands	Examples, alter java, create java, drop java
Public	KILL Commands	Example, kill
Public	Masked_SP_Executio ns_MS_SQL_SERVER	For MS SQL Server, a group that includes a collection of stored procedures (SP) names. If there is an execution of an included procedure, than everything will be masked, even if in quotes. Predefined as empty.
Public	Masked_SP_Executio ns_Sybase	For Sybase, a group that includes a collection of stored procedures (SP) names. If there is an execution of an included procedure, than everything will be masked, even if in quotes. Predefined as empty.
Public	MongoDB Skip Commands	Group Type is Commands
Public	MS-SQL Replication Procedures	Group Type is Objects
Public	MS-SQL Security System Procedures	Group Type is Objects

SQL_APP_NAME	GROUP_DESCRIPTION	MEMBERS
Public	MS-SQL System Procedures	Group Type is Objects
Public	Oracle EBS HRMS Sensitive Objects	Group Type is Objects
Public	Oracle EBS-PCI	Group Type is Objects
Public	Oracle EBS-SOX	Group Type is Objects
Public	Oracle Predefined Users	Group Type is Users
Public	Peer Association Commands	Commands dealing with links/replications of data, examples, links, log shipping, replications, snapshots
Public	Peer Association Procedures	Peer Association Objects, procedures dealing with links/replications of data Examples: Links, log shipping, replications, snapshots
Public	PeopleSoft Objects	Group Type is Objects
Public	PeopleSoft Sensitive Objects	Group Type is Objects
Public	Performance Commands	Examples, analyze, create statistics, update all statistics
Public	Policy Related Entities	Examples, access_rule, gdm_install_policy_header
Public	Potential Overflow Objects	Group Type is Objects
Public	Procedural Commands	Examples, begin, call, execute, exit, repeat, set
Public	PROCEDURE DDL	Examples, alter procedure, create procedure, drop procedure
Public	PSFT App Servers	Group Type is Client IP
Public	PSFT DB Servers	Group Type is Server IP
Public	Public executable procedures	Execute-Only Objects, procedures/functions/Packages that by default granted access to public
Public	Public selectable object	Select-only Objects, tables that by default granted access to public
Public	RESTORE Commands	Examples, restore database, restore log
Public	REVOKE Commands	Examples, revoke object privileges, revoke system privileges
Public	Risk-indicative Error Messages	SQL errors related to security
Public	Sharepoint Servers	
Public	SAP-PCI	Group Type is Objects
Public	SAP App Servers	Group Type is Client IP
Public	SAP DB Servers	Group Type is Server IP
Public	SAP HR Sensitive Objects	Group Type is Objects
Public	Select Command	Examples, select, select list
Public	Sensitive Objects	Examples, activity, sales
Public	SIEBEL App Servers	Group Type is Client IP
Public	SIEBEL DB Servers	Group Type is Server IP
Public	Siebel SIA Sensitive Objects	Group Type is Objects
Public	SPECIAL CASE Source Program	Group Type is Source Programs
Public	Suspicious Objects	Group Type is Objects

Express Security		Predefined as empty.

Security Roles

Security roles are used to grant access to data (groups, queries, reports, etc.) and to grant access to applications (Group Builder, Query-Report Builder, Policy Builder, CAS, Security Assessments, etc).

By default, when a component is initially defined, only the owner (the person who defined it) and the admin user (who has special privileges) are allowed to access and modify that component.

You can allow other users to access the components you define by assigning security roles. For example, if you assign a security role named DBA to an audit process, all users assigned the DBA role will be able to access that audit process.

Note: In order to configure LDAP user import, accessmgr user must have the privilege to run the Group Builder. In certain situations, when changes are made to the role privilege, accessmgr's privilege to Group Builder can be taken away. This results in an inability to save or run successfully LDAP user import. Go to the access management portal, select Role Permissions. Choose the Group Builder application and make sure that there is a checkmark in the all roles box or a checkmark in the accessmgr box.

Assign Security Roles

1. Open or select the item to which you want to assign one or more security roles (a policy or report definition, for example).
2. Click Roles.
3. Check all of the roles you want to assign from the Assign Security Roles list. You can only assign roles that are assigned to your account.
4. Click Apply.

Define a new Security Role

By default, only the special accessmgr user is allowed to create or remove security roles.

1. Login as accessmgr and open the User Role Browser by clicking Access > Access Management > User Role Browser.
2. At the end of the role browser, click Add Role.
3. In the Role Form panel, enter a new Role Name and click Add Role.

Remove a Security Role

By default, only the special accessmgr user is allowed to create or remove security roles. To remove a role assigned to a component, see Assign security roles to a component.

1. Login as accessmgr and open the User Role Browser by clicking Access > Access Management > User Role Browser.
2. Click Delete for any role, and then click Confirm Deletion.

How to install patches

Install a single patch or multiple patches as a background process.

About this task

Use this topic to provide visibility and control over patch installation, status and history. See Central Management for more information.

This how-to topic uses a combination of commands from the CLI and choices from the GUI to help you install the latest Guardium patch. The Guardium system must be rebooted after installing a patch.

Important: Patches downloaded in ZIP format must be unzipped outside the Guardium® system before uploading and installing. Observe the following restrictions for any patch with database structure changes:

- Perform or schedule the patch installation during quiet time on the Guardium system to avoid conflicts with long-running processes such as heavy reports, audit processes, backups, and imports.
- The exact time required for patch installation depends on database utilization, data distribution, and other considerations.
- Install patches in a top-down manner, first patching a central manager before patching aggregators and finally collectors.

In the procedure below, you will follow these steps from the Guardium system that is designated and configured as the Central Manager:

1. Enter the CLI command **store system patch install** to install a single patch or multiple patches to the Central Manager from a network location.
2. Click Setup > Tools and Views > Patch Distribution to move patches from the CM to managed units.

Procedure

Install the patch(es) to the Central Manager

Note: A compressed patch file may contain multiple patches, but only one patch can be installed at a time. To install more than one patch, choose all the patches that need to be installed, separated by commas. Internally the CLI submits requests for each patch on the list (in the order specified by the user) with the first patch taking the request time provided by the user and each subsequent patch three minutes after the previous one. In addition, CLI will check to see if the specified patch(es) are already requested and will not allow duplicate requests.

1. Enter the following command:

```
store system patch install <type> <date> <time>
```

where **<type>** is **sys**, **ftp**, **scp**, or **cd** and **<date>** and **<time>** are the patch installation request date and time formatted as YYYY-mm-dd and hh:mm:ss. If date and time are not entered or if "now" is entered, the installation request time is NOW.

Table 1. Patch install type descriptions and parameters

Name	Description
sys	The sys option is for use when installing a second or subsequent patch from a compressed file that has been copied to the Guardium system by using this command previously. Use this option to apply a second or subsequent patch from a patch file that has been copied to the IBM® Guardium system by a previous store system patch execution. Install from /var/log/guard/patches
ftp or scp	The ftp and scp options copy a compressed patch file from a network location to the Guardium system. To install a patch from a compressed patch file located somewhere on the network, use the ftp or scp option, and respond to the prompts as shown below. Important: Patches downloaded in ZIP format must be unzipped outside the Guardium system before uploading and installing. Observe the following restrictions for any patch with database structure changes: <ul style="list-style-type: none"> • Perform or schedule the patch installation during quiet time on the Guardium system to avoid conflicts with long-running processes such as heavy reports, audit processes, backups, and imports. • The exact time required for patch installation depends on database utilization, data distribution, and other considerations. • Install patches in a top-down manner, first patching a central manager before patching aggregators and finally collectors. Please enter the following information for file transfer: Host to import patch from: User on (host name): Full path to the patch, including name (file name may use wildcard *): (LDAP Password) Password: Enter the scp/ftp port if you need to use a special port, else just press Enter key to continue: The file transfer process can take a while to complete. Leave the terminal open and do not answer any questions until the transfer is complete. Starting transfer, please wait. The file transfer is complete. Do you want to continue (yes or no)? yes List the files in the patches directory: 1. (name of file) Please choose patches to install (1-1, or multiple numbers separated by ",", or q to quit): 1 Install item 1 Patch has been submitted, and will be installed according to the request time, please check installed patches report or CLI (show system patch installed). Please don't forget to remove your media if necessary.

Name	Description
<code>cd</code>	<p>The <code>cd</code> option is for use in installing the patch from a DVD disk. To display a complete list of applied patches, see the Installed Patches report on the Guardium Monitor tab of the administrator portal. There is also an Available Patches report on this same Guardium Monitor tab. To install a patch from a DVD, insert the DVD into the IBM Guardium DVD ROM drive before executing this command. A list of patches contained on the DVD will be displayed.</p> <ul style="list-style-type: none"> To delete a patch install request, use the CLI command <code>delete scheduled-patch</code> Patches remain after installation only on the Central Manager. Standalone or managed unit patch files ARE deleted after installation. To display the available patches: <code>show system patch available</code> To display the already installed patches and patches scheduled to be installed—showing date/time and the install status: <code>show system patch installed</code> Use the <code>fileserver</code> command to start an HTTPS-based file server running on the Guardium appliance. This facility is intended to ease the task of uploading patches to the unit, or downloading debugging information from the unit. Each time this facility starts, it deletes any files in the directory to which it uploads patches. <p>Note: Any operation that generates a file, that the fileserver will access, should finish before the fileserver is started (so that the file is available for the fileserver).</p> <ul style="list-style-type: none"> To start the file, enter the fileserver command: <code>fileserver</code> Starting the file server. You can find it at <code>https://(name of unit)</code> Press ENTER to stop the file server. Open the fileserver in a browser window, and to one of the following: <ul style="list-style-type: none"> To upload a patch, click Upload a patch and follow the directions. To download log data, click Sqlguard logs, go to the file you want, right-click on it, and download as you would any other file. When you are done, return to the CLI session and press Enter to terminate the session.

Use the UI to move the patch(es) from Central Manager to managed units

2. Navigate to `Manage > Central Management > Central Management`.
 3. From the Central Management page, select managed units to receive the patch and click the Patch Distribution button.
 4. From the Patch Distribution page, select the patches to distribute.
- The Patch Distribution page displays an available patch list with dependencies, and allows for the selecting of a patch and installing it to all selected units. The list of available patches is constructed out of the available patches and evaluating the currently installed patches on each of the selected units along with the dependency list of available patches. Patches available but not installable (a dependent patch is missing) are shown in the list as grayed out and cannot be selected. The selection of patch to install is a single selection: only one patch can be installed at a time.
- Click Install Patch Now to install the patch immediately.
 - Click Schedule Patch to schedule patch installation for the future.
- After clicking Install Patch Now, a command is sent to all selected units to install that patch. The process of installing patches happens in the background.
5. Navigate to `Central Management > Central Management > Patch Distribution`.
 6. Click on Patch Installation Status. The Patch Installation Status screen will display for each unit, failed installations and discrepancies - situations such as having one patch being installed on part of the units only, regardless if it failed on other units or was not installed.

Results

The patched systems are now ready to be used; however, remember that the Guardium system must be rebooted after installing a patch.

Support Maintenance

The Support Maintenance feature is password protected and can be used only as directed by Technical Support. Contact Technical Support if you require more information.

Product integration

You can integrate IBM® Guardium® with other products.

- [Configure BIG-IP Application Security Manager \(ASM\) to communicate with Guardium system](#)
Use the Big-IP ASM (from F5 Networks) together with Guardium's real-time database activity monitoring to solve the problem of identity propagation between web application and database application server layers.
- [Embedded integrations](#)
You can use available integrations with Guardium UNIX and Linux® systems.
- [Integrating with IBM Knowledge Catalog for federated data protection](#)
You can enable federated data protection to integrate your IBM Knowledge Catalog service with Guardium Data Protection to help ensure that data protection rules that are defined in IBM Knowledge Catalog are enforced at the data source-level in a consistent way across in-scope data sources. To enable federated data protection, use Guardium query rewrite capabilities to create and run transformations (such as data masking) that are based on IBM Knowledge Catalog rules.
- [PIM Integration with Guardium DAM](#)
Privileged Information Management (PIM) helps organizations to automate and track the use of shared privileged identities and monitor the usage of these shared privileged identities.
- [Configuring an external ticketing system](#)
Use an external ticketing system such as ServiceNow or IBM Resilient to track incidents, problems, and tasks discovered by Guardium.
- [Configuring vulnerability scanner agents](#)
Common Vulnerabilities and Exposures (CVE) scanner agents, such as Nessus and Qualys, gather information about the Guardium system and send it to their third-party portal, which analyzes and generates reports. If the agent can run as root directly on the Guardium system, the resulting report is much more accurate with fewer false positive results. Use `scanner_agent` CLI commands to install and manage root access to CVE scan tools.
- [QRadar and Guardium integration](#)
QRadar and Guardium can work together in a two-way information flow to have the Guardium data protection policies updated automatically and nearly in real-time

- in response to security intelligence events from QRadar.
- **[OPTIM to Guardium Interface](#)**
An OPTIM to Guardium interface, using Protobuf (Universal Feed Agent), sends Optim activity logs to Guardium.
 - **[Combining real-time alerts and correlation analysis with SIEM products](#)**
Distribute contextual knowledge of database activity patterns, structures, and protocols directly to the third-party database of the SIEM system.
 - **[CEF Mapping](#)**
The CEF standard from ArcSight defines a set of required fields, and a set of optional fields.
 - **[LEEF Mapping](#)**
Log Event Extended Format (LEEF) from QRadar

Configure BIG-IP Application Security Manager (ASM) to communicate with Guardium system

Use the Big-IP ASM (from F5 Networks) together with Guardium's real-time database activity monitoring to solve the problem of identity propagation between web application and database application server layers.

This solution uses Google's protocol buffers (.protobuf) as the wire format between BIG-IP ASM and the Guardium® system.

Information about configuring the integration between Big-IP ASM and the Guardium real-time database activity monitoring is provided by [Deploying the BIG-IP LTM with Guardium](#).

Embedded integrations

You can use available integrations with Guardium® UNIX and Linux® systems.

Db2 Warehouse integration

Guardium is integrated into Db2® Warehouse. For more information about integrating a Guardium collector with Db2 Warehouse, see [Configuration options](#) in the *IBM Docs for the Integrated Analytics System*.

Netezza Performance Server (NPS) integration

Guardium is integrated into Netezza® Performance Server. For more information about integrating Guardium with NPS®, see [Enabling query and result sharing with Guardium](#) in the IBM® Docs for the *IBM Netezza Performance Server*.

Integrating with IBM Knowledge Catalog for federated data protection

You can enable federated data protection to integrate your IBM® Knowledge Catalog service with Guardium® Data Protection to help ensure that data protection rules that are defined in IBM Knowledge Catalog are enforced at the data source-level in a consistent way across in-scope data sources. To enable federated data protection, use Guardium query rewrite capabilities to create and run transformations (such as data masking) that are based on IBM Knowledge Catalog rules.

Before you begin

The integration between Guardium and IBM Knowledge Catalog is available for data sources that have data source-specific user-defined functions (UDFs) available. To use the IBM Knowledge Catalog for federated data protection, you must install the UDF for your data source.

To integrate the Guardium query rewrite with IBM Knowledge Catalog transformation, you need:

- IBM Cloud Pak® for Data 4.6 or later with IBM Knowledge Catalog service.
Note: IBM Knowledge Catalog works with the Cloud Pak for Data Data Privacy service to provide masking and transformation. Before you can use this integration, you need to enable both the IBM Knowledge Catalog and the Data Privacy service. Be sure to check the [Known issues for Data Privacy \(Masking flow\)](#) in the IBM Docs for Cloud Pak for Data for any issues that you might need to know about.
- The IBM Knowledge Catalog - Guardium integration must be running.
- One or more users with privileges to run Cloud Pak for Data data protection rules. The users do not need to be admins.
- Guardium Data Protection 11.5 or later.
- A supported data source for which a set of user-defined functions is available along with the user-defined functions for your data source. User-defined functions are precompiled into libraries that are suitable for each data source. For more information about supported data sources and UDFs, see [Adding User-Defined Functions \(UDFs\) for IBM Knowledge Catalog - Guardium integration](#).

Architecture notes

How the IBM Knowledge Catalog - Guardium integration works (IBM Knowledge Catalog view)

The integration adds the policy enforcement point (PEP) from the IBM Knowledge Catalog XACML model. The PEP allows Guardium to use IBM Knowledge Catalog rules for enhanced data protection.

In IBM Knowledge Catalog, a PEP cache stores evaluation responses (decisions) that are received from IBM Knowledge Catalog data protection rules. Each decision is an instance of a computed outcome that is based on a combination of the current policy space and user context.

How transformation integration works (Guardium view)

From a Guardium perspective, the transformation integration takes the following steps:

For more information, see [Column alias parameter](#).

Maximum of 2 conditions for row-level filtering

For row-level filtering, you can include up to two conditions in your IBM Knowledge Catalog query. For more information, see [Setting up a transformation integration](#).

- [Starting the IBM Knowledge Catalog and Guardium Data Protection integration](#)

After your Guardium and IBM Knowledge Catalog systems are correctly configured, you can configure and start the integration from the Guardium UI.

- [Setting up a transformation integration](#)

After the IBM Knowledge Catalog - Guardium integration is working, you can integrate Guardium query rewrite functionality with IBM Knowledge Catalog and the Cloud Pak for Data Data Privacy service to provide masking and transformation for specified data sources.

 - [store wkc configuration](#)
 - [Adding User-Defined Functions \(UDFs\) for IBM Knowledge Catalog - Guardium integration](#)
-

Starting the IBM Knowledge Catalog and Guardium Data Protection integration

After your Guardium® and IBM® Knowledge Catalog systems are correctly configured, you can configure and start the integration from the Guardium UI.

Before you begin

Before you begin, store the IBM Cloud Pak® for Data root certificate on any managed units or stand-alone machines. For more information about storing the Cloud Pak for Data certificates, see [store certificate wkc](#).

Note: Do not use the self-signed certificate that is installed with Cloud Pak for Data. Always use a certificate authority (CA)-signed certificate in production environments.

Procedure

1. To set up policy integration on a Guardium central manager, browse to Protect->Security Policies->Policy Builder for Data.
2. From the Security Policies page, open the Configure WKC window.
 - From a central manager, select Configure WKC.
 - From a stand-alone machine, click Manage, and then select Configure WKC.
3. From the WKC configuration page, enter the following information:
 - Enable WKC data protection rules - Toggle to use IBM Knowledge Catalog data protection.
 - WKC service URI - The URI of the IBM Knowledge Catalog service.
 - Credential type- Select a method to manage credentials:
 - Assign credentials - If you choose to assign credentials, then supply your IBM Knowledge Catalog User name and User password.
 - External password - To support an external credential manager, such as AWS Secrets Manager or CyberArk, select External password, and then select one of the credential managers from the list. Enter the requested information for that credential manager.

Note: If the credential manager password changes, use the [wkc_refresh_external_pwd](#) API to update the password.

- User scope - The owner of this asset. Select either Database user (the default) or Application user. For more information, see [How the Guardium default user works](#).
- Column alias - With column-level transformation, SQL column fields can be transformed by some long IBM Knowledge Catalog UDF function calls. Use Column alias to specify whether to use the original column names or an alias of the function name, which can be shorter and help hide some transformation details (which might provide extra security).

As the database server evaluates the transformed SQL, the transformed function signature displays as the column name in the database client.

For example, using the following input query:

```
select EmpCard from EMPLOYEE
```

You can select one of the following options for how to display the transformed query in the database client.

- Use original column name - Use the original COLUMN_NAME as the IBM Knowledge Catalog UDF alias. The transformed query includes the original column name and the actions taken. The transformed query displays as follows:

```
select WKC.MASK_STRING(0, "XXXXXXXXXX", ". ", EmpCard) AS EmpCard from EMPLOYEE;
```

- Use full function signature - Do not use an alias for the column-transformation UDF. The transformed query displays as follows:

```
select WKC.MASK_STRING(0, "XXXXXXXXXX", ". ", EmpCard) from EMPLOYEE;
```

- Use short function signature - Use the MASKFUNCTIONNAME_COLUMNNAME as the UDF alias. The transformed query includes the masked function name and the original column name. The transformed query displays as follows:

```
select WKC.MASK_STRING(0, "XXXXXXXXXX", ". ", EmpCard) AS MASK_STRING_EmpCard from EMPLOYEE;
```

Regardless of which alias option you select, if the column name in the SQL query statement has a defined alias, then the aliases in the SQL statement are preserved by query rewrite. The column alias option is only available if the SQL column without an alias triggers any column-level transformation.

- Action on unexpected response - Deny is the default. Select Allow to allow the connection.

If Guardium receives an unexpected response (or no response) from IBM Knowledge Catalog, you can choose to allow or deny the connection to IBM Knowledge Catalog. The default is Deny, that is, treat the connection as a IBM Knowledge Catalog policy violation. Click Allow to allow the connection, which treats the connection as approved.

- Cache size - The size of the cache determines the maximum number of decisions that can be stored in memory at any point in time. The default is 1000 decision entries.

- Time to live (minutes) - The time-to-live (in minutes), that is, the amount of time that each decision is available, in the primary cache. After the time-to-live passes, the decision is deleted from cache. Default = 60. The maximum is 1440.
 - Enable persistent cache - If you enable persistent cache, then you must also specify the following parameters.
 - Maximum entries - The maximum number entries to save in cache. The minimum is 1. Default = 100000.
 - Maximum files - The maximum number of files to save in cache. Default = 10. The maximum is 100.
 - Time to live (days) - The time-to-live (in days) for each decision in the persistent cache. Default = 7. The maximum is 30.
4. For central managers, the Collector table displays all of the collectors that are associated with this central manager.
- a. Filter, if needed, and select the collectors to include in the IBM Knowledge Catalog integration.
 - b. Click OK to begin using the IBM Knowledge Catalog data protection rules for the central manager and selected collectors.
- Note: You can also change the parameters for collectors (and stand-alone machines) by using the [store wkc configuration](#) CLI.
5. For a stand-alone machine, click OK to begin using the IBM Knowledge Catalog data protection rules on that machine.

What to do next

After you enable the IBM Knowledge Catalog integration, the integration runs until you disable it. However, be sure to stop the integration before you add new assets to the IBM Knowledge Catalog. If the integration is running when you add assets, the new connections are denied and an error occurs.

After the integration is working, you can add transformation and other processes for specific data sources as described in [Setting up a transformation integration](#).

Setting up a transformation integration

After the IBM® Knowledge Catalog - Guardium integration is working, you can integrate Guardium® query rewrite functionality with IBM Knowledge Catalog and the IBM Cloud Pak® for Data Data Privacy service to provide masking and transformation for specified data sources.

Before you begin

To integrate Guardium query rewrite with IBM Knowledge Catalog transformation, you need:

- Cloud Pak for Data 4.6 or later with IBM Knowledge Catalog service.
Note: IBM Knowledge Catalog works with the Cloud Pak for Data Data Privacy service to provide masking and transformation. Be sure to check the [Known issues for Data Privacy \(Masking flow\)](#) in the IBM Docs for Cloud Pak for Data for any issues that you might need to know about.
- One or more users with privileges to run Cloud Pak for Data data protection rules. The users do not need to be admins.
- Guardium Data Protection 11.5 or later.
Important: Guardium query rewrite must be enabled on the S-TAP used for IBM Knowledge Catalog integration. For more information, see [Enabling query rewrite](#).
- A supported data source for which a set of user-defined functions (UDFs) is available.
- A UDF for your data source. User-defined functions are precompiled into libraries that are suitable for each data source. For more information about the supported data sources and UDFs, see [Adding User-Defined Functions \(UDFs\) for IBM Knowledge Catalog - Guardium integration](#).
- You can include up to two conditions in your IBM Knowledge Catalog query. For more information, see [Filtering rows in data protection rules \(IBM Knowledge Catalog\)](#).

About this task

After the transformation integration is set up and running, you will not see anything different. However, details about the data transformations are available in Guardium reports.

From a Guardium perspective, the transformation integration takes the following steps:

- A customer defines data protection rules in IBM Knowledge Catalog.
- Guardium sends session and request details to IBM Knowledge Catalog for evaluation in the form of a resource key.
- The verdict from IBM Knowledge Catalog is returned and can include a transformation specification that provides details about how to transform the query.
- Guardium uses its query rewrite capabilities to rewrite the query in accordance with the transformation specification.
- The altered query is forwarded to the database server by an S-TAP (or External S-TAP) and the Guardium sniffer.
- The transformed (such as pseudonymized, redacted, or anonymized) data is returned to the database client.

Procedure

1. Have both Guardium and IBM Knowledge Catalog installed and running.
2. Have your data source prepared.
3. Start the integration, as described in [Starting the IBM Knowledge Catalog and Guardium Data Protection integration](#).
4. Acquire and install the UDF for your data source. For more information, see [Adding User-Defined Functions \(UDFs\) for Watson Knowledge Catalog \(WKC\) - Guardium integration](#).
5. Create data protection rules in IBM Knowledge Catalog. You can incorporate Guardium query rewrite policy rules to provide row-level filtering. You can include up to two conditions in your IBM Knowledge Catalog query. For more information, see [Filtering rows in data protection rules \(IBM Knowledge Catalog\)](#).

Results

After the integration is running, you can view the results of the queries in Guardium reports. Create a custom report for the `GDM_QR_LOG` table.

PIM Integration with Guardium DAM

Privileged Information Management (PIM) helps organizations to automate and track the use of shared privileged identities and monitor the usage of these shared privileged identities.

The idea is to integrate PIM activity data with Guardium DAM data, in order to allow visibility to the actual user (person) that logged in to the database.

The diagram illustrates the integration.

The main purpose of this integration is:

- Provide visibility in the Guardium appliances to PIM data such as Lease history (who used the shared accounts), credentials and databases managed by PIM.
- Provide DAM information correlated with PIM information, for example, Guardium can show today's Database user along with actual requests issued by a specific user. This integration will allow use of both the Database user and the actual PIM user that leased the shared ID.

Installation

Guardium patch (v10.1p103) can be used to install PIM integration functionality. PIM integration can be used on standalone Guardium systems as well as in federated environments.

Note: It is assumed that the PIM activity data is already implemented.

Follow these steps

1. Bring data to the Guardium system.

Select a datasource and then select from the Guardium UI: Reports > Report Configuration Tool > Custom Table Builder.

Locate and select three PIM predefined tables and, for each one of them, schedule Automatic Data Upload.

Upload PIM tables to Guardium System

If using a Guardium Central Manager, select from the Guardium UI: Manage > Central Manager > PIM Data Distribution. Do this to schedule data distribution from the Central Manager to all managed units.

2. Once data is brought to the managed units, use this CLI command, store pim_correlation_mode, to enable correlation of PIM data with Guardium session data.

CLI command

```
store pim_correlation_mode
```

Usage: store pim_correlation <state>

where state is on/off. On is to enable and off is to disable.

Show command

```
show pim_correlation_mode
```

3. To run correlation , select from the Guardium GUI:Comply...> Custom Reporting>PIM data correlation.

Correlated data can be seen through reports in Access domain

The screenshot shows the Guardium Query Builder interface. On the left, a sidebar lists navigation options: Welcome, Setup, Manage, Discover, Harden, Investigate, and Protect. Below this is a message: "PIM session in Access Domain". The main area is titled "Query Builder" and contains two panels. The left panel, "Entity List", has a tree view with "Client/Server" expanded, showing "PIM Session" which is circled in red. Other items include TAXIS Global Id, TAXIS Session Id, User Name, Checkout Timestamp, Checkin Timestamp, desc: Credential Tag, desc: Resource Tag, desc: Justification, GMT Checkout Timestamp, Client Server/Session, Session, Access Period, SQL, Application Events, and FULL SQL. The right panel, "PIM correlation", has a header "Main Entity: Session" and a table with columns Seq., Entity, and Attribute. Below the table is a section for "Addition mode" with radio buttons for AND, OR, and HAVING.

Configuring an external ticketing system

Use an external ticketing system such as ServiceNow or IBM Resilient to track incidents, problems, and tasks discovered by Guardium.

Before you begin

Before you can configure Guardium® for external ticketing, make sure that your ticketing system is set up.

Note: Before you configure Guardium to use external ticketing with ServiceNow, make sure that the ServiceNow Event Management Core app is available in your ServiceNow instance. You can download the Event Management Core app from the ServiceNow store.

Depending on your ticketing system and the Guardium system that you configure, you can select the mode to process ticket information, as follows.

- Table - Identifies the type of ticket that is opened on the ticketing system. Each table provides options for the selected system. For example, if you select the Vulnerability Assessment Results system, you can select the specific severity for which you want to automatically create tickets.
 - Event - For Alert and Vulnerability Assessment systems with ServiceNow, select Event to send an event to ServiceNow when a Guardium alert occurs. Upon receiving events, ServiceNow generates alerts based on ServiceNow event and alert management rules.
- No roles are required to create an event, as long as the ServiceNow user account from the Guardium external ticketing configuration has permission to connect to the ServiceNow instance.

Note: Before you configure an external ticketing system with Guardium 12.0 or later, make sure that the correct version of TLS is available. For more information, see [Managing the TLS version](#).

Procedure

- Browse to Setup...Tools and Views...External Ticketing System.
 - Click the icon to open the External Ticketing System Configuration dialog.
 - From the Account tab, use the Account menu to select an existing ticketing system account or click the icon to add an account.
 - From the Add account dialog, select, and configure your ticketing system, as follows:
 - For IBM Resilient, URL is the fully qualified domain name.
 - For ServiceNow, URL is generally `<instanceName>.service-now.com`.
- When you create the first external account, Guardium automatically creates configurations for all of the Guardium systems.
- Enter the username and password for your ticketing system, and then click Test Connection to verify that Guardium can communicate with the ticketing system.
 - Note:
 - The ticketing-system account must be able to create and read records that are used with the integration. For example, if Incident records are used, the user must be able to create and read Incident records.
 - If prompted, follow the on-screen instructions for adding a security certificate for the ticketing system: Download the certificate from the ticketing system and import it into Guardium with the `store certificate keystore trusted console` CLI command.
 - From the Settings tab, select the Guardium system to configure. Systems are specific Guardium features that support external ticketing integration.
 - Then, depending on your ticketing system and the Guardium system that you select, you can take one of the following steps:
 - For IBM Resilient, select the Guardium system that you want to configure from the Settings tab, and then select the Table to configure.
 - For ServiceNow, when you select either Risk Spotter or Threat Analytics, select the Table to configure.

If you select Table mode for ServiceNow, you also need to select the table you want to use. You can search for a table (or other items, such as an assignment group, depending on the Guardium system). To search for a specific table name or other item,

- Click the icon to open the Search page for that item.
- In the search box, enter all or part of the text for the item you want to find, and then click Search.
- Select the item that you want from the list, and click Add.

If needed, click the icon to clear the text.

When you select Vulnerability Assessment in either Event or Table mode, you can also specify the conditions for which you automatically want to create events or tickets. The conditions are defined as part of the Guardium assessment. Enter the following information in Automatically create events/tickets when these conditions are met,

- Severity - Select one or more severity settings for which to create an event or ticket. You can select as many settings as needed.
- Test result score - Select one or more result scores. You can select as many settings as needed.

For more information, see [Introducing Guardium Vulnerability Assessment](#).

8. After you select the Guardium system and Table, use the Guardium fields controls to create the message table that Guardium sends to the ticketing system. The information that you supply depends on the external ticketing system.

IBM Resilient tickets

- Name - A name or description of the external ticket type.
- Description - The Guardium fields to include in each ticket.
- Members - The member of the Resilient team to receive this ticket. A member can be either one person or a group (that is defined in Resilient). Note: In Guardium, you can select only one member. You can add more ticket receivers in Resilient.
- Incident types - Select a Resilient incident type. Note: Guardium automatically creates configurations for all four of the Guardium systems. However, the Incident type field is left blank. Since Incident type is required for Resilient tickets, you need to select an incident type for each Resilient ticket type. You can set the incident type either from the Guardium UI or the Resilient server.
- Click the icon to add a field. For IBM Resilient, you can enter comments to include with a ticket.

ServiceNow tickets

For all ticket types (Tables), you can configure some or all of the following information,

- Short description - A short description of the external ticket type.
- Description - The Guardium fields to include in each ticket
- Assignment group - The ServiceNow group to assign this ticket to.
- Click the icon to configure extra fields. For ServiceNow, you can enter comments to include with a ticket or other information (depending on the Guardium system and table). Note: ServiceNow supports both comments and work notes. Only comments entered into the ServiceNow Additional comments (customer visible) field display in the Guardium External Tickets report.

9. From the Status tab, review ticketing-related log information.

Use the Enable debug checkbox to include debugging-level information in the log.

Note: The Enable debug setting is saved when selected or cleared.

10. Click Save to save the configuration and exit the External Ticketing System Configuration dialog.

11. If needed, configure external tickets for the other available systems that are shown in the External Ticketing System table.

What to do next

After you configure ticketing integration for specific Guardium systems, use the following integration points in the Guardium UI to open new tickets.

Guardium system	Integration point
Alerter	<p>Browse to Protect > Database Intrusion Detection > Alert Builder. Configure an alert. In the Add receiver section, set Notification type to TICKET. Tickets are created when the alert triggers.</p> <p>Attention: Verify that the alerter is active on startup: browse to Setup > Tools and Views > Alerter and select the Active on startup checkbox.</p> <p>External ticketing integrates with the following types of alert notifications:</p> <ul style="list-style-type: none"> • Receivers defined in the Alert Builder • Notifications defined for a security policy in the Policy Builder for Data • Tickets defined for receivers in the Audit Process Builder.
Audit Process	<p>The audit process ticketing system uses the Alert integration point.</p> <p>Browse to Comply > Tools and Views > Audit Process Builder. Begin creating an audit process. From the Send results section, select to add a receiver, and then set Receiver Type to Ticket.</p> <p>When the audit process runs, it generates the audit process result as a PDF, which is attached to the ticket that is sent to the external ticketing system. The URL to the ticket is stored in the Audit result table for external review.</p> <p>Note: Audit process results are purged following standard audit process rules. To set the purging rules, select Show advanced options from the Create New Audit Process or Details for: <audit process> page.</p>
Policy Builder for Data	<p>Policy Builder for Data uses the Alert integration point.</p> <p>Browse to Protect > Security Policies > Policy Builder for Data. Begin creating a security policy. From Rule Action, select ALERT ONCE PER SESSION or ALERT PER MATCH and then select TICKET from the Add New Action window.</p>
Risk Spotter	Browse to Protect > Uncover Threat Vectors > Active Risk Spotter. Select a user from the Risky Users table and use the Actions > Create ticket.
Threat Analytics	Browse to Protect > Uncover Threat Vectors > Active Threat Analytics. Select a case from the table and use the Actions > Create ticket.
Vulnerability Assessment Results	Browse to Harden > Vulnerability Assessment > Assessment Builder. Create and run an assessment, then click View Results. For each result that meets the test result score criteria, click Create ticket to open a ticket.

View tickets that originate from the Guardium system by opening Setup > Reports > External Tickets.

Note: Ticket status is updated every hour. Closed tickets are removed from the report after 30 days of inactivity.

Configuring vulnerability scanner agents

Common Vulnerabilities and Exposures (CVE) scanner agents, such as Nessus and Qualys, gather information about the Guardium® system and send it to their third-party portal, which analyzes and generates reports. If the agent can run as root directly on the Guardium system, the resulting report is much more accurate with fewer false positive results. Use **scanner_agent** CLI commands to install and manage root access to CVE scan tools.

Before you begin

By default, vulnerability scanner agents do not have root access to the Guardium system. Without root access, the scan tools are limited to network-based scans and can detect basic information such as operating system, open ports, and cross-site scripting vulnerabilities. While a non-root scan is useful, it is limited in scope and accuracy, and as a safeguard, the network-based scans tend to result in pessimistic reports with many false-positive results. For more accurate vulnerability scan reports, allow scan tools to access the underlying Guardium system and its supporting applications and libraries (to check for CVEs) without exposing root access or creating other vulnerabilities.

About this task

Install the scanner agent on one Guardium system for each version and patch level in your environment. The scanner results for that system can represent all other systems that are at the same version and patch level. Guardium supports root access for Nessus and Qualys vulnerability scanner agents.

Procedure

1. Download a scanner agent RPM from the vendor.
 - For Guardium 11.x, the agent must support Red Hat ES 7 (x86_64).
 - For Guardium 12.x, the agent must support Red Hat ES 9 (x86_64).Example scanner agent file names:
 - Nessus - NessusAgent-10.4.2-es7.x86_64.rpm - From the Tenable Nessus Agent page.
 - Qualys - QualysCloudAgent.rpm - From the Qualys Cloud Agent page.
2. Import the scanner agent to a Guardium system by using the CLI.
For a list of supported agents, run the [`show scanner_agent_supported`](#) CLI command. The output lists the currently supported agents (`nessus` or `qualys`).
 - Import with SCP - Enter the `import scanner_agent scp <agent>` command and follow the prompts, as described in [`import scanner_agent scp <agent>`](#).
 - Import with the Guardium fileserver - Transfer the file to the fileserver, and then call the `import scanner_agent sys <agent> <filename>` command. For more information about transferring files to the Guardium fileserver, see [`fileserver`](#).
3. Configure the agent by using the [`setup scanner_agent configure <agent>`](#) CLI command and follow the prompts. The information that you need depends on the scanner agent. For more information, see [`setup scanner_agent`](#).
4. For Qualys, run `setup scanner_agent enable <agent>` to enable the agent.
Note: The Nessus agent is automatically enabled after it is configured.
5. Optional: If you use an SSL proxy, you need a certificate from a certificate authority such as DigiCert, Symantec, or Geotrust. Use the [`store_certificate scanner_ca_bundle`](#) CLI command to store the certificate. Call [`show scanner_agent ca_bundle`](#) to get the stored certificate.
Standard (non-SSL) proxies are configured with the agent in step 3.
For more information about managing certificates, see [`Certificates`](#).
6. After you install and enable the agent, it appears in the vendor's portal after a delay of up to 30 minutes.
After the agent appears in the vendor's portal, scanning and other activities are done exclusively through the portal.

QRadar and Guardium integration

QRadar and Guardium can work together in a two-way information flow to have the Guardium data protection policies updated automatically and nearly in real-time in response to security intelligence events from QRadar.

IBM QRadar is a security intelligence tool that provides threat protection by monitoring security information and events, using customizable rules to detect anomalies, as well as providing tools for incident forensics and vulnerability management.

IBM Guardium is a solution for data security and data privacy that helps ensure the integrity of data stored in servers. Guardium uses policies and inclusion/exclusion lists (called Guardium groups) to control access to data.

The QRadar and Guardium solution leverages the QRTrigger framework for triggering actions in response to QRadar security events. Based on configuration settings, QRadar events will cause new members to be added to Guardium groups based on information carried in the event itself. Furthermore the Guardium policy associated

with the group is automatically reinstalled so that membership change takes effect immediately.

Note that the QRadar and Guardium solution can be used to update a single Guardium collector, or a group of them being controlled by a Guardium Central Manager (CM).

QRadar and Guardium together

Traditional QRadar and Guardium integration is a one-way information flow where Guardium sends alerts and Vulnerability Assessment (VA) reports to QRadar.

Common alerting use cases for databases:

- Failed logins
- Unauthorized access
- SQL Error codes (for example, SQL injection attacks)
- Users trying to escalate their privileges
- Users creating triggers and views to indirectly access sensitive data

Now QRadar and Guardium can work together in a two-way information flow.

Additional use cases:

- Block access from a machine that became compromised
- Increase audit levels for access by a user ID that became suspicious
- Increase audit levels for access by a privileged shared user ID that was on-boarded in a Privileged Identity Management (PIM) system

Updating Guardium policies based on QRadar events

The steps to deploying the QRadar and Guardium solution are:

1. Install the solution files.
2. Set up a client ID and secret in Guardium.
3. Configure a Forwarding Destination in QRadar.
4. Configure Rules to dispatch QRadar Events to the solution.
5. If necessary, define Guardium Groups and Policies for integration.

Note that Guardium version 10.1 and later has three predefined groups designed to support this integration:

- QRadarBlockingConnection
- QRadarAlertingConnection
- QRadarLogConnection

Each of these groups has the following tuple structure:

<Client IP>,<Src App>,<DB User>,<Server IP>,<Srv. Name>,<OS User>,<DB Name>

There is a predefined Guardium policy called "QRadarPolicy" with three rules: A blocking rule, an alerting rule, and a logging rule. Each rule is tied to its respective group from the list above.

Setting up Guardium

In order for the QRadar and Guardium solution to be able to authenticate to the Guardium REST API, a client ID must be registered in Guardium and the associated client secret retrieved.

Registering a client ID is done using the grdapi command line utility of Guardium. This operation is performed only once. The result of the client ID registration is a JSON entry containing details for the new client, including the client secret.

```
> grdapi register_oauth_client client_id=qrguardium
ID=0
{"client_id": "qrguardium", "client_secret": "3ac89782-ce55-
4f24-b795-b6c76ecc4045",
"grant_types": "password", "scope": "read,write", "redirect_uri":
"https://joeApp"}
ok
```

Troubleshooting logs

The QRadar and Guardium solution provides a number of log files to assist in managing and troubleshooting operations. These log files include:

Table 1. Log files

Parameter name	Description
guardiumEvents_audit.log	This an audit log of all changes made to Guardium based on QRadar events. Each line is a JSON object that includes identifiers, timestamp and details of the Event handled.
QRListener.log	Log output from the Listener process that receives forwarded event data from QRadar.

Parameter name	Description
HANDLER_<event name>.log	Log output from the dedicated handler AL for a specific Event.
RESPONSE_<event name>.log	Log output from a custom response AL if this AL implements logging based on its AssemblyLine name. For example this can be done by setting the Log Appender File Path parameter to be computed using this Javascript: return "logs/" + task.getShortName() + ".log";

OPTIM to Guardium Interface

An OPTIM to Guardium interface, using Protobuf (Universal Feed Agent), sends Optim activity logs to Guardium.

The objective of this interface is to use Guardium auditing capabilities for OPTIM activities. The auditing capabilities include: Reporting tools (user-defined queries and reports); Audit Processes (workflow automation that enables assigning a task to a role/user/group, user-defined status-flow process, escalation, export...); and, Thresholds Alerts.

The Optim-audit activity information includes the access details, session number, activity type (verb), table (object), details (fields), execution time (response time) and number of errors (records affected).

The data is mapped to the Guardium standard object model.

Enabling OPTIM auditing requires enabling via OPTIM and the steps required in Guardium are: (1) link user to Optim Audit Role; (2) add the predefined reports to the appropriate pane; (3) enable sniffer; and, (4) set policy action to Log Data With Values.

This interface includes an optim-audit role, a default layout (psml file) for the optim-audit role, and seven predefined reports.

These reports are:

- Optim - Failed Request Summary per Optim Server
- Optim - Request Execution per User
- Optim Server Optim - Table Usage Details
- Optim - Request Log
- Optim - Table Usage Summary
- Optim - Request Summary

Note: When creating the optim-audit role and user, only one tab OPTIM Audit will display. Similar to roles with custom layouts that customers can generate, this is a role layout that is meant to be used alone (the optim-audit user has no interest in the other user role tabs) but since the user role is required, layout merging has been turned off when the user has the optim-audit role so that they get only the items of optim interest. Other roles that work in this same way are "review-only" and "inv".

Note: After creating and saving the optim-audit role, click the Generate Layout selection within the User Browser menu and click Reset to get the layout associated with the role. Do this again if changing roles within the User Browser.

Combining real-time alerts and correlation analysis with SIEM products

Distribute contextual knowledge of database activity patterns, structures, and protocols directly to the third-party database of the SIEM system.

About this task

Guardium® pre-processes large volumes of database traffic and distills important information. Then, it provides the condensed summary to external SIEM (Security Incident Event Manager) systems such as ArcSight, Envision, and QRadar. Thus, SIEM products do not have to work as hard to process large traffic streams. Rather, it can concentrate on correlating all activity, alerting on unauthorized or suspicious behavior, and helping with the regulatory compliance requirements on event logs. This Guardium SIEM (Security Incident Event Manager) integration can be done in one of the following ways:

- Syslog forwarding, the most common method for alerts and events.
- Using the CLI command, **store remotelog**, to specify the Syslog forwarding to facility/priority, and host (destination). For more information, see [store remotelog](#).
- Using Guardium templates for ArcSight, Envision, and QRadar
- SCP/FTP (CSV or CEF Files sent to an external repository and the SIEM system must upload and parse from this external repository.)

Guardium distributes its contextual knowledge of database activity patterns, structures, and protocols directly to the third-party database of the SIEM system (Guardium has credentials to the SIEM system. It can also write directly to the SIEM database in the SIEM schema. Contact Guardium support as Guardium's entities must be mapped to the third-party schema.

Note: The SIEM system must enable remote logging to listen for the correct facility and priority, which is defined within syslog. For more information on configuring the facility and priority, see [Facility and priority of syslog messages](#).

By combining Guardium's real-time security alerts and correlation analysis with SIEM and log management products, companies can enhance their ability to:

- Proactively identify and mitigate risks from external attacks, trusted insiders, and compliance breaches;
- Implement automated controls from Sarbanes-Oxley (SOX), the Payment Card Industry Data Security Standard (PCI-DSS), and data privacy regulations;
- Manage system and network events alongside critical logs and events from the core of their data centers – enterprise databases and applications – for enterprise-wide correlation, forensics, incident prioritization, and reporting.

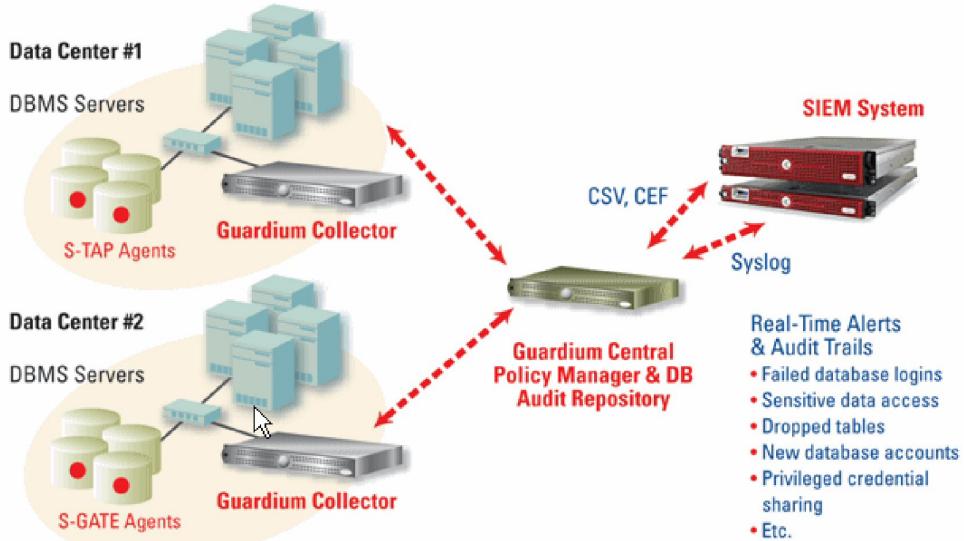

Security Information and Event Management (SIEM) solutions, also referred to as Security Event Management (SEM) solutions, are offered by companies such as QRadar, ArcSight, CA, Cisco MARS, LogLogic, RSA enVision and SenSage. SIEM products are complementary to Guardium's database activity monitoring solution. They can also use Guardium's filtering and preprocessing of database events to provide 100% visibility and database analytics for SOX, PCI-DSS, and data privacy.

SIEM technology provides real-time analysis of security alerts that are generated by network hardware and applications. It helps companies to respond to network attacks faster and to organize the massive amounts of log data that is generated daily. SIEM solutions are log-based correlation engines.

SIEM solutions are primarily focused on detection and security, but not on auditing. They assemble data from other logs and analyze it at a high level. They correlate much more data such as IP addresses and routers but have little database visibility. They do not have forensics-quality, digitally signed, audit monitoring capabilities so they can be used for immediate information, but not historical proof.

Security information and event management (SIEM) users are faced with the challenge of importing raw logs that are generated by internal DBMS utilities. The performance of DBMS logging utilities, the unfiltered information that they produce, and the lack of necessary granular information create challenges.

Through the Guardium user interface, Guardium can be configured easily to integrate with various SIEM tools.

Note: With SIEM integration, the reports and policies do not change on the Guardium system. Users can continue with their existing policies and reports, trigger alerts, and send reports to the SIEM system.

For SIEM-Guardium Integration, there are predefined templates for QRadar, Envision, and ArcSight so you do not need to define them. You can select the appropriate message template within the rule action.

You can change the default message template, specify the parameters for syslog forwarding, and create the CSV or CEF file to export.

Note: CEF is only used for ArcSight. The other SIEM products have a different format and do not use CEF.

In order for the SIEM product to recognize the information that is being sent, the message template must be changed through the Global Profile. This formatting agreement between the SIEM solution and Guardium allows SIEM products to parse incoming messages and update its own database with the new event/data.

1. To open the Global Profile, click Setup > Tools and Views > Global Profile.
2. Click Edit to Named template.

Global Profile

Use aliases in reports unless otherwise specified	<input type="checkbox"/>
PDF footer text	Copyright IBM InfoSphere
Message template	<pre>Alert based on rule ID: %ruleDescription Category: %category Classification: %classification Severity %severity Rule #: %ruleID [%ruleDescription] Request Info: [Session start: %sessionStart Server Type: %serverType Client: %clientIP (%clientHostname) Server: %serverIP (%serverHostname) Client PORT: %clientPort Server Port: %serverPort Service Name: %serviceName Net Protocol: %netProtocol DB Protocol: %DBProtocol DB Protocol Version: %DBProtocolVersion DB User: %DBUser]</pre>
No wrap	<input type="checkbox"/>
Disable accordion menus	<input type="checkbox"/>
Named template	<input type="button" value="Edit"/>

3. Select a template or create a new template with the icon.

The Guardium appliance can be configured to send Syslog messages to remote systems. Specific types of Syslog messages can be sent to specific hosts. The Syslog message type is determined from the facility-priority of the message.

Configure sending to remote systems by using the CLI command [store remotelog](#). You can test communication with the remote server using the CLI command [show remotelog_status](#). For more details on the process, see [remote syslog](#).

Examples of facility are: all, auth, authpriv, cron, daemon, ftp, kern, local0, local1, local2, local3, local4, local5, local6, local7, lpr, mail, mark, news, security, Syslog, user, uucp. Examples of priority are: alert, all, crit, debug, emerg, err, info, notice, warning.

Reports containing information that can be used by other applications or reports that contain large amounts of data can be exported to a CSV file format. Report, Entity Audit Trail, and Privacy Set task output can be exported to CSV (Delimited-separated Value) files. Additionally, CSV file output can be written to Syslog. If the remote Syslog capability is used, the output CSV file is forwarded to the remote Syslog locations.

Each record in the CSV or CEF files represents a row on the report. Contact Guardium Support for a tool that permits the reformatting of CSV files before export.

Each record in the CSV or CEF files represents a row on the report.

To send Syslog messages and export reports to CSV files, complete the following steps.

Note: Do not zip the file within the audit process definition so that the SIEM vendor can parse it correctly.

1. To open the Audit Process Finder, click Comply...> Tools and Views...> Audit Process Builder.
2. Click the  icon to add a process or select an existing process from the drop-down list.
3. Click New Audit Task under Audit Tasks.
4. Enter a description and select Report.
5. Select a report from the drop-down list and enter the CSV/CEF File Label.
6. Select Export CSV file and Write to Syslog. Choose a named template from the drop-down list.
7. Under Task Parameters, choose the Enter Period From >= and Enter Period To <= by using the calendar icon.
8. Click Apply.

CSV/CEF files can also be exported on a schedule to the SIEM host. Modify or add an audit task.

1. Click Comply...> Tools and Views...> Audit Process Builder to open the Audit Process Finder and modify or add an audit task.
2. Choose Export CSV file or Export CEF file.

Note: ACCESS reports can be saved and forwarded in CEF or LEEF format but other reports, such as Guardium Logins, Aggregation Activity Log, and CAS events cannot be mapped to CEF or LEEF.

3. Uncheck the Write to Syslog. Otherwise, Syslog messages will be generated instead of a file.
4. Open the CSV/CEF Export menu by clicking Manage...> Data Management...> Results Export (Files).
5. Select either the SCP or FTP Protocol. Then enter the Host, Directory, Username, Port, and SCP/FTP password.
6. In the Scheduling section, define the Start Time, Restart frequency, Repeat frequency, Schedule by Day/Week or Month, Schedule Start Time. Check the box to automatically run dependent jobs.
7. Click Save to commit the changes or Reset to clear the fields.

To have a policy alert that is routed to Syslog, exception rules, access rules, and extrusion rules must be modified to trigger notifications to be sent to Syslog. This action can be accomplished by going to the Policy Builder. Policy rules can be sent as email or sent to Syslog and forwarded.

1. To open the Policy Builder, click Setup...> Tools and Views...> Policy Builder.
2. Select the policy and click Edit Rule.
3. Click Add Rule...> Add Exception Rule.
4. Enter the Description, Category, Classification, and select a Severity level from the drop-down list.

For every policy rule violation logged during the reporting period, the Policy Violations report provides the Timestamp from the Policy Rule Violation entity, Access Rule Description, Client IP, Server IP, DB User Name, Full SQL String from the Policy Rule Violation entity, Severity Description, and a count of violations for that row. With this report, users can group violations and create incidents, set the severity of each violation, and assign incidents to users.

CEF Mapping

The CEF standard from ArcSight defines a set of required fields, and a set of optional fields.

The latter are called extensions in the CEF standard. Data is mapped to these fields from Guardium® configuration information and reports. Note that not all Guardium fields map to a CEF field, so there may not be a one-to-one relationship between the rows of a printed report and the CEF file produced for that report. Also note that this facility is intended to map data from data access domains (Data Access, Exceptions, and Policy Violations, for example), and not from Guardium self-monitoring domains (Aggregation/Archive, Audit Process, Guardium Logins, etc.).

Note: Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP will be used for the source. If both included in the query, then Client IP takes precedence.

The CEF fields in the following table are always present.

Table 1. Required CEF fields

CEF Field	Guardium Mapping
Version	0 (zero); Currently the only version for the CEF format
Device Vendor	Guardium
Device Product	Guardium
Device Version	Guardium software version number
Signature ID	ReportID
Name	Report Title
Severity	Numeric severity code in the range 0-10, with 10 being the most important event. If not reset in the report, 0 (zero, which translates to Info for Guardium).

The CEF extension fields are optional, and will be present only when the mapping applies. For example, if the report does not contain an access rule description, the act field (the first extension field) will not be present. For more detailed information about the Guardium entities and attributes, see the appropriate entity reference topic.

Table 2. CEF extension fields

CEF Field	Entity	Attribute
severity	Policy Rule Violation	Severity
act	Policy Rule Violation	Access Rule Description
app	Client/Server	DB Protocol
app	Exception	Database Protocol
dst	Client/Server	Server IP
dst	Exception	Destination Address
dhost	Client/Server	Server Host Name

CEF Field	Entity	Attribute
dpt	Session	Server Port
dpt	Exception	Destination Port
dproc	Client/Server	Source Program
duid	Client/Server	OS User
duser	Client/Server	DB User Name
duser	Exception	User Name
end	Exception	Exception Timestamp
end	Policy Rule Violation	Timestamp
end	Access Period	Period End
end	Session	Session End
msg	Exception	Exception Description
msg	Message Text	Message Text
msg	Message Text	Message Subject
msg	SQL	SQL String
src	Client/Server	Client IP
src	Client/Server	Analyzed Client IP
src	Exception	Source Address
shost	Client/Server	Client Host Name
smac	Client/Server	Client MAC
spt	Session	Client Port
spt	Exception	Source Port
start	Exception	Exception Timestamp
start	Policy Rule Violation	Timestamp
start	Access Period	Period Start
start	Session	Session Start
proto	Client/Server	Network Protocol
request	FULL SQL	Full Sql
request	SQL	Sql
cs1	Session	Uid Chain
cs2	Session	Uid Chain Compressed

For more information about CEF, search the web for Common Event Format: Event Interoperability Standard, or visit the ArcSight Website: www.arcgis.com.

LEEF Mapping

Log Event Extended Format (LEEF) from QRadar

The LEEF format consists of an optional syslog header, an LEEF header and a collection of attributes describing the event.

Syslog_Header(optional) LEEF_Header|Event_Attributes

The LEEF header is pipe ('|') separated and attributes are tab separated

Example

Jan 18 11:07:53 host LEEF:Version|Vendor|Product|Version|EventID|Key1=Value1<tab>Key2=Value2<tab>Key3=Value3<tab>...<tab>KeyN=ValueN

Table 1. LEEF Parameters

Parameters	Description
LEEF: Version	Version Integer identifying the version of LEEF used for the log message
Vendor	String identifying the vendor of the device or application sending the event log
Product	Product String identifying product sending the event log Note: The combination of vendor and product must be unique
Version	String identifying the version of the device or application Sending the event log
EventID	ID that uniquely identifies the event
Attributes 1..N	A set of key value pairs attributes for the event separated by the tab character. Order is not enforced. A pre defined set of keys are defined and should be used when possible. LEEF format is extensible and allows for additional key value pairs to be added to the event log. Keys must not contain spaces or equal signs Values must not contain tabs

Example:

```
Jan 18 11:07:53 192.168.1.1 LEEF:1.0|QRadar|QRM|1.0|NEW_PORT_DISCOVERD|src=172.5.6.67 dst=172.50.123.1 sev=5 cat=anomaly
msg=there are spaces in this message
```

Character Encoding

UTF8

Predefined Attributes

Table 2. Predefined Attributes

Key Name	Data Type	Max Length	Description
Cat	string		Event category
devTime	date		Time the device or application emitted the event
devTimeFormat	string		Defined by the java SimpleDateFormat. This is only required if using a customized date format. See Date Format section for further details.
proto	integer		Transport protocol
sev	integer (1-10)		Severity of this event
src	IPv4 or IPv6 address		Source address
dst	IPv4 or IPv6 address		Destination address
VSrc	IPv4 or IPv6 address		Virtual source address
srcPort	integer		Source Port. The valid port numbers are between 0 and 65535.
dstPort	integer		Destination Port. The valid port numbers are between 0 and 65535.
srcPreNAT	IPv4 or IPv6 address		Source address for the message before Network Address Translation (NAT) occurred
dstPreNAT	IPv4 or IPv6 address		Destination address for the message before Network Address Translation (NAT) occurred
srcPostNat	IPv4 or IPv6 address		Source address for the message after Network Address Translation (NAT) occurred
dstPostNat	IPv4 or IPv6 address		Destination address for the message after Network Address Translation (NAT) occurred
usrName	string	255	User name associated with the event
srcMAC	MAC address		Six colon-separated hexadecimal numbers. Example: 1:2D:67:BF:1A:71
dstMAC	MAC address		Six colon-separated hexadecimal numbers. Example: 11:2D:67:BF:1A:71
srcPreNATPort	integer		Source Port. The valid port numbers are between 0 and 65535.
dstPreNATPort	integer		Destination Port. The valid port numbers are between 0 and 65535.
srcPostNATPort	integer		Source Port. The valid port numbers are between 0 and 65535.
dstPostNATPort	integer		Destination Port. The valid port numbers are between 0 and 65535.
identSRC	IPv4 or IPv6 address		
identHostName	string	255	Host name associated with the event. Typically, this parameter is only associated with identity events
identNetBios	string	255	NetBIOS name associated with the event. Typically, this parameter is only associated with identity events
identGrpName	string	255	Group name associated with the event. Typically, this parameter is only associated with identity events.

Custom Attributes

In some cases custom attributes may be required to identify more information about the event being generated. In these cases vendors may define their own custom attributes and include them in the event log. Custom attribute fields should be used only when there is no acceptable mapping in to a predefined field.

Custom attributes keys must be:

- Single word no spaces
- Alphanumeric
- Clear and concise
- Cannot be named the same as any predefined attribute key

Custom attributes may be used for viewing in the QRadar Event Viewer by creating custom properties.

Custom attributes may be used by the QRadar reporting engine by creating customer properties.

Custom attributes can NOT be used for event correlation

Note: Add databaseName=%DBname to the LEEF template in order to capture the MS-SQL database name. Update the existing LEEF template or make a new template by cloning.

Date Formats

You can use any of these predefined formats:

1. Milliseconds since January 1, 1970 (integer)
2. MMM dd yyyy HH:mm:ss, for example, Jun 06 2012 16:07:36
3. MMM dd yyyy HH:mm:ss.SSS, for example, Jun 06 2012 16:07:36.300
4. MMM dd yyyy HH:mm:ss.SSS zzz, for example, Jun 06 2012 02:07:36.300 GMT

If these formats are not suitable, you can define a custom date format in the dTime field by specifying the date format using the dTimeFormat key.

For further information on specifying a date format, visit the SimpleDateFormat page at: <http://java.sun.com/javase/6/docs/api/java/text/SimpleDateFormat.html>

Troubleshooting problems

To isolate and resolve problems with your IBM products, you can use the troubleshooting and support information. This information contains instructions for using the problem-determination resources that are provided with your IBM products, including IBM® Guardium®.

- **[Techniques for troubleshooting problems](#)**

Troubleshooting is a systematic approach to solving a problem. The goal of troubleshooting is to determine why something does not work as expected and how to resolve the problem. Certain common techniques can help with the task of troubleshooting.

- **[Problems and solutions](#)**

Search here for solutions to problems that you encounter.

Techniques for troubleshooting problems

Troubleshooting is a systematic approach to solving a problem. The goal of troubleshooting is to determine why something does not work as expected and how to resolve the problem. Certain common techniques can help with the task of troubleshooting.

The first step in the troubleshooting process is to describe the problem completely. Problem descriptions help you and the IBM technical-support representative know where to start to find the cause of the problem. This step includes asking yourself basic questions:

- What are the symptoms of the problem?
- Where does the problem occur?
- When does the problem occur?
- Under which conditions does the problem occur?
- Can the problem be reproduced?

The answers to these questions typically lead to a good description of the problem, which can then lead you to a problem resolution.

What are the symptoms of the problem?

What is the problem? This question might seem straightforward, however, you can break it down into several more-focused questions that create a more descriptive picture of the problem. These questions can include:

- Who, or what, is reporting the problem?
- What are the error codes and messages?
- How does the system fail? For example, is it a loop, hang, crash, performance degradation, or incorrect result?

Where does the problem occur?

Determining where the problem originates is not always easy, but it is one of the most important steps in resolving a problem. Many layers of technology can exist between the reporting and failing components. Networks, disks, and drivers are only a few of the components to consider when you are investigating problems.

The following questions help you to focus on where the problem occurs to isolate the problem layer:

- Is the problem specific to one platform or operating system, or is it common across multiple platforms or operating systems?
- Is the current environment and configuration supported?
- Do all users have the problem?
- (For multi-site installations.) Do all sites have the problem?

If one layer reports the problem, the problem does not necessarily originate in that layer. Part of identifying where a problem originates is understanding the environment in which it exists. Take some time to completely describe the problem environment, including the operating system and version, all corresponding software and versions, and hardware information. Confirm that you are running within an environment that is a supported configuration; many problems can be traced back to incompatible levels of software that are not intended to run together or have not been fully tested together.

When does the problem occur?

Develop a detailed timeline of events leading up to a failure, especially for those cases that are one-time occurrences. You can most easily develop a timeline by working backward: Start at the time an error was reported (as precisely as possible, even down to the millisecond), and work backward through the available logs and information. Typically, you need to look only as far as the first suspicious event that you find in a diagnostic log.

To develop a detailed timeline of events, answer these questions:

- Does the problem happen only at a certain time of day or night?
- How often does the problem happen?
- What sequence of events leads up to the time that the problem is reported?
- Does the problem happen after an environment change, such as upgrading or installing software or hardware?

Responding to these types of questions can give you a frame of reference in which to investigate the problem.

Under which conditions does the problem occur?

Knowing which systems and applications are running at the time that a problem occurs is an important part of troubleshooting. These questions about your environment can help you to identify the root cause of the problem:

- Does the problem always occur when the same task is being performed?
- Does a certain sequence of events need to happen for the problem to occur?
- Do any other applications fail at the same time?

Answering these types of questions can help you explain the environment in which the problem occurs and correlate any dependencies. Remember that just because multiple problems might have occurred around the same time, the problems are not necessarily related.

Can the problem be reproduced?

From a troubleshooting standpoint, the ideal problem is one that can be reproduced. Typically, when a problem can be reproduced you have a larger set of tools or procedures at your disposal to help you investigate. Consequently, problems that you can reproduce are often easier to debug and solve.

However, problems that you can reproduce can have a disadvantage. If the problem is of significant business impact, you do not want it to reoccur. If possible, recreate the problem in a test or development environment, which typically offers you more flexibility and control during your investigation.

- Can the problem be re-created on a test system?
- Are multiple users or applications encountering the same type of problem?
- Can the problem be re-created by running a single command, a set of commands, or a particular application?

- **[Getting fixes from Fix Central](#)**

You can use Fix Central to find the fixes that are recommended by IBM Support for a variety of products, including Guardium. With Fix Central, you can search, select, order, and download fixes for your system with a choice of delivery options. A product fix might be available to resolve your problem.

- **[Contacting IBM Support](#)**

IBM Support provides assistance with product defects, answers FAQs, and helps users resolve problems with the product.

- **[Basic information for IBM Support](#)**

Before you call IBM Support, collect basic information about IBM Guardium (collector, aggregator, Central Manager; UNIX/Linux S-TAP; Windows S-TAP).

- **[Exchanging information with IBM](#)**

To diagnose or identify a problem, you might need to provide IBM Support with data and information from your system. In other cases, IBM Support might provide you with tools or utilities to use for problem determination.

Getting fixes from Fix Central

You can use Fix Central to find the fixes that are recommended by IBM Support for a variety of products, including Guardium®. With Fix Central, you can search, select, order, and download fixes for your system with a choice of delivery options. A product fix might be available to resolve your problem.

About this task

Procedure

To find and install fixes:

1. Obtain the tools that are required to get the fix. If it is not installed, obtain your product update installer. You can download the installer from [Fix Central](#).
This site provides download, installation, and configuration instructions for the update installer.
2. Select Guardium as the product, and select one or more check boxes that are relevant to the problem that you want to resolve.
3. Identify and select the fix that is required.
4. Download the fix.
 - a. Open the download document and follow the link in the Download Package section.
 - b. When downloading the file, ensure that the name of the maintenance file is not changed.
This change might be intentional, or it might be an inadvertent change that is caused by certain web browsers or download utilities.
5. Apply the fix.
 - a. Follow the instructions in the Installation Instructions section of the download document.
 - b. For more information, see the Installing fixes with the Update Installer topic in the product documentation.
6. Optional: Subscribe to receive weekly email notifications about fixes and other IBM Support updates.

Contacting IBM Support

IBM Support provides assistance with product defects, answers FAQs, and helps users resolve problems with the product.

Before you begin

After trying to find your answer or solution by using other self-help options such as technotes, you can contact IBM Support. Before contacting IBM Support, your company or organization must have an active IBM *maintenance contract name*, and you must be authorized to submit problems to IBM. For information about the types of available support, see the [IBM Support Guide](#).

Procedure

To contact IBM Support about a problem:

1. Define the problem, gather background information, and determine the severity of the problem.
For more information, see the [IBM Support Guide](#).
2. Gather diagnostic information.
3. Submit the problem to IBM Support in one of the following ways:
 - Online through the [IBM Support Portal](#): You can open, update, and view all of your service requests from the Service Request portlet on the Service Request page.
 - By phone: For the phone number to call in your region, see the [Directory of worldwide contacts](#) web page.

Results

If the problem that you submit is for a software defect or for missing or inaccurate documentation, IBM Support creates an Authorized Program Analysis Report (APAR). The APAR describes the problem in detail. Whenever possible, IBM Support provides a workaround that you can implement until the APAR is resolved and a fix is delivered. IBM publishes resolved APARs on the IBM Support website daily, so that other users who experience the same problem can benefit from the same resolution.

Basic information for IBM Support

Before you call IBM Support, collect basic information about IBM® Guardium® (collector, aggregator, Central Manager; UNIX/Linux S-TAP; Windows S-TAP).

Use **support must_gather commands**, which can be run from the CLI to generate specific information about the state of any Guardium system. This information can also be collected through the Guardium GUI.

This information can be uploaded from the Guardium system and sent to IBM Support whenever a Problem Management Report (PMR) is logged.

Encrypt Must Gather

You can configure your system to encrypt the must gather output in **Setup > Tools and Views > Global Profile..**. The default value is unencrypted, and the must gather output is compressed. When the Encrypt Must Gather output check box is checked, all future must gather output is encrypted. You can also enable encryption with the **store encrypt must_gather on** CLI command and disable it with the CLI command **store encrypt must_gather off**.

- [Running must gather in the UI](#)
Must gather collects information that Guardium support can use to help you solve issues. You can run must gather in the UI of a collector, aggregator, or central manager. You can also choose to send the results by email.
- [Running must gather from the CLI](#)
You can run **must_gather** commands from the command line interface of an IBM Guardium collector, aggregator, or central manager.
- [Running the slon looper utility](#)
The slon looper is a utility that allows Guardium to walk (loop) through your Guardium installation to gather information that can help solve customer issues. Configure and run the slon looper from the Guardium Support Information Gathering page.
- [Must gather for UNIX-Linux S-TAP](#)
You can run must gather on the collector from the UI and in the CLI, and on the database by using the **guard_diag** script.
- [Must gather for Windows S-TAP and other Windows agents](#)
Learn how to run the **diag.bat** to produce numerous statistics that help Guardium with diagnostics. Must gather has two options: S-TAP mode for S-TAPs and Standalone mode for other agents that are installed on the database server. Learn about the Pre-Kernel dump verification utility for Windows S-TAP.

Running must gather in the UI

Must gather collects information that Guardium support can use to help you solve issues. You can run must gather in the UI of a collector, aggregator, or central manager. You can also choose to send the results by email.

Procedure

1. Browse to **Manage > Maintenance > Support Information Gathering**.
2. Optional: Add a description in the text box. Enter extra information that you think Guardium support needs to know.
3. If you have a PMR or ticket number, enter it.
4. Optional: Add an email address to send the must gather files to a user. SMTP must be configured.
From **Send Results To:**, select **email:** and complete the email address. Emailed files can also be viewed in **Manage > Maintenance > Support Information Results**.
5. Optional: To start collecting log information at a future time, schedule a start time by clicking the icon.
6. Select the categories whose log information you want to include. Choose the options that most closely reflect your problems.
Note: To help troubleshoot issues for some systems, such as User Interface, Backup, and Scheduler, enter the number of minutes for the must gather to run in **Gather information duration (minutes)**. During the time period that you specify, reproduce the problem so that Guardium can generate the logs that contain the debug information. The default value is 10 minutes.
7. Click **Start** to begin running the must gather report.

Results

To view the results, browse to **Manage > Maintenance > Support Information Results**. You can open or save the **.tgz** file.

What to do next

From the Support Information Results page, you can choose how long to keep the must gather output before it is purged. The default is 30 days. To change the default, select the number of days and click **Apply**.

You can configure and run the Slon looper utility from the Support Information Gathering page. For more information, see [Running the slon looper utility](#).

Running must gather from the CLI

You can run **must_gather** commands from the command line interface of an IBM® Guardium® collector, aggregator, or central manager.

Procedure

1. Open a PuTTY session (or similar) to the appropriate collector, aggregator, or central manager.
2. Log in as user `cli`.
3. Depending on the type of issue, enter the relevant `must_gather` commands into the CLI prompt in the format `support must_gather <issue>`. You might need more than one of the following `must_gather` commands to diagnose the problem.
 - `agg_issues` - Aggregation process issues.
 - `alert_issues` - Alerting issues.
 - `app_issues` - Application issues.
 - `audit_issues` - Audit process issues.
 - `auth_issues` - Authentication issues (including LDAP and multifactor authentication).
 - `auto_create_ie` - Auto create inspection engines issues.
 - `backup_issues` - Backup process issues.
 - `big_data_issues` - Big data issues.
 - `cm_issues` - Central manager issues.
 - `compliance_mon_issues` - Compliance monitoring issues.
 - `datamining_issues` - Data mining issues.
 - `datastreams_issues` - Data streaming issues.
 - `deploy_agents_issues` - Deployment agents issues.
 - `deployment_issues` - Deployment issues.
 - `eagle_eye_issues` - Advanced threat scanning issues.
 - `enterprise_load_balancer_issues` - Enterprise load balancer issues.
 - `entitlement_issues` - Entitlement optimization issues.
 - `go_stream` - Go stream issues.
 - `jproxy_issues` - Jproxy issues.
 - `miss_dbuser_prog_issues` - System database user issues.
 - `native_auditing_issues` - Native auditing issues.
 - `network_issues` - Network architecture issues.
 - `patch_install_issues` - Patch installation and upgrade issues.
 - `purge_issues` - Purge process issues.
 - `risk_spotter` - Risk spotter issues.
 - `scanner_agent_issue`
 - `scheduler_issues` - Scheduler issues.
 - `slon_looper` - Slon looper output.
 - `sniffer_issues` - Sniffer issues.
 - `system_db_info` - Guardium system database or operating space performance issues.
 - `universal_connector_issues` - Universal connector issues.
4. Generate and send the resulting output to IBM Support:
 - Running the `must_gather` can take several minutes. When complete, you can retrieve the file with the `fileserver` command. For more information, see [fileserver](#). On the fileserver, the `must_gather` files are stored in the `..//Access logs//opt-ibm-guardium-log/**/must_gather/` directory. Within the directory, Guardium generates the logs as `.tgz` files.
 - Upload any `must_gather` files to ECUREP by using standard data upload. Specify the PMR number and the file to upload.

Running the slon looper utility

The slon looper is a utility that allows Guardium to walk (loop) through your Guardium installation to gather information that can help solve customer issues. Configure and run the slon looper from the Guardium Support Information Gathering page.

About this task

The slon looper logs message dumps and MustGather information that Guardium technical support can use to help reproduce and resolve customer issues. The slon looper saves a message dump when the conditions that you specify are found in the customer's environment, such as incorrect database usernames or missing session parameters. After these conditions are satisfied, the looper saves the MustGather data alongside the message dump. Guardium technical support can replay the message dumps in IBM's secure environment to reproduce the issue. Typically, message dumps are extensive binary files. In specific scenarios, especially with firewall and query rewrite issues, the looper might log an encrypted text SLON file, as a message dump might not provide the needed insights. Work with Guardium technical support to determine how to configure the slon looper for your needs.

Procedure

1. Browse to `Manage > Maintenance > Support Information Gathering`.
2. Follow the instructions in [Running must_gather in the UI](#), and select Slon looper. Do not select any other categories. Looper configuration displays.
3. Click Select to open the Select looper configuration window.
 - If one or more slon looper configurations are available, select a looper and click Save.
 - If you do not have an existing configuration, click  to open the New looper configuration window. For more information about configuring an slon looper, see [Configuring the slon looper utility](#).
4. After you select an slon looper configuration, click Start to begin running the slon looper.

Results

To view the results, browse to `Manage > Maintenance > Support Information Results`. You can open or save the `.tgz` file.

What to do next

If you need detailed login information to solve your issue, Guardium technical support might suggest that you configure and run the `Login information dump` session level policy. For more information, see [Session-level policies](#) and [Login information dump example](#).

- [Configuring the slon looper utility](#)

Before you can run an slon looper, you need to configure one from the Support Information Gathering page. Use the slon looper to investigate an incoming network traffic problem on the sniffer.

Configuring the slon looper utility

Before you can run an slon looper, you need to configure one from the Support Information Gathering page. Use the slon looper to investigate an incoming network traffic problem on the sniffer.

The slon looper utility allows you to create a looper configuration from Guardium sniffer data. You can create a general slon looper that looks for either specific traffic patterns or searches for information in log files.

Configuring a general slon looper

1. Open the New looper configuration window, as described [Running the slon looper utility](#).
2. Enter a meaningful name for this looper utility.
3. Select the Issue type that reflects your issue. If you don't know, select Other. Depending on the issue type that you select, Guardium sets other parameters. In this case, use the specified defaults.
4. Select Looper options:
In most cases, you can use the defaults. Work with Guardium technical support to determine whether you should make changes to these options.
 - Collect msg-dump - Selected by default.
 - Collect slon file - This file is useful when you need to investigate issues related to the firewall, query rewrite, timing issues, or session level policies.
 - Collect snif must_gather - Selected by default. The slon looper utility analyzes the sniffer log output to help determine sniffer issues.
5. Set the options for running the slon looper:
 - Number of loops - The count of message dumps and "must gather" data instances where conditions for logging (as defined in the looper) are met.
 - Loop duration - The maximum time allotted for looper logging. If the specified conditions aren't met within this period, the slon looper discards the existing message dump and starts again.
 - Looper timeout - The maximum length of time that a looper can run if its conditions aren't met.
 - Max file size - The maximum size of the logged message dump to ensure the server's disk space isn't exhausted.
6. Optionally select an additional filter:
 - a. Select Traffic filters and then select one of the filters from the list.
 - b. Select or enter the information for that filter.
For example, if you select Server IP address, then select an operand and enter an IP address (or use regex to find a range of IP addresses).
7. When you are done, click Save and then click Save again to select the slon looper configuration that you created and return to the Support Information Gathering page.
8. Click Start to run the slon looper utility. You can view the output from the Support Information Results page, as described in [Running the slon looper utility](#).

Or

- a. Select Log files search.
- b. Specify a search string for either the syslog or the sniffer log.

Configuring a custom slon looper

If you work with Guardium technical support on a sniffer issue, your support team might send you an ad hoc sniffer patch to debug an issue or test a fix.

Click Custom and then follow the instructions from your support team to upload and run the ad hoc patch.

Must gather for UNIX-Linux S-TAP

You can run must gather on the collector from the UI and in the CLI, and on the database by using the guard_diag script.

You can run must gather by either of these methods.

- In the S-TAP Control page: Under the specific S-TAP, click . In the S-TAP Commands window, select the command STAP logging, check Run Diagnostics, then click Apply. The logs will get uploaded to the Support Information Gathering Results page.
- Log in to the database server. The location of the diagnostics script (guard_diag) depends on the installation method.
 - Shell: The directory you specified during the S-TAP installation. By default, /usr/local/guardium/guard_stap
 - GIM: /usr/local/guardium/modules/STAP/current/guard_diag
 - .rpm: /opt/guardium/guard_stap/guard_diag. This is hard coded, and cannot be changed.

The script prompts for the location if the script cannot automatically determine where S-TAP is installed. The run time is a few minutes. If no output directory is specified, the script saves the generated .tar file in /tmp. When the script runs and enables logging from the GUI, the .tar file is placed in /var/tmp. The file name is derived from the server name, and the time and date it ran. It always starts with diag.ustap.

The verbosity of the output is set by the diagnostics, and does not need modification.

By default, diagnostics are uploaded to the Support Information Gathering Results page in the collector. The upload is controlled by the guard_tap.ini parameter upload_feature. The default value is 1. For more information, see [upload feature](#).

The S-TAP log file records the successful transfer of a diagnostics .tar file to the appliance. It also records a failure message if the .tar file is not sent to the appliance, with debug details on the failure.

General system data collected:

- Uname -a
- List of kernel modules installed
- Output for one cycle
- Uptime
- Processor number and type
- Dump of most recent syslog
- Netstat output
- IPC list
- Disk free statistics
- Copy of /etc/services
- Directory listing of /etc
- Various platform-specific information
- Contents of /etc/inittab

S-TAP Data collected:

- S-TAP version
- Contents of guard_tap.ini
- Ls -l on the K-TAP device nodes
- A-TAP diagnostics (output of the atap_must_gather.sh) (see [S-TAP is not capturing A-TAP traffic](#))
- All Exit diagnostics (for Db2, this is the output of the db2_exit_health_check.sh. See also [Linux S-TAP is not capturing Db2 exit traffic](#).)
- 30s trace of S-TAP
- K-TAP statistics
- List of all the files in the installation directory
- Verbose debug log for K-TAP (2) and S-TAP (4)
- Database configuration information: Either files, or output from a database command, depending on the database type. For example, Oracle: listener.ora, sqlnet.ora, and tnsnames.ora; Informix: onconfig.* and sqlhosts.*"; Sybase: interfaces and *.cfg; Db2: output of Db2 command: **db2 get dbm cfg**

Limitations:

- Tusc is not installed on all HP-UX operating systems, so tracing the S-TAP PID does not work.
- gzip isn't always installed on the system. The fallback is to compress (final extension of .tar.Z) and failing that, the .tar file is placed in the output directory.
- Topas output on AIX is best interpreted by the terminal since it contains control codes that make it mostly unintelligible when it is opened in an editor.
- The non-root S-TAP has a number of issues related to the diagnostics script.
- In Linux, /var/log/messages is only readable by the root.
- Some Solaris operating systems might not be configured correctly, which causes netstat to print an error.
- The path for the non-root user is rather basic, and as a result, some commands might not run at all. Notably, this known issue happens on HP-UX with gzip.
- Platform-specific requirements:
 - S-TAP: None
 - Linux: None
 - AIX: topas
 - Solaris: top, prtdiag, psrinfo

Supported platforms:

- Linux
- HP-UX
- AIX
- Solaris

Must gather for Windows S-TAP and other Windows agents

Learn how to run the diag.bat to produce numerous statistics that help Guardium with diagnostics. Must gather has two options: S-TAP mode for S-TAPs and Standalone mode for other agents that are installed on the database server. Learn about the Pre-Kernel dump verification utility for Windows S-TAP.

S-TAP mode

Run diag.bat with any of:

- Log in to the database server. From the Windows Start menu, go to IBM Windows S-TAP > Run Diagnostics.
- Log in to the database server. Open the Windows Command Prompt as Administrator. Change the directory to %WINSTAP_DIR%\bin (for example C:\Program Files\IBM\Windows S-TAP\bin). Run diag.bat
- In the S-TAP Control page: Under the specific S-TAP, click . In the S-TAP Commands window, select the command STAP logging, check Run Diagnostics, then click Apply. The logs are listed in the Support Information Gathering Results.

When you run diag.bat as a command prompt, it has a number of **command options**: **diag.bat [h] [v] [s] [k]**

You can specify only one option each time you run the command. For example:

diag.bat h

or

diag.bat help

Command option	Description
h, help	Display help
v, version	Display the version.

Command option	Description
s, summary	Create a summary of important information from several files, such as system.txt and guard_tap.ini and generates a file called summary.txt. This summary file contains the most useful information that you need. Running summary can take a few minutes.
k, keep	Keep all files in the ZIP_SOURCE_DIR after the files are zipped. This is useful if you want to review the files on database DB server without unzipping the zip file. If this option is not specified, all files copied from Guardium folders are removed from the diag folder after the zip is created. <ul style="list-style-type: none"> • ZIP_SOURCE_DIR for S-TAP: %WINSTAP%\Logs • ZIP_SOURCE_DIR for standalone: ~\diag

The output of diag.bat is a compressed file. You can access it:

- In the folder %WINSTAP%\bin\zipTmp on the DB server with a name in the format WSTAP_HOST_YYYY-MM-DDTHH-MM-SSTZD.zip.
- From the Guardium Support Information Gathering Results page.

The compressed file contains numerous files in a few sections:

- root directory of the compressed file: driver logs and environmental details
- install: Installer logs
- diag: environment details and must gather
- ini: guard_tap.ini

These folders display when the product is installed in the database server:

- Windows S-TAP (when root folder is in S-TAP mode): S-TAP configuration and log files
- Guardium Installation Manager: GIM configuration and log files
- Guardium Agent Monitor: GAM configuration and log files
- Windows Fam Monitor: FAM configuration and log files
- CAS: CAS configuration and log files
- FAMCrawler
- FAMforSP
- FAMforNAS
- FDECforNAS
- FDECforSP

When you run **diag.bat**, it creates a log of the process: diag.log. The log files contain the log level (Information, Warning, Error), timestamp, and details of activities. This log can help you if **diag.bat** did not run successfully. It is included in the diagnostics file.

Standalone Must Gather

In Standalone mode you can run the Must Gather (diag.bat) script for any installed Guardium Windows agent: GIM, GAM, FAM monitor, FDEC for SP, FDEC for NAS, FAM for SP, FAM for NAS. You can run it from any folder, for example, C:\tmp.

To run diag.bat, open the Windows Command Prompt as Administrator, and run diag.bat. The output compressed file is generated in %PRODUCT_DIR%\Bin\zip\GRD_WIN_xxxx.zip. The format of the compressed file name is GRD_WIN_%YYYY-MM-DD%T%HH-MM-SS-msec%%TZD%, where TZD is time zone difference. One compressed file is kept in the folder. Older compressed files are deleted automatically.

The Upload feature (controlled by the S-TAP parameter UPLOAD_FEATURE) does not support Standalone must gather.

The directory structure of the standalone must gather is:

- The environment details are in the root directory of the compressed file.
- Driver logs, ini, are under the Windows S-TAP folder.
- Others are the same

If you run **diag.bat** but do not get results, and a warning message displays in ~\zip\GRD_WIN_DIAG_compress-archive_failed.txt, the powershell version is lower than V5.1. You can access the files under the \diag directory. If you can install Windows Management Framework (WMF) V5.1, then **diag.bat** can create the compressed file.

Tip: You can use the standalone mode to troubleshoot failed installations of Windows agents. For example, a Windows GIM installation failed, and nothing is copied to the database server. Copy **diag.bat** V2.1 from the Win GIM V11.3 installer and put it anywhere on the database server (for example C:\work\diag.bat). Open the Windows Command Prompt as Administrator and run C:\work\diag.bat. This gathers the OS information, install logs, and other Guardium logs if they exist.

Table 1. Difference between the modes

	S-Tap Mode	STANDALONE Mode
Location of diag.bat	%WINSTAP_DIR%\bin\diag.bat	Anywhere except Win S-TAP dir
Location of diag.log	%WINSTAP_DIR%\bin\diag\diag.bat	~\diag\diag.log
ZIP source folder	%WINSTAP_DIR%\Logs	~\diag
ZIP target folder	%WINSTAP_DIR%\bin\zipTmp	~\zip
ZIP file name	WSTAP_%HOST%_%YYYY-MM-DDTHH-MM-SSTZD%.zip	GRD_WIN_DIAG_%YYYY-MM-DDTHH-MM-SSTZD%.zip
ZIP tool	ExternalZip.exe	Powershell compress-archive command
Command Options	Supported	Supported
S-TAP features (Run from GUI/ upload)	Supported	NOT Supported

Pre-Kernel dump verification utility for Windows S-TAP

Run this utility before run a kernel dump to ensure that the dump can be created without problems.

Run the utility, SystemVerificationTool.exe, from its location in the S-TAP installed directory.

A window opens with the status, the configured dump type, the CPU size, and the free disk space. If the configuration is good for a kernel dump, the status is The system is correctly configured for a kernel dump. If the configuration is not good for a kernel dump, it informs you why.

Message	What to do
Dump type is not configured as kernel type.	Click the link and follow the procedure to change the dump type, then run the utility again.
There is only one CPU, generating a dump may lock up the CPU.	Kernel dump is not recommended
Disk space is too low to handle the creation of the dump, generating a dump may lock up the CPU.	Free up disk space and run the utility again. The utility requires the smaller of: one third of physical memory, or 10 GB.

- [Running Must Gather V3.0](#)

Running Must Gather V3.0

Listed are a few different methods to run Must Gather V3.0

Method 1. Run Must Gather V3.0 from the GUI

- Login to the Guardium GUI and navigate to the S-TAP Control tab.
- Click the Send Command icon on the target S-TAP Host.
- Select STAP Logging from the drop down menu next to Command.
- Check the Run Diagnostics check box and then press the Apply button.

Note: It may take several minutes or more for this process to complete. The diagnostic files will be archived to a zip file and uploaded to the collector. You can access this information from the Guardium GUI. Login to the Guardium GUI navigate to the Manage section, underneath locate Maintenance, and then click Support Information Results.

Method 2. Run Must Gather from Windows Start Menu

- Login to the DB server where the Windows S-TAP is installed.
- Navigate to the Windows Start menu, then navigate to the IBM Windows S-TAP folder open it and choose the Run Diagnostics application.

Note: The elevated Windows Command Prompt will then open up and the Must Gather script will start. The diagnostic files will be archived and stored to %WINSTAP_DIR%\Bin\zipTmp*.zip . It will also be sent to the collector if the upload feature is enabled in Windows S-TAP.

Method 3. Run Must Gather from Windows Explorer

- Login to the DB server.
- Right click the diag.bat file and choose Run as Administrator.

Note: If you run diag.bat which is under %WINSTAP_DIR%\Bin , it'll run as S-TAP mode and the diagnostic files will be archived and stored to %WINSTAP_DIR%\Bin\zipTmp*.zip. If you run diag.bat which is NOT under %WINSTAP_DIR%\Bin, it'll run as STANDALONE mode and the diagnostic files will be archived and stored to %current_dir%\zip*.zip.

Method 4. Run Must Gather from Windows Command Prompt as the Administrator

- Open Windows Command Prompt as the administrator
- Change the directory to the location where the diag.bat and diag.ps1 files are located.
- Run diag.bat.

Method 5. Run Must Gather Power Shell script (diag.ps1) directly

Must Gather V3.0 is written in Power Shell so you can run diag.ps1 directly without have to use the diag.bat file.

Example 1: Open Windows Command Prompt as the administrator and run powershell ./diag.ps1 on the directory where diag.ps1 is located.

Example 2: Open PowerShell as the administrator and run ./diag.ps1 on the directory where diag.ps1 is located.

Exchanging information with IBM

To diagnose or identify a problem, you might need to provide IBM Support with data and information from your system. In other cases, IBM Support might provide you with tools or utilities to use for problem determination.

Sending information to IBM Support

To reduce the time that is required to resolve your problem, you can send trace and diagnostic information to IBM Support.

Procedure

To submit diagnostic information to IBM Support:

1. Open a problem management record (PMR).
2. Collect the diagnostic data that you need. Diagnostic data helps reduce the time that it takes to resolve your PMR. You can collect the diagnostic data manually or automatically:
 - Collect the data manually.
 - Collect the data automatically.
3. Compress the files by using the .zip or .tar file format.
4. Transfer the files to IBM.

You can use one of the following methods to transfer the files to IBM:

- [The Service Request tool](#)
- Standard data upload methods: FTP, HTTP
- Secure data upload methods: FTPS, SFTP, HTTPS
- Email

Receiving information from IBM Support

Occasionally an IBM technical-support representative might ask you to download diagnostic tools or other files. You can use FTP to download these files.

Before you begin

Ensure that your IBM technical-support representative provided you with the preferred server to use for downloading the files and the exact directory and file names to access.

Procedure

To download files from IBM Support:

1. Use FTP to connect to the site that your IBM technical-support representative provided and log in as anonymous. Use your email address as the password.
2. Change to the appropriate directory:
 - a. Change to the /fromibm directory.

```
cd fromibm
```

- b. Change to the directory that your IBM technical-support representative provided.

```
cd nameofdirectory
```

3. Enable binary mode for your session.

```
binary
```

4. Use the **get** command to download the file that your IBM technical-support representative specified.

```
get filename.extension
```

5. End your FTP session.

```
quit
```

User interface

These sections present troubleshooting and solutions for common user interface problems.

- [**Changes are not saved when you add an inspection engine**](#)
If your changes are not saved when you add an inspection engine, check that the parameters are valid.
- [**HTTP error 403**](#)
If you receive a HTTP error 403, you can disable the Cross-Site Request Forgery (CSRF) protection feature to prevent the error.

- **Java.lang.IllegalStateException**
If you receive a java.lang.IllegalStateException error, clean up the Java servlets.
- **Pages are not loading correctly**
If pages do not load correctly, restart the GUI or use a different browser.

Changes are not saved when you add an inspection engine

If your changes are not saved when you add an inspection engine, check that the parameters are valid.

Symptoms

When you add an inspection engine, the new settings remain for a few minutes and then disappear.

Causes

There is an error in one or more parameter values with either the new inspection engine or a different inspection engine in the S-TAP configuration file guard_tap.ini.

Environment

The Guardium collector user interface is affected.

Resolving the problem

Check that every parameter that must be set for the inspection engine is set to a valid value. For example, some database types require that you set db_install_dir to the path of the installation directory on the server. However, for other database types, this parameter must not be set or must be set to NULL. Check the specific requirements for your database type in the S-TAP Help Book and make sure that everything is correctly set.

HTTP error 403

If you receive a HTTP error 403, you can disable the Cross-Site Request Forgery (CSRF) protection feature to prevent the error.

Symptoms

When you refresh the IBM® Guardium® GUI from the system main page, you receive the following error:

```
HTTP Status 403-
type Status report
message
description Access to the specified resource () has been forbidden
```

Causes

The cause is a feature in Guardium designed to prevent Cross-Site Request Forgery (CSRF). CSRF protection is enabled by default.

Environment

All Guardium configurations (collector, aggregator, central manager) are affected.

Resolving the problem

You can disable this feature by using the following CLI command: **store gui csrf_status off**

Note: If you turn off CSRF protection, the security level of the Guardium system is reduced.

The following command enables protection against Cross-Site Request Forgery. It is enabled by default: **store gui csrf_status on**

You can check the status by running this CLI command: **show gui csrf_status**

Java.lang.IllegalStateException

If you receive a java.lang.IllegalStateException error, clean up the Java servlets.

Symptoms

You receive the following error message.

```
There has been an Error. Please Contact your System Administrator
(java.lang.IllegalStateException)
```

Causes

The error is raised when a method is invoked and the Java VM is in a state that is inconsistent with the method. There might also be corrupted Java servlets that are caused by deadlocks.

Environment

The Guardium system is affected.

Resolving the problem

Wait a few minutes and retry. If the error persists, restart the GUI by logging in as user cli and executing the command **restart GUI**.

To clean up the Java servlets, run the command **support clean servlets**.

If the problem is not resolved, please collect the following tomcat logs and contact IBM® Guardium® Technical Support.

`tomcat_log/localhost.<date_stamp>.log`
`tomcat_log/catalina.<date_stamp>.log`

Pages are not loading correctly

If pages do not load correctly, restart the GUI or use a different browser.

Symptoms

You might see a blank screen or other errors. The problem appears to happen with certain browsers on specific systems but not with others.

Causes

The cause might be restricted to a localized browser or there is a Java virtual machine issue.

Environment

The collector, aggregator, and central manager are affected.

Resolving the problem

To resolve the problem, run **restart GUI** from the CLI prompt on the Guardium system. If that does not help, try the following actions.

- Restart the system.
 - Uninstall and reinstall the Java virtual machine.
 - Uninstall and reinstall the browser.
 - Use a different browser.
-

Troubleshooting Guardium® Data Protection policies

These sections present troubleshooting and solutions for common user interface problems.

- [Query does not appear in the co-relation alert definition](#)
If the query does not appear in the co-relation alert definition, check the count field and sort by time stamp.

-

Query does not appear in the co-relation alert definition

If the query does not appear in the co-relation alert definition, check the count field and sort by time stamp.

Symptoms

You created an access query for creating a co-relation alert. However, in the co-relation alert definition, this query does not appear in the drop-down list.

Causes

The co-relation alert search in the report is based on the time stamp.

Environment

The collector and aggregator are affected.

Resolving the problem

Mark the Add Count check box and sort by time stamp.

Rule does not trigger

If a rule with a value in the policy command field does not trigger as expected, reconfigure the rule.

Symptoms

Rules with a value in the policy Command field do not trigger as expected.

Causes

The cause is a misconfiguration in the command field. The Guardium parser does not consider the command modifiers to be a part of a command.

Environment

Guardium Collectors. The command field in the policy rule is also affected when it is used with wildcard (%).

Resolving the problem

The value in the Command field of the rule must match a value exactly that is shown in SQL Verb, plus a wildcard (%) as needed. This example is correct.

```
GRANT  
GRANT%
```

This example is incorrect.

```
GRANT% TO PUBLIC  
%GRANT% ADMIN OPTION%
```

ADMIN OPTION and **TO PUBLIC** do not match and cannot trigger a rule because the Guardium parser does not recognize them as a part of a command. Generally, the parser does not consider command modifiers to be part of a command. Instead, create a report to inspect the traffic that the policy monitors and include the SQL Verb field from the Command entity in that report. Anything that is listed in the SQL Verb field is recognized by the parser and can be used in the Command field of a policy rule. Several commands can be added to a group and the group can be used in the rule instead of a single command. In this case, each group member must match an entry in SQL Verb. Guardium includes several such command groups that you can use or clone.

REDACT function causes overly masked result

There can be several reasons why the REDACT function causes an overly masked result. Some possible ways to resolve your issue are provided here.

Symptoms

The redact function causes an overly masked result or an ORA-03106 error in Oracle traffic.

Causes

The redact function in the Guardium policy rule is doing a pattern match with the result set. It has a feature to replace the matched string with the user specified character.

Environment

Guardium collectors are affected.

Resolving the problem

Use the regular expression `\x0c{1}[0-9]{8}([0-9]{4})`. This regular expression ensures that it starts with the length of the column followed by 12 digits and replaces the last 4 digits.

For Windows databases:

- For Microsoft SQL with VARCHAR only, you must specify the exact number (from 01 to 99) of characters to redact. Specify the number in angle brackets. For example, to redact the first 10 characters of your string:

```
<10>([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

- For Microsoft SQL, you can also use the following expression to redact the first 6 digits of a 10-digit number:

```
[\x0A\x14]([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

Where |x0A represents 10 bytes and |x14 represents 20 bytes.

Note: For more information about using regex with Windows, see [REDACT - Working with regex on Windows DB servers](#).

REDACT - Working with regex on Windows DB servers

When you use regular expressions with REDACT with Windows database servers, you need to be aware of some caveats and workarounds.

Symptoms

When you use Guardium® REDACT in your policy, the policy does not recognize the following regular expressions:

Regex	Description
{n}	Repeat n times. That is, match the preceding item n times.
/xNN	2-digit hex number. Use / xNN instead (with backslash).
/NNN	3-digit octal number. If possible, specify the ASCII equivalent.

Causes

Windows server does not support all regular expression patterns.

Note: REDACT policies that use regex can only scrub null-terminated data types.

Environment

Guardium collectors that receive data from Windows database servers.

Resolving the problem

Depending on the regex issue, rewrite your regex as follows:

- Instead of {n}, specify each digit that you want to match. For example, instead of the following regex:

```
[0-9]{5}
```

Use the following expression:

```
[0-9][0-9][0-9][0-9][0-9]
```

- Use /|xNN| to signify a 2-digit hexadecimal number, such as /x41/.

Where /|xNN| is a hexadecimal number between 01 to FF (|x00 is not supported).

For example, the hexadecimal number x41 maps to the ASCII character A. In this case, you can use either of the following regular expressions to add the letter A to the beginning of any 4-digit number:

```
[\x41][0-9][0-9][0-9][0-9]
```

Or:

```
A[0-9][0-9][0-9][0-9]
```

To use /|xNN| for redaction, specify the length of the entire string as a 2-digit hexadecimal number, and then wrap the characters to redact in parentheses.

Note: For Microsoft SQL, each character is two bytes. For most other data sources, each character is one byte.

For example, to redact the first 6 digits of a 10-digit number, use the following regex:

For MS SQL data sources:

```
\x14([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

For other (non-MS SQL) data sources:

```
\x0A([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

To make sure that your regex works with most data sources, use the following regex:

```
[\x0A\x14]([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

Where, the /|x0A|x14/ part of the pattern means either-or. The redaction engine first tries the |x0A pattern, and if that doesn't match, it tries the |x14 pattern.

Note: For Microsoft SQL with VARCHAR only, you must specify the exact number (from 01 to 99) of characters to redact. Specify the number in angle brackets. For example, to redact the first 10 characters of your string:

```
<10>([0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9][0-9]
```

- /|NNN| signifies a 3-digit octal number such as 102. Windows S-TAP does not support this pattern.

No perfect alternative pattern exists, but if [NNN] matches to a specific ASCII character, you can replace the octal number with its ASCII counterpart. For example, the octal number 102 maps to the ASCII character B. In this case, you can replace the following regex:

```
[102] [0-9] [0-9] [0-9] [0-9] [0-9]
```

With this expression:

```
B [0-9] [0-9] [0-9] [0-9] [0-9]
```

If one of these patterns does not resolve the problem in your environment, contact IBM® Technical Support if you need further analysis.

SSH sessions and automated CRON jobs that log in to your Oracle database are shown as failed logins

If SSH sessions and automated CRON jobs that log in to your Oracle database are shown as failed logins, amend the policy.

Symptoms

SSH sessions and automated CRON jobs that log in to your Oracle database through SQLPLUS and RMAN with /as sysdba show as failed logins.

Causes

Oracle responds to these logins with the following error on such attempts, even if it is not shown on the screen.

```
ORA-01-17: invalid username/password; logon denied.
```

This error triggers the failed login alert. For example, if the database user WRONGLOGIN is a member of the DBA group, and logs as sqlplus WRONGLOGIN as sysdba, the database authentication of WRONGLOGIN fails. This failure causes the ORA-01-17 error alert to trigger and is reflected in the Guardium log. However, users with sysdba privileges can connect to the database without database authentication so the session is allowed to continue. Both events are captured and recorded.

Environment

Guardium collectors are affected.

Resolving the problem

You can amend the policy to include an allow action before the rule that alerts about failed logins. Create an exception rule in the policy with the following conditions.

```
Client IP=<Server IP>
Source program = SQLPLUS
DB user in trusted group
OS user in group of Oracle DBAs
Net protocol = BEQUEATH (if local BEQUEATH, not TCP)
```

This rule skips the failed login alerts that are caused by the ORA-01-17 error but are still logged. To filter the failed login alerts out of the reports, add these conditions to the end of the conditions list:

```
AND
(
    client IP<>server IP OR
    src prg <> SQLPLUS OR
    db user NOT IN group of trusted OR
    os user NOT IN group of oracle DBAs OR
    net protocol <>BEQUEATH (if this is local BEQUEATH, not TCP )
)
```

Troubleshooting Guardium® Data Protection reports

These sections present troubleshooting and solutions for common problems with reports.

- [Cannot modify the receiver table for an Audit Process after it has been executed at least once](#)
If you cannot modify the receiver table for an audit process, clone the audit process and replace the original.
- [Cannot see multi-byte characters](#)
If you export a Guardium report to PDF and the characters are not correct, switch the PDF font configuration.
- [File system is almost full](#)
If the Guardium file system is almost full, change the log rotation strategy.
- [Guardium audit reports viewed in Microsoft Excel have rows with unexpected characters](#)
If you view an Audit report in .csv and see rows with unexpected characters, use another .csv viewer or view it as a .pdf file.
- [Reports show IP address as 0.0.0.0](#)
- [Request was interrupted or quota exceeded error message](#)
If you receive an error message that states the request was interrupted or the quota was exceeded when you run a report, divide the report into pieces of shorter reporting interval.
- [Scheduled Job Exceptions every 5 minutes](#)
If you receive a Scheduled Job exception every 5 minutes, deactivate the alert from the Anomaly Detection page.

- [Scheduled jobs exception: merge required, delay executing process](#)
If you receive an error message that states merge required, delay executing process, reschedule the Audit process.
- [The database user is not shown correctly in Guardium reports when you monitor Teradata](#)
If Guardium reports do not show the database user correctly when you monitor Teradata, configure the Teradata Database.
- [Unexpected results in Guardium reports with embedded commands](#)
If you receive unexpected results in Guardium reports, configure your policy rules to handle depth by using tuples.

Cannot modify the receiver table for an Audit Process after it has been executed at least once

If you cannot modify the receiver table for an audit process, clone the audit process and replace the original.

Symptoms

After an audit process runs at least once, you can neither remove nor add a receiver. You can also not modify the following properties for a receiver.

- Action Req.
- Cont.
- Appv. if Empty

Causes

After an Audit Process runs at least once, the receiver table is locked and you cannot modify most of the properties.

Environment

All Guardium configurations (collector, aggregator, central manager) are affected.

Resolving the problem

The following steps enable you to modify the receiver table.

1. Clone the audit process.
2. Make changes to the cloned audit process.
3. Delete the original audit process. However, if you do not want to lose the audit process history, you can rename the audit process.
4. Rename the cloned audit process to the name of the original one.

Cannot see multi-byte characters

If you export a Guardium report to PDF and the characters are not correct, switch the PDF font configuration.

Symptoms

You can view reports in the GUI. However, when you export the report to PDF, the characters are not correct or missing. The characters appear as question marks or other symbols in the PDF report.

Causes

The default font in Guardium PDF exports does not show multi-byte characters correctly. For example, Greek, Cyrillic, and Chinese characters do not display correctly.

Environment

The collector, aggregator, and central manager are affected.

Resolving the problem

In version 9 and later, switch the PDF font configuration to resolve the problem.

1. Log in as a user in the CLI.
2. Run the command **store pdf-config multilanguage_support**
3. Select **2 Multi-language**.

File system is almost full

If the Guardium file system is almost full, change the log rotation strategy.

Symptoms

The file system is filling up and approaching 100%.

Causes

Alerts and reports are sent to the syslog and can fill up the file system.

Environment

The collector or aggregator might be affected.

Resolving the problem

By default, the log files rotate weekly and keep five files. However, you can change the log rotation strategy for the log files. Use the following command to keep fewer messages in the system.

```
support logrotate [agg|message] [daily|weekly|monthly] [# of rotations]
```

Guardium audit reports viewed in Microsoft Excel have rows with unexpected characters

If you view an Audit report in .csv and see rows with unexpected characters, use another .csv viewer or view it as a .pdf file.

Symptoms

When you view an Audit report (in .csv format) in Microsoft Excel, you notice that certain rows are filled with unexpected characters. The characters might look similar to what you find in the full SQL column. The problem is not seen in .pdf reports or in GUI reports.

Causes

Microsoft Excel has a limit on what a cell can contain of 32,767 characters. If your captured SQL is longer than this limit, it will spill over onto the next row.

Environment

The Collector, Aggregator, and Central Manager are affected.

Resolving the problem

Use another .csv viewer that has a larger limit on characters per cell or view the audit report as a .pdf file instead.

Reports show IP address as 0.0.0.0

Symptoms

The IP address shows as 0.0.0.0 in Guardium.

Causes

While Guardium is decrypting the traffic, the IP address is initially recorded as 0.0.0.0 because the sniffer does not know what the actual IP address is. After the decryption is completed, a separate thread repopulates the session tables with the correct IP address.

Environment

Any database that encrypts the database traffic is affected.

Resolving the problem

Run the same report after a few minutes. To view the correct client IP for newer traffic, add the field Analyzed Client IP from the client/server domain to the report. It is possible that for some rows, the Analyzed Client IP is blank. If it is blank, the decryption for that piece of traffic is not completed.

Request was interrupted or quota exceeded error message

If you receive an error message that states the request was interrupted or the quota was exceeded when you run a report, divide the report into pieces of shorter reporting interval.

Symptoms

When you run a report in Guardium, you receive the following error message.**Request was interrupted or quota exceeded**.

Causes

The error message **Request was interrupted or quota exceeded** appears when an interactive report does not complete within the 3-minute time limit. The underlying cause is generally the size of the report.

Environment

The collector and aggregator are affected.

Resolving the problem

When encountering this problem, it usually indicates that the report is too large to run in interactive mode. The best practice is to run large reports as an audit process instead. For more information, see [Building audit processes](#).

Scheduled Job Exceptions every 5 minutes

If you receive a Scheduled Job exception every 5 minutes, deactivate the alert from the Anomaly Detection page.

Symptoms

You receive the same message in the Scheduled Jobs Exceptions report at regular short intervals, typically every 5 minutes. This interval is the same as the polling interval that anomaly detection runs on.

An example of the Scheduled Jobs Exceptions report might look like the following.

Timestamp	Exception Description	Count of Exceptions
2013-12-05 15:51:22.0	java.lang.NumberFormatException: empty String	1

The same exception appears every 5 minutes.

Causes

One of the active alerts is causing the error.

Environment

Guardium collectors and the Aggregator are affected.

Diagnosing the problem

You can check the polling interval and active alerts in the Anomaly Detection page. Click Protect > Database Intrusion Detection > Anomaly Detection to open the Anomaly Detection page.

Resolving the problem

Identify the exact alert that is causing the problem and deactivate it.

1. Deactivate one alert from the Anomaly Detection page.
2. Wait for the length of the polling interval to elapse.
3. Check to see whether the errors stop with that alert deactivated.
4. If not, reactivate the alert and deactivate the next one.
5. Repeat steps 2-5 until you try all alerts.

If you find the alert that is causing the problem and need assistance to understand or stop the error, contact IBM Guardium Technical Support and provide the following items:

1. The exact error text and screen capture.
2. Output of the following CLI commands. If requested, specify the length of one polling interval.

```
support must_gather app_issues  
support must_gather alert_issues
```

Scheduled jobs exception: merge required, delay executing process

If you receive an error message that states merge required, delay executing process, reschedule the Audit process.

Symptoms

You receive the following message. **Merge required, delay executing Process**. You might receive several of these messages over a short period.

Causes

The audit process requires the merge process to finish before it can run.

Environment

The aggregator is affected.

Diagnosing the problem

Click Reports > Guardium Operational Reports > Aggregation/Archive Log to open the Aggregation/Archive Log. You can also diagnose the problem in agg_progress.log.

Resolving the problem

Reschedule the audit process to run at least 10 minutes after the merge process.

The database user is not shown correctly in Guardium reports when you monitor Teradata

If Guardium reports do not show the database user correctly when you monitor Teradata, configure the Teradata Database.

Symptoms

When you view records from the monitored Teradata Database in Guardium reports, the database user name field does not show up as expected. The user name is truncated or missing.

Causes

The Teradata Database is not enabled to return the full user name.

Environment

Any Guardium collector that captures data from the Teradata database is affected.

Resolving the problem

Use the following command to enable the Teradata Database to return the full user name, in the correct character set, to the monitoring application. Other applications are not affected.

gtwcontrol -u yes -d

The -d command displays the updated GDO settings.

Note: This setup returns the user name in unencrypted form. If encryption is enabled, the system returns an error message.

Unexpected results in Guardium reports with embedded commands

If you receive unexpected results in Guardium reports, configure your policy rules to handle depth by using tuples.

Symptoms

You see results in your reports that you do not expect or that you believe should be filtered out by the policy. Conversely, you do not capture statements that you expect to capture.

Causes

The SQL usually has several objects and commands that are embedded in the statement. The policy or report definition is not configured to deal with objects or commands at different depths.

Environment

Guardium collectors are affected.

Resolving the problem

Verify that your conditions match the correct object name. Use the correct main entity to show objects or SQL verbs at different depths. If you still see unexpected behavior, use the group builder to define a group of tuples to use in the policy. A tuple allows multiple attributes to be combined to form a single group member.

Note: Tuple supports the use of one slash and a wildcard character (%). It does not support the use of a double slash.

Troubleshooting Guardium® Data Protection issues with assessing and hardening an environment

These sections present troubleshooting and solutions for common problems with assessing and hardening.

- [CAS is not working with Java 1.7 on Windows](#)

If Guardium change audit system is not working with Java version 1.7 on Windows, copy msver100.dll to your CAS bin folder.

- [Vulnerability Assessment exception group members appear in failed test](#)

If members of a test exception group appear in a failed vulnerability assessment test, use an escape sequence for the backslash character.

CAS is not working with Java 1.7 on Windows

If Guardium change audit system is not working with Java version 1.7 on Windows, copy msver100.dll to your CAS bin folder.

Symptoms

Guardium CAS works with older Java versions but not with Java 1.7.

Causes

msver100.dll is missing from <GUARDIUM STAP directory>\cas\bin\

Environment

Guardium CAS on Windows is affected.

Resolving the problem

To resolve the problem, complete the following steps.

1. Find the path where Java 1.7 is installed on your system such as C:\Program Files (x86)\Java\jre7\bin
2. Find the location of the library jvm.dll within the Java path found in the previous step.
3. Edit the cas.cfg file in the <CAS directory>\conf directory. For example, C:\Program Files (x86)\GUARDIUM_STAP\cas\conf\cas.cfg is a typical file path.
4. Find the line corresponding to the JVM such as ;JVM=c:\program files\java\jre1_2_3\bin\client\jvm.dll.
5. Remove the semicolon from the beginning of the line. Then, set the JVM to the path of the library jvm.dll in step 2. **JVM=C:\Program Files (x86)\Java\jre7\bin\server\jvm.dll**.
6. Copy msver100.dll from the bin folder in your Java 7 installation directory to your <CAS directory>\bin folder. For example, copy C:\Program Files (x86)\Java\jre7\bin\msver100.dll to C:\Program Files (x86)\Guardium\GUARDIUM_STAP\cas\bin\msver100.dll.
7. Restart the change audit system.

Note: This is only needed for Java version 1.7. For older versions of Java, this step is not needed.

Vulnerability Assessment exception group members appear in failed test

If members of a test exception group appear in a failed vulnerability assessment test, use an escape sequence for the backslash character.

Symptoms

Some members of a test exception group appear in the details field when you run a vulnerability assessment. The group contains members with a backslash character and a REGEX tag such as **(R) US\John Doe.**

Causes

Special characters can trigger errors when Guardium parses the exception group.

Environment

Guardium collectors are affected.

Resolving the problem

Use an escape sequence for the backslash character or do not use the REGEX tag (use an exact match). Either of these examples work.

`US\John Doe`

`(R) US\\John Doe`

The REGEX tag (R) is used to trigger a regular expression search of the details field to remove any string that matches the regular expression. A backslash or any other character that has a meaning in a regular expression needs a backslash escape sequence to avoid parsing errors. If you do not use the (R) tag, the group member must exactly match the entire line in the details field for Guardium to make a match. To pass the vulnerability test, the details field of the test must be empty.

Troubleshooting Guardium Data Protection configuration

These sections present troubleshooting and solutions for common problems with configuring your Guardium® system.

- [Cannot configure STAP after upgrade](#)
Configure S-TAP in Guardium after you upgrade S-TAP.
- [Guardium fails to recognize the network device VMXNET x](#)
If Guardium fails to recognize the network device VMXNET x, install Guardium on a virtual machine and add the network adapter.
- [Guardium network interface error after system board replacement](#)
If you receive an error message after a hardware repair, reset the network parameters.
- [SSLv3 is enabled](#)
If you receive a warning that `SSLv3 is enabled`, disable SSLv3 to prevent the POODLE exploit.

Cannot configure STAP after upgrade

Configure S-TAP in Guardium after you upgrade S-TAP.

Symptoms

After you upgrade S-TAP using the Guardium Installation Manager (GIM), you cannot configure the database path parameters in the Inspection Engine in Guardium even though the installation results for the module show as successful.

Causes

K-TAP is not properly upgraded if the new S-TAP is installed as a fresh module. Because the old K-TAP module is not removed, there is a protocol mismatch between the old K-TAP module and the new S-TAP.

Environment

S-TAP installed in UNIX and Linux such as AIX, HP-UX, Linux, and Solaris.

Diagnosing the problem

To diagnose the problem, run the `guard_diag` utility to collect must gathering data for Guardium S-TAP.

The following lines are seen in the syslog file.

```
STAP and KTAP Protocol Version Mismatch,  
Exit!!!!: No such file or directory  
Tap_controller::init failed  
GUARD-01: Error Initializing STap
```

The modules log file lists the old K-TAP. For example: `ktap_24276
338760 0`

Resolving the problem

To resolve the problem, follow these steps in the GIM modules installation pane.

1. Set K-TAP Live Update to Y.
2. Set K-TAP_ENABLED to Y and reinstall the new S-TAP.

Guardium fails to recognize the network device VMXNET x

If Guardium fails to recognize the network device VMXNET x, install Guardium on a virtual machine and add the network adapter.

Symptoms

Guardium fails to recognize the network device VMXNET x during the installation on VMware. You receive the error `eth0: unknown interface: No such device` when you install Guardium on VMware as a guest. The error message appears after you restart the system.

Causes

VMXNET x virtual network adapter requires a specific driver that is only contained in VMware tools and no operating system has the driver. Guardium is running on Linux and the installer does not have a driver for VMXNET x.

Environment

The Guardium system is affected.

Resolving the problem

Resolve the problem by completing the following steps.

1. Create a virtual machine on VMware by using a default network adapter such as E1000 or Flexible.
2. Install Guardium on the virtual machine.
3. Install the current GPU cumulative patch for Guardium.
4. After the installation, log on to the CLI console and run the command `setup vmware_tools install` to install VMware tools.
5. Shut down the Guardium system from the CLI console with the command `stop system`.
6. Edit the virtual machine settings with a VMware client tool such as VMware Infrastructure Client. Select the current network adapter and remove it.
7. Add the network adapter called VMXNET.
8. Restart the Guardium system.

Guardium network interface error after system board replacement

If you receive an error message after a hardware repair, reset the network parameters.

Symptoms

After a hardware repair such as replacing the system board on the Guardium appliance, the network connectivity is lost. The following error message occurs for each network interface when the appliance is rebooted.

`rtnetlink answers: no such device`

Causes

After you replace the system board, the MAC address will change. This change causes a disparity between the actual MAC address and what is stored in the interface configuration files.

Environment

Any Guardium appliance (collector, aggregator, or central manager) on which the system board has been replaced and all Guardium versions are impacted.

Resolving the problem

Log in to the appliance from the console as user CLI and reset the network parameters by running the following commands.

```
store network interface reset
store network interface ip <IPv4 or IPv6 address>/prefix
store network routes defaultroute <IPv4 or IPv6 gateway address>
store network resolvers <IPv4 or IPv6 address> [IPv4 or IPv6 address] [IPv4 or IPv6 address]
restart network
```

If the problem is still not resolved, contact Guardium Support for manual intervention.

SSLv3 is enabled

If you receive a warning that `SSLv3 is enabled`, disable SSLv3 to prevent the POODLE exploit.

Symptoms

You receive the following warning: **SSLv3 is enabled.**

Causes

SSLv3 contains a protocol vulnerability known as Padding Guardium® On Downgraded Legacy Encryption (POODLE). If SSLv3 is enabled on your system, this vulnerability allows attackers to force an SSL/TLS fallback to SSLv3, break the encryption, and intercept network traffic in plaintext. The vulnerability is detailed in the National Vulnerability Database as CVE-2014-3566.

Guardium recommends disabling SSLv3 on all systems to prevent the POODLE exploit, and SSLv3 is disabled by default on new Guardium systems. However, older systems and some upgrade scenarios may leave SSLv3 enabled.

This topic describes how to check the status of SSLv3 and disable it if necessary.

Attention: Disabling SSLv3 can disrupt connectivity between a Guardium v10 Central Manager and some managed units running Guardium v9 before GPU 500. If you have a mixed environment with managed units running Guardium v9 before GPU 500, either upgrade the managed units to GPU 500 or apply patch 9501 before disabling SSLv3.

Resolving the problem

1. Verify the status of SSLv3 using the following CLI command: **show sslv3**.
 - If the output indicates **SSL setting is disabled**, SSLv3 is disabled. No additional steps are required to disable SSLv3.
 - If the output indicates **SSL setting is enabled**, SSLv3 is enabled. Continue with this procedure to disable SSLv3.
2. Disable SSLv3 using the following CLI command: **store sslv3 off**. The command output should be similar to the following:

```
Current SSL setting is enabled. Will change to disabled.  
Restarting gui  
Changing to port 8443  
From port 8443  
Stopping.....  
ok
```

3. Verify that SSLv3 is now disabled: **show sslv3**. The output should now indicate **ssl setting is disabled**.

Access management

These sections present troubleshooting and solutions for common problems with access management.

- [Cannot log in to Guardium except as admin or accessmgr](#)
If you cannot log in to the Guardium GUI except admin or accessmgr, check the authentication configuration settings.
- [Guardium accessmgr password reset](#)
If you lose the accessmgr password and cannot log in, contact Guardium support.
- [Guardium CLI password reset](#)
If you lose the cli or guardcli1 - guardcli9 passwords and cannot log in, follow this procedure to reset the passwords.

Cannot log in to Guardium except as admin or accessmgr

If you cannot log in to the Guardium GUI except admin or accessmgr, check the authentication configuration settings.

Symptoms

You are unable to log in to Guardium with any user except admin or accessmgr. You see an invalid user name or password error despite using the correct user and password as defined by accessmgr. You receive the following error message. **Invalid user name and/or password. Please reenter your credentials..**

Causes

The authentication setting is not configured as local.

Environment

The collector, aggregator, and central manager are affected.

Resolving the problem

To solve the problem, change the authentication setting to local. This action enables you to log in as any user defined in the accessmgr.

Guardium accessmgr password reset

If you lose the accessmgr password and cannot log in, contact Guardium support.

Symptoms

You lost the Guardium accessmgr password and cannot log in to the GUI. The account is also locked after successive failed attempts.

Causes

Guardium prohibits multiple failed login attempts.

Environment

The collector, aggregator, and central manager are affected.

Resolving the problem

Log in to the CLI and run the following command: **support reset-password accessmgr**.

```
G10.ibm.com> support reset-password accessmgr
Password for accessmgr account have been successfully reset using keyword:<passkey>
Please provide these number to Guardium Customer Service to receive actual account password.
ok
```

After you receive the new password, unlock the account.

1. Use the following command to unlock the account. **unlock accessmgr**.
2. Log in as accessmgr and edit the accessmgr details to enter a temporary password.
3. Log in again with the temporary password.
4. When you are prompted, enter a new password.

Guardium CLI password reset

If you lose the *cli* or *guardcli1 - guardcli9* passwords and cannot log in, follow this procedure to reset the passwords.

Symptoms

You lost the Guardium the *cli* or *guardcli1 - guardcli9* passwords or otherwise cannot log in to the command line interface and need to reset the passwords.

Environment

This condition and its resolution apply to Guardium collectors, aggregators, and central managers as well as to standalone systems.

Resolving the problem

Use the following procedure to reset CLI account passwords:

1. Open a Guardium VM console and log in as the *rescue* user. You must use the Guardium console: remote SSH access is not allowed for the *rescue* account.
2. Upon logging in, the console displays a single-use passkey. Record this passkey.
3. Contact IBM support and provide the *rescue* user passkey. IBM will decode the passkey and return a single-use password for the *rescue* user.
4. Log in as the *rescue* user using the decoded password provided by IBM.
5. Reset CLI account passwords using the following command (where <username> is *cli* or *guardcli1 - guardcli9*):

```
reset password cli_user <username>
```

Note:

- The *rescue* user passkey is immediately reset after a successful log in. However, if the console times out before the rescue passkey is decoded and used, simply log in again as the *rescue* user and the same passkey is displayed.
- The *rescue* user can also retrieve passkeys or reset passwords for the *root* and *cloudsupport* users using commands equivalent to a standard CLI account:

Rescue command	CLI command
show passkey root	support show passkey root
show passkey cloudsupport	support show passkey cloudsupport
reset password root	support reset-password root
reset password cloudsupport	support reset-password cloudsupport
reset password cli_user	n/a

Aggregation

These sections present troubleshooting and solutions for common problems with aggregation.

- [Cannot convert Guardium collector to aggregator](#)

If you cannot convert a Guardium collector to a Central Manager aggregator, reinstall Guardium and select aggregator during installation.

- [Data Export configuration change from a Guardium managed system's GUI fails with error](#)
If a Data Export configuration change fails, make sure that the shared secret key is the same on the collector and aggregator.
- [Difference between audit process results and report](#)
If there is a difference between your audit process results and the report, check that all appliances are set to the same timezone.
- [HY000 errors after restoring the configuration in an aggregator](#)
If you receive HY000 errors after you restore the configuration in an aggregator, run a dummy import.
- [UI banner warning: Data not exported or archived](#)
- [Health alerts and UI banner warning: Old partitions found](#)

Cannot convert Guardium collector to aggregator

If you cannot convert a Guardium collector to a Central Manager aggregator, reinstall Guardium and select aggregator during installation.

Symptoms

You try to convert a Guardium collector to an aggregator with the command **store unit type manager aggregator**.

However, the following command shows that the unit type is still listed as manager.

```
> show unit type  
Manager
```

Causes

A collector cannot be converted to an aggregator with a CLI command.

Environment

Guardium collectors are affected.

Resolving the problem

To convert a collector to an aggregator, reinstall the Guardium product and select aggregator as the unit type during installation. After you install the aggregator, you can convert it to a central manager aggregator with the command **store unit type manager**.

Data Export configuration change from a Guardium managed system's GUI fails with error

If a Data Export configuration change fails, make sure that the shared secret key is the same on the collector and aggregator.

Symptoms

You attempt to save new settings for the data export and get the error when you click Apply to save the configuration:

Please correct the following errors and try again:
A test data file could not be sent to this host with the parameters given. Please confirm the hostname or IP address is entered correctly, the host is online, the target directory exists and can be written to by the user given, and the password given is correct for that user.

Causes

Guardium attempts to log in with scp to the target host with the user and password that are specified in the Data Export configuration. Then, Guardium attempts to copy a test file to the target directory. The shared secret on this system does not match the Shared Secret on the aggregator you are trying to set this system to export to.

Environment

The Guardium configurations: collector and aggregator are affected.

Resolving the problem

Make sure that the shared secret key is the same on the collector and aggregator. You can use one of the following methods:

1. If you know the shared secret on the aggregator, set the shared secret on the collector to the same value. You can use one of these methods:
 - From CLI: use command **store system shared secret** to set the Shared secret key
 - From GUI, set the shared secret key under Setup->System->System Configuration.
2. Back up the current shared secret on the aggregator and restore it to the collector.
 - On the aggregator, run the CLI command.

```
aggregator backup keys file <user@host:/path/filename>  
Parameters  
user@host: /path/filename
```

For the file transfer operation, specify a user, host, and full path name for the backup keys file. The user that you specify must have the authority to write to the specified directory.

- On the collector, run this command to restore the shared secret key:

```
aggregator restore keys file<user@host:/path/filename>
```

3. Reset the shared secret for both appliances to be the same.

Note: If you change the shared secret for the aggregator, you need to reset the shared secret for all other Guardium systems that export to it.

Difference between audit process results and report

If there is a difference between your audit process results and the report, check that all appliances are set to the same timezone.

Symptoms

You set a report to run on the aggregator as part of an audit process with time parameters, for example, Start of Last Day and End of Last Day. When you look at the results of that report, the first time stamps are always at a set time after 00.00 for example, 02.00. Additionally the last time stamps are always at a set time before 23.59 for example, 21.59. However, when you run the report interactively, the time stamps are shown as expected.

Causes

The collector and aggregator time zones might not be set the same.

Environment

The aggregator is affected.

Diagnosing the problem

Check that all appliances are set to the same timezone. Use the following command. `show system clock timezone`.

Resolving the problem

If the collector and aggregator are not set in the same timezone, configure the timezone of the appliances with the CLI.

```
store system clock timezone list  
store system clock timezone <timezone>
```

Verify that the time is correct on the appliance with the following commands.

```
show system clock datetime  
store system clock datetime
```

You can also synchronize the datetime by using the following commands to manage the time server.

```
show system time_server all  
store system time_server state  
store system time_server hostnames
```

HY000 errors after restoring the configuration in an aggregator

If you receive HY000 errors after you restore the configuration in an aggregator, run a dummy import.

Symptoms

When you restore the configuration of an aggregator or the Central Manager, you receive one or both of these messages.

```
ERROR 1031 (HY000) at line 1: Table storage engine for 'GUARD_USER_ACTIVITY_AUDIT' doesn't have this option  
ERROR 1031 (HY000) at line 1: Table storage engine for 'AGGREGATOR_ACTIVITY_LOG' doesn't have this option
```

Causes

This error condition can occur if there is a temporary mismatch in the internal databases.

Environment

The collector and aggregator are affected.

Resolving the problem

To resolve the problem, run a dummy import.

UI banner warning: Data not exported or archived

Symptoms

After logging into Guardium UI, a banner warning shows Data not exported or archived: [n] days have not been exported or archived and do not meet the purge criteria. Export or archive process failures may be seen in the UI Aggregation/Archive log, and the Days not exported or archived report may indicate missed days.

Causes

Days older than the purge period plus 30 days exists on the system and has not been exported or archived. Allow purge without exporting or archiving is not selected.

Environment

The condition may apply to Guardium collectors and aggregators.

Resolving the problem

1. Check the Days not exported or archived report. For more information, see [Viewing days whose data was not archived or exported](#).
Note: Note this report shows all days that have not been exported or archived. It is not limited to days older than purge age plus 30 days.
2. Decide whether you need to export or archive any of the days indicated in the report, considering the days age and contents.
3. Using the Archive data older than and Ignore data older than values from the report, export or archive the appropriate days. Or, if the days indicated in the report are not needed, select Allow purge without exporting or archiving and run the purge.

Health alerts and UI banner warning: Old partitions found

Symptoms

The condition is marked by the following symptoms:

- The Deployment Health Dashboard on a central manager shows events with the name Old Partitions Found. The events may come from one or many managed units or from the central manager itself.
- After logging into the Guardium UI, a UI banner warning shows Old partitions found: Oldest partition found: p[date].

Causes

The symptoms appear when old partitions exist on the internal system database. The severity of the alert corresponds to the age of the partitions, and the default values are as follows:

- Medium severity: partitions older than the purge age plus 62 days
 - A UI banner warning shows on all systems with a medium severity alert
- High severity: partitions older than the purge age plus 120 days
- Critical severity: partitions older than the purge age plus 240 days

The purge period of the system is shown on the Data Archive page of the Guardium UI, and the date of the oldest partition is shown in the details section in the format YYYYMMDD.

Note: The purge period is based on the ADDITIONAL_PURGE_AGE parameter. The default value is 60 days. Do not change this value without consulting Guardium support. There are several possible root causes for having old partitions on the system, for example:

- Days have not been archived or exported and therefore have not been purged
- Invalid timestamps are causing data to not be purged
- There are corrupted partitions that cannot be dropped by the purge process

Environment

The condition may apply to Guardium collectors, aggregators, and central managers.

Resolving the problem

Resolve the problem using the following guidance:

1. Resolve any existing Data not exported or archived: [n] days have not been exported or archived and do not meet the purge criteria UI banner warnings. These warnings will appear on units where days have not been exported or archived. For more information, see [UI banner warning: Data not exported or archived](#)
2. Upgrade to latest patch bundle. Known cases where purge could not clear partitions may be resolved in latest version.
3. If problem remains, resolution may depend on several factors:
 - How much data is on the Guardium system
 - How many old partitions exist
 - The root cause explaining the old partitions
 - Whether you have previously attempted to clean up the old partitions
 - How many Guardium systems are affected

Contact Guardium support to begin resolving this issue. Provide the following must gather information:

- support must_gather patch_install_issues

- support must_gather agg_issues
- support must_gather system_db_info

Note: The following document contains an internal section that Guardium support can consult to resolve the problem: [IBM Security Guardium v10.0p9998 health check errors - Data older than purge period or Old partitions found.](#)

Internal database

These sections present troubleshooting and solutions for common problems with the internal database.

- [Why is the Guardium internal database is filling up?](#)
If the Guardium internal database is filling up, you can purge the data manually or as part of the regular purge strategy.
- [Managed unit database is filling up](#)
Learn what you can do if your system database is filling up.
- [How to purge off some old audit results from the Guardium appliance](#)
The database is full. Old audit results need purging from the Guardium Appliance.
- [Resolving internal database full problems](#)
The Guardium internal database full percentage is not decreasing, even after a successful purge. Reclaim database space with **OPTIMIZE**.

Why is the Guardium internal database is filling up

If the Guardium internal database is filling up, you can purge the data manually or as part of the regular purge strategy.

Symptoms

- Cannot log in to GUI.
- tomcat error on GUI.
- Size of DB from System View approaching 100%.
- Receiving alerts that indicate the database size is getting larger.

Causes

The Guardium internal database can fill up for many reasons. For more information about a general approach to resolving the situation, see: [Managed unit database is filling up](#). Use the guidelines in [Resolving the problem](#) along with [Managed unit database is filling up](#) to help resolve the problem. If you are unable to take any of the actions, use the general steps in [Managed unit database is filling up](#) to lower the database size.

The reason that the internal database fills up can often be determined by analyzing the largest tables in the database. Each table has different processes that cause it to grow and different strategies for managing its size.

Resolving the problem

1. Check the largest tables in CLI. Enter: `support show db-top-tables all`
Example output:

Table	Size (M)	I/D %	Unused(M)	Est. Rows	Name
132526	17	22621	46144369	GDM_CONSTRUCT_TEXT	
20669	213	25	6738570	GDM_CONSTRUCT_INSTANCE	
19399	126	11	1051215	GDM_POLICY_VIOLATIONS_LOG	
1038	241	4	254991	REPORT_RESULT_DATA_ROW	
987	172	24	166504	GDM_SESSION	
860	29	0	516276	GDM_FIELD	
743	248	7	90036	GDM_OBJECT	

2. Start with your largest table. Use the actions to help reduce the size in the long term. The most common largest tables are listed here, with the causes for filling up, and the actions to stop the problem in the long term. The list is not exhaustive. Use this information along with an overall purging strategy.

GDM_CONSTRUCT_TEXT

Cause

- All data that is captured by a policy rule with Log full details action is written to this table.

Actions

- Use Log full details as little as possible in the policy. If this table is constantly filling up, review your reports and policy definition to ensure you are not capturing excess traffic with this action.

GDM_POLICY_VIOLATIONS_LOG

Cause

- All policy rules with alerting action, except Alert only write to this table, and they send alerts by the defined method (for example, Syslog). Correlation alerts log to this table if Log policy violation is selected in the definition.

Actions

- Review the alerting rules in your policy. Ensure that they are not alerting excessively, for example alert per match is not used simultaneously with alert once per session. If data needs to be forwarded to remote SIEM, but not seen in Guardium reports, use the action alert only.
- Check in the policy violations report Comply>Reports>Incident Management for the most common alerts. A recent change in the environment might cause a spike in alerts. For example, a new application might create thousands of failed login requests. Investigate the cause of the most common alerts and modify the policy if appropriate.

REPORT_RESULT_DATA_ROW

Cause

- The results of audit processes are stored in this table. They are only purged when:

- They are cleared from all receiver to-do lists.
- The conditions for removal in the definition are met. (By default the results of the last five runs are kept)

This table is not purged by a purge that is started in the GUI.

Action

- See [How to purge off some old audit results from the Guardium appliance](#).

One or more of GDM_CONSTRUCT, GDM_FIELD, GDM_OBJECT, GDM_SENTENCE

Cause

- The exception table can be filled with Guardium created exceptions (for example - parser errors) or exceptions from the monitored database (for example - SQL errors).

Actions

- Many types of exceptions are logged in this table. The first step is to identify which are the most common. You can use predefined reports in the Exceptions domain to find which exceptions are most common.
- The report Exceptions Type Distribution shows the number of each exception. Double-click the chart to drill down into further details, like a breakdown per server or client. You can also define your own query in the Exceptions Tracking domain. If the exceptions are coming from monitored traffic, consult with the service owner of that traffic in your organization. If not, you can contact Guardium support with details of your investigation.

Managed unit database is filling up

Learn what you can do if your system database is filling up.

Symptoms

- Cannot log in to GUI.
- tomcat error on GUI.
- The Used Disk: in the DB Utilization of the System Monitor page is approaching 100%.
- Receiving alerts that indicate the database size is getting larger.

Causes

Common causes are:

- Spikes in the captured data.
- A policy setting that allows logging of too much data in the internal database.
- Keeping too many days of data on the internal database.
- Collecting data from too many S-TAPs.

Resolving the problem

The quickest way to reduce the Used Disk: is to induce a purge of some older data now.

In this scenario Purge data older than 30 days is set, and you have all necessary backups and archives of your system. Now you want to purge off slightly more data.

1. Note the current Used Disk: in the DB Utilization of the System Monitor page.
2. Go to Manage > Data Management > Data Archive.
3. Set Purge Data Older than to 25 days.
4. Verify that the Purge checkbox is checked.
5. Verify that the Archive checkbox is cleared.
6. Verify that the Allow purge without exporting or archiving is checked.
7. Click Run Once now.
8. Check progress of the purge in Reports > Guardium Operational Reports >> Aggregation/Archive Log.
 - a. Right-click the Archive and select detail log.
 - b. Review the status of the purge process in the log.
9. When the purge is finished, note the current Used Disk: in the DB Utilization of the System Monitor page.

If the difference in the Used Disk: is in the right direction, then consider running the commands again for slightly fewer days. For example, purge older than 20 days.

- Remember to check the Archive checkbox when you complete these ad hoc purges.

Looking at the causes for this problem you might want to also consider:

- See the [Why is the Guardium internal database is filling up](#).
- Amend the policy to capture only the necessary data. For example, not all cases require capturing Full SQL.
- Switch one or more of the S-TAPs to another collector
- Amend the Archive and Purge settings to purge more data off each day.
- Ensure that the Schedule is set to run once per day.
- After you purge data, you might need to optimize the database. See [Resolving internal database full problems](#).
- If that does not help or you cannot access the GUI, contact Guardium Support.

How to purge off some old audit results from the Guardium appliance

The database is full. Old audit results need purging from the Guardium Appliance.

Symptoms

The database is full.

Causes

Normal purging of audit results is set in the audit process definition by the Keep for a minimum of x days or y runs option. Normal purging of audit results does not occur if the items in the Audit Process To-Do List were not handled or signed off. For example, if the To-Do List has items from 6 months ago, then no audit results since 6 months ago are purged.

Resolving the problem

Users must handle their To-Do Lists in a timely fashion, so the purging happens and the database does not fill up. Adding a Receiver is not mandatory when you create a new Audit Process. An Audit Process without a receiver can be used when results of the Audit Process are sent to the third-party application, and the Audit Process results do not need to be viewed or signed. If you still want to add a receiver but not require viewing or signing the Audit Process results, clear the To-Do List checkbox, but set the Email format field to Full Results (PDF or CSV). In this scenario, the status gets set to VIEWED and the receiver does not have to view the results to make them eligible for purge. If the To-Do List checkbox is cleared but the Email format field is set to None or Links only, the To-Do entry is created for the receiver because:

- These types of notifications do not set the status to VIEWED.
- The results cannot be purged.

The internal Guardium table **REPORT_RESULT_DATA_ROW** often gets large if the audit jobs or To-Do Lists are not handled or signed off.

Manual purge command

This command is a way to manually purge audit results. Use it only if the normal audit results purge is not working. It is recommended to contact Technical Support to understand why normal purge is not working. Use this command only when absolutely necessary to deal with audit tasks that produce a high number of records and take up too much disk space. Consult with Technical Support before you run this command. The response includes a warning message and a confirmation step.

- support clean DAM_data audit_results <start_date> <end_date>
- support clean DAM_data audit_results <end_date>

Resolving internal database full problems

The Guardium internal database full percentage is not decreasing, even after a successful purge. Reclaim database space with **OPTIMIZE**.

Symptoms

You can see whether the internal database is full in a number of ways:

- You recently purged data off the system but the data % did not decrease.
- The response to the CLI command **support show db-top-tables all** shows that the total size of the largest tables is much smaller than the total disk space available for the database.
- The syslog has messages that report a full database.
- Output of CLI command: **support show db-status used %**
- Mysql Disk Usage column in GUI>Guardium Monitor>Buffer Usage Monitor report.
- The output to the CLI command **support show db-top-tables all** shows a large amount of unused space (**Unused (M)**) in some tables.

Causes

The purge removed the data from the database, but did not necessarily reduce the size of the database files. Some database tables might need to be optimized to make the newly cleared space available.

Diagnosing the problem

Check the largest tables and database full percentage before and after you purge data by using CLI commands:

- support show db-status used %
- support show db-top-tables all

After the purge the largest tables sizes decreased significantly, but the database full % did not change. Also, the database might have a large amount of unused space. The numbers in this example are on a small test system. The columns, specifically the **Unused (M)**, shows how many Megabytes can be reclaimed. In this example, 7 MB of space can be reclaimed from **GDM_CONSTRUCT_TEXT**.

```
xxx.yyy.zzz.com> support show db-top-tables all
Table Size (M) | I/D % | Unused(M) | Est. Rows | Name
----- | ----- | ----- | ----- | -----
 1616 |    28 |      0 | 6038005 | REPORT_RESULT_DATA_ROW
   121 |    51 |      7 | 336557 | GDM_CONSTRUCT_TEXT
    13 |   223 |      4 | 21834 | GDM_CONSTRUCT_INSTANCE
     8 |    20 |      0 | 65149 | DB_ERROR_TEXT
```

Resolving the problem

Note: In live environments, it is only recommended to optimize when significant space (for example, 20 GB or more) can be reclaimed.

Optimize the internal TURBINE database tables as follows.

Note: The time to complete OPTIMIZE depends on the size of the underlying tables. And OPTIMIZE needs to stop the inspection-core. Run OPTIMIZE during a quiet time and let the command run to completion.

1. If the appliance is a collector, stop the inspection-core in the CLI.

```
stop inspection-core
```

2. Start the optimize process. The process might take up to several hours to complete depending on the size of the database tables. You can optimize the database in one of two ways.

- Optimize all tables, in the CLI, enter: diag, 4. Perform Maintenance Actions, 2. TURBINE Optimize.
- Optimize specific tables only. This might be appropriate if you know that a certain table has recently been heavily purged, and you can save time optimizing only one table. The CLI command is:

```
support optimize tables <database name> <table name>
```

For example:

```
support optimize tables TURBINE GDM_CONSTRUCT_TEXT
```

3. When the optimize is complete, enter:

```
start inspection-core
```

Example OPTIMIZE of one table that uses this method

You can see that 7 MB is reclaimed after the OPTIMIZE on that table is finished.

```
xxx.yyy.zzz.com> support show db-top-tables all
Table Size (M) | I/D % | Unused(M) | Est. Rows | Name
-----|-----|-----|-----|-----
 1616 |   28 |      0 | 6038005 | REPORT_RESULT_DATA_ROW
 121 |   51 |      7 | 336557 | GDM_CONSTRUCT_TEXT
 13 | 223 |      4 | 21834 | GDM_CONSTRUCT_INSTANCE
 8 |   20 |      0 | 65149 | DB_ERROR_TEXT
```

..etc...

```
No tables with more than 80% of free space used found.
ok
```

```
xxx.yyy.zzz.com> support optimize tables TURBINE GDM_CONSTRUCT_TEXT
This process can take some time, please wait...
Processing GDM_CONSTRUCT_TEXT...
TURBINE.GDM_CONSTRUCT_TEXT optimize note Table does not support optimize, doing recreate + analyze instead
TURBINE.GDM_CONSTRUCT_TEXT optimize status OK
ok
```

```
xxx.yyy.zzz.com> support show db-top-tables all
Table Size (M) | I/D % | Unused(M) | Est. Rows | Name
-----|-----|-----|-----|-----
 1616 |   28 |      0 | 6038005 | REPORT_RESULT_DATA_ROW
 122 |   51 |      0 | 350893 | GDM_CONSTRUCT_TEXT
 13 | 223 |      4 | 21834 | GDM_CONSTRUCT_INSTANCE
 8 |   20 |      0 | 65149 | DB_ERROR_TEXT
```

..etc..

```
No tables with more than 80% of free space used found.
ok
xxx.yyy.zzz.com>
```

Central management

These sections present troubleshooting and solutions for common problems with central management.

- [**A user is disabled in a Guardium managed unit, but shows as enabled on Central Manager**](#)

If a user is disabled in a Guardium managed unit but shows as enabled on Central Manager, run the Portal User Sync.

- [**Central Manager does not recognize the new version of upgraded units**](#)

If the Central Manager does not recognize the new version of upgraded units, select the upgraded units and refresh the page.

- [**Scheduled tasks do not fire at the scheduled time**](#)

If scheduled tasks do not fire at the scheduled time, schedule the import time to run after the portal user sync.

- [**Torque exception in Central Management view of GUI**](#)

If there is a torque exception in Central Management, delete the custom group and create a new group.

A user is disabled in a Guardium managed unit, but shows as enabled on Central Manager

If a user is disabled in a Guardium managed unit but shows as enabled on Central Manager, run the Portal User Sync.

Symptoms

A user is disabled in the managed unit. The user's account is re-enabled in the Central Manager but the user is still showing as disabled in the managed unit. The user's account shows as enabled in the Central Manager.

Causes

The user's account in the Central Manager is not synchronized with the managed unit.

Environment

A combination of the Central Manager, collector, or aggregator might be affected.

Resolving the problem

To synchronize the current user status between the Central Manager and the managed unit, run a Portal user sync.

1. Log in to the Central Manager as an admin user.
2. Click [Manage > Central Management > Portal User Sync](#) to open the Portal User Synchronization.
3. Click Run Once Now.

If the user's account between the managed unit and the Central Manager is still not synchronized, contact the IBM Guardium Technical Support for assistance.

Central Manager does not recognize the new version of upgraded units

If the Central Manager does not recognize the new version of upgraded units, select the upgraded units and refresh the page.

Symptoms

The Central Manager might not immediately recognize the new version of an upgraded aggregator or collector it manages. Pushing a patch from the Central Manager, which requires the new version, can result in an error that shows the unit is still at the previous version.

The managed unit's old version still displays in the Central Management view of the GUI. The unit ping times in that view, which implies good communication between the Central Manager and managed units.

Causes

The GUI needs to be refreshed to pull the new version information.

Environment

The Guardium Central Manager is affected.

Resolving the problem

In the Central Management view of the GUI, select the upgraded units and push Refresh. This action pulls the new version information from the units.

Scheduled tasks do not fire at the scheduled time

If scheduled tasks do not fire at the scheduled time, schedule the import time to run after the portal user sync.

Symptoms

Import fails and you receive the following message in agg_progress.log.

```
* 05/20 04:00:01 --- Import cannot start  
(guard_agg|turbine_backup.sh|restore_from_file.pl already running)  
* 05/20 20:00:46 --- Merge cannot start - aggregation still active
```

Causes

There is a conflict with the Central Manager portal user sync.

Environment

The aggregator is affected.

Diagnosing the problem

Find out which task is running in the background. Click [Reports > Guardium Operational Reports > Aggregation/Archive Log](#) to open the Aggregation/Archive Log.

Resolving the problem

To resolve the problem, schedule the import time to run after the portal user sync. Run the portal user sync every hour and the import time 30 minutes after that time.

Torque exception in Central Management view of GUI

If there is a torque exception in Central Management, delete the custom group and create a new group.

Symptoms

Selecting a certain custom group in the Central Management view of the Guardium GUI displays an error instead of the managed units in the group.

`org.apache.torque.TorqueException: Failed to select one and only one row.`

After the exception appears, it shows for any group or view under the Central Management tab. The exception even appears for groups that were previously working until you log out of the GUI and log back in.

Causes

This torque exception might occur if one of the managed units in the group was unregistered from the managed unit instead of the Central Manager.

Environment

Guardium Central Manager is affected.

Resolving the problem

Delete the custom group and create a new group that contains the same members.

S-TAPs and other agents

These sections present troubleshooting and solutions for common problems with S-TAPs and other agents.

- [Error opening shared memory area when you configure Guardium COMM_EXIT_LIST for DB2](#)
If you receive an error message when you configure Guardium COMM_EXIT_LIST, authorize the DB2 instance owner with the guardctl command.

- [UNIX S-TAP cannot start: buffer size too large](#)
If a UNIX S-TAP cannot start, its buffer size might be too large.
- [S-TAP does not start automatically on Linux](#)
If the S-TAP agent for DB2 or Oracle does not start automatically on Linux, check for the /etc/event.d/ directory.
- [S-TAP returns not FIPS 140-2 compliant](#)
If you receive an error that about FIPS 140-2, change the configuration through the S-TAP Control page.
- [The K-TAP kernel module is still present after the uninstallation of S-TAP](#)
If the K-TAP kernel module is still present after the uninstallation of S-TAP, manually remove it.
- [Windows S-TAP service crashes on startup with error ID 1000](#)
If the S-TAP crashes with error ID 1000, check the SOFTWARE_TAP_IP parameter in the guard_tap_ini configuration file.
- [S-TAP is not capturing A-TAP traffic](#)
Use the A-TAP script to output detailed information on the A-TAP configuration.
- [Linux S-TAP is not capturing Db2 exit traffic](#)
Use the Db2 exit health check script to check and optionally fix the Db2 IE parameters.
- [Insufficient memory when installing UNIX S-TAP](#)
If you receive the following error: `modprobe: ERROR: could not insert 'ktap': Cannot allocate memory`, your system might not have enough memory.

Error opening shared memory area when you configure Guardium COMM_EXIT_LIST for DB2

If you receive an error message when you configure Guardium COMM_EXIT_LIST, authorize the DB2 instance owner with the guardctl command.

Symptoms

After you configure **DB2 COMM_EXIT_LIST** to use Guardium **libguard** and restart the DB2 server, you get the following error in the DB2 diag log.

```
2013-06-28-11.41.12.306169-300 E870950E486 LEVEL: Severe  
PID : 15764 TID : 139905833363200 PROC : db2sysc 0  
INSTANCE: db2001 NODE : 000
```

```
APPHDLL : 0-16
HOSTNAME: dbhost1
EDUID : 54 EDUNAME: db2agent () 0
FUNCTION: DB2 UDB, DRDA Communication Manager, sqljcCommexitLogMessage,
probe:234
DATA #1 : String with size, 91 bytes
WARNING: Shmem_access /.guard_writer0 failed Error opening shared memory area errno=2 err=8
```

Causes

The following message indicates that the Guardium library was unable to create the shared memory device that it requires.

```
Shmem_access /.guard_writer0 failed
Error opening shared memory area
errno=2
err=8
```

The DB2 instance owner must be added as an authorized user using the **guardctl** command.

Environment

Guardium collectors that use DB2 Exit (Version 10) Integration with S-TAP are affected.

Resolving the problem

The DB2 instance owner must be added as an authorized user by using the **guardctl** command.

1. Stop the DB2 instance.
2. Authorize the DB2 instance owner.
3. Start the DB2 instance.

If the Guardium Installation Manager (GIM) is not installed, authorize the DB2 instance owner with the following command.

```
<guardium_installdir>/bin/guardctl
authorize-user<db2 instance owner>
```

If the Guardium Installation Manager (GIM) is installed, authorize the DB2 instance owner with the following command.

```
<guardium_installdir>/modules/ATAP/current/files/bin/guardctl
authorize-user<db2 instance owner>
```

For example, if the DB2 instance owner is db2001 and GIM is installed in /usr/local/guardium, the command is
`/usr/local/gim/modules/ATAP/current/files/bin/guardctl`
`authorize-user db2001`.

Guardium fails to collect shared memory traffic from Informix

If Guardium fails to collect shared memory traffic from Informix, check the inspection engine configuration.

Symptoms

Guardium S-TAP does not collect shared memory traffic from Informix.

Causes

The inspection engine is not correctly configured.

Environment

Any S-TAP collection from any Informix system can be affected.

Resolving the problem

Check the inspection engine configuration under [Manage > Activity Monitoring > S-TAP Control](#). Ensure that the value in the Process Name field matches the result of the following command on the database server.

```
ls -lrt /INFORMIXTMP/.inf.*
```

Informix: /INFORMIXTMP/.inf.sqlexec Applies to all Informix platforms but Linux. For Informix with Linux, example: /home/informix11/bin/oninit

Informix must be running for this command to return a value.

For Linux servers using A-TAP, A-TAP must be configured to collect any shared memory traffic. Set the value to the same value as the --db-info parameter in the A-TAP configuration before you activate A-TAP.

High CPU and I/O Use in Guardium S-TAP host

If you observe a high CPU or I/O usage, review the configuration for all of the inspection engines.

Symptoms

You observe a high CPU or I/O usage by the Guardium S-TAP process.

Causes

The following items are common causes.

1. An error in the configuration of one of the inspection engines. If there are errors in an inspection engine, the S-TAP process restarts frequently or tries to reconnect to the inspection engine repeatedly.
2. The K-TAP portion of the S-TAP is sending connection information along with a confirmation request to the S-TAP. This step is causing delays.
3. ORACLE RAC is used, but the **unix_domain_socket_marker** parameter is not set in the S-TAP configuration file to avoid monitoring potentially large amounts of Oracle RAC traffic.
4. The User ID Chain (UID chain) feature is enabled, for example, **parameter hunter_trace=1** in the S-TAP configuration file. Hunter trace is used for UID chain and can be quite CPU intensive for S-TAP.
5. The firewall is enabled (**firewall_installed=1**). This firewall forces S-TAP to request verdicts for each new session that is observed which can hurt S-TAP performance.

Environment

All S-TAPs

Resolving the problem

Based on the cause, take the corresponding actions.

1. Review the configuration for all of the inspection engines and make sure that there are no errors in any of the parameters. For example, make sure the database installation directory, executable, ports, and any other parameters applicable to your inspection engine are correctly set with no misspellings or wrong values.
2. Set S-TAP configuration parameter **ktap_fast_tcp_verdict** to 1 (**ktap_fast_tcp_verdict = 1** in the **guard_tap.ini** configuration file) and restart the S-TAP. Here are the possible settings.
ktap_fast_tcp_verdict=0: KTAP confirms that the session is the database connection that the inspection engine configured by checking ports and Ips.
ktap_fast_tcp_verdict=1: KTAP does not send the request to S-TAP while the session's ports are in the range.
3. Disable the UID Chain feature if not needed by setting **hunter_trace=0** and restarting the S-TAP.
4. Set **firewall_installed=0** if SGATE is not needed and restart the S-TAP.

UNIX S-TAP cannot start: buffer size too large

If a UNIX S-TAP cannot start, its buffer size might be too large.

Symptoms

The S-TAP cannot start and issues the following messages:

```
mmap: Not enough space  
Can't initialize: Can't mmap buffer file /tmp/stabbuf/192.168.100.107.0.buf  
Error Initializing: Stab cannot initialize SQLGuard queue
```

Causes

The S-TAP is unable to allocate enough memory to match the buffer file.

Resolving the problem

Reduce the buffer file size for the S-TAP. The size is specified in the **buffer_file_size** parameter in the **guard_tap.ini** file.

You can also use the following formula to calculate the total memory that is used by the S-TAP buffers:

number of sqlguard main connections * buffer_file_size

For example, if you have 3 connections and **buffer_file_size** is set to 1 GB, then you need a total of 3 GB of memory for S-TAP buffers (3 *1GB = 3GB).

S-TAP does not start automatically on Linux

If the S-TAP agent for DB2 or Oracle does not start automatically on Linux, check for the **/etc/event.d/** directory.

Symptoms

The S-TAP process does not automatically start on Linux even though the **/etc/inittab** file shows a correct U-TAP entry.

Causes

Various Linux distributions such as RedHat 6 deprecated the use of the traditional init daemon that uses the etc/inittab file. They replaced it with an init process called upstart. Upstart uses the /etc/event.d and /etc/init directories for the automated start, stop, and respawn of processes such as U-TAP.

The S-TAP installer now checks for the existence of the /etc/event.d directory. If it exists, then entries in /etc/init are created for use by upstart. If it does not exist, then entries in /etc/inittab are created for use by the traditional init daemon.

If /etc/event.d is missing for any reason on a system with upstart, the inittab file is populated instead. The S-TAP process does not start or respawn when needed.

Environment

S-TAPs running on Linux are affected.

Resolving the problem

Check for the existence of the /etc/event.d/ directory.

If the /etc/event.d/ directory does not exist, complete the following steps to resolve the situation.

1. Uninstall the existing S-TAP installation.
2. Create the /etc/event.d dir as user root (mkdir /etc/event.d) .
3. Install the S-TAP.

S-TAP returns not FIPS 140-2 compliant

If you receive an error that about FIPS 140-2, change the configuration through the S-TAP Control page.

Symptoms

Supported: - Solaris X86 - Linux x86/64 - Linux x86/32 - Linux S390X - Linux IA64

Not Supported: - Solaris SPARC - AIX PowerPC - HPUX RISC - HPUX IA64 - Linux PowerPC

You see the following message in the S-TAP event log.

```
LOG_ERR: To enable FIPS  
140-2 mode set use_tls=1
```

Causes

FIPS 140-2 is a U.S. government security standard for cryptographic modules. If you see this message, it indicates that the S-TAP configuration does not meet government requirements.

Note: This message does not indicate that there is an error with the S-TAP.

Environment

Guardium S-TAP is affected.

Supported: Solaris X86; Linux x86/64; Linux x86/32; Linux S390X; Linux IA64

Not Supported: Solaris SPARC; AIX PowerPC; HPUX RISC; HPUX IA64; Linux PowerPC

Resolving the problem

To enable FIPS compliance, the guard_tap.ini file must have the following settings.

```
use_tls=1
```

You can change the configuration by using one of the following methods.

1. Click Manage > Activity Monitoring > S-TAP Control.
2. Modify the details section for the relevant S-TAP and use the TLS check boxes.
3. Restart the S-TAP.

You can also edit the guard_tap.ini file on the DB server directly and restart the S-TAP.

The K-TAP kernel module is still present after the uninstallation of S-TAP

If the K-TAP kernel module is still present after the uninstallation of S-TAP, manually remove it.

Symptoms

The K-TAP kernel module is still present after the uninstallation of S-TAP on a Solaris server.

Causes

The server did not restart properly to remove the K-TAP kernel module on Solaris servers.

Environment

Solaris

Diagnosing the problem

Check on the Solaris server by running both **modinfo | grep ktap** and **ls -al /dev/*tap***.

Resolving the problem

Manually remove the K-TAP kernel with the following steps.

1. Check that /etc/init.d/upguard is removed.
2. Remove /kernel/drv/sparcv9/ktap* and /kernel/drv/ktap*.
3. Run **modinfo | grep ktap** to get the name of the loaded driver.
4. Then, run **rem_drv<loaded driver>**. For example: **rem_drv ktap_36821**.
5. Remove /dev/ktap* and /dev/guard_ktap.
6. Restart the server.
7. Run **modinfo | grep ktap** to make sure that the driver is no longer loaded.
8. Remove GIM and gsvr entries from /etc/inittab (if you are using GIM only).
9. Manually clean up remaining files in /usr/local/guardium.

Windows S-TAP service crashes on startup with error ID 1000

If the S-TAP crashes with error ID 1000, check the SOFTWARE_TAP_IP parameter in the guard_tap_ini configuration file.

Symptoms

The S-TAP on a Windows server does not start. The Windows event log shows errors from Guardium S-TAP with event ID 1000.

```
Log Name: Application
Source: Application_Error
Event ID: 1000
Task Category: (100)
Level: Error
Keywords: Classic
Description:
Faulting application name: guardium_stapr.exe, version: 9.0.0.0
Exception code: 0x40000015
```

Causes

S-TAP cannot connect to the Windows system because the wrong SOFTWARE_TAP_IP is specified in the guard_tap.ini file.

Environment

Any Guardium S-TAP for Windows is affected.

Resolving the problem

Ensure the SOFTWARE_TAP_IP parameter in the guard_tap.ini configuration file matches the correct IP address of the Windows server. This parameter is passed on the installation CLI or in the IBM® Guardium® Installation Manager (GIM) parameters.

S-TAP is not capturing A-TAP traffic

Use the A-TAP script to output detailed information on the A-TAP configuration.

Symptoms

A-TAP traffic is not getting reported to Guardium.

Causes

Incorrectly configured IE parameters can prevent transmission of A-TAP traffic to the Guardium system.

Environment

Linux-type database server.

Resolving the problem

Use the A-TAP script to output details of the A-TAP configuration. The script is named **atap_must_gather.sh**. The script is located in the `guard_stap` bin directory. You can run it from anywhere with the full path.

The script runs a health check on each activated DB. The script output is written to a text file in the local `/tmp` directory, for example `/tmp/atap_must_gather.18-11-20_152824.txt`. Send this file to IBM Technical Support.

Linux S-TAP is not capturing Db2 exit traffic

Use the Db2 exit health check script to check and optionally fix the Db2 IE parameters.

Symptoms

Db2 Exit traffic is not getting reported to Guardium.

Causes

Incorrectly configured IE parameters can prevent Db2 Exit traffic from getting reported to the Guardium system.

Environment

Linux environment using Db2 Exit.

Resolving the problem

Use the Db2 exit script to check the Db2 IE configurations, and optionally to make any required fixes identified by the script. The script is located in the `guard_stap` bin directory. You can run it from anywhere with the full path. The script has two options: `./db2_exit_health_check.sh [check | fix]`

By default it performs the health check only. The fix option rectifies any IE parameters errors identified by the script. The script runs a health check on each DB section, performing the following:

1. Find exit ie in `guard_tap.ini` file
2. Validate `db_install_dir`
3. Find the db user and group
4. Check if the db user is authorized
5. Check if `db_install_dir` matches with `DB2_HOME` or `DB2 HOME`
6. Check if DB2 EXIT LIB is in place correctly
7. Check permission of DB2 EXIT LIB path and DB2 EXIT LIB
8. Check if DB2 EXIT LIB is updated with currently installed S-TAP
9. Check if DB2 EXIT LIB is loaded

The script output lists the problems found for each IE, and if you used the fix option, it presents the problem (`ERROR`), the corrective action taken (`ACTION`) and the results of the corrective action. The output for a properly configured DB2 IE is `DB2 Exit IE in <DB name> has a GOOD setup.`

User response: Optional. When you have particular actions that are performed by particular users, use one or more of the `ts*Response` elements.

Insufficient memory when installing UNIX S-TAP

If you receive the following error: `modprobe: ERROR: could not insert 'ktap': Cannot allocate memory`, your system might not have enough memory.

Symptoms

When trying to install S-TAP, K-TAP fails with the following error `modprobe: ERROR: could not insert 'ktap': Cannot allocate memory`.

Causes

The K-TAP installation can fail when the kernel has insufficient memory. This kind of error usually indicates that there is system resource issue on the server.

Environment

Any Guardium Linux-UNIX S-TAP.

Resolving the problem

Make sure that your system has sufficient kernel memory allocated.

Collectors

These sections present troubleshooting and solutions for common problems with collectors.

- [Nanny process is killing sniffer](#)
If the nanny process is killing the sniffer, you might have too much traffic coming in.
- [Sniffer cannot connect to UNIX S-TAP](#)

Nanny process is killing sniffer

If the nanny process is killing the sniffer, you might have too much traffic coming in.

Symptoms

A message similar to the following is reported one or more times in Guardium system log (messages) or Alerts:

Nanny process error condition. The nanny process killed the sniffer. VmData was *number* and was over the limit.

Causes

The sniffer memory usage reached over 90% of the available memory and the nanny process has restarted it, which is expected behavior of the product.

Environment

Guardium collector

Resolving the problem

If you are observing this message frequently, there is too much traffic coming to the Guardium system. Reduce traffic to this Guardium system to resolve this message. For example, you may move some STAPs to a collector with less load, ignore some traffic in your policy, or implement load balancing to spread the traffic among more than one collector.

If the message is observed on very few occasions, it is most likely a momentary spike in traffic. To resolve the message, identify the reason for the spike and avoid the trigger. For example, you can review which processes were running at that time, identify the ones generating more traffic. If this message always coincides with a particular process or processes running, reduce the concurrent traffic at that time. For example, you can move heaviest process to run at a different time, or ignore some of this traffic through a policy.

Sniffer cannot connect to UNIX S-TAP

Symptoms

When you specify a different number of threads, such as 20, by using the command `snif -t 20`, the sniffer cannot connect to the UNIX S-TAP. In the GUI console, the status of the S-TAP is inactive.

Causes

The sniffer starts with six threads by default. When the number of threads exceeds the limitation, the sniffer cannot connect to the UNIX S-TAP because of undefined behavior.

Environment

UNIX S-TAP is affected.

Resolving the problem

Reduce the number of threads to make sure that the connection can be established successfully.

Troubleshooting Guardium Installation Manager (GIM)

These sections present troubleshooting and solutions for common problems with GIM.

- [Error installing the Guardium Installation Manager \(GIM\)](#)
If GIM does not install properly, create the directory manually.
- [Guardium Installation Manager \(GIM\) service does not start in Windows](#)
If the Guardium Installation Manager (GIM) service does not start in Windows, reinstall GIM in a folder that is reserved for 32-bit applications.

Error installing the Guardium Installation Manager (GIM)

If GIM does not install properly, create the directory manually.

Symptoms

When you attempt to install the Guardium Installation Manager (GIM) on RHEL6, you see the following error message.

```
cp:  
cannot stat '/usr/local/GIM/modules/central_logger.log': No such file  
or directory Installation failed
```

Causes

Various Linux distributions such as RedHat 6 deprecated the use of the traditional init daemon that uses the etc/inittab file. They replaced it with an init process called Upstart. Upstart uses the /etc/event.d and /etc/init directories for the automated start, stop, and respawn of processes.

Environment

The Guardium Installation Manager (GIM) is affected.

Resolving the problem

To fix the issue, complete the following steps.

- Remove the partial GIM installation.
- Create the /etc/event.d directory manually with the command **mkdir /etc/event.d**
- Run the GIM installer.

Guardium Installation Manager (GIM) service does not start in Windows

If the Guardium Installation Manager (GIM) service does not start in Windows, reinstall GIM in a folder that is reserved for 32-bit applications.

Symptoms

After you successfully installed the Guardium Installation Manager (GIM) on Windows, you notice that the service is not running.

Causes

GIM is a 32-bit application. If you are using a Windows 64 bit, GIM might be installed in Program Files instead of Program Files(x86).

Environment

GIM is affected.

Resolving the problem

Install GIM in Program Files(x86) because it is a Windows folder that is reserved for 32-bit applications.

File activity

These sections present troubleshooting and solutions for common problems with file activity and classification.

- [File activity is not logged in investigation dashboard or reports](#)
- [File activity from removable disk is not logged in investigation dashboard](#)
- [File activity appears in reports but not the investigation dashboard](#)
- [Some files missing from classification results](#)
- [Partial file discovery \(entitlement\) results in reports and investigation dashboard](#)
Reports and investigation dashboard are not showing complete discovery (entitlement) results.
- [File classification results are missing from reports and investigation dashboard](#)
- [File activity logs](#)
Learn where the File activity monitoring (FAM) log files are located.
- [FAM bundle fails to install](#)
After installing the GIM client, the FAM bundle installation fails.

File activity is not logged in investigation dashboard or reports

Symptoms

There is no file activity logged in the investigation dashboard or predefined reports, such as: File Activities, File Entitlement, Files Count of Activity Per Client, Files Count of Activity Per Server, Files Count of Activity Per User, Files Privileges

Resolving the problem

Check the following:

- Verify the FAM license is installed and on UNIX servers the S-TAP is active.
- Make sure you are not logged in as root in your file server for activities. Activities from root, (UID0) are not logged by default.
- On Linux/AIX, check the file path specified in your policy rule. For example, /testdir/ monitors a file called testdir and not the files in a directory called testdir. Specify /testdir/* to monitor files in the testdir directory.
- On Windows, if you use domains and your policy rule specifies a user, make sure the domain is specified. For example, svldev\Maryjane instead of just Maryjane.

File activity from removable disk is not logged in investigation dashboard

Symptoms

File activity from removable disk is not logged in investigation dashboard

Environment

FAM_SCAN_EXCLUDE_REMOTE_DIRECTORIES is set to true

Resolving the problem

Install the file activity monitoring policy *before* mounting the removable disk.

File activity appears in reports but not the investigation dashboard

Symptoms

You see file activity in the predefined reports, but not in the investigation dashboard.

Resolving the problem

Verify the configuration using the guard API:

- To send crawled data to quick search: `grdapi enable_fam_crawler activity_schedule_interval=2 activity_schedule_units=MINUTE entitlement_schedule_interval=10 entitlement_schedule_units=MINUTE`
- To enable quick search (with option to also include violations): `grdapi enable_quick_search includeViolations=true schedule_interval=2 schedule_units=MINUTE`

Some files missing from classification results

Symptoms

Some files are missing in the classification results.

Causes

The following are file types are *not* supported for classification: DAT, JPG, JPEG, GIF, TIF, TIFF, BMP, WAV, MOV, MP3, MP4, AVI, MPG, WMA, WMV, P7S, XFDL, XFD, FRM, JAR

Partial file discovery (entitlement) results in reports and investigation dashboard

Reports and investigation dashboard are not showing complete discovery (entitlement) results.

Symptoms

The discovery (entitlement) results that appear in reports and investigation dashboard is incomplete. Results for some files do not appear.

Resolving the problem

Verify that the document types and locations are included in your GIM configurations for discovery. Check the following GIM configuration parameters:

- FAM_SCAN_EXCLUDE_FILES
- FAM_SCAN_EXCLUDE_DIRECTORIES
- FAM_SCAN_EXCLUDE_EXTENSIONS
- FAM_SCAN_EXCLUDE_FILES
- FAM_SCAN_MAX_DEPTH

File classification results are missing from reports and investigation dashboard

Symptoms

File classification results are missing from reports and investigation dashboard.

Causes

Classification is an additional process that goes beyond metadata discovery.

Resolving the problem

Assuming your software requirements are met for the IBM Content Classification engine (<http://www-01.ibm.com/support/docview.wss?uid=swg27020838>) that is used for classification, verify the following GIM configurations:

- Ensure that the GIM parameter FAM_IS_DEEP_ANALYSIS= TRUE
- Verify that Decision Plan names are correct in FAM_ICM_CLASS_DECISION_PLANS setting and that the list of Decision Plans is delimited with a semicolon
- Verify that all listed Decision Plans (.dpn) files exist in the following location on the file server: %FAM_HOME%\conf\ContentClassification

User response: Optional. When you have particular actions that are performed by particular users, use one or more of the ts*Response elements.

File activity logs

Learn where the File activity monitoring (FAM) log files are located.

Symptoms

Cannot find FAM logs, or change debug level

Resolving the problem

FAM logs are located in:

- Windows: The FAM agent log file is called StapAT.ctl and resides in C:\Program Files\IBM\Windows S-TAP\Logs. The FAM installer log is C:\IBM Windows S-TAP.ctl drive. The Services logs are named FAMsvc.ctl and FsMonitor.ct, and are located in the log folder under the install path.
- Linux: FAM errors and debug logs are named guard_stap.fam.txt. The default location in UNIX is /tmp, and is configured by tap_log_dir. The debug level is configured by tap_debug_output_level.

FAM bundle fails to install

After installing the GIM client, the FAM bundle installation fails.

Symptoms

When attempting to install the FAM bundle, the system responds with a message similar to:

```
-1,GIM - Failure point : dependencyViolation (Dependency violation (FAM) : Missing mandatory dependency - STAP at GIM.pm line 3176, <MYFILE> line 20.)
```

Causes

The S-TAP bundle must be installed before installing the FAM bundle.

Environment

Relevant only in Linux / UNIX environments.

Resolving the problem

Verify the S-TAP for FAM is installed, then install the FAM bundle. See [Installing and activating file activity monitoring components](#).

Investigation dashboard

These sections present troubleshooting and solutions for common problems with the investigation dashboard.

- [Troubleshooting the investigation dashboard and enterprise search](#)

Use the GuardAPI to diagnose investigation dashboard and enterprise search issues.

Troubleshooting the investigation dashboard and enterprise search

Use the GuardAPI to diagnose investigation dashboard and enterprise search issues.

Symptoms

Enterprise search is enabled but the investigation dashboard is not showing full data; or a datamart is not exporting data as expected.

Causes

Causes can be any of:

- Enterprise search is not enabled.
- Firewall issue prevents communication between the central manager and the managed units.
- SSL exception prevents communication between the central manager and the managed units.
- Hardware on central manager is not sufficient to run enterprise search.
- Datamart is not extracted due to either error or missing schedule.
- Internal Guardium® search engine is down.
- Internal Guardium search engine did not upgrade successfully.

Diagnosing the problem

The GuardAPI command **test_solr** runs diagnostics on your system. The output indicates if there are any problems, and gives detailed instructions on resolving them. Follow the instructions provided. Here are three example of output.

Figure 1. Output to solr_test, no details, no issues reported

```
clusterMachineState: "No issues found."
```

Figure 2. Output to solr_test, with details, no issues reported

```
il-vm17.guard.swg.usma.ibm.com:
  isQuickSearchEnabled: "success"
  HardwareRequirementTest: "success"
  isSolrAlive: "success"
  ClusterConnectivity: "success"
  extractionStatus: "success"
  isClusterStateUp: "success"
  isThereClientSessionWarningInLog: "success"
  isThereSSLEceptionInLog: "success"
  isThereExceptionInUpgradeLog: "success"
```

Figure 3. Output to solr_test, no details, issue reported

If you cannot complete the installation of a new Guardium patch, stop the interfering process and reinstall the patch.
- [**Missing file or directory after new Guardium S-TAP installation**](#)
- [**Partition error installing Guardium**](#)
If you receive a partition error, select Custom installation and specify the disk location and size explicitly.
- [**Patch installation fails: No such file or directory**](#)
If the patch installation fails, check that the file matches the MD5SUM of the downloaded patch.

Checksum error during S-TAP installation

Follow these steps to rectify the download and transfer of the S-TAP installer file.

Symptoms

You receive an error similar to the following when you run the S-TAP installer to install Guardium S-TAP, indicating that either the md5 checksum or sha1 checksum is incorrect.

```
./guard-stap-v81_r26808_1-aix-6.1-aix-powerpc.sh
Verifying archive integrity...Error in checksums: 2082112805 is
different from 3728267449
```

Causes

The installer file is corrupted. The file became corrupted when the file was transferred to the database server or when the product was downloaded.

Environment

S-TAP on any server.

Resolving the problem

- If you are using FTP make sure it is set to binary mode.
- Try to transfer to the database server again.
- If that does not succeed, download the product again.

Guardium S-TAP returns an illegal cp: option - f error message

If the S-TAP installation fails with cp: illegal option - f, run the command which cp and change the file path.

Symptoms

The S-TAP installation fails with the following error message.

```
A directory called 'guardium' containing Guardium software needs to be created under a path provided.  
Enter the path prefix [/usr/local]? /opt/guardium  
Directory /opt/guardium/guardium/guard_stap does not exist, would you like to create it [Y/n]? Y  
Run STAP as root, or as user 'guardium' [R/u]? R  
Please be patient... This might take more than a minute.  
Copying installation files...  
cp: illegal option -- f  
UX:vxf5 cp: INFO: V-3-21462: Usage: cp [-i] [-p] f1 f2  
cp [-i] [-p] f1 ... fn d1  
cp [-i] [-p] [-r|-R] [-e { force | ignore | warn}] d1 d2
```

Causes

The path to /usr/bin/cp is different from what the installer expects.

Environment

The UNIX/Linux database server is affected.

Resolving the problem

Run the command **which cp**

If **which cp** returns a value other than /usr/bin/cp, run the command **export PATH=/usr/sbin:/usr/bin:\$PATH**.

Rerun the command **which cp** to confirm that the path is /usr/bin/cp.

Installing a new Guardium patch does not complete

If you cannot complete the installation of a new Guardium patch, stop the interfering process and reinstall the patch.

Symptoms

When you install a new patch it does not complete. The status column in the CLI command **show system patch installed** shows one of the following messages.

```
STEP: Setting "java" off  
STEP: Setting "amei" off  
STEP: Setting "sqlw" off
```

Causes

Tomcat, the inspection core, or another process on the machine interfered with the patch installation.

Environment

The Collector, Aggregator, and Central Manager are affected.

Resolving the problem

To install the new Guardium patch, stop any processes from interfering with the installation.

1. Delete the patch that is stuck by using the command **delete scheduled-patch**.
2. Restart the system by using the command **restart system**.
3. After the system restarts, stop the GUI and inspection core by using the commands **stop gui** and **stop inspection-core**.
4. Reinstall the patch and restart the GUI and inspection core by using the commands **restart gui** and **start inspection-core**.

Missing file or directory after new Guardium S-TAP installation

Symptoms

When you attempt to install S-TAP, you receive the following error message.

```
Tap_controller::init failed Opening pseudo device /dev/guard_ktap No such file or directory
```

In addition, /dev/*ktap* does not exist.

Causes

There are many possible reasons why the K-TAP device creation can fail. The following are the most common causes.

- You did not use the module files, including the K-TAP module for the Linux kernel.
- You did not specify the Flex Loading option to load the K-TAP module from the module files.
- A previous K-TAP module from an old installation is still running or installed.

Environment

All Linux and UNIX operating systems in which the IBM® Guardium® S-TAP product can be installed are affected.

Resolving the problem

To resolve the problem, take the following steps.

1. Run these commands as root.

```
<STAP directory>/KTAP/guard_ktap_loader stop  
<STAP directory>/KTAP/guard_ktap_loader uninstall  
<STAP directory>/KTAP/guard_ktap_loader install  
<STAP directory>/KTAP/guard_ktap_loader start
```

2. Check whether the K-TAP device is now created with the command **ls /dev/*ktap***. If it was created, issue is resolved. If not, continue to next step.
3. Stop the S-TAP process **guard_stap** if it is running. You can check whether it is running with command **ps -ef | grep guard_stap**.
4. Verify that the S-TAP process is not running with the command **ps -ef | grep guard_stap**.
5. Uninstall the S-TAP.
6. Confirm that the S-TAP directory is gone.
7. Check whether a K-TAP module is still running from an old installation. Use the appropriate command for your operating system.

```
Linux      : lsmod | grep ktap  
Solaris    : modinfo | grep tap  
HP-UX     : lsdev | grep tap  
AIX       : genkex | grep tap
```

If a device such as **ktap_<release>** is listed, then a K-TAP module is running.

8. If you find a K-TAP module is running in previous step, run the following steps to stop and uninstall the K-TAP module.

```
<STAP directory>/KTAP/guard_ktap_loader stop  
<STAP directory>/KTAP/guard_ktap_loader uninstall
```

Restart the server.

9. If you are using the Guardium Installation Manager (GIM), go to **Manage > Module Installation > Set up by Client**, select the client and click **Reset connection**. Wait for the server to reappear in the client list.
10. Reinstall the S-TAP. If you are using GIM to install the S-TAP, reinstall the S-TAP bundle with GIM and the following commands.

```
KTAP_ALLOW_COMBO=Y  
KTAP_LIVE_UPDATE=Y  
KTAP_ENABLED=Y
```

Partition error installing Guardium

If you receive a partition error, select Custom installation and specify the disk location and size explicitly.

Symptoms

When you install the Guardium appliance in VMWare, you receive the following error:

```
Error Partitioning  
Could not allocate requested partitions.  
Partitioning failed: Could not allocate partitions as primary partitions.  
Not enough space left to create partition for /boot.
```

Causes

When you install the Guardium system with VMWare, if you select Typical, VMWare uses configuration parameters that are predefined for the OS type in VMWare. These configuration parameters might not be suitable for this installation.

Environment

All Guardium configurations (collector, aggregator, central manager) are affected.

Resolving the problem

Select Custom installation and specify the disk location and size explicitly. Specify a disk size that is large enough for your monitoring and audit needs. After it is configured, Guardium does not support adding disk space to the system.

Patch installation fails: No such file or directory

If the patch installation fails, check that the file matches the MD5SUM of the downloaded patch.

Symptoms

Patch installation in Guardium fails with the error `patch.reg`:
`No such file or directory.`

Causes

The following cases can cause the patch installation to fail.

- The patch was not downloaded in binary mode and corrupted the file.
- The compressed file itself was uploaded to the Guardium system.
- The patch was received from Guardium support and has the PMR number prefixed to the file name.
- The patch was uploaded to the Guardium system from a Windows FTP server.

Environment

The collector, aggregator, and central manager are affected.

Resolving the problem

Verify that the contents of the file match the MD5SUM of the downloaded patch. If the compressed file cannot be extracted or the MD5SUM does not match, download the file in binary mode.

If the compressed file itself was uploaded to the Guardium system, extract the compressed file and upload only the patch.

If there is a PMR number prefixed to the file name, remove the number and then upload the patch to the Guardium system.

If the patch is uploaded from a Windows FTP server, specify the exact file name with the correct case.

z/OS

These sections present troubleshooting and solutions for common problems with z/OS.

- [z/OS S-TAP fails to show active the Guardium system](#)
If z/OS S-TAP fails to show active on the Guardium system, restart the inspection-core.

z/OS S-TAP fails to show active the Guardium system

If z/OS S-TAP fails to show active on the Guardium system, restart the inspection-core.

Symptoms

z/OS S-TAP fails to show active on the Guardium system after you start it for the first time. The policy is correctly configured with a DB2 or IMS Collection Profile and installed. The z/OS S-TAP is properly configured to use port 16022. All messages on the mainframe indicate connectivity.

Causes

If the collector has not been actively used as a collector since being built and configured, the sniffer appears to time out port 16022.

Environment

z/OS is affected.

Resolving the problem

Restart the inspection-core by using the CLI command `restart inspection-core`.

Guardium universal connector

Using the Guardium universal connector to work with other data sources.

The Guardium universal connector enables Guardium Data Protection and Guardium Insights to get data from potentially any data source's native activity logs without using the S-TAP.

You can access the documentation that is related to the Guardium Universal Connector as follows:

- [Developing new plug-ins for Guardium Data Protection](#)
- [Configuring the Guardium universal connector](#)
- [Configuring policies for the universal connector](#)
- [Monitoring connector and data flow status](#)
- [Troubleshooting Universal Connectors](#)
- [Guardium Universal Connector FAQs](#)
- [**Overview**](#)
Quick overview of the steps that are available to configure the Guardium universal connected end-to-end.
- [**Configuring policies for Universal connector**](#)
Policies for the Guardium universal connector are created and managed just like all other Guardium policies.
- [**Creating and managing secrets**](#)
Store secrets in the universal connector keystore to achieve higher security, instead of writing the passwords in plain text within a connector configuration. Store secrets before you add a connector configuration that is using a secret. Restart the universal connector to make the new or updated secrets available for universal connector configurations.
- [**Enabling universal connector on collectors**](#)
Enable the Guardium universal connector on collector by using the Guardium UI or by using the API commands.
- [**Adding connectors and plug-ins**](#)
The Guardium universal connector is the Guardium entry point for native audit logs. The Guardium universal connector identifies and parses the received events, and converts them to a standard Guardium format. The output of the Guardium universal connector is forwarded to the Guardium sniffer on the collector, for policy and auditing enforcements. Configure Guardium to read the native audit logs by customizing a pre-defined template for data sources that have pre-defined plug-ins (Amazon S3, MongoDB, and MySQL), or with your own plug-in.
- [**Universal connector configuration**](#)
12.1 and later You can centrally manage the Guardium® Managed Units where the Universal Connector is installed.
- [**Configuring universal connectors**](#)
Use the legacy Configure Universal Connector page on a Managed Unit to configure universal connectors.
- [**Monitoring connector and data flow status**](#)
The connectors are displayed in the standard Guardium reports and UI pages. You can check the general status of the connector by using the API or use the UI to view the status.
- [**Troubleshooting universal connectors**](#)
Use this page to systematically approach toward the solutions for the Universal Connector problems.

Overview

Quick overview of the steps that are available to configure the Guardium universal connected end-to-end.

Important: Your role must include S-TAP Management Application role permission.

1. Allocate Guardium collectors to receive the audit files.
2. For the data source types supported by Guardium, do the following.
 - a. Configure the native audit logs on the data source that Guardium can parse, and then configure the data shipper to forward the audit logs to the Guardium universal connector.
 - b. Configure the Guardium universal connector to read the native audit logs. For more information, see [Adding connectors and plug-ins](#) topic.
Note: If you are using secrets or sensitive information in the configuration, see [Creating and managing secrets](#) topic before you configure a new connector.
3. For a data source that does not have off-the-shelf support by Guardium, follow the instructions that are detailed in [upload a plug-in](#) topic.
4. Enable the universal collector feature on the designated Guardium collectors or the stand-alone system. For more information, see [Enabling universal connector on collectors](#) topic to enable the Guardium universal connector on collectors.

Configuring policies for Universal connector

Policies for the Guardium universal connector are created and managed just like all other Guardium policies.

The Guardium universal connector supports the following rule actions:

- Alert daily
- Alert only
- Alert per match
- Alert per time granularity
- Log full details
- Log full details with replaced values
- Log masked details
- Log only
- No parse (supported by connectors that use the sniffer parser to parse traffic.
For example, S3 and MongoDB plug-ins does not support this rule action. MySQL does support this rule action)
- Record values separately
- Quick parse (supported by connectors that use the sniffer parser to parse traffic.
For example, S3 and MongoDB plug-ins does not support this rule action. MySQL does support this rule action)
- Quick parse no fields (supported by connectors that use the sniffer parser to parse traffic.
For example, S3 and MongoDB plug-ins does not support this rule action. MySQL does support this rule action)

- Skip logging

For more information on actions, see [Actions](#).

Creating and managing secrets

Store secrets in the universal connector keystore to achieve higher security, instead of writing the passwords in plain text within a connector configuration. Store secrets before you add a connector configuration that is using a secret. Restart the universal connector to make the new or updated secrets available for universal connector configurations.

Procedure

1. Create a secret. Log in to the Guardium CLI and create the key by using the following grdapi command.

```
grdapi universal_connector_keystore_add key=<key_name> password=<key_value>
```

Note: Spaces are not allowed after and before = in this grdapi command.

2. Verify whether the keys are entered successfully by using the following command.

```
grdapi universal_connector_keystore_list
```

3. Add a key as an environment variable in the connector configuration.

a. Log in to Guardium and then go to the [Configure Universal Connector](#) page.

b. Upload jdbc driver (JAR file)

c. Add or edit a connector configuration to use a secret. Instead of writing the secret in plain text, type the key that you created as an environment variable.

For example:

```
jdbc { ... jdbc_connection_string => "jdbc:..." jdbc_user =>
"${MYSQL_USERX_NAME}" jdbc_password => "${MYSQL_USERX_PASSWORD}" ... }
      jdbc_password => "${MYSQL_USERX_PASSWORD}"
```

d. Save the configuration.

Note: To use the JDBC input plug-in, you need to upload a driver (JAR file) and then add the configuration.

4. To update a secret, you need to remove the key, add it again, and then restart the universal connector with overwriting old instance option.

a. To remove the key, run the following command.

```
grdapi universal_connector_keystore_remove key=<key_name>
```

b. To make sure that the key is no longer available to configurations, force the universal connector to fully restart, run the following command.

```
grdapi run_universal_connector overwrite_old_instance="true"
```

c. Listing the secret keys. To retrieve your updated list of the secrets after adding, removing, and updating keys, run the following command.

```
grdapi universal_connector_keystore_list
```

Enabling universal connector on collectors

Enable the Guardium universal connector on collector by using the Guardium UI or by using the API commands.

About this task

Tip: To simplify managing multiple collectors, create a managed unit group and use the API. For more information, see [Creating managed unit groups](#).

Attention: When you restart your Guardium system, restart the Guardium universal connector by using the following API command.

```
grdapi run_universal_connector
```

Procedure

1. On each collector that has connectors, enable the universal connector.

- For CLI, use the following commands:

```
grdapi run_universal_connector
```

To enable on multiple collectors by using the API, on the central manager enter.

```
grdapi run_universal_connector api_target_host=group:<managed unit group name>
```

- For Guardium UI, click **Setup** > **Tools** > **Tools and Views** > **Configure Universal Connector** and then click **Enable**.

2. Verify the connector status by using the following instructions.

- For CLI, use the following API command on managed unit.

```
grdapi get_universal_connector_status
```

- For Guardium UI: Verify that the **Disabled** option is active on the **Configure Universal Connector** page, which indicates that the Guardium Universal Connector is enabled.

Adding connectors and plug-ins

The Guardium universal connector is the Guardium entry point for native audit logs. The Guardium universal connector identifies and parses the received events, and converts them to a standard Guardium format. The output of the Guardium universal connector is forwarded to the Guardium sniffer on the collector, for policy and auditing enforcements. Configure Guardium to read the native audit logs by customizing a pre-defined template for data sources that have pre-defined plug-ins (Amazon S3, MongoDB, and MySQL), or with your own plug-in.

Before you begin

You must have permission for the role S-Tap Management. Admin user has this role by default.

About this task

Pre-defined plug-ins: Guardium has a few pre-defined plug-ins for specific data sources: Amazon S3, MongoDB, and MySQL. In this scenario, you do not need to upload a plug-in. Instead, you can use the corresponding template to help you to configure the input and the filter. The templates include all required fields. The input and filter sections conform to the sections in an Elastic Logstash configuration file, described [here](#).

The default MongoDB connector is the preferred method of ingesting data. It does not require any additional configuration on Guardium if you use the default configuration. By default, the Guardium universal connector listens for MongoDB audit log events that are sent over Syslog (TCP port 5000, UDP port 5141) and Filebeat (port 5044). If you cannot use these ports, or if a parameter does not display in the reports as you expect, update the MongoDB connector configuration to match your system.

Important: Each connector requires unique ports. Do not use the default ports for a customized connector configuration. Also, each connector must have a unique type, and the filter configuration must use that type.

For example, if the input configuration includes:

```
udp { port => 5141 type => "syslogMongoDB" }
```

then the filter must match it:

```
if [type] == "syslogMongoDB" {
```

Tip: When you save a connector configuration, Guardium stops the universal connector, verifies the new connection syntax, and initiates the new connection. Then, it restarts the universal connector. To prevent unnecessary loss of data during this stop period (usually about 1 minute), verify new configurations on a test Guardium system before you add them to your live system.

Procedure

1. On the collector, click **Setup** > **Tools and Views** > **Configure Universal Connector**.
2. Click the add icon.
3. For pre-defined plug-ins:
 - a. Enter name in the Connector name field.
 - b. From the Connector template drop-down list, select the template that most closely matches your system and follow the instructions in the sections that describe each template.
 - c. Click **Save**. Guardium validates the new connector, and enables the universal connector if it was disabled. After it is validated, it appears in the **Configure Universal Connector** page.
4. For offline plug-in package and related files, see further instructions in [upload a plug-in](#).

Universal connector configuration

12.1 and later You can centrally manage the Guardium® Managed Units where the Universal Connector is installed.

- By default, the option to centrally manage the Universal Connectors is enabled which automatically disables the traditional Configuring Universal Connector page.
- The traditional Configuring Universal Connector page is enabled only when you are upgrading to Guardium Data Protection version 12.1 and the Universal Connector data source is configured before the upgrade.
- If you are upgrading to Guardium Data Protection version 12.1, and you previously have not configured any universal connectors, the traditional Configure Universal Connector page is disabled. If you want to use the traditional Configure Universal Connector page to configure the Universal Connectors, use the grdapi modify_guard_param and update the LEGACY_UC_CONFIG_ENABLED parameter as follows:

```
grdapi modify_guard_param paramName=LEGACY_UC_CONFIG_ENABLED paramValue=1
```

- If you are upgrading to Guardium Data Protection version 12.1 and you have a Universal Connector that is enabled on a collector, use the traditional Configuring Universal Connector page to configure the Universal Connector. In this case, you cannot install the data source profiles by using the Central Manager until you manually delete the Universal Connector configurations on the collector and disable the traditional mode by using the GuardAPI modify_guard_param. To disable the traditional mode, update the LEGACY_UC_CONFIG_ENABLED parameter as follows:

```
grdapi modify_guard_param paramName=LEGACY_UC_CONFIG_ENABLED paramValue=0
```

Note: The `modify_guard_param` API is available with the Guardium Data Protection 12.1 version (fresh install) as well as Guardium Platform Upgrade flows.

- [**Creating credentials**](#)

12.1 and later Create, modify, delete, and refresh credentials for data sources such as JDBC, Google Cloud, AWS, and AWS Role ARN, which are used in the data source profiles.

Creating credentials

12.1 and later Create, modify, delete, and refresh credentials for data sources such as JDBC, Google Cloud, AWS, and AWS Role ARN, which are used in the data source profiles.

Creating credentials

1. In Guardium Data Protection Central Manager, or standalone machine, click [Manage > Universal Connector > Credential Management](#).
2. To create new credentials, click the add  icon and enter the following details.

Table 1. Managing credential parameters

Parameters	Description
Name	Enter the name of the data source connection.
Description	Enter the data source description.
Credential type	Select one of the following credential types: <ul style="list-style-type: none"> • Google Cloud • JDBC • AWS • AWS Role ARN
• JDBC username and JDBC password • Service Account JSON key file • AWS access key ID and AWS secret access key • AWS Role ARN	Enter the details according to the type of credential that you selected.

Note: You can use the same credentials for multiple profiles.

The Credential Management table displays the credential details. When you hover over the Used in profile column, it displays the names of the data source profiles in which the credentials are used.

To search credentials by name, enter the credential name in the Filter field.

Creating data source profiles

12.1 and later Create a data source profile to configure Universal Connectors on Managed Units. You can also install, uninstall, reinstall the created profiles along with enabling, disabling, restarting, and troubleshooting Universal Connectors.

Procedure

1. In Guardium Data Protection Central Manager, or Standalone machine, click [Manage > Universal Connector > Datasource Profile Management](#).
2. To create a data source profile, click the add  icon and enter values in the following fields.

Table 1. Managing data source parameters

Parameters	Description
Name	Enter the name of the data source connection.
Description	Enter the data source description.
Plug-in	Select the plugin.
Credential	Enter the credentials that you created in the Credential Management page. To create new credentials, click the add  icon to create credentials. For more information, see Creating credentials . This field is displayed only if the plugin requires credentials.
Kafka cluster	Select the appropriate Kafka cluster from the available Kafka cluster list or to create a Kafka cluster, see Creating Kafka clusters . This field is displayed only if the plug-in requires the Kafka cluster.

Parameters	Description
Parameters <ul style="list-style-type: none"> • Maximum poll records • Poll timeout (milliseconds) 	Depending on the type of plug-in that is selected in the Plug-in field, enter the parameters value. For example, if you select Document DB over CloudWatch Logs plug-in, then see DocumentDB-Guardium Logstash filter plug-in . By default, the Maximum poll records value is 1000 and Poll timeout value is 500. To get more efficient results, you can increase the Kafka cluster partition by setting the Maximum poll record value as 2000. Restriction: Once you increase then partitions, they cannot be decreased. After you update the Maximum poll records value, reinstall the profile.
Initial Time (milliseconds)	The timestamp from which the connector starts polling for changes in the database. Setting this to 0 means the connector starts from the earliest available data. If used for incremental data fetching, this parameter ensures that only new data (after the initial time) is retrieved.
Hostname	Specifies the hostname or IP address of the Oracle database server. It is the address where the Oracle instance can be accessed for establishing a JDBC connection.
JDBC driver library	The Oracle JDBC driver JAR file (ojdbc8.jar) is required for the connector to communicate with the Oracle database. Download the Oracle JDBC driver JAR file and uploaded the driver to the Kafka Connect environment.
Port	Specifies the port number used to connect to the Oracle database. The default port number is 1521, but it can vary depending on the Oracle configuration. Port 1521 must be open and accessible for the connection.
Service Name / SID	Specifies the Oracle service name (or SID if it's an older configuration) for Kafka connector to connect. The service name uniquely identifies a database service within an Oracle environment and is provided by the database administrator

3. Click OK.
4. Select a profile, and select the relevant installation option from the Install list.
5. Click Actions and select one of the following applicable options:

Enable UC

Use this option to enable the UC on the applicable collectors.

Disable UC

Use this option to disable the UC on the applicable collectors.

Restart UC

Use this option to restart the UC on the applicable collectors.

Troubleshoot

Troubleshoots the collector for errors in the uc-logstash.log and logstash-plain.log file.

6. Click OK.
7. Download the server (data source) CA certificate to ensure that Syslog accepts the communication with data source.
 - a. Click Download server CA.
 - b. Copy the certificate to the database server and note the location. For more information, see [Installing an appliance certificate to avoid a browser SSL certificate challenge](#).

What to do next

If you have selected a plugin that requires a Kafka cluster, complete the following steps after creating the Kafka cluster and data source profile: [Configure native audit and rsyslog on Datasource Server](#).

Creating Kafka clusters

Create and manage the Kafka clusters for the data sources that require Kafka clusters.

Before you begin

Run the following command on the CLI to convert a new Managed Unit into a Kafka node.

```
store unit type kafka-node
```

Procedure

1. Click Manage > Universal Connector > Kafka Cluster Management.
2. Click the add  icon.
3. In the Name field, enter a unique cluster name.
4. To create a member in the Cluster member grid, click the add  icon.
5. From the Select units to add list, select the Kafka nodes, and click OK.
Note: Add at least three Kafka nodes in one cluster for equal load balancing.
6. Optional: If you want to authenticate database servers with the Kafka cluster, select Enable client authentication then upload a valid client certificate for each database server or a set of signing certificates to be used for validation of incoming connections.
7. Select one or more Kafka nodes from the Cluster member grid to create a Kafka cluster.
Expand the cluster and view the individual node Status and Details in the grid
8. Use the Start, Stop and Restart options to start, stop and restart the individual clusters.
Note: You can restart one or more nodes from a cluster
9. Download the server (Kafka cluster) CA certificate to ensure that syslog accepts the communication with Kafka cluster.
 - a. On the Kafka cluster management page, select a cluster from the grid and click Download server CA.
 - b. Copy the certificate to the database server and note the location. For more information, see [Installing an appliance certificate to avoid a browser SSL certificate challenge](#).

Results

The Kafka cluster is created successfully.

Note:

- To ensure no data failover and appropriate load balancing, define the same configuration name on the Managed Unit on all Universal Connectors in the same Kafka Cluster.
- You cannot direct data flow from different types of databases to the same Kafka cluster.

Managing plug-ins

12.1 and later Upload new plugins for the data sources that are not preinstalled on Guardium.

About this task

By default, Guardium® Data Protection provides the following preinstalled plugins that you can use to create profiles.

- Aurora MySQL over CloudWatch Logs Input
- AWS MSSQL over JDBC
- Azure Postgres over Event Hub
- Dynamo over CloudWatch Logs
- Firebase over Google Pub/Sub
- MongoDB over Filebeat
- MySQL Over Filebeat
- OUA over JDBC connect
- Postgres over Kafka
- Postgres over SQS
- S3 over CloudWatch Logs

What to do next

Create a data source profile. For more information, see [Creating data source profiles](#).

Configuring universal connectors

Use the legacy Configure Universal Connector page on a Managed Unit to configure universal connectors.

About this task

Note: If you want to configure the Universal Connector using the new flow, then see [Universal connector configuration](#).

Restriction:

- If you upgrading to Guardium Data Protection version 12.1, and previously you have not configured any universal connectors on the Managed units, then in such case the Configure Universal Connector page is disabled. If you want to use Configure Universal Connector page to configure universal connectors then use the grdapapi modify_guard_param and update the LEGACY_UC_CONFIG_ENABLED as follows:

```
grdapapi modify_guard_param paramName=LEGACY_UC_CONFIG_ENABLED paramValue=1
```

Procedure

1. On the Collector, go to Setup > Tools and Views > Configure Universal Connector page.
2. Ensure that the Universal Connector is enabled.
3. To add a new configuration, click the add  icon.
4. Select the applicable connector template or use the .conf file from the GitHub repository. For example, see the [auroraMysqlCloudwatch.conf](#) file for Aurora-MySQL-Guardium Logstash filter plug-in.
Important: If you are configuring more than one filebeat connector on a single Managed Unit, then ensure to update the tags parameter in the filter plugin configuration file with unique values for each configuration. Not using unique values may affect the system performance.
5. In the Connector Name field, enter a unique connector name.
Ensure that the name does not contain special characters other than underscore(_) and hyphen (-).
6. Click Save.

Results

The Universal Connector is now configured and ready to receive new events from the data source.

Monitoring connector and data flow status

The connectors are displayed in the standard Guardium reports and UI pages. You can check the general status of the connector by using the API or use the UI to view the status.

Connector Status

The connectors display in the S-TAP pages of the UI only after data is received in the connector. Guardium creates the connector instance after data is received. If the connector does not have active traffic, then the connector does not display in the S-TAP Status or Events pages.

To verify that a new connector was configured successfully, and to see the connector status on the S-TAP status, run a test command on the data source and make sure you can see the new connector status.

You can typically see the connectors and their status in the following Guardium pages:

- S-TAP Status page. The connectors are indicated by using the following elements:
 - S-TAP Host - **database host: database port: UCn**.
 - S-TAP Version - **Universal connector Vn.n.n**.
 - Status - Indicates data flow by **Active** or **Inactive**.
- S-TAP Events
- Central manager pages:
 - In the Deployment Health Topology, click **Expand S-TAPs**. For more information, see [Deployment health topology and table views](#).
- In the Deployment Health Table, in the S-TAPs tab, you can identify connectors by
 - Under Hostname or IP address, the address ends in :UCn.
 - Under Version, the name is **Universal connector Vn.n.n..**

For details about the Deployment Health Table, see [Deployment health topology and table views](#).

- In the [Deployment health dashboard](#), S-TAPs by version chart, the Guardium universal connectors appear as S-TAPs with version numbers. In all other charts, the connectors are treated the same as S-TAPs.
- Enterprise S-TAP View to check S-TAP status. This report requires configuration. See [External data correlation][External data correlation](#)). Check for data flow in the Status column. The status Active indicates data flow.
- Detailed Enterprise S-TAP View. The Status column. The status Active indicates data flow. This report requires configuration. See [External data correlation][External data correlation](#)).

Note: If the universal connector displays in red, then it might be because of one of the following reasons:

- It was enabled, and then disabled.
- Data did not flow in over an hour.
- An issue occurred on the universal connector.

To view the connector status, run the following API command.

```
grdapi get_universal_connector_status
```

Data flow status

To view the data that is sent into Guardium, view the following pages.

- The connectors appear in many reports, similar to S-TAPs. Reports show data for connectors only if the connectors have policies that are installed, just like Guardium collectors. Make sure that you have a policy that is installed with the **Log Full Detail** rule action. Add reports to a dashboard, for example:
 - Full SQL (Clone and edit this report to test that other fields are inserted correctly into Guardium).
 - SQL Errors. You might need to add the description field to see your custom errors, if you pass a string to Guardium representing your custom error text.
 - Failed Login Attempts
- [Investigation dashboard](#). Data indexing is delayed by 2 minutes.

Restriction: An object that is deleted from a bucket is not specified in native audit events if the deletion was made from an S3 console. The delete operation appears in reports and the investigation dashboard, but the object name is not included.

- Set up Compliance Monitoring. For more information, see [Smart assistant for compliance monitoring](#). In the Database tab, you can identify data sources for monitoring.
- The Compliance monitoring page displays databases, if Guardium supports your DB and data is flowing into Guardium. This view updates once per hour, and displays databases that had remote activity in the past hour. You do not see anything here if you run commands directly from your DB server.

Troubleshooting universal connectors

Use this page to systematically approach toward the solutions for the Universal Connector problems.

- [Troubleshooting tool](#)

The troubleshooting tool helps you identify and resolve issues in UC connections. The troubleshooting tool scans your Logstash log files and searches for known

errors. Once it finds errors, it notifies you along with a description of the problem. Also, the troubleshooting tool checks the status of Sniffer and Squid services and informs you if either of them is inactive.

- [Logstash StackOverflow error due to large plug-in config file](#)

Troubleshooting tool

The troubleshooting tool helps you identify and resolve issues in UC connections. The troubleshooting tool scans your Logstash log files and searches for known errors. Once it finds errors, it notifies you along with a description of the problem. Also, the troubleshooting tool checks the status of Sniffer and Squid services and informs you if either of them is inactive.

About this task

To avoid old or irrelevant messages, the tool scans for errors in the Logstash logs file starting from the last time you ran troubleshooting. For example, if you last ran troubleshooting 3 hours ago, the troubleshooting tool will now only scan for errors from the past 3 hours. If this is your first time running the troubleshooting tool, it scans from the beginning of the Logstash logs file.

You can run the troubleshooting tool in the following 2 ways:

Restriction:

- The troubleshooting tool searches for errors starting from the last time you ran it. If you have not run the tool in a long time, it can take some time until new errors are observed and caught by the troubleshooting tool.
- The troubleshooting tool does not solve the issues. Rather, it gives you the relevant information about the root cause of the error so that you can fix it.

Procedure

1. Run the troubleshooting tool by using the following grasping.

```
grdapic universal_connector_troubleshooting
```

OR

2. Run the troubleshooting tool by using the Guardium Data Protection UI as follows.
Go to the Configure universal connector page and click Run troubleshooting.

Logstash StackOverflow error due to large plug-in config file

When you configure more than ten Universal Connectors on one collector, you might get the following StackOverflow error:

```
FATAL Logstash:109 - uncaught error (in thread Ruby-0-Thread-35: /usr/share/logstash/logstash-core/lib/logstash/java_pipeline.rb:289)
java.lang.StackOverflowError: null
    at org.logstash.config.ir.expression.EventValueExpression.toString(org/logstash/config/ir/expression/EventValueExpression.java:51)
~[logstash-core.jar:?]
    at java.lang.StringConcatHelper.stringOf(java/lang/StringConcatHelper.java:453) ~[?:?]
    at org.logstash.config.ir.expression.unaryTruthy.toRubyString(org/logstash/config/ir/expression/unary/Truthy.java:36) ~[logstash-core.jar:?]
    at org.logstash.config.ir.compiler.EventCondition$Compiler.buildCondition(org/logstash/config/ir/compiler/EventCondition.java:112)
~[logstash-core.jar:?]
    at org.logstash.config.ir.CompiledPipeline$CompiledExecution.lambda$compileDependencies$6(org/logstash/config/ir/CompiledPipeline.java:546) ~[logstash-core.jar:?]
    at java.util.stream.ReferencePipeline$3$1.accept(java/util/stream/ReferencePipeline.java:197) ~[?:?]
```

To avoid the stack overflow error, you can aggregate all connections and use one of the following optimized options.

Option 1

If you are configuring all the Universal Connectors from the same database type but different account IDs.
Consider the following existing workflow with three different connectors that have the same logic:

```
postgresql1:
  input { cloudwatch_logs { log_group=>"postgresql1", type=>"postgresql1" }
  filter {if type="postgresql1" {...} }

postgresql2:
  input { cloudwatch_logs { log_group=>"postgresql2", type=>"postgresql2" }
  filter {if type="postgresql2" {...} }

postgresql3:
  input { cloudwatch_logs { log_group=>"postgresql3", type=>"postgresql3" }
  filter {if type="postgresql3" {...} }
```

Following is the optimized workflow with 3 different connectors that have the same logic:

```
input {
  cloudwatch_logs { log_group=>"postgresql1", type=>"postgresql" }
  cloudwatch_logs { log_group=>"postgresql2", type=>"postgresql" }
  cloudwatch_logs { log_group=>"postgresql3", type=>"postgresql" }
```

```

}
filter {if type=="postgresql" {...} }

See the following example of CloudWatch plug-in config file with three different accounts, <ACCOUNT_ID_1>, <ACCOUNT_ID_2> and <ACCOUNT_ID_3>.

cloudwatch_logs {
log_group => ["<LOG_GROUP>"]
start_position => "end"
access_key_id => "<ACCESS_KEY_1>"
secret_access_key => "<SECRET_KEY_1>"
region => "<REGION_1>"
interval => 2
event_filter => ""
codec => multiline {
pattern => "((?<ts>[^A-Z]{3})*)UTC:(?<client_ip>[^:]*):(?<db_user>[@:]*)@(?<db_name>[^:]*):(?<session_id>[^:]*):(?  
<logger>LOCATION|DETAIL|STATEMENT|HINT):%{GREEDYDATA:sql_full_log})|(^s))"
negate => false
what => "previous"
}
type => "postgres"
add_field => {"account_id" => "<ACCOUNT_ID_1>"}
}

```

```

cloudwatch_logs {
log_group => ["<LOG_GROUP>"]
start_position => "end"
access_key_id => "<ACCESS_KEY_2>"
secret_access_key => "<SECRET_KEY_2>"
region => "<REGION_2>"
interval => 2
event_filter => ""
codec => multiline {
pattern => "((?<ts>[^A-Z]{3})*)UTC:(?<client_ip>[^:]*):(?<db_user>[@:]*)@(?<db_name>[^:]*):(?<session_id>[^:]*):(?  
<logger>LOCATION|DETAIL|STATEMENT|HINT):%{GREEDYDATA:sql_full_log})|(^s))" negate => false
what => "previous"
}
type => "postgres"
add_field => {"account_id" => "<ACCOUNT_ID_2>"}
}

```

```

cloudwatch_logs {
log_group => ["<LOG_GROUP>"]
start_position => "end"
access_key_id => "<ACCESS_KEY_3>"
secret_access_key => "<SECRET_KEY_3>"
region => "<REGION_3>"
interval => 2
event_filter => ""
codec => multiline {
pattern => "((?<ts>[^A-Z]{3})*)UTC:(?<client_ip>[^:]*):(?<db_user>[@:]*)@(?<db_name>[^:]*):(?<session_id>[^:]*):(?  
<logger>LOCATION|DETAIL|STATEMENT|HINT):%{GREEDYDATA:sql_full_log})|(^s))" negate => false
what => "previous"
}
type => "postgres"
add_field => {"account_id" => "<ACCOUNT_ID_3>"}
}

```

Options 2

If you are configuring all the Universal Connectors from the same database type, within the same database account and with same account ID. Consider the following existing workflow with three different connectors that have the same logic:

```

postgresql1:
input { cloudwatch_logs { log_group=>"postgresql1", type=>"postgresql1" }
filter {if type=="postgresql1" {...} }

postgresql2:
input { cloudwatch_logs { log_group=>"postgresql2", type=>"postgresql2" }
filter {if type=="postgresql2" {...} }

postgresql3:
input { cloudwatch_logs { log_group=>"postgresql3", type=>"postgresql3" }

filter {if type=="postgresql2" {...} }

```

Following is the optimized workflow with 3 different connectors that have the same logic:

```

input { cloudwatch_logs { log_group=>"postgresql1, postgresql2, postgresql3", type=>"postgresql" }
filter {if type=="postgresql" {...} }

```

See the following example of CloudWatch plug-in config file with same account ID.

```

cloudwatch_logs {
log_group => ["<LOG_GROUP_1>", <LOG_GROUP_2>, <LOG_GROUP_3>]
#e.g. [/aws/rds/instance/database-1/postgresql1, /aws/rds/instance/database-2/postgresql1, /aws/rds/instance/database-  
3/postgresql1]
start_position => "end"
access_key_id => "<ACCESS_KEY>"
secret_access_key => "<SECRET_KEY>"
region => "<REGION>"
interval => 2
event_filter => ""
codec => multiline {

```

```

pattern => "((({<ts>[^A-Z]{3}}*)UTC:({<client_ip>[^:]*) : ({<db_user>[^@]*)@({<db_name>[^:]*) : ({<session_id>[^:]*) : (?
<logger>LOCATION|DETAIL|STATEMENT|HINT}:{%{GREEDYDATA:sql_full_log}}|(^s))"
negate => false
what => "previous"
}
type => "postgres"
add_field => {"account_id" => "<ACCOUNT_ID>"}
}

```

Windows: S-TAP user's guide

The Guardium S-TAP is a lightweight software agent installed on database servers and file servers. The S-TAP generally accounts for between 1% - 3% of CPU usage. In most installations, the impact is negligible with no noticeable impact on performance. The information collected by the S-TAPs is the basis of all Guardium traffic reports, alerts, visualizations, etc.

For data activity monitoring, the S-TAP monitors activity between the client and the database and forwards that information to the Guardium collector. The database traffic is logged into the collector based on criteria specified in the security policy. You can reduce the amount of traffic that is originally sent to the collector by ignoring trusted connections or ignoring traffic from specific IPs.

MySQL limitations: For MySQL, TCP is the only supported protocol. In addition, Windows S-TAP does not support MySQL encrypted traffic.

- [Windows: S-TAP authentication guidelines](#)
Most the S-TAP services run under a standard nonprivileged user account. Learn about this account, and the Guardium Services group.
- [Windows: S-TAP protocol 8](#)
The new S-TAP protocol 8 reduces CPU usage and memory usage. The two S-TAP protocols co-exist and use the same guard_tap.ini configuration file. You choose which protocol you want to use for each S-TAP.
- [Windows: Install, upgrade, and uninstall the S-TAP agent](#)
You can install, upgrade, and uninstall S-TAPs by using a few methods. Learn about each one and understand what works best for you.
- [Windows: Configuring S-TAP](#)

This section provides detailed instructions or examples for configuring monitoring on various databases.
- [Windows: S-TAP operation and performance](#)
- [Windows: Scheduling S-TAP diagnostics](#)
You can schedule S-TAP diagnostics by using the S-TAP Diagnostic Scheduler user interface.

Windows: S-TAP authentication guidelines

Most the S-TAP services run under a standard nonprivileged user account. Learn about this account, and the Guardium Services group.

During a typical, fresh installation, the majority of the S-TAP services are installed under the Local Service account by default, except for GIM, FAM for NAS/SP and FDEC for NAS/SP services, which default to Local System.

During a fresh, custom, install users can select the custom account of their choice, including standard, nonprivileged, user accounts.

Upgrades continue to use whatever service account was in place at the time of the fresh install with one important exception. Services that run under Local System (except for GIM and NAS/SP) are converted to run under Local Service during an upgrade to one of V10.6.0.178, V11.0.1.x, and V11.1.0.x and higher. This effectively transitions an installation to run under a standard user account rather than an account with full privileges. If the original fresh installation used a custom account, you can remove that account from all privileged groups (like Administrators) after the upgrade.

The focal point of all S-TAP security checks is a local group named "Guardium Services" that are created during installation. The service account selected for the Guardium services by the user, whether it be Local Service or some custom account, is added as a member to the Guardium Services group. All service, file, and registry access are then granted to the Guardium Services group on behalf of those services, files, and registry keys that the Guardium services must access and control. If the system administrator manually changes the service account for the Guardium services at a later date, the new account must be manually added into the local system's Guardium Services group as a member.

The Guardium Services group grants only those privileges that are required to the services that require them. In most cases, there are no special requirements and the services run completely non-privileged. The Guardium Database Monitor service and the DB2 Tap service must, however, be granted the privilege **SeDebugPrivilege**.

Windows: S-TAP protocol 8

The new S-TAP protocol 8 reduces CPU usage and memory usage. The two S-TAP protocols co-exist and use the same guard_tap.ini configuration file. You choose which protocol you want to use for each S-TAP.

Changes include,

- New parameters in the guard_tap.ini configuration file. Some of the protocol 7 parameters are not valid for protocol 8. See all parameters, new and old, in [Editing the protocol 8 S-TAP configuration parameters](#).
- [Windows: Multi-threading S-TAP for increased throughput](#).
- Logging is saved in a circular text log. See [Windows: Log and debug files](#).
- Choose your S-TAP protocol by using the GIM parameter WINSTAP_V8_PROTOCOL, or the guard_tap.ini parameter V8_PROTOCOL, where:
 - 0 - Disabled (protocol 7)
 - 1 - Enabled (protocol 8)
- See [General parameters](#) and [Protocol 8 General parameters](#).

Windows: Install, upgrade, and uninstall the S-TAP agent

You can install, upgrade, and uninstall S-TAPs by using a few methods. Learn about each one and understand what works best for you.

The Base Filtering Engine (BFE) service must be running for the S-TAP installation. If the service exists but is not running, Guardium attempts to start it.

S-TAPs require .NET Framework 4.5 or higher version. If the .NET 4.5 or higher environment does not exist, S-TAP installs .NET 4.5.2.

All files and directories under Windows S-TAP and all Guardium® Windows agents installed directories give full control permission to the *Guardium Services* group. Guardium agents are designed so that Guardium creates the *Guardium Services* group the first time that you install Windows S-TAP or any other Guardium Windows agent.

S-TAP installation creates one installation log called `C:\IBM Windows S-TAP.ctl`.

The Windows S-TAP can be uninstalled without restarting. Upgrade your S-TAP to 11.4 (or later), reboot the S-TAP once, for example, in the next maintenance window. Then, you can uninstall the S-TAP without rebooting the database server or restarting database instances. A fresh install of the 11.4 (or later) S-TAP out of the box is fully uninstallable without requiring a reboot. Db2® exit monitoring requires a one time stop of the Db2 instances to install the Guardium interface DLL. After that, the S-TAP can be installed and uninstalled without stopping any instances.

Enterprise load balancing

During installation of an S-TAP on Windows, you can configure the S-TAP to use Enterprise Load Balancing features. For more information, see [Enterprise Load Balancing](#).

- [Windows: Install S-TAP agents installation flow](#)

Verify prerequisites, then install an S-TAP on Windows servers using the Deploy Monitoring Agents tool, the Guardium Installation Manager (GIM), the wizard, or the command line interface (CLI).

- [Windows: S-TAP monitoring mechanisms support matrix](#)

Select your S-TAP setup depending on the data that you want to monitor or block. Use this table to identify the monitoring mechanisms that can perform the operations that you require, per operating system and database.

- [Windows: Auto discovery of database instances during installation and upgrade](#)

When you install an S-TAP, it can auto-discover database instances and create inspection engines for the discovered instances.

- [Windows: Prerequisites: Installing S-TAP](#)

Review the disk space and port prerequisites before installing S-TAP:

- [Windows: Use GIM to install, upgrade, uninstall the S-TAP](#)

Use GIM Setup by Client to manage your S-TAPs.

- [Windows: Use interactive installer \(wizard\) to install, upgrade, uninstall the S-TAP](#)

- [Windows: Use CLI to install, upgrade, uninstall the S-TAP](#)

- [Windows: Remove the S-TAP using Add/Remove Programs](#)

You can use Add/Remove Programs to uninstall S-TAP no matter how it was installed. (For GIM installs, best practice ie to uninstall with GIM.)

- [Windows: S-TAP installation flow on Oracle RAC](#)

Configure S-TAPs in an Oracle RAC.

- [Windows: Managing S-TAP when upgrading your database](#)

Use these guidelines for managing your Windows S-TAP when upgrading your database.

- [Windows: Managing S-TAP when upgrading your database operating system](#)

Use these guidelines for managing an S-TAP, when upgrading the operating system (OS) of your database. This is relevant for all S-TAPs, regardless of the installation method.

- [Windows: When to restart or reboot the database server after installing or upgrading S-TAP](#)

In general, you do not need to reboot the database server after you install or upgrade Windows S-TAP unless you are upgrading between versions or when stated otherwise in the release notes.

Related concepts

- [Deploy monitoring agents](#)
- [Guardium Installation Manager](#)

Windows: Install S-TAP agents installation flow

Verify prerequisites, then install an S-TAP on Windows servers using the Deploy Monitoring Agents tool, the Guardium Installation Manager (GIM), the wizard, or the command line interface (CLI).

Depending on your license key, you can use the same S-TAP agent for both file server and database activity monitoring. FAM does not require any specific S-TAP configuration.

This flow describes installing S-TAP on a single database reporting to one collector.

1. Plan the installation, review these topics:

- [Windows: S-TAP monitoring mechanisms support matrix](#)
- [Windows: Auto discovery of database instances during installation and upgrade](#)
- [Windows: Discover database instances](#)

2. Verify the prerequisites.

- [Windows: S-TAP disk space requirements](#)
- [Windows: Guardium port requirements for S-TAP](#)
- If you are installing with GIM, the GIM client must be installed on the target database server. See [Installing the GIM client on a Windows server](#).

3. Install the S-TAP by one of:

- [Deploy monitoring agents](#)
- [Windows: Use GIM to install, upgrade, uninstall the S-TAP](#)
- [Windows: Use interactive installer \(wizard\) to install, upgrade, uninstall the S-TAP](#)

- [Windows: Use CLI to install, upgrade, uninstall the S-TAP](#)

During S-TAP installation, if auto-discovery is enabled, it auto-discovers databases and creates inspection engines for the discovered databases. The auto-discovery process runs once at the time of S-TAP installation and does not automatically repeat. Post-installation, it runs periodically and sends the details to the primary (current active) S-TAP host. You can modify the configuration after the installation is complete.

4. Configure any of the optional components if required by your system.

- [Windows: S-TAP installation flow on Oracle RAC](#)
- [Windows: Configuring the Db2 Exit library](#)
- [Windows: S-TAP load balancing models and configuration guidelines](#)

5. Reboot or restart if required ([Windows: When to restart or reboot the database server after installing or upgrading S-TAP](#)).

6. Complete the S-TAP configuration.

- [Configuring S-TAP in the S-TAP Control page](#)
- Advanced users only: [Editing the protocol 7 and protocol 8 S-TAP configuration parameters](#) and [Editing the protocol 8 S-TAP configuration parameters](#)

7. If required, configure [Enterprise Load Balancing](#).

Windows: S-TAP monitoring mechanisms support matrix

Select your S-TAP setup depending on the data that you want to monitor or block. Use this table to identify the monitoring mechanisms that can perform the operations that you require, per operating system and database.

For example, you might want to track the following information or perform one of the following procedures:

- Local traffic only
- Local and network traffic
- Shared memory
- Encrypted data
- Monitor and block
- Monitor only

The [Guardium support matrix](#) covers the most common platforms, database types, and protocols supported by Guardium monitoring mechanisms. The table presents general guidelines. Other combinations that are not presented here might be supported. Some of the supported setups that are shown here might depend on specific configurations. Contact Technical Support to verify the best setup for your specific needs. Empty cells indicate that the combination is not supported.

Windows: Auto discovery of database instances during installation and upgrade

When you install an S-TAP, it can auto-discover database instances and create inspection engines for the discovered instances.

By default, auto discovery runs once during S-TAP installation. It discovers the database instances, populates inspection engines according to its discovery, and updates the S-TAP configuration file guard_tap.ini. When the installation is complete, auto discovery is disabled to prevent the S-TAP from overwriting user-modified inspection engine configurations. The Guardium® Discovery Agent is installed with the S-TAP package on a database server.

Auto discovery is controlled by the guard_tap.ini parameter AUTO_DISCOVERY. For more information, see [Discovery parameters](#) or [Protocol 8 Discovery parameters](#).

During an upgrade, auto-discovery identifies new database instances but does not create inspection engines for the new instances.

CAUTION:

If you enable auto-discovery before upgrading the S-TAP, then **all** inspection engines are updated according to the discovered instances. If you changed the port range, for example, it reverts during the upgrade if auto discovery is enabled.

If you want to retain the inspection engine configurations, disable auto discovery before the upgrade.

All Windows S-TAP database types are supported for auto-discovery.

The auto discovery parameters should be left at their default values, except for advanced users. Discovery also uses these parameters:

- software_tap_host: IP address or hostname of the database server on which the S-TAP is installed.
- sqlguard_ip: S-TAP discovery results are sent to this IP. (The Guardium system with primary=1 in the SQLguard parameters.)

Instance discovery is configured and run independently of auto discovery. For more information, see [Windows: Discover database instances](#).

Windows: Prerequisites: Installing S-TAP

Review the disk space and port prerequisites before installing S-TAP:

- [Windows: S-TAP disk space requirements](#)

Verify the disk space requirements before installing your S-TAP.

- [Windows: Guardium port requirements for S-TAP](#)

If there is a firewall between Guardium® components (for example, between a Guardium system and an S-TAP on a Windows database server), you must verify that the ports used for connections between those components are not being blocked.

Windows: S-TAP disk space requirements

Verify the disk space requirements before installing your S-TAP.

Disk Space	Description
------------	-------------

Disk Space	Description
S-TAP program files	S-TAP uses the Microsoft .NET Framework. If this is not already installed, it requires 5GB free space GIM Install: 300 MB non-GIM Install: 180 MB
Buffer file	50 MB

Windows: Guardium port requirements for S-TAP

If there is a firewall between Guardium® components (for example, between a Guardium system and an S-TAP on a Windows database server), you must verify that the ports used for connections between those components are not being blocked.

Use your firewall management utility to check, and open as relevant, the ports listed below.

Table 1. Port Requirements for Windows servers

Port	Protocol	Guardium system connection to ...
9500/9501	TCP	Alive messages for S-TAP using Protocol 7
9800/9801	TCP	Alive messages for S-TAP using Protocol 8
9500	TCP	Clear S-TAP
9501	TLS	Encrypted S-TAP

Windows: Use GIM to install, upgrade, uninstall the S-TAP

Use GIM Setup by Client to manage your S-TAPs.

- [Windows: Installing S-TAP agent with GIM Setup by Client](#)

When you install S-TAPs on your database servers with the GIM Setup by Client, you can install, upgrade, and manage agents on individual servers or groups of servers. This includes monitoring processes that were installed under its control, modifying S-TAP parameters, and performing other management tasks.

- [Windows: S-TAP GIM installation parameters](#)

Understand the parameters (each with a short description) that are typically used in your GIM installation.

- [Windows: Upgrading S-TAP agent with GIM Setup by Client](#)

- [Windows: Uninstalling an S-TAP agent with GIM Set up by Client](#)

Learn how to uninstall the S-TAP agent and the GIM bundle from the database server. If S-TAP was installed with GIM, uninstall it with GIM. Otherwise, you need to manually remove the S-TAP folder from the GIM directory on the DB server.

Windows: Installing S-TAP agent with GIM Setup by Client

When you install S-TAPs on your database servers with the GIM Setup by Client, you can install, upgrade, and manage agents on individual servers or groups of servers. This includes monitoring processes that were installed under its control, modifying S-TAP parameters, and performing other management tasks.

Before you begin

Verify the following before you begin:

- Review the Windows S-TAP installation requirements at [Windows: Prerequisites: Installing S-TAP](#).
- Your database server and operating system are supported.
- The intended S-TAP installation directory is empty or does not exist.
- The GIM client is installed on the database server where you will install an S-TAP.
- The GIM client on the database server is communicating with the Guardium system. (Look for the client IP in Manage > Module Installation > GIM Processes Monitor.)
- Obtain the S-TAP module from either [Fix Central](#), or your Guardium representative.

About this task

After installing a GIM client on the database server, installation of the S-TAP for Windows is scheduled from the Guardium system.

The only required parameter is WINSTAP_INSTALL_DIR. It cannot be modified after the installation. All other parameters can be modified after installation.

You can input any parameter in the Setup by Client page, in the Choose parameters row, using the command WINSTAP_CMD_LINE with the syntax **parameter=value** for [TAP] parameters, or with the syntax **-param value** for CLI parameters ([Windows: S-TAP command line installation parameters](#)), and they are added or updated in the file guard_tap.ini.

CAUTION:

There is no validation of input when using the WINSTAP_CMD_LINE.

Procedure

1. Upload the Windows S-TAP module for installation.
 - a. On the Guardium® system, navigate to Manage > Module Installation > Upload Modules.

- b. Click Choose File and select the S-TAP module you want to install.
 - c. Click Upload to upload the module to the Guardium system.
After uploading, the module is listed in the Import Uploaded Modules table.
 - d. In the Import Uploaded Modules table, click the check box next to the S-TAP module you want to install.
The module is imported and made available for installation. After the module is imported, the Upload Modules page is reset and the Import Uploaded Modules table is empty.
2. Follow the GIM instructions in [Set up by Client](#) and refer to [Windows: S-TAP GIM installation parameters](#).
- While the default parameters are acceptable for most installations, you are required to provide a WINSTAP_INSTALL_DIR value. The default value is C:/Program Files/IBM/Windows S-TAP. This is the only required parameter.
 - If WINSTAP_TAP_IP (equivalent to the -taphost command line parameter) is not specified, the GIM_CLIENT_IP value is used.
 - If WINSTAP_SQLGUARD_IP (equivalent to the -appliance command line parameter) is not specified, the GIM_URL value is used.
 - Optionally enable enterprise load balancing. See the parameter description in [Windows: S-TAP GIM installation parameters](#).
 - If you want to disable auto-discovery, set WINSTAP_AUTO_DISCOVERY=0. For more information, see [Windows: Auto discovery of database instances during installation and upgrade](#).

What to do next

In the Success popup, click Show Status to open the Status window to monitor the software install/upgrade. Click  to refresh the results. If an install/upgrade has a failed status, click Uninstall if you see the button, otherwise, click Reset connection. You can also view the status of the module installation by reviewing the report at Manage > Reports > Install Management > GIM Clients Status.

Verify that the S-TAP is communicating with the Guardium system by browsing to Manage > Activity Monitoring > S-TAP Control and reviewing the S-TAPs status and configuration.

Related concepts

- [Guardium Installation Manager](#)

Windows: S-TAP GIM installation parameters

Understand the parameters (each with a short description) that are typically used in your GIM installation.

Depending on which protocol you are using, parameters are listed in either [Editing the protocol 7 and protocol 8 S-TAP configuration parameters](#) or [Editing the protocol 8 S-TAP configuration parameters](#).

CAUTION:

Do not modify advanced parameters unless you are an expert user or you are consulting with IBM Technical Support.

Attention: If a parameter is available through both the GIM and the command line interface (CLI), then the GIM parameter, including any defaults, always overwrites any value that is available from **WINSTAP_CMD_LINE**.

Table 1. Parameters applicable to all .NET installers

GIM parameter	Description
QUIET	Install silently. (Does not require value)
WINSTAP_INSTALL_DIR	The installation directory. The default installation path is C:\Program Files\IBM\Windows S-TAP

Table 2. Other S-TAP parameters

GIM parameter	Description
WINSTAP_AUTO_DISCOVERY	Controls auto-discovery of database instances. When enabled during installation, the agent discovers database instances on the server, populates inspection engines, and updates the guard_tap.ini configuration files. The parameter value is 1 during a fresh installation and changes to 0 after the initial installation. For more information, see Windows: Auto discovery of database instances during installation and upgrade . Valid values: <ul style="list-style-type: none"> • 0: disable • 1: enable
WINSTAP_ENABLED	Enables or disables S-TAP and its services. Default is enabled (1).
WINSTAP_ENABLE_GAM	Enables the Guardium Agent Monitor service (GAM). Default is disabled (0).
WINSTAP_INSTALLER_LOG_DIR	Specifies the location for storing the S-TAP installer log files. Use this parameter if you don't want to use the default location (C:).
WINSTAP_SQLGUARD_IP	The SQLGUARD IP. You can set up multiple appliances by specifying this parameter multiple times, each with a unique value.
WINSTAP_TAP_IP	The local/client IP. Required for unattended installation.

Table 3. S-TAP parameters that default to ON. The following parameters are set to either ON or 1 for some parameters by default. Setting these parameters to any value other than ON or 1 disables the parameter.

GIM parameter	Description
WINSTAP_TCP_DRIVER_INSTALLED	To use the TCP driver, set WINSTAP_TCP_DRIVER_INSTALLED=1 (the default). To disable the TCP driver, set this parameter to 0.

GIM parameter	Description
WINSTAP_NAMED_PIPE_DRIVER_INSTALLED	To use the named pipe driver, set NAMED_PIPE_DRIVER_INSTALLED=1 (the default). Specifies the named pipe that is used by MS SQL Server for local access. If a named pipe is used, but nothing is specified in this parameter, S-TAP attempts to retrieve the named pipe name from the registry. In rare cases, the S-TAP named pipes driver can interact with other third-party software in ways that slow the server down. To turn off the named pipes driver, set this parameter to 0. The named pipes driver is removed at the next system reboot. Note: If you turn off the named pipes driver, then the S-TAP does not capture named pipes traffic.
WINSTAP_DB2_TAP_INSTALLED	Enables sniffing Db2 shared memory traffic.
WINSTAP_DB2_EXIT_DRIVER_INSTALLED	Enables Db2 Integration with S-TAP.
WINSTAP_ORA_DRIVER_INSTALLED	Enables sniffing Oracle ASO and SSL traffic.

Table 4. Enterprise load-balancing parameters. For more information, see [Enterprise load balancing](#).

GIM parameter	Description
WINSTAP_LOAD_BALANCE_R_IP	Required if you are configuring enterprise load balancing. If blank, enterprise load balancing is disabled. The IP address or hostname of the central manager or managed unit this S-TAP uses for load balancing. Dynamic parameter. When you modify the value in the guard_tap.ini, you do not need to restart the S-TAP for the updated values to take effect.
WINSTAP_INITIAL_BALANCER_TAP_GROUP	The name of the S-TAP group that this S-TAP belongs to, for enterprise load balancing.
WINSTAP_INITIAL_BALANCER_MU_GROUP	The name of the managed unit group that the app-group is associated with. Requires a defined LB-APP-GROUP. The managed unit group must exist on the central manager before it can be used during installation of the S-TAP.
WINSTAP_LOAD_BALANCE_R_NUM_MUS	The number of managed units the enterprise load balancer allocates for this S-TAP.

Note: S-TAP parameters cannot be changed via the interactive installer during upgrade. After you upgrade, you can change S-TAP parameters either from the Guardium UI or by using the [update_stap_config](#) API.

Windows: Upgrading S-TAP agent with GIM Setup by Client

Before you begin

Verify the following before you begin:

- Review the Windows S-TAP installation requirements at [Windows: Prerequisites: Installing S-TAP](#).
- Obtain the S-TAP module from either [Fix Central](#), or your Guardium representative.

Note: **Db2 servers.** When upgrading an S-TAP from 11.3 or before to 11.4 or later on Db2 servers, the S-TAP cannot continue to capture the Db2 server traffic. Stop and restart your Db2 instances after the S-TAP upgrade to resume capturing Db2 traffic. Subsequent upgrades do not require you to restart the instances.

Important: When you upgrade Windows S-TAP from 10.x to 11.x (or newer) using GIM, the FIREWALL properties are reset to the default values. Set WINSTAP_FIREWALL_INSTALLED=1 during the upgrade if you are using the firewall (S-GATE).

Procedure

1. Upload the Windows S-TAP module for upgrade.
 - a. On the Guardium® system, go to **Manage > Module Installation > Upload Modules**.
 - b. Click Choose File and select the S-TAP module you want to install.
 - c. Click Upload to upload the module to the Guardium system.

After uploading, the module is listed in the Import Uploaded Modules table.

 - d. In the Import Uploaded Modules table, click the check box next to the S-TAP module you want to install.

The module is imported and made available for upgrade. After the module is imported, the Upload Modules page is reset and the Import Uploaded Modules table is empty.
2. Go to **Manage > Module Installation > Set up by Client**.
3. In the Choose clients section, select the database servers where you want to update software. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients.
Click Next to continue.
4. In the Choose bundle section, use the Select a bundle menu to identify your upgrade version. Click Next to continue.
5. If you are upgrading from 10.x to 11.0 (or newer), and you use the firewall: In the Choose parameters section, set WINSTAP_FIREWALL_INSTALLED to 1.
6. Click Install to begin the software upgrade. Or use the  icon to schedule the installation, then click OK to continue.
7. To create the Guardium API syntax for the current configuration in the Setup by Client, click Generate GuardAPI. If enough information is available, it generates API commands for multiple clients in the GuardAPI commands dialog. If there isn't enough information, it shows a default template.

What to do next

In the Success popup, click Show Status to open the Status window to monitor the software install/upgrade. Click  to refresh the results. If an upgrade has a failed status, click Uninstall if you see the button, otherwise, click Reset connection. You can also view the status of the module installation by reviewing the report at Manage > Reports > Install Management > GIM Clients Status.

If you see a Failed installation status for a bundle or module, open the Choose bundle section, select the client, click Uninstall, and use the  icon to monitor the installation status. If Uninstall is not available, open the Choose clients panel, select the affected client, and click Reset connection. Use the  icon to monitor the client list as the connection is reset.

Verify that the S-TAP is communicating with the Guardium system by browsing to Manage > Activity Monitoring > S-TAP Control and reviewing the S-TAPs status and configuration.

Windows: Uninstalling an S-TAP agent with GIM Set up by Client

Learn how to uninstall the S-TAP agent and the GIM bundle from the database server. If S-TAP was installed with GIM, uninstall it with GIM. Otherwise, you need to manually remove the S-TAP folder from the GIM directory on the DB server.

Before you begin

About this task

The Windows S-TAP can be uninstalled without reboot. Upgrade your S-TAP to 11.4 or later, reboot the S-TAP once, for example, in the next maintenance window. Then, you can uninstall the S-TAP without rebooting the database server or restarting database instances. A fresh install of the 11.4 or later S-TAP out of the box is fully uninstallable without requiring a reboot.

Procedure

1. Go to Manage > Module Installation > Set up by Client.
2. In the Choose clients section, select the database servers from which you are uninstalling the S-TAP. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients. Click Next to continue.
3. In the Choose bundle section, select the bundle that you want to uninstall from the drop-down list.
Tip:
 - You can filter the clients, for example, by name, module, Selected bundle actions, and client OS. The resulting selection is persistent; **the action is applied only to the filtered list of clients**. You can see that the number of clients in the Choose Clients section is greater than the number in Configure Clients section.
 - Clear the Show only latest versions checkbox to view and work with earlier versions of a bundle.
 - Clear the Show only bundles checkbox to identify individual modules within a bundle.
 - Select the Show only compatible clients checkbox to hide clients that are not compatible with the selected bundle.The Configure Clients row shows the number of clients that have that specific bundle running. Click Next to continue.
4. Click Uninstall. The system prompts for confirmation. Click Yes.

- [Windows: Upgrading the S-TAP agent using the interactive installer](#)

The interactive installer is useful for smaller deployments or whenever a guided, step-by-step installation experience is required.

Windows: Installing S-TAP agent by using the interactive installer

The interactive installer is useful for smaller deployments or whenever a guided, step-by-step installation experience is required.

Before you begin

Verify the following before you begin:

- Review the Windows S-TAP installation requirements at [Windows: Prerequisites: Installing S-TAP](#).
- Verify that your database server and operating system are supported. For more information, see [System requirements](#) and the [Windows: S-TAP monitoring mechanisms support matrix](#).
- Identify the IP address of the database server where you are installing the S-TAP, including any virtual IP addresses.
- Identify the IP address of the Guardium® system that will control the S-TAP.
- Verify that the intended S-TAP installation directory is empty or does not exist.
- Obtain the S-TAP module from either [Fix Central](#), or from your Guardium representative.

About this task

When you install an S-TAP on a database server, you must provide the IP address or host name of the Guardium system that will receive data from the S-TAP. After the S-TAP has connected to the Guardium system, go to the [Manage > Activity Monitoring > S-TAP Control](#) page and complete the S-TAP configuration.

If you want to disable auto-discovery, clear the Start S-Tap Service checkbox. For more information, see [Windows: Auto discovery of database instances during installation and upgrade](#).

- You can change some Windows S-TAP parameters from the interactive installer (but not all). Use the GUI after you install the S-TAP to change S-TAP parameters that you can't change from the installer.

Note: You cannot install or run Windows S-TAP on a domain controller.

When you install an S-TAP from the wizard, you can uninstall it from the wizard, the command line, or Windows Add/Remove Programs.

Procedure

1. Log on to the database server with a system administrator account.
2. Copy the S-TAP module to your database and start the Guardium Windows S-TAP Install Wizard.
Attention: To install an S-TAP on Windows 2012 or later, you must use administrative privileges. Right-click the installer and choose Run as Administrator.
3. Read the license agreement on the Guardium License screen. To continue installation, select I accept the terms of the license agreement and click Next.
4. Provide the requested content on the Customer Information screen, then click Next to continue. The default values are appropriate for most installations.
5. Select one of the following installation types and then click Next to continue:
 - Typical: a typical installation is appropriate for most users.
 - Compact: a compact installation assumes that other features such as Enterprise Load Balancing are not required.
 - Custom: a custom installation allows you to modify more S-TAP installation options such as the software choices, installation directory, and the user account that runs the Windows S-TAP process.
6. Optional: Enable Enterprise Load Balancing by selecting the Enable Load Balancing checkbox on the Load Balancing Options screen. Click Next to continue.
 - a. If you enable Enterprise Load Balancing, provide the load balancer IP address in the Load Balancer Host Address field.
 - b. Click Advanced Options to specify any additional Enterprise Load Balancing options.
For more information, see [Enterprise Load Balancing](#).
7. Verify the Software Tap Host Address and provide Appliance Address(es) on the Network Addresses screen, then click Next to continue.
 - The Software Tap Host Address specifies the address of the database where the S-TAP is being installed.
 - One or more Appliance Addresses specify the Guardium system addresses that control the S-TAP. Provide multiple addresses (typically not more than three) on separate lines to establish failover systems for the S-TAP or when configuring S-TAP load balancing with the participate_in_load_balancing parameter.
Attention: If you do not want the S-TAP service to be enabled after installation, clear the Start S-Tap Service checkbox. If the S-TAP Service is not started, auto discovery of databases and creation of inspection engines is also disabled.
The Install Wizard Completed page appears after a successful installation.
8. Click Finish to close the installer.

What to do next

Verify that the S-TAP is communicating with the Guardium system by browsing to [Manage > Activity Monitoring > S-TAP Control](#) and reviewing the S-TAPs status and configuration.

Related tasks

- [Windows: Remove the S-TAP using Add/Remove Programs](#)
- [Windows: Uninstalling S-TAP using the command line](#)

Windows: Upgrading the S-TAP agent using the interactive installer

The interactive installer is useful for smaller deployments or whenever a guided, step-by-step installation experience is required.

Before you begin

Verify the following before you begin:

- Review the Windows S-TAP installation requirements at [Windows: Prerequisites: Installing S-TAP](#).
- Verify that your database server and operating system are supported. For more information, see [System requirements](#) and [Windows: S-TAP monitoring mechanisms support matrix](#).
- Identify the IP address of the database server where you will upgrade the S-TAP, including any virtual IP addresses.
- Obtain the S-TAP module from either [Fix Central](#), or your Guardium representative.

Note: You cannot install or run Windows S-TAP on a domain controller.

Note: **Db2 servers.** When upgrading an S-TAP from 11.3 or before to 11.4 or later on Db2 servers, the S-TAP cannot continue to capture the Db2 server traffic. Stop and restart your Db2 instances after the S-TAP upgrade to resume capturing Db2 traffic. Subsequent upgrades do not require you to restart the instances.

Procedure

1. Log on to the database server using a system administrator account.
2. Copy the S-TAP module to your database and start the Guardium Windows S-TAP Install Wizard.
Attention: When installing an S-TAP on Windows 2012 or later, you must use administrative privileges. To do this, right-click the installer and choose Run as Administrator.
3. Read the license agreement on the Guardium License screen. To continue installation, select I accept the terms of the license agreement and click Next.
4. Provide the requested content on the Customer Information screen, then click Next to continue. The default values are appropriate for most installations.

- [Windows: Upgrading S-TAP using the command line](#)
You can upgrade the Windows S-TAP from the command line using the setup command.
- [Windows: Uninstalling S-TAP using the command line](#)
You can use the command line to uninstall S-TAP no matter how it was installed. (For GIM installs, best practice is to uninstall with GIM.)

Windows: Installing S-TAP agent using the command line interface

The command-line installer provides a scriptable solution that is especially useful for managing large deployments.

Before you begin

Verify the following before you begin:

- Review the Windows S-TAP installation requirements at [Windows: Prerequisites: Installing S-TAP](#).
- Verify that your database server and operating system are supported. For more information, see [System requirements](#) and the [Windows: S-TAP monitoring mechanisms support matrix](#).
- Identify the IP address of the database server where you are installing the S-TAP, including any virtual IP addresses.
- Identify the IP address of the Guardium® system that will control the S-TAP.
- Verify that the intended S-TAP installation directory is empty or does not exist.
- Obtain the S-TAP module from either [Fix Central](#), or from your Guardium representative.

Note: You cannot install or run Windows S-TAP on a domain controller.

Note: **Db2 servers.** When upgrading an S-TAP from 11.3 or before to 11.4 or later on Db2 servers, the S-TAP cannot continue to capture the Db2 server traffic. Stop and restart your Db2 instances after the S-TAP upgrade to resume capturing Db2 traffic. Subsequent upgrades do not require you to restart the instances.

About this task

If you want to disable auto-discovery, specify NOAUTODISCOVERY during the installation. For more information, see [Windows: Auto discovery of database instances during installation and upgrade](#).

Procedure

1. Log on to the database server using a system administrator account.
2. Copy the installer to your database, and using the Windows Command Prompt, navigate to the Windows S-TAP installer directory.
For example,

```
cd c:\Windows-STAP-V10.6.0.0.89
```

You should find a **setup.exe** executable in the installer directory.

3. Install the S-TAP using the **setup.exe** executable with the appropriate parameters.

The required parameters are:

- INSTALLPATH, the default is used if you do not specify
- TAPHOST
- APPLIANCE

All parameters, except INSTALLPATH, can be updated after the installation. A typical install command is:

```
setup.exe -UNATTENDED -APPLIANCE 10.0.147.234 -TAPHOST 10.0.145.41
```

where:

- -UNATTENDED (required) invokes the command-line installer.
- -APPLIANCE specifies the IP address of the Guardium system that will control the S-TAP.
- -TAPHOST (required) specifies the client IP address where the S-TAP is being installed.

For a complete description of the **setup.exe** executable and its parameters, see [Windows: S-TAP command line installation parameters](#).

What to do next

Verify that the S-TAP is communicating with the Guardium system by browsing to Manage > Activity Monitoring > S-TAP Control and reviewing the S-TAPs status and configuration.

Related reference

- [Windows: S-TAP command line installation parameters](#)

Windows: S-TAP command line installation parameters

Understand the parameters (each with a short description) that you can use in your script and GIM installation.

In a CLI installation, you install an S-TAP by using **setup.exe** with the appropriate parameters, as follows,

setup.exe -PARAMETER value

Do not use “=” signs to assign values to the parameters. The only time “=” is used when you want to add a parameter to the TAP section of the guard_tap.ini file directly as it is typed in the command line.

To add parameters that are not specified here but are required in the guard_tap.ini file, append the [TAP] section by specifying the parameter and value with an = sign, for example:

```
setup.exe -UNATTENDED -INSTALLPATH "C:\Program Files\IBM\Windows S-TAP" -APPLIANCE 10.0.148.160 -TAPHOST 10.0.146.160 QRW_INSTALLED=0  
QRW_DEFAULT_STATE=0
```

Important: The TAPHOST, APPLIANCE, INSTALLPATH attributes are required.

Attention: If a parameter is available through both the GIM and the command line interface (CLI), then the GIM parameter, including any defaults, always overwrites any value that is available from **WINSTAP_CMD_LINE**.

Table 1. Parameters applicable to all .NET installers

Command line parameter	GIM parameter	Description
UNATTENDED	QUIET	Install silently. (Does not require a value).
INSTALLPATH	WINSTAP_INSTALL_DIR	The installation directory. Default installation path is C:\Program Files\IBM\Windows S-TAP
UNINSTALL		Uninstall. A value is not required.
CUSTOMER		Change a customer name.
COMPANY		Change a company name.
SERVICEUSER		Specify a user to run the service under.
SERVICEPASSWORD		The password for the user.

Table 2. Other S-TAP Parameters

Command line parameter	Description
APPLIANCE	The SQLGUARD IP. You can set up multiple appliances by specifying this parameter multiple times, each with a unique value.
ENABLEGAM	Enables the Guardium Agent Monitor service (GAM).
DISCOVERY-PORT	S-TAP Discovery connects to the Guardium system with this port. Default=8443. Only used in UNATTENDED mode.

Command line parameter	Description
INSTALLERLOGPATH	Specifies the location for storing the S-TAP installer log files. Use this parameter if you don't want to use the default location (C:).
NOAUTODISCOVERY	Prevents database instance discovery from running during the installation. A value is not required. For more information, see Windows: Auto discovery of database instances during installation and upgrade .
START	Controls whether S-TAP is started or not after installation. Attention: This parameter defaults to on and can be disabled only by setting its value to 0. Any value other than 0 set the parameter to on.
TAPHOST	The local/client IP. Required for unattended installation.

Table 3. S-TAP Parameters that default to ON.. Unless otherwise noted, the default value for each parameter is ON. Enter any other value to turn off the parameter.

Command line parameter	GIM parameter	Description
V8PROTOCOL	WINSTAP_V8_PROTOCOL	Default = OFF. Note: To use V8 protocol, set this parameter to ON.
TCP	WINSTAP_TCP_DRIVE_R_INSTALLED	Use TCP driver.
NMP	WINSTAP_NAMED_PIPE_DRIVER_INSTALLED	Allows you to specify the named pipe used by MS SQL Server for local access. If a named pipe is used, but nothing is specified in this parameter, S-TAP attempts to retrieve the named pipe name from the registry. In rare cases, the S-TAP named pipes driver can interact with other third-party software in ways that slow the server down. To turn off the named pipes driver, set this parameter to 0. The named pipes driver is removed at the next system reboot. Note: If you turn off the named pipes driver, then the S-TAP does not capture named pipes traffic.
DB2SHMEM	WINSTAP_DB2_TAP_INSTALLED	Enables sniffing Db2 shared memory traffic.
DB2EXIT	WINSTAP_DB2_EXIT_DRIVER_INSTALLED	Enables Db2 integration with S-TAP.
ORACLEPLUGIN	WINSTAP_ORA_DRIVE_R_INSTALLED	Enables sniffing Oracle ASO and SSL traffic.

Table 4. Enterprise Load Balancing parameters

Command line parameter	GIM parameter	Description
LOAD-BALANCER-IP	WINSTAP_LOAD_BALANCER_IP	Required if you are configuring load balancing. This option specifies the IP address of the central manager or managed unit for the S-TAP to use for load balancing. <ul style="list-style-type: none"> • S-TAP parameters cannot be changed via the interactive installer during upgrade. Use the Guardium® UI after the upgrade to change S-TAP parameters. • To configure the enterprise load balancer to run on a managed unit, the S-TAP must be at V10.1 or higher.
LB-APP-GROUP	WINSTAP_INITIAL_BALANCER_TAP_GROUP	Optional. The application group name that this S-TAP belongs to for enterprise load balancing. Attention: Group names with spaces or special characters are not supported.
LB-MU-GROUP	WINSTAP_INITIAL_BALANCER_MU_GROUP	Optional. The managed unit group name to associate with the app-group. Requires a defined LB-APP-GROUP. A managed unit group must exist on the central manager before it can be used during installation of S-TAP. Attention: Group names with spaces or special characters are not supported.
LB-NUM-MUS	WINSTAP_LOAD_BALANCER_NUM_MUS	The number of managed units the enterprise load balancer allocates for this S-TAP.

Windows: Upgrading S-TAP using the command line

You can upgrade the Windows S-TAP from the command line using the setup command.

Before you begin

Note: **Db2 servers.** When upgrading the S-TAP V11.3 and lower to V11.4 and higher on DB2 servers, the S-TAP cannot continue to capture the DB2 server traffic. Stop and restart your Db2 instances after the S-TAP upgrade to resume capturing DB2 traffic. Subsequent upgrades do not require restart of the instances.

Procedure

1. Log on to the database server system using a system administrator account.
2. Change to the directory containing the S-TAP setup program.
3. Run the setup program with the following options: **setup -UNATTENDED**

Windows: Uninstalling S-TAP using the command line

You can use the command line to uninstall S-TAP no matter how it was installed. (For GIM installs, best practice is to uninstall with GIM.)

About this task

This procedure removes the installed S-TAP while making sure the configuration file is saved for future use. The Windows S-TAP can be uninstalled without reboot. Upgrade your S-TAP to 11.4 (or later), reboot the S-TAP once, for example, in the next maintenance window. Then, you can uninstall the S-TAP without rebooting the database server or restarting database instances. A fresh install of the 11.4 (or later) S-TAP out of the box is fully uninstallable without requiring a reboot.

Procedure

1. Log on to the database server system using a system administrator account.
2. Copy the current S-TAP configuration file to a safe location (a non-Guardium directory). Look for this file in C:\Program Files (x86)\IBM\Windows S-TAP\Bin\guard_tap.ini.
3. Change to the directory containing the S-TAP setup program.
4. Run the setup program with the following options: **setup -UNINSTALL**

Windows: Remove the S-TAP using Add/Remove Programs

You can use Add/Remove Programs to uninstall S-TAP no matter how it was installed. (For GIM installs, best practice is to uninstall with GIM.)

About this task

This procedure removes the installed S-TAP while making sure the configuration file is saved for future use.

Procedure

1. Log on to the database server system using a system administrator account.
2. Copy the current S-TAP configuration file to a safe location (a non-Guardium directory). Look for this file in C:\Program Files\IBM\Windows S-TAP\Bin\guard_tap.ini.
3. From the Add/Remove Programs control panel, remove IBM® Security Guardium® S-TAP.

Windows: S-TAP installation flow on Oracle RAC

Configure S-TAPs in an Oracle RAC.

Procedure

1. Install S-TAP on all nodes. In case GIM is used, install GIM client on all nodes, then install S-TAP on all nodes.
2. Configure the S-TAP parameter STAP_TAP_IP: public IP configured for the node. (Can be configured through GIM UI.)
 - The parameter STAP_ALTERNATE_IPS is not required.
 - If the Oracle database is encrypted (ASO/SSL) make sure the parameter ORA_DRIVER_INSTALLED=1
 - If the Oracle inspection engine is auto-discovered, it already contains all required parameters including INSTANCE_NAME.

Windows: Managing S-TAP when upgrading your database

Use these guidelines for managing your Windows S-TAP when upgrading your database.

Procedure

1. Upgrade your database.
2. If using exit: make sure the exit library is in the appropriate place (for example if there is a new DB location directory).
3. Check that the inspection engine for the database is correct (for example, the version number).
4. If changes in the IE were made, restart the S-TAP.

Windows: Managing S-TAP when upgrading your database operating system

Use these guidelines for managing an S-TAP, when upgrading the operating system (OS) of your database. This is relevant for all S-TAPs, regardless of the installation method.

Before you begin

- Verify that the installed Windows S-TAP agent supports the new OS version. If not, upgrade Windows S-TAP before or after upgrading the OS, using the same method as the S-TAP installation. See the [Guardium support matrix](#).

About this task

The GIM parameter auto_install_on_db_server_os_upgrade controls GIM's ability to auto-upgrade all bundles. If enabled, when the database server boots up after an operating system upgrade, GIM automatically downloads and installs these bundles. This parameter is disabled by default to prevent unintentional bundle upgrades. It's easiest to enable the parameter before you upgrade the database operating system.

If the parameter is disabled when you upgrade the database operating system, the GIM client detects that the operating system changed, and it changes the _x suffix of the version to _0. You can see the version in the Set up by Client, for example, 10.6.1.4_r123456_0. To resolve the mismatch between the GIM client and the database operating system, do one of:

- Enable the GIM global parameter auto_install_on_db_server_os_upgrade, which automatically upgrades all the GIM clients with the latest bundle of the operating system they support.
- Do not enable auto_install_on_db_server_os_upgrade, and upgrade the GIM clients manually.

It is best to update all your GIM-installed modules as soon as possible after the upgrade, whether manually or automatically. K-TAP is not loaded after an operating system upgrade.

Procedure

1. Back up the guard_tap.ini file. You probably won't need it, but retain it until the S-TAP is functioning as expected after the upgrade.
2. Upgrade the operating system of the database.
3. Restart Windows S-TAP.

Windows: When to restart or reboot the database server after installing or upgrading S-TAP

In general, you do not need to reboot the database server after you install or upgrade Windows S-TAP unless you are upgrading between versions or when stated otherwise in the release notes.

You do not need to reboot for any fresh S-TAP installation.

However, you do need to reboot the database server to update the NmpProxy driver when you upgrade between versions. For example, a reboot is required if you upgrade from Windows S-TAP 11.2 (or earlier) to 11.3 (or later). However, if there are no issues with your current NmpProxy functionality, you can delay the reboot until the next maintenance cycle.

If you are not certain about reboot requirement for particular version you are using, check with your Technical Support representative. Restart/reboot requirements are the same for GIM and non-GIM implementations.

Reboot database servers only when you need to upgrade the driver.

Windows: Managing S-TAP when upgrading your database

Use these guidelines for managing your Windows S-TAP when upgrading your database.

Procedure

1. Upgrade your database.
2. If using exit: make sure the exit library is in the appropriate place (for example if there is a new DB location directory).
3. Check that the inspection engine for the database is correct (for example, the version number).
4. If changes in the IE were made, restart the S-TAP.

Windows: Managing S-TAP when upgrading your database operating system

Use these guidelines for managing an S-TAP, when upgrading the operating system (OS) of your database. This is relevant for all S-TAPs, regardless of the installation method.

Before you begin

- Verify that the installed Windows S-TAP agent supports the new OS version. If not, upgrade Windows S-TAP before or after upgrading the OS, using the same method as the S-TAP installation. See the [Guardium support matrix](#).

About this task

The GIM parameter auto_install_on_db_server_os_upgrade controls GIM's ability to auto-upgrade all bundles. If enabled, when the database server boots up after an operating system upgrade, GIM automatically downloads and installs these bundles. This parameter is disabled by default to prevent unintentional bundle upgrades. It's easiest to enable the parameter before you upgrade the database operating system.

If the parameter is disabled when you upgrade the database operating system, the GIM client detects that the operating system changed, and it changes the _x suffix of the version to _0. You can see the version in the Set up by Client, for example, 10.6.1.4_r123456_0. To resolve the mismatch between the GIM client and the database operating system, do one of:

- Enable the GIM global parameter auto_install_on_db_server_os_upgrade, which automatically upgrades all the GIM clients with the latest bundle of the operating system they support.
- Do not enable auto_install_on_db_server_os_upgrade, and upgrade the GIM clients manually.

It is best to update all your GIM-installed modules as soon as possible after the upgrade, whether manually or automatically. K-TAP is not loaded after an operating system upgrade.

Procedure

1. Back up the guard_tap.ini file. You probably won't need it, but retain it until the S-TAP is functioning as expected after the upgrade.
2. Upgrade the operating system of the database.
3. Restart Windows S-TAP.

Configuring S-TAP in the S-TAP Control page

Use the S-TAP Control page to view all S-TAPs that are managed by this Guardium system, manage individual S-TAPs, and perform a few operations on all S-TAPs.

Before you begin

You must be logged in to a Guardium system that is the active host for the S-TAP.

About this task

During the installation process, a user might make an error in configuring an S-TAP, which is not detected until after the installation process finishes. For instance, a user might forget to enter an IP address or use the wrong IP address when they define an SQL Guard IP. To remedy these types of mistakes, you can modify some of the S-TAP configurations.

You can safely change the parameters that are in the GUI. Parameters that do not appear in the GUI are advanced parameters. Do not change them without instructions from Guardium support.

All configuration changes require that you restart the S-TAP agent. If you modify parameters in the GUI or with GIM, the S-TAP is restarted transparently. If you need to restart the S-TAP manually (for example after you modify the configuration by using API or directly in the guard_tap.ini file), use the [Send command](#), or see [Windows: Starting S-TAP using GIM](#), or [Windows: Starting S-TAP without GIM](#).

If you installed your S-TAP by using the Guardium Installation Manager (GIM), you can update some parameters through the GIM GUI or API.

S-TAP status can be one of:

- Green: Online
 - Yellow: Indicates an S-TAP or a database server error. To see details about a specific error, click  to open the S-TAP event log.
Typical errors, along with their resolutions, include:
 - CPU exceeds threshold: The CPU_USAGE_LIMIT is exceeded by the number of minutes determined by CPU_USAGE_INTERVALS_ALLOWED.
Resolution: Take one of the following steps:
 - Restart the S-TAP.
 - Increase the system CPU.
 - Verify and, if needed, modify, the CPU parameter values in either the guard_tap.ini file or through the GIM parameters.
 - Handle count exceeds threshold: The HANDLE_COUNT_LIMIT is exceeded by the number of minutes determined by HANDLE_COUNT__INTERVALS_ALLOWED.
Resolution: Take one of the following steps:
 - Restart the S-TAP.
 - Verify and, if needed, modify, the HANDLE_COUNT parameter values in either the guard_tap.ini file or through the GIM parameters.
 - S-TAP memory usage exceeds threshold: The MEM_USAGE_LIMIT is exceeded by the number of minutes determined by MEM_USAGE_INTERVALS_ALLOWED.
Resolution: Take one of the following steps:
 - Restart the S-TAP.
 - Increase S-TAP memory.
 - Verify and, if needed, modify, the S-TAP memory values in either the guard_tap.ini file or through the GIM parameters.
 - DBMonitor service down.
Resolution: Restart the S-TAP by clicking Accept.
 - DLLs not loaded correctly: Certain DLLs that support Db2 Exit or encrypted traffic might not be loaded correctly.
Resolution: Verify the relevant parameters in guard_tap.ini and then restart the S-TAP.
 - Drivers not running or loaded: An issue exists with the S-TAP drivers.
Resolution: Restart the drivers manually by running the net start <driver_name> command from an administrative command prompt. The driver name is included in the error message.
- The S-TAP drivers for your system depend on the S-TAP protocol. For more information about protocols, see [Windows: S-TAP protocol 8](#). For more information about the S-TAP drivers, see either, [Driver parameters](#) or [Protocol 8 Driver parameters](#).
- Load Balancer is down: The load balancer is unreachable by the S-TAP.
Resolution: Check the load balancer and restart if needed. Verify the load balancer IP address by clicking Modify. If you make changes, click Accept.
 - Out of range ini parameter values: One or more S-TAP parameters in the TAP section of the guard_tap.ini file are outside of the acceptable range.
Resolution: Modify the relevant parameter values by taking one of the following steps:
 - Click Modify, if available (not all parameters can be modified from the Modify page) and then click Accept
 - Modify the parameters from the guard_tap.ini file.
 - Modify the parameters from GIM.

If problems persist, contact Guardium support.

Note: When you modify S-TAP parameters in the GUI or through the GuardAPI, S-TAP checks the values before it saves the parameters. When the S-TAP identifies an erroneous value, the value is not saved and Guardium creates an error in the S-TAP event log. The S-TAP uses default values so that it can keep sending traffic.

- Red: Offline

Procedure

1. Click Manage > Activity Monitoring > S-TAP Control to open S-TAP Control.

2. Perform operations on all S-TAPs in the page.

- Refresh: Refresh display of S-TAPs.
- Add All to Schedule: Add all displayed S-TAPs to the S-TAP verification schedule. See [Windows: Inspection engine verification](#).
- Remove All from Schedule: Remove all displayed S-TAPs from the S-TAP verification schedule.
- Comments: Add comments. See [Comments](#).

3. Identify the S-TAP to be configured by its IP address or the symbolic hostname of the database server on which it is installed. View and perform operations on individual S-TAPs.

Option	Description
Delete: 	Click Delete to remove an S-TAP. Deleting S-TAPs is useful to clean up your display when you know that an S-TAP is inactive, or when the Guardium unit is no longer listed as a host in the S-TAP's configuration file. In either of these cases, the S-TAP displays indefinitely with an offline status if you do not delete it. You cannot remove an active S-TAP from the list. Clicking Delete does not stop an S-TAP from sending information, and does not remove the Guardium host from the list of hosts that are stored in the S-TAP's configuration file.
Refresh: 	Click Refresh to fetch a copy of the latest S-TAP configuration from the agent. The S-TAP display does not auto-refresh.

Option	Description
Send Command: 	Opens the S-TAP Commands window, where you can run various commands on the S-TAP host. <ul style="list-style-type: none"> • Restart. Restarts the S-TAP in the mode you select. <ul style="list-style-type: none"> • 0: Restarts the S-TAP. Use this mode in environments without enterprise load balancing. • 1: Restarts the S-TAP process while preserving the data in the S-TAP buffer. (The S-TAP picks up the new configuration from the enterprise load balancer without flushing the buffers.) Used in the enterprise load balancer environment. • S-TAP logging: Starts S-TAP logging for debugging purposes, at the log level you enter in Level and for the duration you enter in Duration Sec. See DEBUGLEVEL in Debug parameters and Protocol 8 Debug parameters. • Run Diagnostics: Run the S-TAP diagnostics script (and upload the results to the Guardium system) • Revoke Ignore: All sessions that are ignored by a revocable ignore policy become available, and S-TAP starts capturing the traffic for those sessions. • Run Database Instance Discovery: Runs the database instance discovery once, immediately. (By default, it runs once every 24 hours.) Select Replace Inspection Engines only if you want to override defined inspection engines with discovered details, and restart the S-TAP. For a full description of this option, see Windows: Discover database instances. You can specify rules that manage how discovered details on database instances are implemented, or not. For more information, see Database discovered instances rules.
Edit S-TAP configuration: 	Opens the S-TAP configuration window. Parameters that do not appear in the GUI are advanced parameters. Do not modify them unless you are an advanced user, or you are instructed to modify them by Guardium Technical Support. <ul style="list-style-type: none"> • S-TAP Control: Details • S-TAP Control: Change auditing • S-TAP Control: Application server user identification • S-TAP Control: Guardium Hosts • S-TAP Control: Firewall Details • S-TAP Control: Inspection Engines
Show S-TAP Event Log: 	Click to open the S-TAP event log, where you can see events such as connect, disconnect, GIM server configuration. This log is useful for troubleshooting.
Add to Schedule	If selected, adds the individual S-TAP to the scheduled verification.
Revoke All Ignored Sessions	A database might be running many sessions, some of which are currently ignored. Clear this option to stop ignoring traffic from ignored sessions.

S-TAP Control: Details

Understand the parameters in the Details section of the S-TAP Control in the GUI.

Parameter	Default value	Description
Version		The S-TAP version.
Devices	none	Which interfaces to listen on. Use ifconfig to find the correct interface.
Load balancing	0	<p>Controls S-TAP load balancing to Guardium® systems. Valid values:</p> <ul style="list-style-type: none"> • 0: No load balancing. • 1: Load balancing. Traffic is balanced between the primary and secondary servers, which are defined in the SQLGuard section. • 2: Redundancy. Fully mirrored S-TAP sends all traffic to all primary and secondary servers, which are defined in the SQLGuard section. • 3: Hardware load balancing. Guardium uses a load balancer such as F5 or Cisco. S-TAP sends the traffic to the load balancer, which forwards it to one of the collectors in the pool. <p>Use the primary parameter in the Guardium Hosts section to specify primary, secondary, tertiary, or more, servers. If this parameter is set to 0, and you have more than one Guardium system monitoring traffic, then the non-primary Guardium systems are available for failover.</p> <p>This parameter is also used in enterprise load balancing. For more information, see Enabling enterprise load balancing and associating an S-TAP with a central manager.</p>
Trace files dir	INSTALLDIR	The Directory in which access tracer files are stored.
App. server user Identification		

Parameter	Default value	Description
TLS Use	0	<ul style="list-style-type: none"> <input checked="" type="checkbox"/> do not encrypt traffic between the S-TAP agent and the Guardium system. Warning: The traffic between the agent and Guardium system is in clear text. <input checked="" type="checkbox"/> Use SSL to encrypt traffic between the S-TAP agent and the Guardium system. <p>Guardium recommends encrypting network traffic between the S-TAP and the collector whenever possible. Only in cases where the performance is a higher priority than security should this be disabled.</p>
Compress. level	0	Data compression level, from 1 to 9. 0=no compression.
All can control	0	Defines which Guardium system control this S-TAP. Valid values: <ul style="list-style-type: none"> <input checked="" type="checkbox"/> S-TAP is controlled by the primary Guardium system only. <input checked="" type="checkbox"/> S-TAP can be controlled by any Guardium system.
Load Balancer host name or IP address		<p>The IP address of the central manager or managed unit this S-TAP should use for load balancing.</p> <ul style="list-style-type: none"> If using enterprise load balancing while Load balancing and Managed units, failover data is not sent to the secondary system. Instead, failover data is sent to the system allocated by the load balancer to replace the failed server. This is true only as long as the Central Manager is running and Enterprise Load Balancer is active. If the load balancer is not available then traffic is rerouted to secondary sqlguard_ip. S-TAP parameters cannot be changed via the interactive installer during upgrade. Use the Guardium UI after the upgrade to change S-TAP parameters. If configuring the enterprise load balancer to run on a managed unit, the S-TAP must be at V10.1 or higher.
Managed Units		The number of managed units the enterprise load balancer allocates for this S-TAP.
Restricted logging		Controls restricted logging on the collector. Use this to evaluate the number of records affected by an SQL command, while masking the actual query. This parameter can only be set by user root on the DB server. Valid values: <ul style="list-style-type: none"> 0: Unrestricted. 1: Log with masking. Only logins are allowed (sent packets are flagged with LOGALWAYSMASK). Forces encryption to be on in the S-TAP regardless of any other settings; traffic is sent to the collector only after the collector has indicated that it is aware of the parameter value. Otherwise, the S-TAP logs a message that traffic can't be sent, and its status is red in the S-TAP Control page. 2: All packets are allowed (sent packets are flagged with LOGACCESSIONLY)
Discovery interval		<p>The interval at which the S-TAP reports database instance discovery results to the collector. Select only if you want to change the discovery interval from its default of 24 hours. When you select this option, the UI updates with two radio buttons: Hour and Minute. Type in any positive integer to set the discovery interval in either hours or minutes. Valid values:</p> <ul style="list-style-type: none"> Hours: maximum of 24 Minutes: 5 - 1440 <p>Clear the Enable discovery interval checkbox to disable.</p>

S-TAP Control: Change auditing

Understand the parameters in the Change Auditing section of the S-TAP Control in the GUI.

GUI	Default value	Description
Task checkpoint	task_checkpoint	Internal handle program machine state in case of host failure.
Client checkpoint	client_checkpoint	File used to restart processing. A series of files is created. Each version of the file ends with a unique number.
Checkpoint period	3600	Interval time, in seconds, for the check.
Fail over file	fail_over_file	Name of the outgoing messages buffer. The database writes to this file when the Guardium® system cannot be reached. During this time, the file can grow to the maximum size specified. When the limit is reached, a second file is created, with the same name with the digit 2 appended to the end of the name. (At this point CAS begins trying to connect to a secondary server.) If that file also reaches the maximum size, the first file is overwritten. If the first file fills again, the second file is overwritten. Thus, following an extended outage, you might lose data, but an amount of data up to twice the size of the Failover File Size Limit is stored.
Fail over file size limit	50000	Failover file maximum size, in KB. The disk space requirement is twice what you specify here because the system maintains two failover files. If you specify -1, the file size is unlimited, but it is recommended that you cap the file size.
Max rec. attempts	5000	Number of reconnect attempts when connection is lost. The maximum number of times CAS attempts to reconnect to the Guardium system. Set this value to -1 for unlimited reconnection attempts. The default cas_max_reconnect_attempts and cas_reconnect_interval define an interval of about 3.5 days. After reaching the maximum, CAS continues to run, writing to the failover files, but it does not attempt to reconnect with a Guardium host.
Reconnect interval	60	Wait time, in seconds, between reconnect attempts.
Raw data limit	1000	Maximum number of KB written for an item when the Keep data checkbox is marked in the item template. If you specify -1, the size is unlimited.
Md5 size limit	1000	Maximum size of a data item, KB, on which the MD5 checksum calculation is performed. If you specify -1, there is no limit.

S-TAP Control: Application server user identification

Understand the parameters in the Application server section of the S-TAP Control in the GUI.

Parameter	Default value	Description
Session timeout		
Ports	8080	Comma-separated list of ports, or hyphens for inclusive ranges of ports, on which the Java™ application is accessed by a web browser.
Login pattern		Comma-separated list of strings specifying the login pattern that is passed to the application. This pattern is passed to the Java application to identify a user login.
Username prefix		Comma-separated list of strings specifying the prefix to the username for a given session. This is the pattern the Java application uses to indicate the username of the given session.
Username postfix		Comma-separated list of strings specifying the postfix to the username for a specific session. This pattern is passed to the Java application to indicate the end of the value for the given variable that indicates the username.
Session pattern		Comma-separated list of strings specifying the start of an end-user session, using a particular database session. This pattern specifies the [change of] end-user session for a specific database connection.
Session prefix		Comma-separated list of strings specifying the session identifier.
Session postfix		Comma-separated list of strings specifying where the session ends.
Session ID pattern		Comma-separated list of strings specifying the identifier for marking which end-user session a specific connection is continuing with.
Session ID prefix		Comma-separated list of strings specifying what identifies or precedes the session_id in a specific users indicator packet.
Session ID postfix		Comma-separated list of strings specifying where the session ID ends.

S-TAP Control: Guardium Hosts

Understand the parameters in the Guardium Hosts section of the S-TAP Control in the GUI.

Parameter	Description
Guardium Host	IP address or hostname of the Guardium system that acts as the host for the S-TAP. You can define multiple hosts by clicking Modify, and opening the Guardium Hosts section.
Active	<ul style="list-style-type: none"> • <input checked="" type="checkbox"/> : connection is active. • <input type="checkbox"/> : connection is not active. <p>You can change the primary S-TAP by clicking Modify, and opening the Guardium Hosts section.</p>

S-TAP Control: Firewall Details

These parameters affect the behavior of the S-TAP with respect to the firewall.

Name	Default value	Description
Firewall installed		Firewall feature enabled. Valid values: <ul style="list-style-type: none"> • <input checked="" type="checkbox"/> : disabled. • <input type="checkbox"/> : enabled.
Firewall timeout	10	Time, in seconds, to wait for a verdict from the Guardium® system. If the firewall times out, the value of the parameter Firewall fail close determines whether to block or allow the connection. Valid values: 0-10.
Firewall default state	0	Valid values: <ul style="list-style-type: none"> • 0: Firewall is activated per session when triggered by a rule in the installed policy. • 1: All traffic is watched for firewall policy violations • 2: All traffic is watched for firewall policy violations for the initial priority_count packets (guard_tap.ini parameter). S-TAP watches the initial part of every new session to your DB. This is useful when you have session based policies, firewall rules based on the user, or some other information that is passed early in the session. It limits the impact of firewall on the performance. Instead of watching every bit of the session (Firewall default state=1) and waiting for an UNWATCH verdict, S-TAP simply unwatches automatically if no WATCH or DROP is sent.
Firewall fail close	<input checked="" type="checkbox"/>	The action when the verdict cannot be set by the policy rules, for example the Firewall timeout expires. Valid values: <ul style="list-style-type: none"> • <input checked="" type="checkbox"/> : the connection goes through. • <input type="checkbox"/> : the connection is blocked.
Firewall force watch		When Firewall default state=0 (off), then Firewall force watch specifies the network/mask of the IPs you want the firewall to watch, overriding the default (off). Valid value: comma separated list of IP/mask values.
Firewall force unwatch		When Firewall default state=1 (on), then Firewall force unwatch specifies the network/mask of the IPs you want the firewall to ignore, overriding the default (on). Valid value: comma separated list of IP/mask values.

S-TAP Control: Inspection Engines

Understand the parameters in the Inspection Engines section of the S-TAP Control page.

Each inspection engine has a set of parameters. The parameters for each IE depend on the type of database.

Note: Inspection engines are created automatically. Do not change the parameter values unless instructed to do so by Technical Support.

Parameter	Default value	Description
Protocol		The type of data repository being monitored.
Instance Name		The name of the database instance on this server. Required when MS SQL Server is using encryption, or MS SQL Server using Kerberos Authentication. (MSSQLSERVER is the default.)
Port range		Starting port range specific to the database instance. Together with port_range_end defines the range of ports monitored for this database instance. There is usually only a single port in the range. For a Kerberos inspection engine, set the start and end values to 88-88. If a range is used, do not include extra ports in the range, as this could result in excessive resource consumption while the S-TAP attempts to analyze unwanted traffic.
Port range		Ending port range specific to the database instance.
Named Pipe		Specifies the named pipe used by MS SQL Server for local access. If a named pipe is used, but nothing is specified in this parameter, S-TAP attempts to retrieve the named pipe name from the registry.
KTAP DB Real Port	4100	Used only when the K-TAP monitoring mechanism is used. Identifies the database port to be monitored by the K-TAP mechanism.
Client Ip/Mask		<p>Identifies the clients to be monitored, using a list of addresses in IP address/mask format: n.n.n/n.m.m.m. If an improper IP address/mask is entered, the S-TAP does not start. Valid values:</p> <ul style="list-style-type: none"> • null=select all clients • 127.0.0.1/255.255.255.255=local traffic only <p>networks and exclude networks cannot be specified simultaneously. If the IP address is the same as the IP address for the database server, and a mask of 255.255.255.255 is used, only local traffic will be monitored. An address/mask value of 1.1.1.1/0.0.0.0 monitors all clients.</p>
Exclude Client Ip/Mask		A list of client IP addresses and corresponding masks that are excluded from monitoring. This option allows you to configure the S-TAP to monitor all clients, except for a certain client or subnet (or a collection of these). networks and exclude networks cannot be specified simultaneously.
TEE Listen Port-Real Port	12344	Deprecated. Replaced by the parameter real_db_port when the K-TAP monitoring mechanism is used. Was required when the TEE monitoring mechanism. The Listen Port is the port on which S-TAP listens for and accepts local database traffic. The Real Port is the port to which S-TAP forwards traffic.
Connect To Ip	127.0.0.1	IP address for S-TAP to use to connect to the database. Some databases accept local connection only on the real IP address of the machine, and not on the default (127.0.0.1). When K-TAP is enabled, this parameter is used for Solaris zones and AIX WPARs and it should be the zone IP address in order to capture traffic. When Tee is enabled, this parameter is the IP address for S-TAP to use to connect to the database. Some databases accept local connection on 127.0.0.1, while others accept local connection only on the 'real' IP of the machine and not on the default (127.0.0.1).
DB User		
DB Install Dir	NULL	DB2, Informix, or Oracle: Enter the full path name for the database installation directory. For example: /home/oracle10. All other database types enter: NULL
Process Name		Database's running executables that are to be monitored. For example, a DB2 IE would be TAP_DB_PROCESS_NAMES=DB2SYSCS.EXE
DB2 Shared Mem. Adjust.	20	Required when DB2 is selected as the database type, and shared memory connections are monitored. The offset to the server's portion of the shared memory area. Offset to the beginning of the DB2 shared memory packet, depends on DB2 version, 32 in the earlier versions, 80 in 8.2.1 and later.
DB2 Sh. Mem. Client Pos.	61440	The offset to the client's portion of the shared memory area. Required when DB2 is selected as the database type, and shared memory connections are monitored. The client offset can be calculated by taking the value of the DB2 parameter ASLHEAPSZ and multiplying by 4096 to get the appropriate offset. The default for this parameter is 61440 decimal. This parameter is calculated by taking the DB2 database configuration value of ASLHEAPSZ and multiplying by 4096. To get the value for ASLHEAPSZ, execute the following DB2 command: db2 get dbm cfg and look for the value of ASLHEAPSZ. This value is typically 15 which yields the 61440 default. If it's not 15, take the value and multiply by 4096 to get the appropriate client offset.
DB2 Shared Mem. Size		DB2 shared memory segment size. Required when DB2 is selected as the database type, and shared memory connections are monitored.
	NULL	For Oracle or MS SQL Server only, when named pipes are used. For Oracle, the list usually has two entries: oracle.exe,tnslsnr.exe. For MS SQL Server, the list is usually just one entry: sqlservr.exe. For a DB2, Oracle, or Informix database, enter the full path name for the database executable. For example: <ul style="list-style-type: none"> • Oracle: /home/oracle10/prod/10.2.0/db_1/bin/oracle • Informix: /INFORMIXTMP/.inf.sqlexec. Applies to all Informix platforms but Linux. • Informix with Linux, example: /home/informix11/bin/oninit • MYSQL: mysql • All other database types: NULL
Encryption	0	Activate ASO or SSL encrypted traffic for Oracle (versions 11 and 12) and Sybase on Solaris, HPUX and AIX. For Oracle, specify db_version in the ini file (e.g. db_version=12) For any Oracle requiring instrumentation, if you are using encryption=1 in the guard_tap.ini (which is not supported on Linux), you must instrument prior to setting that parameter.
	1	1=database traffic participates in load balancing. 0=database traffic does not participate in load balancing.
Intercept Types	NULL	Protocol types that are intercepted by the IE. Valid values: <ul style="list-style-type: none"> • NULL: auto intercepts all protocols the Database supports • Comma separated list: IE intercepts these protocol types only.
Identifier	NULL	Optional. Used to distinguish inspection engines from one another. If you do not provide a value for this field, Guardium auto populates the field with a unique name using the database type and GUI display sequence number.

Parameter	Default value	Description
DB Version	9	The database version. Used for capturing A-TAP traffic.
Unix Socket Marker	Null	Specifies UNIX domain sockets marker for Oracle, MySQL and Postgres. Usually the default value is correct, but when the named pipe or UNIX domain socket traffic does not work then you need to make sure this value is set correctly. For example, for Oracle, unix_domain_socket_marker should be set to the KEY of IPC defined in tnsnames.ora. If it is NULL or not set, the S-TAP uses defined default markers identified as: * MySQL - "mysql.sock" * Oracle - "./oracle/" * Postgres - ".s.PGSQL.5432"

Windows: Configuring S-TAP with `guard_config_update`

You can use the `guard_config_update` script to update your S-TAP configuration (without using the GUI).

About this task

Note: Parameter names are not case-sensitive.

Procedure

- From an administrative command prompt, browse to Windows S-TAP_>Bin.
- Run `guard_config_update` with the parameters that you need to set for your environment.

Parameter	Description
--help (or -h)	List all of the <code>guard_config_update</code> parameters.
--list-ie	List the names of all inspection engines, such as Db2 or MSSQL, on this machine.
--list-sqlguard	List the SQLGUARD address for this machine. For example: <code>VM02.TEST.MYCOMPANY.COM</code>
--list-all-tap-parameters	List the parameters that are in the Tap section. For information about individual parameters, see either Editing the protocol 7 and protocol 8 S-TAP configuration parameters or Editing the protocol 8 S-TAP configuration parameters depending on which protocol your site uses. Note: The output includes some hidden parameters.
--list-sections sectionName	List the section name and associated values in the specified <code>sectionName</code> , for example: <code>guard_config_update.exe --list-sections sqlguard [SQLGUARD_VM02.TEST.MYCOMPANY.COM] PRIMARY=1 SQLGUARD_IP=vm02.test.mycompany.com</code>
--list-services	Lists all S-TAP related services and their associated statuses.
--set-tap-parameter parmName1=parmValue1;parmName2=parmValue2...	Change one or more Tap parameters, where: <ul style="list-style-type: none">• parmName = The name of the parameter to change.• parmValue = The new value for the parameter. For example: <code>guard_config_update.exe --set-tap-parameter upload_feature=1;TENANT_ID=stuff10;ALL_CAN_CONTROL=1 Updated Tap section upload_feature=1 Updated Tap section TENANT_ID=stuff10 Updated Tap section ALL_CAN_CONTROL=1</code>
--set-tap-parameter-force parmName1=parmValue1;parmName2=parmValue2...	Change the specified parameter values for parameters that you cannot change in GIM.
--set-service serviceName1=action1;serviceName2=action2...	Configure one or more S-TAP related services on the database server to perform a specified action, where <code>action</code> can be one of the following: <ul style="list-style-type: none">• Service status:<ul style="list-style-type: none">• start• stop• restart• Windows settings Startup type:<ul style="list-style-type: none">• enable - Set to <i>Automatic</i>.• disable - Set to <i>Disabled</i>.
--set-sqlguard-ip ip/hostname	Change the address or hostname of the primary SQLGUARD appliance. Note: You can change only the primary SQLGUARD IP address.
--set-sqlguard section1,parmName1=parmValue1;section2,parmName2=parmValue2...	Modify the values for one or more SQLGUARD sections.
--set-ie section1,key1=value1;key2=value2...	Modify inspection engine values.
--add-sqlguard sectionName1;sectionName2..	Add an appliance (SQLGUARD) to the guard-tap.ini.

Parameter	Description
--add-ie sectionName1,key1=value1;key2=value2	Modify inspection engines values. To see the value in an inspection engine, use the --list-sections parameter. For example: C:\Program Files\IBM\Windows S-TAP\Bin>guard_config_update.exe --list-ie COUCH1 COUCHBASE1 DB21 ... C:\Program Files\IBM\Windows S-TAP\Bin>guard_config_update.exe --list-sections DB21 [DB_DB21] DB2_CLIENT_OFFSET=61440 DB2_FIX_PACK_ADJUSTMENT=80 DB_TYPE=DB2 DB_VERSION=11 ...
--remove-ie sectionName1,sectionName2	Remove inspection engines by section name.
--remove-sqlguard sectionName1,sectionName2..	Remove sections by the SQLGUARD section name.

3. When you are done, restart the GUARDIUM_STAP service, for example:

```
--set-service GUARDIUM_STAP=restart
```

Windows: Discover database instances

The instance discovery agent runs once per day, by default. It reports new database instances, listener, and port information to the Guardium® system. It does not update the inspection engine configurations.

Instance discovery uploads its findings to the Discovered Instances report of the associated Guardium system.. You can add datasources and inspection engines to Guardium by using the Actions menu in the report.

You can modify the discovery frequency in the UI, by modifying the parameter Discovery interval in the [S-TAP Control: Details](#) page, or the DISCOVERY_INTERVAL parameter in the guard_tap.ini . For more information, see [Discovery parameters](#) or [Protocol 8 Discovery parameters](#).

You can run the database instance discovery manually in the S-TAP Control page by clicking  Send, and selecting Run Database Instance Discovery. If you start a manual discovery while a scheduled discovery is running, the new request is ignored. To avoid an instance where S-TAP discovery does not open the Informix database, it is recommended to start Informix databases by using the full path to the executable.

Important: Do not check Replace Inspection Engines unless you want to overwrite the existing inspection engine configurations.

You can define rules to manage inspection engine creation on discovered database instances. For more information, see [Database discovered instances rules](#). This configuration is used when you run the Send command in the S-TAP Control page. Do not check Replace Inspection Engines when using the rules.

Instance discovery is configured and run independently of auto discovery. For more information, see [Windows: Auto discovery of database instances during installation and upgrade](#).

Windows: Configuring an Inspection Engine

Configure or modify an inspection engine in the S-TAP Control pane.

Before you begin

You must be logged in to the Guardium system that manages the S-TAP.

About this task

Do not configure an S-TAP inspection engine to monitor network traffic that is also monitored directly by a Guardium system that is hosting the S-TAP, or by another S-TAP reporting to the same Guardium system. That would cause the Guardium system to receive duplicate information: it would not be able to reconstruct sessions, and it would ignore that traffic.

You can also add inspection engines directly in the guard_tap.ini file, see [Editing the protocol 7 and protocol 8 S-TAP configuration parameters](#).

You can define up to 50 inspection engines per S-TAP.

Procedure

1. Navigate to Manage > Activity Monitoring > S-TAP Control.
2. In the row of the S-TAP, click  .
The S-TAP Configuration window opens.
3. Scroll to the bottom of the inspection engines, and click  next to Add Inspection Engine....
4. Select the protocol and enter the port range. The window refreshes with the relevant parameters, some with their default values.
5. Configure all required parameters, and click Add. If you are missing parameters, the system informs you what is missing.

Windows: Inspection engine verification

S-TAP verification confirms that the S-TAPs and their inspection engines in your environment are running and actively monitoring database activity. Understand verification, and define a schedule to regularly verify S-TAPs.

Verification checks the sniffer operation and communication between the Guardium system and the inspection engines. You can enable verification for all S-TAP clients on your system, or individual S-TAP clients, or individual inspection engines.

Verification is supported for these database types:

- Db2
- Db2 Exit (Db2 version 10)
- FTP
- Kerberos
- Mysql
- Oracle
- PostgreSQL
- Sybase
- exclude IE
- MSSQL

There are two types of verification:

Standard verification

Checks the sniffer operation, and the communication between the S-TAP and the inspection engine. During standard verification, Guardium® attempts to log in to database defined in the inspection engine with user `resutlfd`, based on the assumption that no such user exists on the target system. (If that user exists, use advanced verification instead.) Depending on the installed policy, failed login alerts might be triggered for that login attempt. Next, the verification process checks whether it can connect to the selected inspection engine on the database server. It expects to receive a response that indicates a failed login. If a different response is received, you might have to investigate further.

Some error messages from individual databases do not indicate a specific problem. For example, on several supported databases, the error code that is returned for a wrong port can also mean that the database itself is not started.

Advanced verification

Use advanced verification to avoid failed login requests, and manage individual inspection engines. During advanced verification, Guardium logs into the database that is defined in the configured datasource. It runs `select * from non_existent_table`. Depending on the installed policy, this SQL might appear in reports or alerts.

- [Windows: S-TAP verification](#)
The S-TAP verification process checks several configuration parameters and attempts to connect to the inspection engines.
- [Windows: Configure standard verification](#)
Use this task to add all inspection engines on a specific S-TAP client host to the verification schedule.
- [Windows: Configure advanced verification](#)
Use this task to run advanced verification on individual inspection engines on a specific S-TAP client host, and to add individual inspection engines to advanced verification.
- [Windows: Configuring the S-TAP verification schedule](#)
You can configure the schedule for running S-TAP verification.

Windows: S-TAP verification

The S-TAP verification process checks several configuration parameters and attempts to connect to the inspection engines.

Before connecting to the database, the verification process checks whether the sniffer process is running on the Guardium® system. The sniffer is responsible for communicating with each S-TAP and processing the data that is received. If the sniffer is not running, responses from the S-TAP are not recognized.

The verification process attempts to log in to your database's STAP client with an erroneous user ID and password, to verify that this attempt is recognized and communicated to the Guardium system.

Next the verification process checks whether it can connect to the selected inspection engine on the database server. It expects to receive a response that indicates a failed login. If a different response is received, you might have to investigate further.

Some error messages from individual databases do not indicate a specific problem. For example, on several supported databases, the error code returned for a wrong port can also mean that the database itself is not started.

Windows: Configure standard verification

Use this task to add all inspection engines on a specific S-TAP client host to the verification schedule.

About this task

As an alternative to this procedure, you can:

- Use the API command `verify_stap_inspection_engine_with_sequence`.
- Use the procedure in [Windows: Configure advanced verification](#) to configure verification on individual inspection engines, by clicking Verify in step 4. The system immediately outputs results. Failed checks are shown first, with recommendations for next steps. Checks that succeeded are shown in a collapsed section at the end of the list. In some situations, it might be useful to review the successful checks in order to choose among possible next steps.

Procedure

1. Access Manage > Activity Monitoring > S-TAP Control.
2. Use these options:
 - Add All to Schedule: add all inspection engines for all displayed S-TAPs to verification.
 - Remove All from Schedule: remove all inspection engines for all displayed S-TAPs from verification.
 - Add to Schedule: add all inspection engines of the selected S-TAP client to the schedule.If an S-TAP does not have the option All Can Control enabled, you can only change its status if your Guardium system is the primary system for this S-TAP.
3. Click Refresh.
4. To verify now, go to Manage > Activity Monitoring > S-TAP Verification Scheduler and click Run Once Now.
5. By default, the system waits five seconds before displaying verification results. If your network latency is high, this might not be enough time to receive the expected response from the database server. If you need to allow more time, you can use the `store_stap_network_latency` CLI command to change the period.

What to do next

View the verification results in the S-TAP Verification page (Manage > Reports > Activity Monitoring > S-TAP Verification page).

Windows: Configure advanced verification

Use this task to run advanced verification on individual inspection engines on a specific S-TAP client host, and to add individual inspection engines to advanced verification.

Procedure

1. Access Manage > System View > S-TAP Status Monitor.
2. Click anywhere in the row of the S-TAP.
The window refreshes with the individual inspection engines of this host.
3. To output immediate verification results, take the following steps:
 - a. Click one inspection engine, and click Advanced Verify.
 - b. 12.0 Optionally, under Datasource, select Show only matching S-TAP host or select a name from the Name list to search for a specific inspection engine.
12.1 and later Optionally, under Datasource, make sure that Show only matching S-TAP host and host is selected. If you select a datasource for which the IP address or port does not match the datasource, then an error message is returned.
 - c. Click Verify.The S-TAP Verification Results opens. Failed checks are shown first, with recommendations for next steps. Checks that succeeded are shown in a collapsed section at the end of the list. In some situations, it might be useful to review the successful checks in order to choose among possible next steps.
4. By default, the system waits five seconds before it displays verification results. If your network latency is high, five seconds might not be enough time to receive the expected response from the database server. If you need to allow more time, you can use the `store_stap_network_latency` CLI command to change the period.
5. To add to or remove individual inspection engines to the verification schedule:
 - a. Select one or more inspection engines.
 - b. Click Add to Schedule or Remove from Schedule

What to do next

View the results of schedules verification in the S-TAP Verification page (Manage > Reports > Activity Monitoring > S-TAP Verification).

Windows: Configuring the S-TAP verification schedule

You can configure the schedule for running S-TAP verification.

About this task

The same schedule is used for all S-TAPs that are scheduled for verification. Once a schedule is defined, you can click the Pause button in the S-TAP Verification Scheduler to temporarily stop the verification process while keeping it active. Use the Run Once Now button to run the verification once in real-time.

Procedure

1. Click [Manage > Activity Monitoring > S-TAP Verification Scheduler](#) to open the S-TAP Verification Scheduler.
 2. In the S-TAP Verification Scheduler portion of the page, click **Modify Schedule**.
 3. In the Schedule Definition dialog, use the drop-down lists and check boxes to schedule when verification runs.
This schedule is applied to all S-TAPs that are scheduled for verification.
 4. Click **Save** to save your changes.
-

Windows: S-TAP load balancing models and configuration guidelines

Understand the S-TAP load balancing models, and choose the one appropriate to your setup.

Failover

S-TAP sends traffic to one collector (primary) and fails over to the secondary as needed. The S-TAP agents are configured with a primary and at least one secondary collector IP. If the S-TAP agent cannot send the traffic to the primary collector, the S-TAP agent automatically fails over to the secondary. It continues to send data to the secondary host until either the secondary host system becomes unavailable, the primary host becomes available again, or until the S-TAP is restarted (at which point it attempts to connect to its primary host first). If the secondary host system becomes unavailable, it fails over to another secondary if there is one defined. In the second case S-TAP fails over from the secondary Guardium® host back to the Primary Guardium host.

Set up a primary and up to two secondary collectors. You can either define one collector as a standby failover collector only, or a few failover collectors. When you use one standby failover, one collector is usually sufficient for 4-5 collectors. When you use a few failover collectors, each one should run at a maximum 50% capacity, so that there are always resources for additional load. Choose the setup that works best with your architecture, database, and data center layout. If the primary becomes available, the S-TAP fails back from the secondary Guardium host back to the Primary Guardium host.

The S-TAP restarts each time configuration changes are applied from the active host.

1. In the Details section of the S-TAP Control window, set the value of the Load balancing parameter to 0; In the **Guardium Hosts** section: add at least one secondary Guardium Host.
Note: If you are not an advanced user, do not update the default failover configuration default values.
2. Before designating a Guardium system as a secondary host for an S-TAP, verify these items.
 - The Guardium system must have connectivity to the database server where S-TAP is installed. When multiple Guardium systems are used, they are often attached to disjointed branches of the network.
 - The Guardium system must not have a security policy that will ignore session data from the database server where S-TAP is installed. In many cases, a Guardium security policy is built to focus on a narrow subset of the observable database traffic, ignoring all other sessions. Either make sure that the secondary host will not ignore session data from S-TAP or modify the security policy on the Guardium system as necessary.

Enhanced failover mechanism to avoid data loss

12.1 and later

The main goal of failover mechanism is to preserve the session parameters when switching the S-TAP to the secondary collector. The regular failover mechanism saves session parameters in the form of failover messages that are received from the primary collector over the network. If a failover occurs, the mechanism forwards the failover messages to the secondary collector. In rare cases, the failover messages are lost. To address this, the enhanced failover mechanism, also saves session parameters in the form of several raw database protocol packets. If a failover is required and the failover messages are lost, the failover mechanism forwards the raw database packets to the secondary collector.

Load Balancing

This configuration balances traffic from one database onto multiple collectors. This option is useful when you must monitor all traffic (comprehensive monitoring) of an active database. (Note that for outliers detection, the collectors must be under the same aggregator and central manager in order for the aggregator to process all related data.) When the generated traffic is large and you need to house the data online on a collector for an extended period, use this method because it performs session-based load balancing across multiple collectors. An S-TAP can be configured in this manner with up to 10 collectors.

Complete the following configuration procedure in the Details section of the S-TAP Control window:

- Set the value of the Load balancing parameter to 1 for balancing the load.

Internal load balancing

12.1 and later

The Internal Load Balancer (ILB) helps avoid data loss caused due to collector overload.

The ILB evaluates the data load and helps avoid the data loss by proactively forecasting the load on the collector and redirecting the traffic to another collector to balance this load.

On the sniffer, ILB dynamically determines the number of sessions that a sniffer can accept from the S-TAP. This value is based on the collector's capacity for session information and processing collector load.

ILB sends two values to the S-TAP: the total number of allowed sessions on the appliance and the total number of sessions currently opened in the sniffer.

Note: The calculation of current sessions includes all the connected S-TAPs.

Each S-TAP keeps count of open sessions and uses the allowed session count to determine whether it can send new session data to the existing collector.

If number of open sessions is more than the allowed session count, then the S-TAP redirects new sessions to another collector.

If the number of open sessions do not exceed the allowed session count then the S-TAP may send the new sessions to existing collector.

Enabling internal load balancer

12.1 and later

Enabling on Windows

1. To enable the internal load balancer feature on S-TAP, set the INTERNAL_LOAD_BALANCER_ENABLED parameter to 1 . Default value = 0. Value range = 0, 1.
2. Also, set the PARTICIPATE_IN_LOAD_BALANCING to 1 for Windows.
Default value = 0. Valid values = 0 - 3.

Enabling on Collector

1. Create a session-level policy. For more information on creating session-level policy, see [Creating session-level policies](#).
2. In the Rule action field, select CONFIGURE.
3. In the Option field, select ILB and click OK.

Grid

With Grid, the S-TAP communicates to the collector through a load balancer, such as f5 and Cisco. The S-TAP agent is configured to send traffic to the load balancer. The load balancer forwards the S-TAP traffic to one of the collectors in the pool of collectors. You also can configure failover between load balancers for continuous monitoring if the load balancer should fail.

The persistence of S-TAP is configured by the failover parameters:

- TAP_MIN_TIME_BEFOREFAILOVER: The time interval, in minutes, after which the S-TAP switches to secondary Guardium system if: it cannot connect to its primary Guardium system; it can connect to its primary Guardium system but cannot write to its buffer. Default is 5.
- TAP_MIN_HEARTBEAT_INTERVAL: Maximum time the S-TAP attempts to write to the primary Guardium system buffer before attempting to write to the secondary Guardium buffer. Default is 30 sec, meaning it tries to write at least 5*60/30 times before failover.

S-TAPs in the F5 environment upload their log files and results of running diagnostics (all files from ..\Logs folder except for memory dumps) to the active collector and central manager (if exists) to the location ./var/IBM/Guardium/log/stap_diagnostic/

1. In the Details section of the S-TAP Control window, set the value of the Load balancing parameter to 3 for the grid model.
2. All can control = 1.
3. Guardium Host = <the IP of the Virtual IP of the balancer, to which all S-TAP database clients point to>.

Redundancy

In redundancy, the S-TAP communicates its entire payload to multiple collectors. The S-TAP is configured with more than one collector (often only two) and communicates the identical content to both. This option provides full redundancy of the same logged data across multiple collectors. It can also be used for logging data and alert on activity at different levels of granularity.

In the Details section of the S-TAP Control window, set the Value of the Load balancing parameter to 2 for redundancy. For more information, see [S-TAP Control: Details](#).

Windows: Configuring the Db2 Exit library

The Db2 Exit mechanism enables Guardium to pick up all Db2 traffic, whether encrypted or not and whether local or remote. This solution simplifies the S-TAP configuration, and provides native Db2 support.

About this task

Db2 Exit embeds a Guardium library into Db2 by using the Db2 Exit mechanism. The Db2 Exit communicates directly with the Guardium S-TAP to forward all Db2 traffic, whether encrypted or not, and both local and remote. Db2 Exit captures TCP and SHM traffic.

Db2 Exit supports terminate.

The guard_tap.ini DB2_PROTOCOLS and WINSTAP_DB2_PROTOCOLS GIM parameters specify the protocols that the Db2 Exit picks up.

- For unencrypted TCPIP traffic, you can use the default value, which is `LOCAL,PIPES,SSL` (with no spaces between values). In this case, TCPIP traffic is picked up from the WFP Monitor driver. However, WFP Monitor ignores encrypted traffic.
- For encrypted TCPIP traffic, include the `TCPIP` parameter to DB2_PROTOCOLS to allow TCPIP to pick up the encrypted traffic, for example:

`DB2_PROTOCOLS=LOCAL,PIPES,SSL,TCPIP`

Limitations

- Db2 Exit does not support the firewall, redact, or query rewrite functions.
- If you add `TCPIP` to DB2_PROTOCOLS, Db2 Exit captures TCPIP traffic in all ports. In this case, you do not need to specify PORT_RANGE_START and PORT_RANGE_END in the Db2 Exit inspection engine.
However, if you do not specify `TCPIP` in DB2_PROTOCOLS, the WFPMonitor driver picks up TCP traffic. In this case, the WFPMonitor driver refers to PORT_RANGE_START and PORT_RANGE_END in the Db2 exit inspection engine.

Procedure

1. Create a folder within the Db2 SQLLIB folder, for each instance: \$DB2PATH\security\plugin\commexit\instance_name. For example, C:\Program Files\IBM\SQLLIB\security\plugin\commexit\DB2_01
2. Copy the corresponding DLLs from the S-TAP installation directory into the created directories:
 - For 32-bit Db2 - GuardiumInterfacex86.dll
 - For 64-bit Db2 - GuardiumInterfacex64.dll
3. Stop the Db2 instance, or instances, and issue the following command:

- For 32 bit - UPDATE DBM CFG USING COMM_EXIT_LIST GuardiumInterfaceX86
 - For 64 bit - UPDATE DBM CFG USING COMM_EXIT_LIST GuardiumInterfaceX
4. Start the Db2 instances.
5. Add an inspection engine for Db2 Exit with protocol Db2 Exit. Go to Manage > Activity Monitoring > S-TAP Control. See parameter descriptions in [Inspection engine parameters](#). Advanced users can also modify the guard_tap.ini, but it's best to use the GUI since it completes some of the information automatically, and does some validation. If you modify the guard_tap.ini file, set these parameters:
- [DB_DB2_EXIT1]
 - DB_TYPE=DB2_EXIT
 - INSTANCE_NAME=Service_name
- In the TAP section, set the parameter DB2_EXIT_DRIVER_INSTALLED=1
- The service name is not the instance name. You can determine the service name by using the db2tap utility in the S-TAP installation folder, or from the Control Panel. Set the instance name to the portion of the service name that follows the second dash (-) delimiter. For example, if the service name in the Control Panel is DB2 - DB2COPY1 - DB2-01-0, set INSTANCE_NAME to DB2-01-0.
6. To stop Db2 Exit, issue the following command, and then restart Db2:
- ```
db2 UPDATE DBM CFG USING COMM_EXIT_LIST NULL
```

## Windows: Upload dump files from the S-TAP to the collector and central manager

You can configure the S-TAP to automatically upload dump files upon restart, to the collector and the central manager, or only the collector.

The guard\_tap.ini parameter **upload\_feature** controls this upload feature:

- 0: No automatic upload.
- 1: Upload files to the collector and the central manager.
- 2: Upload files **only to the collector**, even if there is a central manager.

If enabled, when the S-TAP restarts, and it detects a new dump file in one of the monitored folders, it:

1. Collects all of the information (dump file, log files, etc.) from Program Files\IBM\Windows S-TAP\Logs.
2. Compresses the files.
3. Uploads the .zip file to the collector and/or central manager, to the folder /var/IBM/Guardium/log/stap\_diagnostic.

The .zip file name is in the format: WSTAP\_<computer name>\_<ISO time of file creation>.zip

The files on the collector are purged to prevent excessive disk space usage. If the total space used is greater than 10 GB, the oldest files are purged to bring the size down to less than 10 GB. Files older than one month are purged, irrelevant of the disk space used. Only the files in /var/IBM/Guardium/log/stap\_diagnostic are purged.

If the upload of a .zip file would result in /var going over 70%, then the .zip file is not uploaded.

For an S-TAP that was installed with GIM, the GIM server uses the threshold2 value defined in **Utilization\_Threshold** for System Var Disk Usage, which is 70% by default. If the file to upload would result in system var disk usage over the threshold2 value, the upload is rejected. You can modify this value. See [update\\_utilization\\_thresholds](#).

## Windows: Build and configure FreeTDS for Guardium

FreeTDS allows Unix/Linux machines to connect to an SQL Server on Windows machines.

### Before you begin

Verify these requirements for using FreeTDS successfully with Guardium®, such that all information (DB\_USER, SOURCE\_PROGRAM, etc.) is included in the Guardium reports.

- FreeTDS V1.00.111 or later
- OpenSSL Support in FreeTDS
- Kerberos Support in FreeTDS
- TDS Version Auto in FreeTDS
- Domain Joined Linux System
- Domain Joined SQL Server Windows System Setup for Kerberos Logins

### About this task

To determine what version of FreeTDS you have and what type of support has been compiled into the program, execute the command **tsql -C** to see the FreeTDS characteristics on your machine. You should see something like:

```

Compile-time settings (established with the "configure" script)
 Version: freetds v1.00.111
 freetds.conf directory: /usr/local/etc
 MS db-lib source compatibility: no
 Sybase binary compatibility: no
 Thread safety: yes
 iconv library: yes
 TDS version: auto
 iODBC: no
 unixodbc: no
 SSPI "trusted" logins: no
 Kerberos: yes
 OpenSSL: yes
 GnuTLS: no
 MARS: no

```

## Procedure

1. Download a suitable C/C++ compiler package and an OpenSSL package. See instructions in the users guide [www.freetds.org](http://www.freetds.org) for more details and for the download of the latest FreeTDS package.
2. Unpack the tarball and then set your folder to the FreeTDS kit root folder. Enter the following commands:

```

$./configure --enable-krb5 --with-openssl
$ make
$ su root
Password
$ make install

```

3. Test that the SQL Server logs in to a system named “node” and determine whether Kerberos is being used. Enter the commands:

```

$ tsql -S node
1> select auth_scheme from sys.dm_exec_connections where session_id = @@SPID
2> go
auth_scheme
KERBEROS
(1 row affected)

```

## Windows: S-TAP configuration per database type

This section provides detailed instructions or examples for configuring monitoring on various databases.

- [Windows: Db2 configuration for SSL](#)  
Db2 configuration for SSL requires the following parameters in the guard\_tap.ini.

## Windows: Db2 configuration for SSL

Db2 configuration for SSL requires the following parameters in the guard\_tap.ini.

- DB2\_EXIT\_DRIVER\_INSTALLED=0
- DB2\_SSL\_DRIVER\_INSTALLED=1
- DB2\_TAP\_INSTALLED=0

The Db2 service needs to be restarted following the S-TAP configuration, to inject the DB2 SSL library.

## Windows: Stopping S-TAP using GIM

With GIM, you can stop S-TAP without logging into the database server.

### About this task

Use the following steps to change the WINSTAP\_ENABLED parameter and schedule the S-TAP startup on the database server.

### Procedure

1. Navigate to Manage > Module Installation > Set up by Client.
2. In the Choose clients section, select the database servers whose S-TAPs you want to stop. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients. Click Next to continue.
3. In the Choose bundle section, select your S-TAP bundle. Click Next.  
After selecting a software bundle, the Selected bundle action column indicates the action that will be performed for each client. You can stop the S-TAPs that have the status Update parameters.
4. In the Choose parameters section, type WINSTAP\_ENABLED and type in the value 0. Click Next.
5. In the Configure clients section, use the table to review the changes you want to make.
6. Click Install.
7. Click OK to stop the S-TAP now, or use the  icon to schedule the stop time, then click OK.

## Windows: Starting S-TAP using GIM

With GIM, you can start S-TAP without logging into the database server.

### About this task

Use the following steps to change the WINSTAP\_ENABLED parameter and schedule the S-TAP startup on the database server.

### Procedure

1. Navigate to Manage > Module Installation > Set up by Client.
2. In the Choose clients section, select the database servers whose S-TAPs you want to start. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients. Click Next to continue.
3. In the Choose bundle section, select your S-TAP bundle. Click Next.  
After selecting a software bundle, the Selected bundle action column indicates the action that will be performed for each client. You can start the S-TAPs that have the status Update parameters.
4. In the Choose parameters section, type WINSTAP\_ENABLED and type in the value 1. Click Next.
5. In the Configure clients section, use the table to review the changes you want to make.
6. Click Install.
7. Click OK to start the S-TAP now, or use the  icon to schedule the start time, then click OK.

## Windows: Starting S-TAP without GIM

Learn to start S-TAP from the database server.

### About this task

Note: When Windows S-TAP encounters a fatal error during start up that is due to configuration problems (unknown local IP address, more than 1 primary SQL-Guard defined, etc.) it logs the reason to the Windows event log. In some cases an exit after a failure may cause a crash and another logged event. This crash should not cause any concern if it is preceded by the event explaining the reason for the failure.

### Procedure

1. Log on to the database server system using a system administrator account.

2. From the Services control panel, start the IBM Security Guardium S-TAP.
3. Log in to the Guardium® system to which this S-TAP reports. Verify that the Status light in the S-TAP control panel is green.

## Windows: Stopping S-TAP without GIM

Learn to stop S-TAP from the database server.

### Procedure

1. Log on to the database server system using a system administrator account.
2. From the Services control panel, stop the IBM Security Guardium S-TAP.
3. Log in to the UI of the Guardium® system to which this S-TAP was reporting, verify that the Status light in the S-TAP control panel is now red.

## Windows: Multi-threading S-TAP for increased throughput

S-TAP multi-threading can be used in certain workloads to increase the throughput of data in the S-TAP. It works by preserving multiple threads from the point of traffic interception through to the point at which traffic is sent to the collector.

If the S-TAP is dropping a lot of traffic, or if there is evidence that intercepting the traffic is impacting the database performance, then you might consider enabling multiple S-TAP threads. An increased number of S-TAP threads means that the S-TAP increases its throughput to the collectors. But it also means that S-TAP might use more CPU and more memory. Multi-threading does not rectify a slow or busy network.

There are no definitive rules, you first modify the configuration, then fine-tune the results. The S-TAP has a maximum of 8 connections to each of its collectors.

When one or more Guardium® systems can not be reached, a failover mechanism redirects the traffic from one Guardium system to another.

### Limitations

- Multi-threading is supported only for the TCP/IP and Named Pipes protocols. Multi-threading is supported on any platform but only for those protocols.
- Policies have to be the same on all Guardium system because the policies dictate what happens to a system's traffic. If the policies are different, there's no guarantee which policy is in effect on a given session.
- Multi-threading S-TAP requires V11.3 **Protocol 8**. It is not available in V11.3 Protocol 7. To enable Protocol 8, in the TAP section of the guard\_tap.ini, set the parameter V8\_PROTOCOL=1.

## Configuration Guidelines

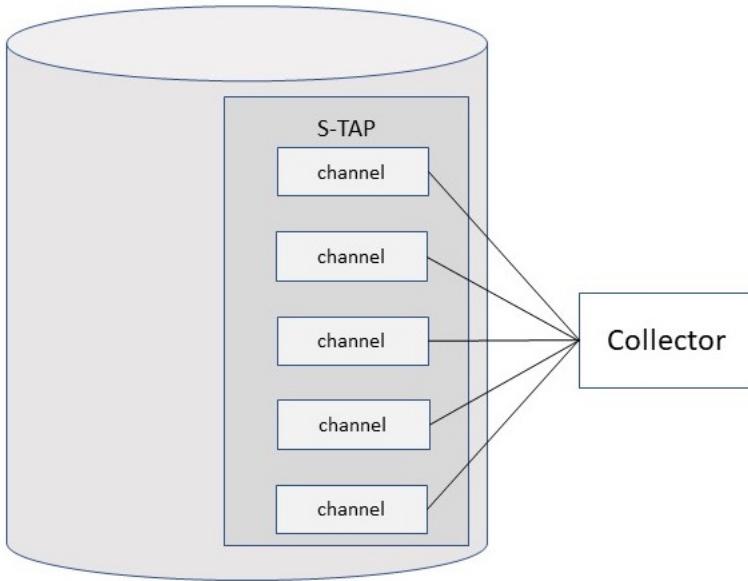

The parameter TCP\_CHANNELS in the TAP section of the guard\_tap.ini file determines the number of channels to each collector. It affects all collectors defined in the guard\_tap.ini file.

### Implementing multi-threading or increasing the number of threads

Set or increase the TCP\_CHANNELS parameter in the corresponding TAP section.

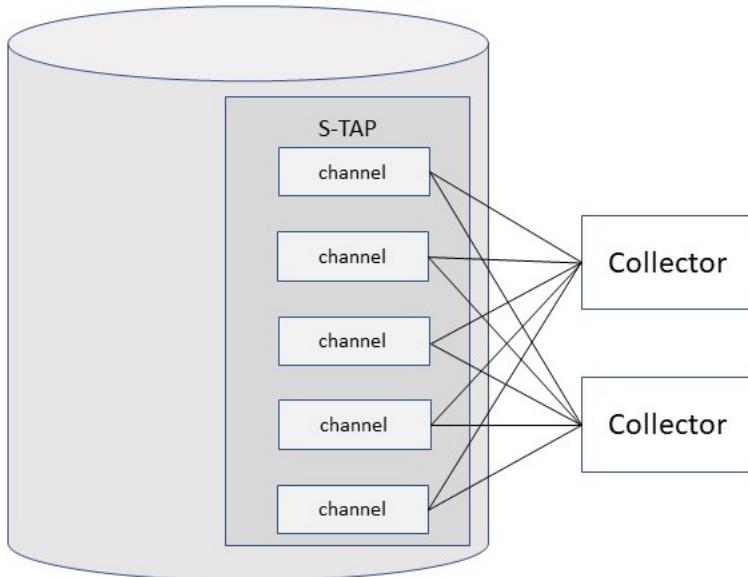

### Example: One collector, five threads

```
[TAP]
...
TCP_CHANNELS=5
[SQLGUARD_1]
SQLGUARD_IP=n.n.n.n
PRIMARY=1
```

## Example: Two collectors, five threads

```
[TAP]
...
TCP_CHANNELS=5
[SQLGUARD_1]
SQLGUARD_IP=n.n.n.n
PRIMARY=1
[SQLGUARD_2]
SQLGUARD_IP=n.n.n.n
PRIMARY=2
```

## Windows: Capturing encrypted MSSQL traffic

Understand the correlation driver that is used for capturing encrypted MSSQL traffic.

The correlation driver facilitates the communications between the Guardium® DLLs that are injected into the SQL Server Process and the Guardium traffic drivers (WFP, NMP). The Guardium DLLs get the encryption key used by the S-TAP to decrypt the SQL Server traffic, but the DLLs do not know which session (IPs, ports) that the encryption key belongs to. The correlator driver matches the encryption key to the session in the traffic drivers (WFP, NMP) so that the DLLs can then apply the proper key to the proper session. Finally, the DLLs supply the encryption key to the proper session in the traffic drivers that use the correlation driver so the traffic drivers can deliver the encryption key to the S-TAP. The S-TAP uses the encryption key to decrypt the SQL Server traffic for the session and sends it to the appliance.

The correlation DLLs in an SQL Server depend on the correlation driver, which depends on the traffic drivers (WFP, NMP). Without either the correlation DLLs or the correlation driver, Guardium cannot decrypt traffic. In all cases, the login packet for an SQL Server session is always encrypted. Missing or malfunctioning correlation DLLs or driver results in sessions that are missing their DB username, source program, and a few other fields. If the entire session is encrypted, and the correlation DLLs or the driver are missing or malfunctioning, then no traffic for this session reaches the collector.

The S-TAP holds traffic back for a session until it receives the encryption key. After it receives the encryption key, it decrypts the traffic it's holding and releases it to the appliance. It then decrypts any subsequent traffic and sends that to the appliance as well. However, if the encryption key does not show up before the `guard_tap.ini` parameter `CORRELATION_TIMEOUT` threshold, then the S-TAP gives up and sends the traffic to Guardium as is. In that case, for unencrypted traffic, the sessions are missing DB username, source program, and other fields. With fully encrypted traffic, no traffic is seen.

## Windows: Alerts on uninstalled S-TAPs

---

Uninstalling an S-TAP might be evidence of harmful activity. The predefined S-TAP Uninstall Alert notifies when an S-TAP is uninstalled. You can view the S-TAP Uninstall Events report in My Dashboards.

By default the alert is scheduled hourly. View and optionally configure the Alert Receivers in the Alert Builder: Protect > Database Intrusion Detection > Alert Builder. Tip: Best practice is to leave the alert settings at their defaults. If you need to change the configuration, run the CLI command `restart gui` so that the changes take effect. The alert writes to SYSLOG in the format: Alert Name: STAP Uninstall Alert. Alert Description: STAP Uninstall Alert... ...<S-TAP host>. The S-TAP host uniquely identifies the S-TAP. It is usually the database IP.

## Related concepts

---

- [Predefined alerts](#)
- 

## Windows: Deleting inactive S-TAPs in a centralized environment

---

You can use a cron job on the central manager to delete all inactive S-TAP instances.

## Procedure

---

1. Go to Manage > System View > Enterprise S-TAP View.
2. In the Actions menu, select Add API mapping.
3. In the Add API Mapping dialog, search for and select `delete_inactive_stap`.
4. In the Enterprise S-TAP view, right-click in any row and select Invoke > `delete_inactive_stap`
5. Create a script to schedule running this API periodically on the central manager.

Sample shell script for running the API:

```
#!/bin/bash

echo >> ${GUARD_LOG_DIR}/delete_inactive_staps.log
echo >> ${GUARD_LOG_DIR}/delete_inactive_staps.log

echo Deleting inactive staps from all managed units $dateStr >> ${GUARD_LOG_DIR}/delete_inactive_staps.log
date >> ${GUARD_LOG_DIR}/delete_inactive_staps.log

#Run the delete inactive stap command from CM for all S-TAPs on all managed_units

echo -e "grdapi delete_inactive_stap stapHost=all api_target_host=all_managed" | su - cli >>
${GUARD_LOG_DIR}/delete_inactive_staps.log

exit 0
```

6. Create a cron job to run the script after the report is refreshed, at whatever interval you decide for both the report refresh and the cron job.

## Windows: Monitoring S-TAP in the GUI

---

Use these standard reports and views to monitor your S-TAP status in the GUI.

You can create alerts that are based on exceptions that are created by S-TAPs, but other domains that are used by S-TAP reports are system-private and cannot be accessed by users.

## System View

---

**S-TAP Status Monitor** in the System Monitor window: For each S-TAP reporting to this Guardium® system, this report identifies the S-TAP Host, S-TAP Version, DB Server Type, Status (active or inactive), Last Response Received (date and time), Instance Name, Primary Host Name, and true/false indicators for: MS SQL Server Shared Memory, DB2® Shared Memory, Win TCP, Local TCP monitoring, Named Pipes Usage, Encryption, Firewall, DB install Dir, DB port Min and DB Port Max.

Click any line to view the inspection engines that are configured for this S-TAP. The bread crumbs show where you are; click ALL S-TAPs to return to the list of S-TAP. For more details, see [Windows: Inspection engine verification](#).

**S-TAP Status Monitor:** For each S-TAP reporting to this Guardium system, this report identifies the S-TAP Host, DB Server Type, S-TAP Version, Status (active or inactive), Inspection Engine status, Last Response Received (date and time), Primary Host Name, and true/false indicators for: Firewall and Encrypted. Click the S-TAP Status and the Inspection Engine status to see the Verification status on all Inspection Engines.

**S-TAP Events:** For each S-TAP reporting to this Guardium system, this report identifies the S-TAP Host, Timestamp, Event type (Success, Error Type, and so on), and Tap Message.

If no messages display in the S-TAP Events panel, the production of event messages may have been disabled in the configuration file for that S-TAP. If this is the case, you may be able to locate S-TAP event messages on the host system in the Event Log.

## Tap Monitor

**Primary Guardium Host Change Log:** Log of primary host changes for S-TAPs. The primary host is the Guardium system to which the S-TAP sends data. Each line of the report lists the S-TAP Host, Guardium Host Name, Period Start, and Period End.

**S-TAP Status:** Displays status information about each inspection engine that is defined on each S-TAP Host. This report does not have From and To date parameters, since it is reporting current status. Each row of the report lists the S-TAP Host, DB Server Type, Status, Last Response, Primary Host Name, Yes/No indicators for the following attributes: Shared Memory Driver Installed, Db2 Shared Memory Driver Installed, Named Pipes Driver Installed, and App Server Installed. In addition, it lists the Hunter DBS.

**Inactive S-TAPs Since:** Lists all inactive S-TAPs that are defined on the system. It has a single runtime parameter: QUERY\_FROM\_DATE, which is set to now -1 hour by default. Use this parameter to control how you want to define *inactive*. This report contains the same columns of data as the S-TAP Status report, with the addition of a count for each row of the report.

## Windows: Log and debug files

The S-TAP can create log and debug files. The files are located in the logs directory under the installation directory.

## Protocol 8

### Debug files

Debug is disabled by default. The guard\_tap.ini parameter DEBUGLEVEL enables debug and controls the level. See [Protocol 8 Debug parameters](#).

The debug log is STAP.CTL and is located in the logs directory, under the installation directory.

The debug log is exclusively for logging all telemetry and status information. You can view these files using Notepad.

The following guard\_tap.ini parameters control what gets logged to the STAP.CTL log file and how verbose it is.

- LOG\_WFP\_CONNECTIONS: the particular protocol's status information. The default is 0, which means that is not logged to the STAP.CTL file. A value of 1 logs things like connection establishment, connection termination, and a few others for the protocol in question.
- LOG\_NMP\_CONNECTIONS: same as LOG\_WFP\_CONNECTIONS
- LOG\_DB2\_CONNECTIONS: same as LOG\_WFP\_CONNECTIONS
- LOG\_INFORMIX\_CONNECTIONS: same as LOG\_WFP\_CONNECTIONS
- LOG\_ORA\_CONNECTIONS: same as LOG\_WFP\_CONNECTIONS
- LOG\_LEVEL: The verbosity of the overall logging of the S-TAP output to the Stap.ctl circular text log file. The default is 4, and it ranges from 0 to 10. The higher the number, the more verbose the logging.
- KERNEL\_DEBUG\_LEVEL: The verbosity of the overall logging for the driver-based .CTL files.

Auto discover debug messages are also logged in stap.ctl. Each [AD<dbtype>] has logs of the indicated DB type. Logs include step-by-step success or failure discovery of instance names, process names, ports, named pipes, and so on. Examples:

```
`I 05/10/2020 14:46:34.917 ADmssql: Start discovering 64-bit instances.
`W 05/10/2020 14:46:34.917 ADmssql: Registry path not found: SOFTWARE\Wow6432Node\Microsoft\Microsoft SQL Server\Instance Names\SQL
`I 05/10/2020 14:46:34.917 ADoracle: Start discovering
```

### Traffic debug log

The traffic log is a file with a .txt extension in the Logs directory, under the installation directory. You can initiate traffic logging in two ways.

- From the collector, trigger traffic collection, for up to 4 minutes of S-TAP traffic. Click Send Command, and select S-TAP logging in the S-TAP Control page. For more information, see [Send command](#).
- From the database server, change the DEBUGLEVEL parameter to a non-zero value in the .INI file. The S-TAP creates a recording of traffic in binary format. When you set it back to 0, it is converted into human readable form. The V8 S-TAP can detect .ini parameter changes without having to be restarted, so you can change the DEBUGLEVEL parameter back to 0 in the .ini file without restarting the S-TAP.

Both methods create a traffic debug log file in the S-TAP Logs folder. While traffic is being recorded, the size of the traffic file remains at 0 bytes, which is normal. When the traffic collection ceases, either because the time interval elapsed or because you changed the DEBUGLEVEL parameter back to 0, the S-TAP converts the recorded binary traffic into human readable form. As this happens, the size of the traffic file grows if you're watching it in Explorer. You need to wait until the size of the file stops increasing before you access the file and copy it off to another system. DO NOT stop the S-TAP during either traffic recording or traffic conversion, or you'll lose all the traffic that you recorded. The S-TAP automatically waits for the conversion to be completed before shipping the traffic log file to the collector when the collection of traffic is triggered from the collector itself.

## Protocol 7

---

Debug is disabled by default. The guard\_tap.ini parameter DEBUGLEVEL enables debug and controls the level. See [Debug parameters](#).

Logs and debug logs are in the bin/stap\_buffer/ folder.

Auto discover debug messages are logged in logs/Stap.ctl. Each **[AD<dbtype>]** has logs pf the indicated DB type . Logs include step-by-step success or failure discovery of instance names, process names, ports, named pipes, and so on. Examples:

```
`I 05/10/2020 14:46:34.917 ADmssql: Start discovering 64-bit instances.
`W 05/10/2020 14:46:34.917 ADmssql: Registry path not found: SOFTWARE\Wow6432Node\Microsoft\Microsoft SQL Server\Instance Names\SQL
`I 05/10/2020 14:46:34.917 ADoracle: Start discovering
```

---

## Windows: S-TAP statistics

The S-TAP statistics are sent by the S-TAP to the sniffer are stored on the collector. You can see the statistics in the predefined S-TAP Statistics report.

You can create alerts based on results.

The guard\_tap.ini parameter STAP\_STATISTIC specifies the interval at which the S-TAP sends statistics to the sniffer. Valid values are:

- Positive integer: for hours
- Negative integer: minutes
- 0: do not send

The default is -5. This is also the minimum.

S-TAP counters:

- Total dropped packets: Packets dropped due to insufficient buffer space in the S-TAP service.
- Total dropped bytes: Bytes dropped due to insufficient buffer space in the S-TAP service.
- Collector count
- Collector names: Comma-separated list of all the collectors that are assigned to the S-TAP
- Collector total dropped packets: Comma-separated list of the packets that are dropped due to insufficient buffer space in the S-TAP, cataloged by collector.
- Collector total dropped bytes: Comma-separated list of the bytes that are dropped due to insufficient buffer space in the S-TAP, cataloged by collector.

NMP counters:

- Software TAP Host
- Tap name (driver name)
- Tap version
- Timestamp
- Total packets: Total packets that pass through the driver
- Total bytes: Total bytes that pass through the driver
- Total dropped packets: Total packets that are dropped due to insufficient buffer space in the driver.
- Total dropped bytes: Total bytes that are dropped due to insufficient buffer space in the driver.
- Total ignored packets: Total packets that are ignored due to Ignore commands from the appliance or priority queue transitions.
- Total ignored bytes: Total bytes that are ignored due to Ignore commands from the appliance or priority queue transitions.
- Total ignored reply packets: Total packets of server reply data that is ignored due to ignore reply commands from the appliance, DB ignore bypass, or priority queue transitions.
- Total ignored reply bytes: Total bytes of server reply data that is ignored due to ignore reply commands from the appliance, DB ignore bypass, or priority queue transitions.

WFP counters:

- Software TAP Host
- Tap name (driver name)
- Tap version
- Timestamp
- Total packets: Total packets that pass through the driver
- Total bytes: Total bytes that pass through the driver
- Total dropped packets: Total packets that are dropped due to insufficient buffer space in the driver.
- Total dropped bytes: Total bytes that are dropped due to insufficient buffer space in the driver.
- Total ignored packets: Total packets that are ignored due to Ignore commands from the appliance or priority queue transitions.
- Total ignored bytes: Total bytes that are ignored due to Ignore commands from the appliance or priority queue transitions.
- Total ignored reply packets: Totals of server reply data that is ignored due to ignore reply commands from the appliance, DB ignore bypass, or priority queue transitions.
- Total ignored reply bytes: Totals of server reply data that is ignored due to ignore reply commands from the appliance, DB ignore bypass, or priority queue transitions.

## Windows: Monitoring with the Guardium Agent Monitor

---

The Guardium Agent Monitor (GAM) process monitors Guardium agent performance and responsiveness. Use GAM for detailed analysis during troubleshooting.

Note: Set the GAM service to off by default as it requires configuration specific to the environment in which it is installed. Improper configuration can cause serious operational issues. GAM is a tool to aid in troubleshooting and otherwise is not required.

Monitoring covers the following services:

- CPU usage

- Memory
- Handles
- Number of threads
- Alive

If a monitored agent exceeds a configured threshold, or if it does not respond to the console request, the following actions can be taken, in any combination:

- Automatically run **diag.bat** (or the name of your diagnostics application file).
- Automatically stop or restart the service..
- Automatically perform a core dump.

Guardium Agent Monitor is installed when S-TAP is installed but is not enabled by default. When S-TAP is uninstalled, GAM is uninstalled.

Note: Just like S-TAP, GAM requires administrative privileges. When you install GAM, run with "Run as Administrator" as an administrative user. If you run it as a non-admin user, GAM returns an **Access Denied** error.

The default installation location for GAM is the parent folder of S-TAP (C:\Program Files\IBM\Guardium Agent Monitor).

The default location for GAM output is the \Bin\ subfolder.

After you enable GAM, make sure that the process is running on the database server (resmon.exe).

Guardium Activity Monitor (GAM) is listed in the Services as IBM Security Guardium Resource Monitor Service, which has a Service Name property of Guardium Resource Monitor.

For an example of how GAM works, see [Resource monitoring example](#).

## Global level configuration

The following parameters pertain to the GAM service process and defined in [Global] section.

| resmon.ini          | Default value | Description                                                                                                                                                                                                                                                 |
|---------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NUMBER_OF_SERVICES  | 1             | Number of services being monitored. The minimum is 0, there is no maximum.                                                                                                                                                                                  |
| UPDATE_INTERVAL     | 1             | The length, in seconds, of the interval between polling metrics.                                                                                                                                                                                            |
| DEBUG               | 1             | Deprecated.                                                                                                                                                                                                                                                 |
| NUMBER_BYTES_IN_LOG | 200           | Maximum number of KB for the GAM log. There is no maximum size.                                                                                                                                                                                             |
| ACTION              | 1             | Determine whether to generate a dump when your system exceeds certain thresholds such as THREAD_COUNT_LIMIT or MEM_USAGE_LIMIT. Valid values: <ul style="list-style-type: none"> <li>• 0: Do not generate a dump.</li> <li>• 1: Generate a dump.</li> </ul> |
| FULLDUMP            | 0             | Valid values: <ul style="list-style-type: none"> <li>• 0: Generate a mini-dump.</li> <li>• 1: Generate a full dump when dump is generated.</li> </ul> Note: A full dump takes more time.                                                                    |
| CPUAVE              | 1             | Defines the way to calculate the average CPU time. <ul style="list-style-type: none"> <li>• 0: Percentage of one core.</li> <li>• 1: Average percentage of all cores in system.</li> </ul>                                                                  |
| MDTIMEOUT           | 1000          | Timeout of generating a dump in milliseconds. A dump is not generated if the time is exceeded.                                                                                                                                                              |

## Service level configuration

The following parameters apply to each service and are defined in the [Service\_N] section. The name of the section can be anything except [Global]. For [Service1], Name=GUARD\_STAP is defined by default.

| resmon.ini         | Default value | Description                                                                                                                                                                                                                           |
|--------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name               | GUARDIUM_STAP | The name of the Windows Service for GAM to monitor.                                                                                                                                                                                   |
| NAMEDPIPE_INTERVAL | 30            | For supported Windows S-TAPS only. The interval, in seconds, to check aliveness (supported agents only). Set to 0 to disable.<br>For more information about named pipes, see <a href="#">Inspection engine parameters</a> .           |
| DIAGACTION         | 0             | Run diagnostic on action. <ul style="list-style-type: none"> <li>• 0: Do not run diagnostics.</li> <li>• 1: Run diagnostics (usually <b>diag.bat</b>) when the monitored service exceeds the limit in specified intervals.</li> </ul> |
| DIAGNAME           | diag.bat      | Diagnostic file name. When set to <b>diag.bat</b> , GAM calls the application from the same directory as the service process.                                                                                                         |
| DIAG_PARAMETER     | (none)        | Diagnostic parameters. If the parameter has spaces, the parameter must be enclosed with quotation marks ("").                                                                                                                         |

### CPU Threshold Configuration

| resmon.ini            | Default value | Description                                                                                                                                                          |
|-----------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU_LOAD_LIMIT        | 10            | Percentage CPU threshold at which either action is taken, or UPDATE_INTERVAL starts counting occurrences of reaching threshold.<br>The minimum is 1. Maximum is 100. |
| CPU_INTERVALS_ALLOWED | 10            | Number of intervals the CPU can be above the threshold before it triggers an action (used with UPDATE_INTERVAL to set a time limit).                                 |

| resmon.ini      | Default value | Description                                                                                                                                                                                                                                  |
|-----------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UPDATE_INTERVAL | 1             | Valid values: <ul style="list-style-type: none"> <li>• 0: Take action when CPU reaches its load limit.</li> <li>• 1: Take action when CPU reaches its load limit the number of times that are specified by CPU_INTERVALS_ALLOWED.</li> </ul> |

#### Memory Usage, Handle Count and Thread Count Thresholds Configuration

| resmon.withi                    | Default value | Description                                                                                                                         |
|---------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| MEM_USAGE_LIMIT                 | 150000        | Lower-level threshold in KB. An action is triggered if this limit is exceeded for more intervals than MEM_USAGE_INTERVALS_ALLOWED.  |
| MEM_USAGE_INTERVALS_ALLOWED     | 30            | Number of intervals allowed for the lower limit threshold before an action is triggered (used with UPDATE_INTERVAL for time limit). |
| MEM_USAGE_PEAK_LIMIT            | 200000        | Upper level threshold in KB. An action is triggered if this threshold is exceeded once.                                             |
| HANDLE_COUNT_LIMIT              | 500           | Lower-level threshold. An action is triggered if this limit is exceeded for more intervals than HANDLE_COUNT_INTERVALS_ALLOWED.     |
| HANDLE_COUNT_INTERVALS_ALL_Owed | 20            | Number of intervals allowed for the lower limit threshold before an action is triggered (used with UPDATE_INTERVAL for time limit). |
| HANDLE_COUNT_PEAK_LIMIT         | 1000          | Upper level threshold. An action is triggered if this threshold is exceeded once.                                                   |
| THREAD_COUNT_LIMIT              | 200           | Lower-level threshold. An action is triggered if this limit is exceeded for more intervals than THREAD_COUNT_INTERVALS_ALLOWED.     |
| THREAD_COUNT_INTERVALS_ALL_Owed | 20            | Number of intervals allowed for the lower limit threshold before an action is triggered (used with UPDATE_INTERVAL for time limit). |
| THREAD_COUNT_PEAK_LIMIT         | 300           | Upper level threshold. An action is triggered if this threshold is exceeded one time.                                               |

## Action Configuration

The actions that can be triggered are described under Core Dump Configuration and Diagnostic Configuration. The second and third actions are only initiated if they are triggered within the ACTION\_RESET\_INTERVAL of the previous action. If the ACTION\_RESET\_INTERVAL time has elapsed with no new triggers, then the next trigger starts a new cycle starts with the FIRST\_ACTION.

| resmon.ini             | Default value | Description                                                                                                                                                                                              |
|------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FIRST_ACTION           | 1             | Valid values: <ul style="list-style-type: none"> <li>• 0: No action.</li> <li>• 1: Take action then restart the service.</li> <li>• 2: Take action then stop the service without restarting.</li> </ul>  |
| SECOND_ACTION          | 1             | Valid values: <ul style="list-style-type: none"> <li>• 0: No action.</li> <li>• 1: Take action then restart the service.</li> <li>• 2: Take action, then stop the service without restarting.</li> </ul> |
| THIRD_ACTION           | 2             | Valid values: <ul style="list-style-type: none"> <li>• 0: No action.</li> <li>• 1: Take action then restart the service.</li> <li>• 2: Take action, then stop the service without restarting.</li> </ul> |
| ACTION_RESET_INTERVALS | 60            | Number of seconds before resetting the action count. For example, if an action is triggered after more than 60 seconds since the previous action, FIRST_ACTION is applied.                               |

## Resource monitoring example

This example shows how the Guardium Agent Monitor (GAM) settings interact to provide meaningful information. This example tracks memory usage settings. However, the same pattern applies to other resources.

Let's say that you have the following settings:

- NAME=GUARDIUM\_STAP
- UPDATE\_INTERVAL=1
- MEM\_USAGE\_LIMIT=150000
- MEM\_USAGE\_INTERVALS\_ALLOWED=30
- MEM\_USAGE\_PEAK\_LIMIT=200000
- ACTION=1
- FULLDUMP=0
- DIAGACTION=1
- DIAGNAME=diag.bat
- FIRST\_ACTION=1
- ACTION\_RESET\_INTERVALS=60
- SECOND\_ACTION=2
- THIRD\_ACTION=2

GAM monitors memory usage of GUARDIUM\_STAP service (as specified in NAME) every second (UPDATE\_INTERVAL). If MEM\_USAGE-LIMIT exceeds 150 MB 30 consecutive times (MEM\_USAGE\_INTERVALS\_ALLOWED) or if MEM\_USAGE\_PEAK\_LIMIT exceeds 200 MB once, GAM takes the following actions:

- Generate a mini-dump (ACTION and FULLDUMP)
- Run `diag.bat` (DIAGACTION and DIAGNAME)

- Restart the service (FIRST\_ACTION).
- If the same symptoms occur within 60 seconds (ACTION\_RESET\_INTERVALS), GAM takes the same actions (SECOND\_ACTION).
- If the same symptoms occur again within 60 seconds, GAM generates a mini-dump, runs `diag.bat`, and stops the service without restarting (THIRD\_ACTION).

## Windows: Troubleshooting S-TAP problems

You can use the S-TAP Status monitor tab of the System View to begin investigating any problems. Sometimes you might need to use other tools, particularly if you are monitoring databases for which the inspection engines cannot be verified.

If an S-TAP is not connected to your Guardium® system

Check whether the IBM Security Guardium S-TAP service is running on the database server:

Check the IBM Security Guardium S-TAP service and see that it's running.

Make sure that sniffer is running on the server with the S-TAP service.

Check the communication between the sniffer and S-TAP.

For more information about possible errors, see [Table 2](#).

How to identify the S-TAP version?

- From the GUI, the S-TAP version number is displayed in `Manage > System View > S-TAP Status Monitor`
- Alternatively, you can display the S-TAP version number from the command line of the database server.

Run debug from the command line to quickly identify configuration issues

Turn on debug from the GIM GUI or the command line. See debug levels in [Debug parameters](#).

Verify the connection between the database server and the Guardium system

- Verify that you can ping the Guardium system at `sqlguard_ip` from the database server.
- If the ping is successful, verify that you can telnet to the following ports on the Guardium system: 9500/9501 for S-TAP on Protocol 7, or 9800/9801 for S-TAP on Protocol 8.

If there is a firewall between the database server and the Guardium system

Verify that the following ports are open for traffic between these two systems: TCP port 9500 or TLS port 9501 for encrypted connections for S-TAP on Protocol 7, or TCP port 9800 or TLS port 9801 for encrypted connections for S-TAP on Protocol 8.

Verify that the `sqlguard_ip` parameter is set to the correct guardium hostname or the IP for the Guardium system that you are connecting to.

1. Click `Manage > Activity Monitoring > S-TAP Control` to open S-TAP Control.
2. Locate the S-TAP Host for the IP address that corresponds to your database server.
3. Expand the Guardium Hosts subsection, and verify that the active Guardium Host is correctly configured.
4. If necessary, click Modify to update the Guardium Hosts.

Where is the debug file located?

If the debuglevel > 0, then the log from the previous S-TAP session (if it exists) is saved as: `%STAP_DIR%\Bin\StapBuffer\stap_%HOSTNAME%YY-MM-DD%HHMMDD%.old` and the new log is created as: `%STAP_DIR%\Bin\StapBuffer\stap_%HOSTNAME%YY-MM-DD%HHMMDD%.new`.

In addition to this, start-up logs containing just messages related to S-TAP start-up are always generated in `%STAP_DIR%\Logs: startup_%HOSTNAME%YY-MM-DD%HHMMDD%.old` startup\_%HOSTNAME%YY-MM-DD%HHMMDD%.new.

Severe spikes in traffic, and traffic getting dropped

This symptoms could be due to a buffer overflow. Check the debug log for a message indicating buffer overflow. Advanced users only: consider enabling the dynamic buffer feature. See `dynamic_buffer_increase` in [General parameters](#).

Verify that the S-TAP process is not repeatedly restarting

To verify the process, go to services and check the status of Guardium services.

Verify that S-TAP Approval is not turned on

If S-TAP Approval is turned on, any new S-TAP that connects to the Guardium system is refused.

1. Click `Manage > Activity Monitoring > S-TAP Certification` to open S-TAP Certification.
2. Look at the S-TAP Approval Needed checkbox. If this box is checked, new S-TAPs can connect to this Guardium system only after they are added to the list of approved S-TAPs.
3. If S-TAP Approval is turned on, access the Approved Tap Clients report to view a list of approved S-TAPs. If the S-TAP that you are investigating is not on this list, return to the S-TAP Certification page, enter the IP address of the S-TAP in the Client Host field, and click Add.

For more information, see [Allow \(approve\) S-TAP connection to Guardium \(S-TAP certification\)](#).

S-TAP verification issues

The verification process attempts to log in to your database's STAP client with an erroneous user ID and password to verify that this attempt is recognized and communicated to the Guardium system. Your S-TAP might be configured in a way that prevents the inspection engine message from reaching the Guardium system from which the request was made.

These configuration details include:

- Load balancing: if the S-TAP is configured to return responses to more than one Guardium system, the error message might be sent to a different Guardium system.
- Failover: If secondary Guardium systems are configured for the S-TAP, the error message might be sent to a secondary Guardium system if the primary Guardium system is too busy.
- `db_ignore_response`: if the S-TAP is configured to ignore all responses from the database, it does not send error messages to the Guardium system.
- Client IP/mask: if any mask is defined that is not 0.0.0.0, it might prevent the error message from being sent.
- Exclude IP/mask: if any mask is defined that is not 0.0.0.0, it might prevent the error message from being sent.

## Windows: Scheduling S-TAP diagnostics

You can schedule S-TAP diagnostics by using the S-TAP Diagnostic Scheduler user interface.

### Before you begin

You must be logged in to the Guardium system that is the active host for the S-TAP®.

### Procedure

1. Browse to Manage > Activity Monitoring > S-TAP Diagnostic Scheduler.

You can see all the Windows S-TAP hosts that are listed under the S-TAP Hosts column that are managed by the Guardium system. This is the same list that is present on the S-TAP Control page.

2. Select one or more S-TAP hosts and click Add to schedule. The following options are available to run the diagnostics:

- Click Create Schedule to create a schedule to run the diagnostics and enter the details.
- Click Run Once to run the diagnostic immediately.

Important: After you run the diagnostics, click refresh to view the diagnostic results in the grid.

3. To remove the S-TAP hosts from the diagnostic schedule, select one or more S-TAP hosts from the S-TAP Hosts list and click Remove from schedule.

4. Optional: Click edit icon to edit the following S-TAP host details:

- Participate in scheduled diagnostics
- Level
- Duration

## Linux-UNIX: S-TAP user's guide

The Guardium S-TAP is a lightweight software agent installed on database servers and file servers. The S-TAP generally accounts for between 2% - 5% of CPU usage. In most installations, the impact is negligible with no noticeable impact on performance. The information collected by the S-TAPs is the basis of all Guardium traffic reports, alerts, visualizations, etc.

For data activity monitoring, the S-TAP monitors activity between the client and the database and forwards that information to the Guardium collector. The database traffic is logged into the collector based on criteria specified in the security policy. You can reduce the amount of traffic that is originally sent to the collector by ignoring trusted connections or ignoring traffic from specific IPs.

**MySQL limitations:** For MySQL, TCP is the only supported protocol. In addition, Windows S-TAP does not support MySQL encrypted traffic.

- [Linux-UNIX: S-TAP functionality](#)  
Familiarize yourself with these concepts before starting an S-TAP installation on a UNIX system.
- [Linux-UNIX: Installing, upgrading and uninstalling S-TAP agents](#)  
There are a few methods of installing, upgrading and uninstalling S-TAPs. Learn about each one and understand what works best for you.

- [Linux-UNIX: Using automation tools with the S-TAP and sample scripts](#)  
Guardium UNIX S-TAP has many script based interfaces to assist in the installation, configuration, and maintenance of the UNIX S-TAP agents. The following links provide you with the information necessary to create the automation scripts that work in your environment.

## Linux-UNIX: S-TAP monitoring mechanisms support matrix

Select your S-TAP setup depending on the data you want to monitor or block. Use this table to identify the monitoring mechanisms (Exit libraries, K-TAP, A-TAP) that can perform the operations you require, per operating system and database.

For example, you may want to track or perform one or more of the following:

- local traffic only
- local and network traffic
- shared memory
- encrypted data
- monitor and block
- monitor only

[Guardium support matrix](#) covers the most common platforms, database types, and protocols, supported by Guardium's monitoring mechanisms. The table presents general guidelines. There may be other combinations that are not presented here that are supported. Some of the supported setups presented here may be dependent on specific configurations. Contact Customer Support to verify the best setup for your specific needs. Empty cells indicate that the combination is not supported.

The exit libraries are preferred over all other monitoring mechanisms. If you cannot use an exit library, K-TAP is the next choice, then A-TAP, and finally PCAP.

## Linux-UNIX: S-TAP monitoring mechanisms

The Guardium® UNIX S-TAP uses several different monitoring mechanisms to collect database traffic. During configuration, you can choose the method that best meets your requirements. All mechanisms filter the traffic to reduce network overhead and increase performance.

You choose the mechanism during installation. All mechanisms filter the traffic so that only database-related traffic for specific sets of client and server IP addresses is collected. The mechanisms are presented here in order of preference: exit libraries, K-TAP, A-TAP, PCAP. See [Linux-UNIX: S-TAP monitoring mechanisms support matrix](#) and choose the mechanism that meets your needs.

### Exit libraries

The exit libraries are the preferred monitoring mechanism. They give the best performance, and can handle both local and network traffic, whether encrypted or not. They always capture DB\_USER. The only disadvantage is that exit libraries are supported only for Db2, Informix, and Teradata.

They require configuration on the database. If you upgrade the S-TAP version, then the exit library requires a restart, though you can restart whenever you choose. See [Linux-UNIX: Configuring Exit libraries](#).

### K-TAP

K-TAP is a kernel module that is installed into the operating system. It supports all protocols and connection methods (for example, TCP, TLI, SHM, Named Pipes). When enabled, it observes access to a database server by hooking into the mechanisms that are used to communicate between the database client and server. With Linux, the kernel frequently updates, and there are many kernel versions. The K-TAP version depends on the Linux version. See [Linux-UNIX: S-TAP compilation of K-TAP](#).

K-TAP is installed during S-TAP installation. If K-TAP fails to install, PCAP is installed instead. After it is installed, it can be enabled or disabled with a configuration file setting. If you do not load K-TAP during the S-TAP installation, and decide later that you want to use it, you need to reconfigure and restart the S-TAP.

### A-TAP

The A-TAP (application-level tap) sits in the application layer to support monitoring of encrypted database traffic, which cannot be done in the kernel by K-TAP. A-TAP monitors communication between internal components of the database server. It picks up unencrypted data in the application layer, and sends it to the K-TAP. K-TAP is a proxy to pass data to S-TAP, which then sends it to the Guardium collector.

With A-TAP, instead of capturing data from the kernel, where the data is still encrypted, Guardium captures data by loading a TAP library before executing the original database binary. The A-TAP libraries are a no-op (no interface). The libraries tap the database in application-mode, after the data is decrypted or before it is encrypted by the database. Hence there are no changes made to how the database would normally operate other than the encrypted traffic is now being captured by Guardium. This means that you do not need to update scripts and tools to call the Guardium code before executing the Oracle code.

A-TAP is included in every S-TAP but must be configured separately for each database instance to be monitored. See [Linux-UNIX: A-TAP management](#).

#### Restrictions:

- A-TAP is not supported in an environment where a 32-bit database is located on a 64-bit server.

#### When to use A-TAP?

A-TAP is required when DBMS encryption in motion is used, but there may be other internal database implementation details such as shared memory that require it.

Informix and Db2 on Linux integrate with Guardium more closely using an exit and thus are the recommended method for shared memory support when applicable.

### PCAP

PCAP is a packet-capturing mechanism that listens to network traffic from and to a database server. In a UNIX environment, since the K-TAP captures all network traffic, PCAP is rarely used. PCAP is used to capture local TCP/IP traffic on the device.

#### Restriction:

- PCAP only works on ports (no shared memory, and so on).

The PCAP uses the client IP/mask values for all local inspection engines to determine what to monitor and report. A PCAP that is installed with an S-TAP with multiple inspection engines that have different client IP/mask values, captures traffic from all clients that are defined in all inspection engines. The PCAP might be processing and sending more information to the Guardium system than you intend.

## Linux-UNIX: S-TAP to collector encryption

S-TAP agents can be configured to communicate with collectors over the network in an encrypted (TLS) manner.

Guardium recommends encrypting network traffic between the S-TAP and the collector whenever possible, only in cases where the performance is a higher priority than security should this be disabled. There is a small impact on performance when enabling encryption. The default S-TAP configuration is no encryption, to avoid any performance impact.

Before you determine the best choice for your environment, consider the following factors:

- Configuring the S-TAP with TLS requires extra time for encryption that might affect performance on the database server where the S-TAP agent is installed. The appliance (collector) also requires time to decrypt this traffic.
- If applications and database users are communicating with the database in an unencrypted manner, configuring the S-TAP agent to communicate over the network with encryption may not make your network safer.

In general, it makes sense to encrypt S-TAP traffic if the data that is sent to an appliance on a different network is encrypted, or if the database traffic that is monitored is network encrypted.

Encryption is enabled during the inspection engine configuration, and can be modified at any time.

## Linux-UNIX: UID chains

UID chain is a mechanism that allows S-TAP (by way of K-TAP) to track the chain of users that occurred before a database connection.

You can change usernames several times before you connect to the database. For example, you can run the following commands: **ssh informix@barbet**, then **su - db2inst1**, then **su -**, then **su - oracle9**, and end with **sqlplus scott/tiger@onora1**. With UID Chains, Guardium® can trace this process back to the process that called it, and back to the original (offending) user.

The UID chain values vary by OS platform. For example, under AIX the string IBM might appear as a prefix. For MongoDB, you can use a UID chain to determine the DB\_USER for reports, as MongoDB does not include OS\_USER in the login packet.

Enabling UID chains should not affect performance.

See the [Guardium support matrix](#) for a full list of operating systems and databases that support UID chains.

## Limitations

- For Solaris Zones, user IDs might be reported instead of usernames.
- The SSH client's IP address and port are added to the UID chain.
- PostgreSQL on Solaris 11 with zones is not supported, due to zone configuration not allowing access from primary to subordinate zones in some directories.
- Solaris Zones and AIX® WPAR - set the db2bp\_path in the guard\_tap.ini file to the full path of the db2bp executable file (the full path of the relevant db2bp as seen from the global zone/wpar).
- UID Chains are not reported for Inter-process Communication (IPC) on Solaris 8/9.
- UID chains are not detected for Hadoop databases.
- UID chain does not support local TCP on Linux for Db2. In addition, Db2 exit requires a specific version of the database to support UID chains.
- When running as a non-root user, UID chain does not work for Db2 Shared Memory (SHM) with S-TAP.
- Guardium does not log UID chain for network traffic.
- Guardium might not log UID chain for very short sessions since Guardium relies on the process ID of the application to determine the UID chain. If the process that starts the session exits before S-TAP can examine it, UID chain does not work.
- UID is not captured for Cassandra Datastax when Audit logging is used.
- UID is not captured for Cassandra Apache when Audit logging is used.
- UID chain is supported in these scenarios that require A-TAP for intercepting the traffic:
  - Sybase SSL traffic when the min and max port are set in the executor.
  - Mongo and Postgres SSL traffic.
  - Teradata encrypted traffic.

All other scenarios that require A-TAP are not supported.

## Configuring UID chain

You can control UID configuration with the following parameters,

- **hunter\_trace** - Enable this guard\_tap.ini parameter to log UID chain for all database connections.
- **uid\_chain\_sshd\_ip** - Enables adding an SSH client IP:port to the UID chain when SSH is identified as one of the processes in the chain.

The UID chains are logged in the collectors,

- **UID\_CHAIN** - The full chain of users, for example,  

```
(1,root,init [5])>(3746,root,/usr/sbin/sshd -o PidFile=/var/run/sshd.init.pid)>
(6948,root,sshd: root@pts/2)>(6950,root,-bash)>(7481,root,su - informix)>(7482,informix,-bash)>
(7522,informix,su - db2inst1)>(7523,db2inst1,-bash)>(7941,db2inst1,su - oracle12)>
(7942,oracle12,-bash)>(7982,oracle12,sqlplus)
```
- **UID\_CHAIN\_COMPRESSED** - The UID chain, excluding the first user and the last user, in this example, *informix, db2inst1*.

## UID chains in reports

To view UID chains in reports, use the UID Chain and UID Chain Compressed attributes in the Session entity.

Note: When you call the UID Chain or UID Chain Compressed attributes in a report, you might see a delay of up to 3 minutes in the UID Chain response. UID chains can be logged to Syslog with %%compressed\_uid\_chain or %%uid\_chain alert messages.

## Purging of UID chain records

UID chain records that are older than 2 hours are purged when the regular inference process runs. (Inference goes over all the records and consolidates them.) Records that are older than 24 hours are purged on a nightly basis.

## Linux-UNIX: Proxy firewall

Learn how to monitor traffic that originates from a proxy server.

While S-TAP is normally deployed on a database server, a K-TAP based firewall can be deployed to a proxy server. By utilizing S-GATE, you can monitor traffic that originates from the proxy server. See [Linux-UNIX: Application server parameters](#) and S-GATE Actions (Blocking Actions) in the Policies help topic for more information on setting appserver parameters and using S-GATE within Policies.

## Linux-UNIX: Using automation tools with the S-TAP and sample scripts

Guardium UNIX S-TAP has many script based interfaces to assist in the installation, configuration, and maintenance of the UNIX S-TAP agents. The following links provide you with the information necessary to create the automation scripts that work in your environment.

|                                                |                                                                                                             |

## Linux-UNIX: Installing, upgrading and uninstalling S-TAP agents

There are a few methods of installing, upgrading and uninstalling S-TAPs. Learn about each one and understand what works best for you.

- [Linux-UNIX: Install S-TAP agents installation flow](#)

Verify prerequisites, then install an S-TAP on Linux, Solaris, AIX and HP-UX servers using the Deploy Monitoring Agents tool, Guardium Installation Manager (GIM), the RPM, or the shell installer.

- [Linux-UNIX: S-TAP installation prerequisites](#)

Verify all prerequisites before starting your S-TAP installation.

- [Linux-UNIX: Before you start installing S-TAP](#)

Read these notes before you start to install an S-TAP.

- [Linux-UNIX: Use GIM to install, upgrade, uninstall the S-TAP](#)

- [Linux-UNIX: Use RPM to install, upgrade, uninstall the S-TAP](#)

You can manage your S-TAP agent with .rpm on RHEL and for SUSE Linux databases.

- [Linux-UNIX: Use shell installer to install, upgrade, uninstall the S-TAP](#)

- [Linux-UNIX: Use native installers to install, upgrade, uninstall the S-TAP](#)

The native installer provides a shell for the shell installer. The only advantage is that it ensures that S-TAP is registered in the operating system asset repository. This registration is not required by Guardium® for the installation of the S-TAP, but it might be a requirement at your company. Use the native installer only when necessary.

- [Linux-UNIX: S-TAP upgrade workflows per monitoring mechanism](#)

The S-TAP upgrade workflow depends on your monitoring mechanism: K-TAP, exit library, A-TAP. Use these workflows together with the specific upgrade procedure.

- [Linux-UNIX: Working with K-TAP](#)

K-TAP is a kernel module that is installed into the database server operating system during S-TAP installation. After it is installed, it can be enabled or disabled with a configuration file setting. When enabled, it observes access to a database server by hooking the mechanisms used to communicate between the database client and the server. With K-TAP you do not need to change how database clients connect to the server.

- [Linux-UNIX: Special environments configuration](#)

Use these procedures for as relevant for systems with Zones, RAC, WPAR, clusters.

- [Linux-UNIX: What to restart or reboot on the database server after installing or updating S-TAP](#)

This topic details what needs to be rebooted or restarted after you install or upgrade your UNIX or Linux S-TAP. Restart and reboot requirements are the same for GIM and non-GIM implementations.

- [Linux-UNIX: Managing a GIM-, RPM-, and shell-installed S-TAP during a database upgrade](#)

Only the A-TAP needs handling when you upgrade a database with a GIM, RPM, or shell-installed UNIX S-TAP. If a system is running multiple databases, the S-TAP can continue to run and monitor all other databases not being upgraded.

- [Linux-UNIX: Managing GIM clients during a major upgrade of the database server operating system](#)

When you upgrade the operating system on your database server, use the GIM client to automatically upgrade itself and the GIM bundles (for example, GIM, S-TAP, CAS) installed on the Linux-UNIX database. However, most operating systems do not support a major upgrade, for example from RHEL7 to RHEL8.

- [Linux-UNIX: Managing an RPM- or shell-installed S-TAP during a major upgrade of the database server operating system](#)

When you upgrade the operating system on your database server, you need to uninstall the S-TAP, and install a new version. However, most operating systems do not support a major upgrade, for example, from RHEL7 to RHEL8.

- [Linux-UNIX: Managing a GIM-, RPM-, or shell-installed S-TAP during a minor or kernel upgrade of the database server operating system](#)

A minor database operating system upgrade can include a new operating system kernel. Use this task for both a minor upgrade or a kernel upgrade.

## Linux-UNIX: Install S-TAP agents installation flow

Verify prerequisites, then install an S-TAP on Linux, Solaris, AIX and HP-UX servers using the Deploy Monitoring Agents tool, Guardium Installation Manager (GIM), the RPM, or the shell installer.

Depending on your license key, you can use the same S-TAP agent for both file server and database activity monitoring. FAM does not require any specific S-TAP configuration.

This flow describes installing S-TAP on a single database reporting to one collector. See the related topics for additional information on S-TAP in clusters and zones.

1. Plan the installation, review these topics:

- [Linux-UNIX: S-TAP monitoring mechanisms support matrix](#)
- [Linux-UNIX: S-TAP monitoring mechanisms](#)
- [Linux-UNIX: S-TAP to collector encryption](#)
- [Enterprise Load Balancing](#)

2. Verify prerequisites.

- [Linux-UNIX: Database version and directory requirements](#)
- The database has sufficient disk space available ([Linux-UNIX: Disk space requirements for S-TAP](#)).
- The ports that are required for communication between the collector and the S-TAP are open ([Linux-UNIX: Port requirements for S-TAP](#)).
- Identify required IP addresses and check database connectivity ([Linux-UNIX: System details and checks](#)).
- If you are installing with GIM, the GIM client must be installed on the target database server. See [Installing the GIM client on a UNIX server](#).

3. Install S-TAP by one of

- [Deploy monitoring agents](#)
- [Linux-UNIX: Installing the S-TAP client with GIM Setup by Client](#)
- [Linux-UNIX: Installing the S-TAP agent with RPM](#)

- [Linux-UNIX: Installing the S-TAP client by using the shell installer](#)

During S-TAP installation, if auto-discovery is enabled, it auto-discovers databases and creates inspection engines for the discovered databases. The auto-discovery process runs once at the time of S-TAP installation and does not automatically repeat. You can modify the configuration after the installation is complete.

4. Configure any of the optional components if required by your system.

- [Linux-UNIX: Kerberos-authenticated database traffic](#)
- [Linux-UNIX: Solaris Zones configuration](#)
- [Linux-UNIX: Oracle RAC S-TAP configuration](#)
- [Linux-UNIX: Configure S-TAP for Db2 WPAR](#)
- [Linux-UNIX: Configure S-TAP for SELinux](#)
- [Linux-UNIX: Activating and deactivating A-TAP on all nodes of a Db2 Cluster](#)
- [Linux-UNIX: Configure delayed cluster disk mounting](#)

5. Reboot or restart if required ([Linux-UNIX: What to restart or reboot on the database server after installing or updating S-TAP](#)).

6. Complete the S-TAP configuration.

- [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#)
- Advanced users only: [Linux-UNIX: Editing the S-TAP configuration parameters](#)

7. If required, configure [Enterprise Load Balancing](#).

## Linux-UNIX: S-TAP installation prerequisites

Verify all prerequisites before starting your S-TAP installation.

- [Linux-UNIX: Database version and directory requirements](#)

Review these database releases, patch level components, and directories, before you install an S-TAP or any associated agent.

- [Linux-UNIX: Disk space requirements for S-TAP](#)

Review these disk space requirements before you install an S-TAP or any associated agent.

- [Linux-UNIX: Port requirements for S-TAP](#)

If a firewall is located between the Guardium® system and an S-TAP agent, verify that the ports that are used for connections between those components are open.

- [Linux-UNIX: System details and checks](#)

Verify these prerequisites, including system details; and that your database is communicating with Guardium .

## Linux-UNIX: Database version and directory requirements

Review these database releases, patch level components, and directories, before you install an S-TAP or any associated agent.

Table 1. Linux, Solaris, AIX and HP-UX database versions requirements

| DB Type                    | Version                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Linux                      | make version 3.81 or later. To view your version of the make utility, run the command: <code>make -v</code>                                                                         |
| Oracle ASO, HP-UX<br>11.11 | LD_PRELOAD must be installed. It is installed by patch PHSS_28436 or later.                                                                                                         |
| TLS                        | For S-TAP on a server, either /dev/random or /dev/urandom must be present on the server. See the TLS port requirements in <a href="#">Linux-UNIX: Port requirements for S-TAP</a> . |

Note: A root user that installs GIM or S-TAP needs permissions to create and delete users and groups.

Table 2. Required directories per platform

| Requirement Type                               | Linux                                       | Solaris                                     | AIX                                         | HP-UX                                       |
|------------------------------------------------|---------------------------------------------|---------------------------------------------|---------------------------------------------|---------------------------------------------|
| Installation folder does not exist or is empty | /usr/local/guardium/guard_stap              | /usr/local/guardium/guard_stap              | /usr/local/guardium/guard_stap              | /usr/local/guardium/guard_stap              |
| File exists                                    | /bin/sh                                     | /bin/sh                                     | /bin/sh                                     | /bin/sh                                     |
| File exists                                    | /bin/sed or /usr/bin/sed                    | /bin/sed or /usr/bin/sed                    | /bin/sed or /usr/bin/sed                    | /bin/sed or /usr/bin/sed                    |
| File exists                                    | tar, awk, grep, tr                          |
| File exists                                    | dd and /dev/zero                            | dd and /dev/zero                            | dd and /dev/zero                            | prealloc                                    |
| File exists                                    | uuencode in /usr/bin or /tmp or perl exists | uuencode in /usr/bin or /tmp or perl exists | uuencode in /usr/bin or /tmp or perl exists | uuencode in /usr/bin or /tmp or perl exists |

## Linux-UNIX: Disk space requirements for S-TAP

Review these disk space requirements before you install an S-TAP or any associated agent.

Table 1. Linux, Solaris, AIX, and HP-UX: S-TAP disk space requirements

| Item | Disk Space |
|------|------------|
|------|------------|

| Item                | Disk Space                                                                                                                                                                                                                                                                                                                     |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S-TAP program files | GIM Installation <ul style="list-style-type: none"> <li>• AIX: 400 MB</li> <li>• HP-UX: 500 MB</li> <li>• Linux: 450 MB</li> <li>• Solaris: 400 MB</li> </ul><br>non-GIM Install: <ul style="list-style-type: none"> <li>• AIX: 300 MB</li> <li>• HP-UX: 400 MB</li> <li>• Linux: 350 MB</li> <li>• Solaris: 300 MB</li> </ul> |
| FAM program files   | 600 MB minimum                                                                                                                                                                                                                                                                                                                 |
| Buffer file         | By default, the S-TAP uses anonymous memory to stage data for transmission to the Guardium system. If you configure the S-TAP to use a buffer file, the size defaults to 50 MB. The size is controlled by the <code>buffer_file_size</code> parameter in the <code>guard_tap.ini</code> file.                                  |

## Linux-UNIX: Port requirements for S-TAP

If a firewall is located between the Guardium® system and an S-TAP agent, verify that the ports that are used for connections between those components are open.

Use your firewall management utility to check, and open as relevant, the ports listed.

Table 1. Port Requirements for Linux, Solaris, AIX and HP-UX servers

| Port  | Protocol | Guardium system connection to ... |
|-------|----------|-----------------------------------|
| 16016 | TCP      | Clear S-TAP                       |
| 16018 | TLS      | Encrypted S-TAP                   |
| 16020 | TCP      | Regular pooled connections        |
| 16021 | TLS      | TLS pooled connections            |
| 16022 | TCP      | Feed protocol                     |
| 16023 | TLS      | Encrypted S-TAP TLS               |

## Linux-UNIX: System details and checks

Verify these prerequisites, including system details; and that your database is communicating with Guardium .

- Obtain the IP address of the database server on which you are installing S-TAP. If virtual IPs are used, note those as well (you will need to configure those later, when completing the configuration).
- If installing on the central manager, identify the IP address of the collector that will control this S-TAP, and to which this S-TAP will report.
- If installing on a server with secure boot enabled, enroll the Guardium S-TAP key on the database server before installing S-TAP. For more information, see [Linux-UNIX: Enrolling a K-TAP signing key](#).
- If installing a locally built (custom) K-TAP with secure boot on, use the `kernelModuleSigning.sh` utility to sign the K-TAP. For more information, see [Linux-UNIX: Signing and enrolling a locally built K-TAP](#).
- Verify connectivity between the database server and the collector. On the database, enter `nmap -p <port> <ip_address>`. For example, to check that port 16018 (the port Guardium uses for TLS) is reachable at IP address 192.168.3.104, enter the command `nmap -p 16018 192.168.3.104`

Typical output looks like:

```
Starting nmap V. 3.00 Interesting ports on g4.guardium.com (192.168.3.104): Port State Service 16018/tcp open unknown
```

## Linux-UNIX: Before you start installing S-TAP

Read these notes before you start to install an S-TAP.

When you install an S-TAP agent, the installation program checks whether the `guardium` group exists. If the group does not exist, the installation program creates it. If you use certain components or features, such as A-TAP or Db2 Exit, you must add users to this group to ensure proper functioning. These requirements are described in the relevant sections.

The installation process creates log files for the entire S-TAP package (S-TAP, K-TAP, A-TAP, PCAP, and Discovery). The log files are good for troubleshooting failed installations. Locations include `/var/tmp`, `/tmp`, and `/var/log`.

The installation process updates `inittab`, `upstart`, and `rc` scripts.

S-TAP installs into `/usr/local/guardium`.

When you define the [Linux-UNIX: S-TAP install script parameters](#), Guardium® suggests that you keep the default settings (`--userinst` and `--root`). These choices install the files with the `guardium` user as the owner, but keeps the appropriate privileges when the S-TAP runs.

When you define the installation script parameters, you can specify the installer user as either *root* (–rootinst) or the guardium user (–userinst). When the installer populates the files, it can populate them so they are owned by either the root user or by the guardium user. When the S-TAP runs, it always starts as the user *root*, but if you specify –user, then the S-TAP drops privileges to the guardium user level after it starts running.

Note: You cannot specify –rootinst with –user because the privileges don't line up. In this case, the installer returns an error and exits. Additionally, if the files are owned by *root*, you cannot run as *user*.

If you choose to run the S-TAP as the guardium *user* (and not *root*), you might encounter some issues and limitations. Running S-TAP as the guardium user can cause some databases or protocols to stop working because of permission levels. Verify that the database path or exec file has permission that allows the user guardium to read. Depending on your environment, limitations can include,

- Discovery has limited functionality.
- Database on AIX® WPAR and Solaris Zones might not work, check the permission to access the installation path or exec file.
- For Oracle BEQ, restart S-TAP after you start or restart the database.
- For Informix® shared memory, restart S-TAP after you start or restart the database.
- For Db2 shared memory,
  - When ktap\_fast\_shmem is set to 0, if **shmctl** fails because of permission issues, then in most cases, change the S-TAP to run as *root*.
  - When ktap\_fast\_shmem is set to 1, if shared memory segment has *read permission by group*, then make sure that the Db2 instance is added to user (Guardium) group. On each server, only one Db2 configuration is supported.
  - If shared memory segment has *read permission by Db2 user only*, then S-TAP must run as *root*. (Open a Db2 shared memory session, run the command **ipcs -ma**, and check MODE on the output.)

## Linux-UNIX: Use GIM to install, upgrade, uninstall the S-TAP

### • [Linux-UNIX: Installing the S-TAP client with GIM Setup by Client](#)

Use the Guardium® Installation Manager Setup by Client to install the S-TAP agent either from a stand-alone Guardium appliance, or from the Central manager to schedule installation on one or more databases.

### • [Linux-UNIX: S-TAP GIM installation parameters](#)

Understand the parameters (each with a short description) that are typically used in your GIM S-TAP agent installation.

### • [Linux-UNIX: Upgrading an S-TAP agent with GIM Setup by Client](#)

Use the GIM tool to upgrade your S-TAP agent.

### • [Linux-UNIX: Uninstalling S-TAP agent with GIM Setup by Client](#)

Learn how to uninstall the S-TAP agent and the GIM bundle from the database server. If S-TAP was installed with GIM it's highly recommend to uninstall with GIM. Otherwise you would need to manually remove the S-TAP folder from the GIM directory on the DB server.

## Linux-UNIX: Installing the S-TAP client with GIM Setup by Client

Use the Guardium® Installation Manager Setup by Client to install the S-TAP agent either from a stand-alone Guardium appliance, or from the Central manager to schedule installation on one or more databases.

### Before you begin

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct S-TAP installer script, from either [Fix Central](#), or your Guardium representative. The script name identifies the database server operating system.

### About this task

After the installation, you can manage all parameters and monitor processes that were installed under its control. If you install by using one of the other installation methods, fewer agent parameters can be modified using GIM.

### Procedure

1. Verify that the GIM client is installed on the database server. See [Installing the GIM client on a UNIX server](#).
2. Upload the relevant S-TAP module to the Guardium Installation Manager appliance.
  - a. Go to **Manage > Module Installation > Upload Modules**.
  - b. Click **Choose File** and select the S-TAP module that you want to install.
  - c. Click **Upload** to upload the module to the appliance.The module appears in the Import Uploaded Modules table.
  - d. In the Import Uploaded Modules table, click the check box next to the S-TAP module you want to install.The module imports and becomes available for installation. The Upload Modules page resets and the Import Uploaded Modules table is now empty.
3. Navigate to **Manage > Module Installation > Set up by Client**.
4. In the Choose clients section, select the database servers where you want to install the S-TAP module. Select individual clients using check boxes in the table, or use the **Select client group** menu to select a group of clients. Click **Next** to continue.

Attention:

  - To create a client group, click  to open the Create client group dialog. Click **Add Clients** to open the Existing Clients window, select the clients, and click **OK**.
  - To import clients from a CSV file. Click **Import from CSV**, and selecting your CSV file. Modify the field delimiter if relevant. Click **Load** to create a group of type Client Hostname, with Application type of Public. This group can be accessed and managed from the Group Builder.
  - After you modify the client list, click  to update the display.
  - Use **Reset Connection** to remove GIM client information from the Guardium system before reregistering the client. After clicking **Reset Connection**, it might take a few minutes before the status of the GIM client process is reflected.

- Select a client and click View Installed Modules. The View Installed Modules window shows all the modules that are installed on this client (including S-TAP), their versions, and if any module is in pending state for all the selected clients. (The module COMMON, if it appears, can be ignored.)
  - When you create or update a group and edit the Client Name of GIM clients, the host name and address must reflect a valid value for a GIM client that is connected to the Guardium system. If an invalid host name is specified, the edited client does not appear as a member of the group. Adding clients by IP address is not supported.
5. In the Choose bundle section, use the Select a bundle menu to identify the software you want to install.  
After selecting a software bundle, the Selected bundle action column indicates Install, the action that will be performed for each client:
- Tip:
- You can filter the clients, for example, by name, module, Selected bundle actions, and client OS. The resulting selection is persistent; **the action is applied only to the filtered list of clients**. You can see that the number of clients in the Choose Clients section is greater than the number in Configure Clients section.
  - Clear the Show only latest versions checkbox to view and work with earlier versions of a bundle.
  - Clear the Show only bundles checkbox to identify individual modules within a bundle.
  - Select the Show only compatible clients checkbox to hide clients that are not compatible with the selected bundle.
- Attention:
- By default, the Select a bundle menu shows only the latest uploaded bundle version regardless of platform or compatibility with selected clients. To install a different bundle version for a specific platform or client, clear the Show only latest versions check box and select the required bundle.
  - If you upload and import new bundles while using the Set up by Client tool, refresh the browser to see the new bundles.
  - If you already have a bundle scheduled for installation, installing a new bundle removes the existing schedule.
- Click Next to continue.
6. In the Choose parameters section, specify values for required and optional parameters. Use the or to add or remove optional parameters. Use the to search for parameters by name or description.
- These parameters are mandatory:
- STAP\_TAP\_IP: the IP address or FQDN of the database server or node on which the STAP is being installed (equivalent to the -taphost command line parameter). If not specified, the GIM\_CLIENT\_IP value is used.
  - STAP\_SQLGUARD\_IP: the IP address or FQDN of the primary collector with which this STAP communicates (equivalent to the -appliance command line parameter). If not specified, then, the GIM\_URL value is used.
- Attention: See the enterprise load balancing parameters in [Linux-UNIX: S-TAP GIM installation parameters](#).
- Important: Unless identified as a client-specific parameter, values provided in the Choose parameters section are applied to all client installations. For client-specific parameters, the value field is disabled and values are defined per-client in the Configure clients section.
- Click Next to continue.
7. In the Configure clients section, use the table to review and edit parameter values for each client.
- Editable parameters show a icon next to the parameter value. Click the icon to edit the value.
8. Click Install to begin the software installation. Use the icon to schedule the installation, then click OK to continue.

## What to do next

Verify S-TAP status:

- In the Success popup, click Show Status to open the Status window to monitor the software install/upgrade. Click to refresh the results. If an install/upgrade has a failed status, click Uninstall if you see the button, otherwise, click Reset connection.
- View the module status in the report at Manage>Reports>Install Management>GIM Clients Status
- Verify that the row of the S-TAP has a green status (first column) in Monitor>Maintenance>S-TAP Logs>S-TAP Status

## Linux-UNIX: S-TAP GIM installation parameters

Understand the parameters (each with a short description) that are typically used in your GIM S-TAP agent installation.

Most parameters are also listed in [Linux-UNIX: Editing the S-TAP configuration parameters](#).

CAUTION:

Do not modify advanced parameters unless you are an expert user or IBM Technical Support advised to make the changes.

Table 1. General Parameters

| GIM parameter                | Description                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_TAP_IP                  | The IP address or FQDN of the database server or node on which the S-TAP is being installed (equivalent to the -taphost command line parameter). If not specified, the GIM_CLIENT_IP value is used. |
| STAP_SQLGUARD_IP             | The IP address or FQDN of the primary collector with which this S-TAP communicates (equivalent to the -appliance command line parameter). If not specified, then, the GIM_URL value is used.        |
| STAP_ADDITIONAL_SQLGUARD_IPS | List of space-delimited additional SQLGUARD IP addresses.                                                                                                                                           |
| STAP_ENABLED                 | Enables S-TAP when installation is complete. Default=1 (yes)                                                                                                                                        |
| STAP_FAM_ENABLED             | Enables FAM monitoring. Disabled by default. During upgrade, if the CLI parameter FAM was enabled in v10.1.4 or a prior version, then this parameter is enabled upon upgrade.                       |

| GIM parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_UPLOAD_FEATURE            | Whether or not the S-TAP uploads snapshots and new K-TAP modules to the GIM server to which it reports. Valid values: <ul style="list-style-type: none"><li>• 0: Disabled</li><li>• 1: Enabled for all (snapshots and K-TAP modules)</li><li>• 2: Enabled for snapshot; disable for K-TAP modules</li></ul>                                                                                                      |
| KTAP_ENABLED                   | Enables the K-TAP module. Default=1 (yes)                                                                                                                                                                                                                                                                                                                                                                        |
| KTAP_ALLOW_MODULE_COMBO        | Controls the FlexLoad mechanism: If the bundle does not have an exact kernel match, it installs the best match. If the K-TAP cannot be installed or does not start, a query is presented to the user whether to continue installation. Default=N                                                                                                                                                                 |
| KTAP_LIVE_UPDATE               | Enables the K-TAP update without requiring a server reboot. Default=Y                                                                                                                                                                                                                                                                                                                                            |
| GIM_ALLOW_CUSTOM_BUNDLES       | Control uploading of custom K-TAP bundle. <ul style="list-style-type: none"><li>• 0: Custom bundles are not allowed.</li><li>• 1: Allows installation of custom compiled K-TAP bundles.</li></ul> Default = 0<br>This parameter cannot be changed from the GUI or API. Only the OS Admin can change the value from 0 to 1 after GIM is installed. This parameter must be enabled on each DB server individually. |
| KTAP_PREVENT_EXACT_MATCH_BUILD | When enabled, K-TAP local builds are disabled. It is <b>not recommended</b> to enable this parameter since it decreases the possibility of finding a matching module for the running kernel.                                                                                                                                                                                                                     |
| KTAP_AIX_LOG_ROTATE_FILE_SIZE  | This parameter, together with KTAP_AIX_LOG_ROTATE_NFILES, configure the ktap.log rotation on AIX servers. When the file size reaches this threshold, in KB, it rotates. This parameter does not need modification. Valid values: >= 10. Default = 512                                                                                                                                                            |
| KTAP_AIX_LOG_ROTATE_NFILES     | The ktap.log rotation on AIX servers is enabled, by default, during installation or upgrade from previous version. This parameter specifies the maximum number of files to keep. This parameter does not need modification. Valid values: >= 2. Default=2                                                                                                                                                        |

Table 2. Enterprise Load Balancing parameters. For more information, see [Enterprise load balancing](#).

| GIM parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_LOAD_BALANCER_IP            | Required if you are configuring enterprise load balancing. If blank, enterprise load balancing is disabled.<br>The IP address or hostname of the central manager or managed unit this S-TAP uses for load balancing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| STAP_INITIAL_BALANCER_TAP_GROUP  | The name of the S-TAP group that this S-TAP belongs to, for enterprise load balancing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| STAP_INITIAL_BALANCER_MU_GROUP   | The name of the managed unit group that the app-group is associated with. Requires a defined LB-APP-GROUP. The managed unit group must exist on the central manager before it can be used during installation of the S-TAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| STAP_LOAD_BALANCER_NODE_AFFINITY | Whether the S-TAP connects to more than one managed unit, for enterprise load balancing. Some scenarios need all traffic to go to the same collector. With Oracle ATAP, for example, the analyzed client IP only shows if both the encrypted and unencrypted sessions go to the same managed unit. Valid values: <ul style="list-style-type: none"><li>• 0: Disabled. The S-TAP traffic goes to, at a maximum, the number of managed units specified by load_balancer_num_mus.</li><li>• 1: Enabled. The S-TAP traffic goes to one managed unit, and has, at a maximum, the number of connections (to that managed unit) specified by load_balancer_num_mus.</li></ul> See <a href="#">load_balancer_num_mus</a> |
| STAP_LOAD_BALANCER_NUM_MUS       | The number of managed units the enterprise load balancer allocates for this S-TAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Linux-UNIX: Upgrading an S-TAP agent with GIM Setup by Client

Use the GIM tool to upgrade your S-TAP agent.

### Before you begin

Verify the following before you begin.

- The GIM client on the database server is communicating with the Guardium system.
- Obtain the S-TAP module from either [Fix Central](#), or your Guardium representative.
- Certain Guardium® Data ProtectionS-TAP updates combined with certain sniffer patches do not support the ability to transfer DB\_USER in the event of a failover. Make sure that you have installed compatible patches, as described in [Determining whether Guardium Data Protection Linux/UNIX S-TAP and Sniffer patches are compatible](#).

### About this task

- Before starting a GIM Set up by Client upgrade, you can check whether any of the database servers need to be rebooted during the S-TAP upgrade. This check is for GIM Set up by Client upgrades only; it does not cover any other upgrade scenarios. If the bundles were installed from the managed unit, run the S-TAP Agent Upgrade Pre-Check report on the managed unit. If all clients are managed by the central manager (all GIM clients point to the central manager, which is best practice and the recommended setup), run the S-TAP Agent Upgrade Pre-Check report from the central manager. The reboot status of GIM clients that point to a managed unit is not captured in a report that is run on the central manager. Verify that the GIM agent is installed on the database server before you run the report. (None of the other modules or bundles need to be installed). All database servers that are listed in the report will need reboot. Reboot is required in this scenario:
  - Upgrading with a non-live upgrade (KTAP\_LIVE\_UPGRADE=N), irrespective of whether the source and target versions are the same.
- To upgrade from a shell installed S-TAP to a GIM-controlled S-TAP: Upgrade the S-TAP using shell, to the target version. Then install the bundle-GIM STAP installer. Reboot is not required.

- In a GIM upgrade, there are two scenarios you must avoid: A-TAP users are active (causing the upgrade to fail), and maintenance is running on the databases. A typical scenario is: database server maintenance is planned for 12 midnight and you want to upgrade the S-TAP at 1AM. Use this general flow to successfully upgrade your S-TAPS.
  1. Schedule your upgrades with GIM.
  2. Disable any GIM upgrades from deploying: **configurator.sh --delayed\_bundle\_deployment enable**
  3. Wait for the database maintenance to complete.
  4. Check if A-TAP users are active (assuming the DBs are down, disable them if there are any): <GIM INSTALL DIR>/ATAP/current/files/bin/guardctl list-active
  5. Enable GIM upgrades: **configurator.sh --delayed\_bundle\_deployment disable**

## Procedure

---

1. Upload the S-TAP module for upgrade.
  - a. On the Guardium system, go to **Manage > Module Installation > Upload Modules**.
  - b. Click **Choose File** and select the S-TAP upgrade module.
  - c. Click **Upload** to upload the module to the Guardium system.  
The module is listed in the Import Uploaded Modules table.
  - d. In the Import Uploaded Modules table, click the checkbox next to the S-TAP module you want to upgrade to.  
The module is imported and made available for upgrade. After the module is imported, the Upload Modules page is reset and the Import Uploaded Modules table is empty.
2. Go to **Manage > Module Installation > Set up by Client**.
3. In the **Choose clients** section, select the database servers where you want to update software. Select individual clients with the checkboxes in the table, or use the **Select client group** menu to select a group of clients.  
Click **Next** to continue.
4. In the **Choose bundle** section, use the **Select a bundle** menu to identify your upgrade version. Click **Next** to continue.
5. Optional: You can modify the flex load mechanism with the parameter **KTAP\_ALLOW\_MODULE\_COMBOS** in the **Choose parameters** section. This parameter applies to all servers unless you specify values individually in the **Configure clients** section.
6. Click **Upgrade** to begin the software upgrade. Or use the icon to schedule the installation, then click **OK** to continue.
7. To create the Guardium API syntax for the current configuration in the **Setup by Client**, click **Generate GuardAPI**. If enough information is available, it generates API commands for multiple clients in the **GuardAPI commands** dialog. If there isn't enough information, it shows a default template.

## What to do next

---

In the Success popup, click **Show Status** to open the Status window to monitor the software upgrade. Click to refresh the results. If an upgrade has a failed status, click **Uninstall** if you see the button, otherwise, click **Reset connection**. You can also view the status of the module upgrade by reviewing the report at **Manage > Reports > Install Management > GIM Clients Status**.

Verify that the S-TAP is communicating with the Guardium system by browsing to **Manage > Activity Monitoring > S-TAP Control** and reviewing the S-TAPs status and configuration.

## Linux-UNIX: Uninstalling S-TAP agent with GIM Setup by Client

---

Learn how to uninstall the S-TAP agent and the GIM bundle from the database server. If S-TAP was installed with GIM it's highly recommend to uninstall with GIM. Otherwise you would need to manually remove the S-TAP folder from the GIM directory on the DB server.

## Before you begin

---

- Verify that the GIM client on the database server is communicating with the Guardium system.
- If the database is using an exit library, disable the exit library, and then delete the exit library.
- If A-TAP is active, de-activate it before uninstalling the S-TAP. See [Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines](#).

## Procedure

---

1. Navigate to **Manage > Module Installation > Set up by Client**.
2. In the **Choose clients** section, select the database servers from which you are uninstalling the S-TAP. Select individual clients using check boxes in the table, or use the **Select client group** menu to select a group of clients. Click **Next** to continue.
3. In the **Choose bundle** section, select the bundle you want to uninstall from the drop-down list.  
**Tip:**
  - You can filter the clients, for example, by name, module, Selected bundle actions, and client OS. The resulting selection is persistent; **the action is applied only to the filtered list of clients**. You can see that the number of clients in the **Choose Clients** section is greater than the number in **Configure Clients** section.
  - Clear the **Show only latest versions** checkbox to view and work with earlier versions of a bundle.
  - Clear the **Show only bundles** checkbox to identify individual modules within a bundle.

- Select the Show only compatible clients checkbox to hide clients that are not compatible with the selected bundle. The Configure Clients row shows the number of clients that have that specific bundle running. Click Next to continue.
- 4. Click Uninstall. The system asks for confirmation. Click Yes.
- 5. Reboot the database server to remove K-TAP from the drivers.

## Linux-UNIX: Installing the S-TAP agent with RPM

---

You can install and update S-TAP on a Linux server using the RPM. The advantage of installing by RPM is that you install and maintain S-TAP using the same method that you manage all other software on the database server.

### Before you begin

---

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct S-TAP installer script, from either [Fix Central](#), or your Guardium representative. The script name identifies the database server operating system.
- The S-TAP shell installer does not install if there is already an RPM installed (preventing double installation).
- RPM is supported for RHEL and for SUSE Linux databases.

### About this task

---

RPM names have the format: **guard-stap-10.0.0.89165-1-rhel-6-linux-x86\_64.x86\_64.rpm**, where the first three numbers are the release number of STAP (10.0.0, 10.1.2, etc) and the fourth number is the code revision (89165). The number immediately following is the package iteration which would increment in the case of adding K-TAP modules to the RPM.

There is a single RPM for the 32-bit S-TAPs and two RPMs for the 64-bit S-TAPs so that the 64-bit S-TAP does not have a dependency on 32-bit libraries if 32-bit exit libraries are not required. The extra RPM looks like **guard-stap-32bit-exit-libs-10.1.0.89165-1-rhel-6-linux-x86\_64.x86\_64.rpm** and has a dependency on the main RPM.

By default, the installation process checks the Linux kernel to determine whether a K-TAP module has been created to work with that kernel. If it exists, it installs (sets **ktap\_installed = 1**). If there is none, K-TAP does not install unless you have enabled Loader Flexibility, which aids in the installation of currently built modules when an exact match does not exist. When Loader Flexibility is enabled, it attempts to build a K-TAP to match your Linux kernel.

RPM installs S-TAP to /opt/guardium; this location cannot be changed. **tap\_ip** is set automatically to the hostname of the system. **sqlguard\_ip** is set to 127.0.0.1 as a placeholder for proper configuration. Complete the configuration after the installation, as described in this procedure.

RPM logs are saved to /opt/guardium/rpm\_logs

You can run the **guard-config-update** script as root user or a non-root user. Use the **help** command to see your permitted functions.

## Procedure

---

1. Unzip the S-TAP package.
2. Log in to the database server as **root** and copy the RPM to /tmp.
3. To enable Loader Flexibility, set the Linux environment variable **NI\_ALLOW\_MODULE\_COMBO="Y"**. (This is particularly useful if you are using a service to push the RPMs, then you don't need to access every machine and set the parameter after installation.) Otherwise you can use the **guard-config-update** parameter **--set-flexload**.
4. Run the **rpm -i <RPM\_NAME>** command.  
The S-TAP installs.
5. Run **guard-config-update** with the **--retry-ktap-load** parameter.
6. Take one of the following steps to complete the configuration:
  - Change the directory to /opt/guardium, and running the script **guard-config-update**, using the parameters described in [Linux-UNIX: S-TAP guard-config-update parameters for RPM installation and update](#).
  - Update the S-TAP parameters in the UI. See [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#).

## What to do next

After installation completes, verify S-TAP status:

- Verify that the row of the S-TAP has a green status (first column) in Monitor > Maintenance > S-TAP Logs > S-TAP Status

## Linux-UNIX: S-TAP guard-config-update parameters for RPM installation and update

Learn about the guard-config-update parameters used for installing an S-TAP agent, and updating its configuration.

You can use the guard-config-update script to update your S-TAP configuration (without using the GUI), whether S-TAP was installed with GIM, RPM, or shell. See [Linux-UNIX: Configure S-TAP with guard-config-update](#)

Table 1. guard-config update parameters

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --stap-dir                                    | S-TAP install directory if not default (default: /usr/local/guardium).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| --migrate-to-insights [tenant ID] [routeName] | Migrate an S-TAP to Guardium® Insights. Parameters:<br><br>tenant ID<br>The Guardium Insights tenant ID, including the <i>TNT_</i> prefix.<br>routeName<br>The DNS hostname for the Guardium Insights deployment. The DNS hostname is the same as the URL for the UI (without the https:// prefix).<br><br>Note: Before migrating the S-TAP, Guardium Insights must have a signed, trusted certificate that the S-TAP can locate. Store the certificate either in the default location ( <code>INSTALL_DIR/etc/pki/certs/trusted/ca.cert.pem</code> , where <code>INSTALL_DIR</code> is the Guardium Data Protection installation directory or configure a different location in the <code>guard_tap.ini</code> by using the <code>guardium_ca_path</code> parameter. If you specify a custom location, you must manually store the certificate (that is, you cannot use the <code>push_insights_trust</code> API). You can also use the <code>migrate_stap_config</code> API to migrate S-TAPs. |
| --set-tap-ip [IP or hostname]                 | Set <code>tap_ip</code> in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> (default: <code>rh5u9x64t.guard.swg.usma.ibm.com</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| --set-sqlguard-ip [IP or hostname]            | Set <code>sqlguard_ip</code> in SQLGuard_0 section in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> (default: <code>127.0.0.1</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| --add-sqlguard [ID] [IP or hostname]          | Add SQLGuard_ID section to S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| --remove-sqlguard [ID]                        | Remove SQLGuard_ID section from the S-TAP config file. <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| --modify-sqlguard [ID] [parameter] [value]    | Set SQLGuard_ID section parameter to value in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> . Parameters:<br><br><code>sqlguard_ip</code><br>IP address or hostname of SQLGuard unit<br><br><code>sqlguard_port</code><br>Port used to connect to SQLGuard unit (default: 16016)<br><br><code>primary</code><br>Order of preference (1=primary, 2=secondary, 3=tertiary, and so on)<br><br><code>num_main_thread</code><br>Number of main connections to use for this SQLGuard, used with <code>participate_in_load_balancing = { 1, 4 }</code> (default: 1)<br><br><code>connection_pool_size</code><br>Number of data connections per main connection to SQLGuard unit (default: 0)                                                                                                                                                                                                                                                                              |
| --modify-tap [parameter] [value]              | Set TAP section parameter to value in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> . For the list of <code>guard_tap.ini</code> parameters, see <a href="#">guard_tap.ini parameters</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| --help-config [option]                        | Show information about an option in the ini, if available (show all available if none specified).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| --set-flexload [0 or 1]                       | Controls the K-TAP FlexLoad mechanism: 0: disable, 1: enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --retry-ktap-load                             | Retry K-TAP loading (useful after installing dev packages, updating after K-TAP request, or changing flexload; automatically restarts S-TAP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --discover-ies                                | Run discovery and replace all Inspection Engines with those discovered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --stop [service]                              | Stop service (S-TAP, or monitor) temporarily (Solaris services and inittab treat this as permanent disable, does not auto-start on boot until re-enabled).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --start [service]                             | Start service (S-TAP, or monitor) if not already running (implies enable).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --restart [service]                           | Restart service (S-TAP, or monitor) if already running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --disable [service]                           | Prevent service (S-TAP, or monitor) from running again.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --enable [service]                            | Configure service (S-TAP, or monitor) for automatic start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| --status                                      | Show which services are started and if they are configured to start automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                            | Description                                                                                                                                     |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| --show-tap [option]                  | Shows the value that is currently stored for a parameter in the TAP section of the guard_tap.ini file.                                          |
| --show-ies                           | Shows the currently configured inspection engines in the guard_tap.ini file.                                                                    |
| --set-ktap-prevent-exact-match-build | Enable or disable the K-TAP local build. It is recommended to leave the KTAP local build enabled, which is the default setting when installing. |

Table 2. guard.\_tap.ini parameters

| Parameter                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| all_can_control                   | Defines which Guardium system controls this S-TAP. Valid values: <ul style="list-style-type: none"><li>• 0: S-TAP is controlled by the primary Guardium system only.</li><li>• 1: S-TAP can be controlled by any Guardium system.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| tap_debug_output_level            | Set debugging level (must be an integer >= 0, but not 2 or 3). Valid when server_side_masking_installed is 1 and firewall_default_state is 1.<br>Cannot be configured to the same range as firewall_force_unwatch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_request_handler_enable             | Allow the database to access K-TAP without manual configuration (requires a defined db_user in the IE section). Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                |
| fam_enable                            | Global enable/disable for FAM. Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul> <p>FAM rules must be defined in order for FAM to run. If rules are not defined, enabling this parameter opens a connection to the Guardium system on port 16022 (or 16023 if using encryption), but FAM remains essentially disabled.</p>                                                                                                                                                                                                                       |
| kafka_reader_enabled                  | Enables Cloudera Navigator integration using Kafka publish and consume. Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| kafka_bootstrap_servers               | Required. The comma separated list of host_name:port pairs are used to establish the initial connection to the Kafka cluster. After the initial connection is established, all servers in the cluster are used. Consider specifying more than one bootstrap in case one is down. Example:<br>hostnameofbroker1:9092,hostnameofbroker2:9092.                                                                                                                                                                                                                                                        |
| kafka_topic_name                      | Required. The topic name in the Kafka cluster that Cloudera publishes audits to, and that S-TAP reads audits from.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| kafka_group_name                      | Required. Assigns the S-TAP to this Kafka consumer group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| kafka_ssl_ca_location                 | Required if kafka_use_tls = 1. Path to the certificate authority (CA) for verifying the Kafka cluster certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| kafka_debug                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| kafka_extra_config                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| force_server_ip                       | Forces the reported server IP of the database to be the value stored in tap_ip. Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                |
| tenant_id                             | To use an S-TAP with Guardium Insights, the Guardium Insights tenant ID is required, including the TNT_ prefix. For example:<br><b>tenant_id=TNT_N5YBRAPBWRYAPFLQWABCDE</b>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| enable_dynamic_ring_buffers           | Dynamically adds and removes S-TAP buffers for each main connection during peak traffic to prevent an overflow in the S-TAP buffer. If S-TAP failover happens, data in all buffers is moved to the new buffers.<br>Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                             |
| enable_ktap_dynamic_ring_buffers      | Dynamically adds and removes K-TAP buffers for each main connection during peak traffic, to prevent an overflow in the K-TAP buffer. If K-TAP failover happens, data in all buffers is moved to the new buffers.<br>Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                            |
| enable_stap_soft_restart              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| buffer_percentage_for_priority_packet | Allows you to adjust the buffer percentage for priority packets. Increasing the value reserves more space for priority packets.<br>When Guardium reaches the buffer usage maximum (that is, 100% - buffer_percentage_for_priority_packet, non-priority packets are dropped to help ensure that priority packets get through.<br>The range is 1 (1%, the default) to 5 (5%).                                                                                                                                                                                                                        |
| use_exit_db_type                      | Allows database auto-discovery to discover any databases that have Exit protocols and add those instances to Discovered Instances report.<br>Valid values: <ul style="list-style-type: none"> <li>• 0: Do not autodiscover databases that have Exit protocols.</li> <li>• 1: Discover databases that have Exit protocols. For more information, see <a href="#">Using Exit discovery</a>.</li> </ul>                                                                                                                                                                                               |
| db_exit_list                          | Discover databases that are supported with Exits. When an Exit database type is discovered, K-TAP is automatically disabled.<br>When use_db_exit is set to 0, this parameter is ignored.<br>Valid values (when use_db_exit is set to 1): <ul style="list-style-type: none"> <li>• All - Discovery discovers databases supported with Exit along with other non-Exit databases.</li> <li>• None: Discovery does not discover any databases with Exits.</li> <li>• &lt;DB type&gt; : Discovery discovers only the specified database. DB type can be: DB2, INFORMIX, NETEZZA, or TERADATA</li> </ul> |
| stap_buf_mem_percent                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| load_balancer_node_affinity          | Whether the S-TAP connects to more than one managed unit, for enterprise load balancing. Some scenarios need all traffic to go to the same collector. With Oracle ATAP, for example, the analyzed client IP only shows if both the encrypted and unencrypted sessions go to the same managed unit. Valid values: <ul style="list-style-type: none"> <li>• 0: Disabled. The S-TAP traffic goes to, at a maximum, the number of managed units specified by load_balancer_num_mus.</li> <li>• 1: Enabled. The S-TAP traffic goes to one managed unit, and has, at a maximum, the number of connections (to that managed unit) specified by load_balancer_num_mus</li> </ul> See <a href="#">load_balancer_num_mus</a> . |
| guardium_ca_path                     | Location of the Certificate Authority certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| sqlguard_cert_cn                     | The common name to expect from the Sqlguard certificate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| initial_balancer_mu_group            | The managed unit group name to associate with this S-TAP (by the central manager load balancer) when installing an S-TAP. The group name is sent with each request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| initial_balancer_tap_group           | The S-TAP group name to associate with this S-TAP (by the central manager load balancer) when installing an S-TAP. The group name is sent with each request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| load_balancer_recheck_interval       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| transmit_session_losses_metadata     | Determines whether to create a SessionLossesMetadata message that report metadata if packets are dropped for a given session. Valid values: <ul style="list-style-type: none"> <li>• 0 (disabled). Do not send the SessionLossesMetadata message.</li> <li>• 1 (enabled). Send the SessionLossesMetadata, but only when a new collector is found.</li> </ul>                                                                                                                                                                                                                                                                                                                                                         |
| discovery_ora_use_port_ranges        | Enable S-TAP discovery of Oracle databases to combine discovered instances based on port ranges. This setting works with a single unix_domain_socket_marker. Multiple unix_domain_socket_marker configurations require separate instances. Valid values: <ul style="list-style-type: none"> <li>• 0: disabled</li> <li>• 1: enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                       |
| global_session_key                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| internal_load_balancer_time_interval |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Linux-UNIX: Upgrading S-TAP using RPM

### Before you begin

Obtain the correct S-TAP installer script, from either [Fix Central](#), or your Guardium representative. The script name identifies the database server operating system. Note: Certain Guardium® Data ProtectionS-TAP updates combined with certain sniffer patches do not support the ability to transfer DB\_USER in the event of a failover. Make sure that you have installed compatible patches, as described in [Determining whether Guardium Data Protection Linux/UNIX S-TAP and Sniffer patches are compatible](#).

### About this task

RPM names have the format: **guard-stap-10.6.0.0.89165-1-rhel-6-linux-x86\_64.x86\_64.rpm**, where the first three numbers are the release number of STAP (10.0.0, 10.1.2, etc) and the fourth number is the code revision (89165). The number immediately following is the package iteration which would increment in the case of adding K-TAP modules to the RPM.

There is a single RPM for the 32-bit S-TAPs and two RPMs for the 64-bit S-TAPs so that the 64-bit S-TAP does not have a dependency on 32-bit libraries if 32-bit exit libraries are not required. The extra RPM looks like **guard-stap-32bit-exit-libs-10.1.0.89165-1-rhel-6-linux-x86\_64.x86\_64.rpm** and has a dependency on the main RPM.

RPM logs are saved to /opt/guardium/rpm\_logs

You can run the guard-config-update script as root user or a non-root user. Use the help command to see your permitted functions.

All S-TAP configuration persists during the upgrade.

### Procedure

1. Unzip the S-TAP package and copy the RPM to /opt/guardium of the database server.
2. Run the command: `rpm -U <RPM_NAME>`. If you want to modify the FlexLoad mechanism value, include the parameter in the rpm command: --set-flexload, where 0 disables the feature, and 1 enables it.

### What to do next

After the upgrade completes, verify S-TAP status:

- Verify that the row of the S-TAP has a green status (first column) in Monitor > Maintenance > S-TAP Logs > S-TAP Status

# Linux-UNIX: Uninstalling S-TAP using RPM

Learn how to uninstall the S-TAP agent from a Linux server using the RPM.

## Before you begin

---

- If the database is using an exit library, disable the exit library, and then delete the exit library.
- If A-TAP is active, de-activate it before uninstalling the S-TAP. See [Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines](#).

## Procedure

---

1. To get the RPM name, run: `rpm -qa | grep guard_stap`
2. Run `rpm -e <RPM_NAME>`

## Results

---

After uninstalling S-TAP, the directory /opt/guardium still exists, but should only contain /opt/guardium/guard\_stap/guard\_tap.ini.rpmsave and /opt/guardium/rpm\_logs.

# Linux-UNIX: Installing the S-TAP client by using the shell installer

Use the shell installer, either in interactive mode or non-interactive mode, to install the S-TAP client on Linux, Solaris, HPUX, and AIX database servers.

## Before you begin

---

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct S-TAP installer script, from either [Fix Central](#), or your Guardium representative. (The installation fails if the version is incorrect.) The script name identifies the database server operating system. The S-TAP package name is in the format: `guard-stap-10.6.0.0_r123456_1-rhel-5-linux-x86_64.sh`, where the first three numbers are the release number, followed by the revision number, in this example r123456.
- Alternately, download the consolidated installer that contains support for all versions for a particular operating system. For example, `guard-stap-11.4.0.0_r110473_trunk_1-suse.sh` can install any suse system of any version or CPU. These packages are much larger than the version-specific packages, though.

## About this task

---

Interactive mode must be run individually on each system, and is therefore recommended for individual S-TAPs. It provides validation at each step, which means less chance of errors. It is useful for smaller deployments or whenever a guided, step-by-step installation experience is required. The system prompts for the basic configuration, and verifies your input immediately, so that the installation does not result in errors.

By default, K-TAP is installed automatically during S-TAP installation. The S-TAP installer checks if the K-TAP is available for the kernel version. If the installation process does not find a matching K-TAP, it attempts to build one to match your Linux kernel. If the K-TAP cannot be installed or does not start, a query is presented to the user whether to continue installation. See [Linux-UNIX: Working with K-TAP](#).

If /tmp is mounted with the `noexec` option, you can set the shell variable TMPDIR to some other directory that is not mounted `noexec` (typically ~/tmp). For example, `TMPDIR=~/tmp` `/var/tmp/guard-stap-11.1.0.0_r107068_trunk_1-ubuntu-18.04-linux-x86_64.sh`.

If any stage of the installation fails, undo all of the steps up to that point. Do not leave the S-TAP partially installed.

## Procedure

---

1. Log on to the database server using the `root` account. (S-TAP must always be installed by root.)
2. Designate an installation directory and verify it has sufficient disk space, approximately 400 MB - 500 MB total.
3. Copy the S-TAP installer to the local disk on the database server, typically to `/tmp`.
4. For interactive mode, run the installer script.

```
./guard-stap-guard-<release number>_<revision number>_1-rhel-5-linux-x86_64.sh
```

The only value that you must enter is the IP address of your Guardium collector, or the collector name. All other values can be left at their defaults. The installer typically prompts as follows.

```
Enter the path prefix [/usr/local]?
Directory /usr/local/guardium/guard_stap does not exist, would you like to create it? [Y/n]
System library path [/usr/lib]?
Run STAP as root, or as user 'guardium'? [R/u]
Install STAP as root, or as user 'guardium'? [r/U]
Would you like to run guard_discovery? [Y/n]
Do you want to configure load balancer functionality? [y/N]
IP address of the SQL Guard unit:
Do you want to edit the parameters file? [y/N]
```

```
If you later update your kernel to another version, we can
try to load the closest fitting delivered module. This
feature is not enabled by default, but we recommend enabling
it to reduce delays in support. Note that if all the
packages require to build natively are installed, a local
build to generate an exact matching module will be attempted
prior to looking for non-exact matches.
Do you wish to enable this feature (y/N/h)?
```

If you choose yes to the prompt Would you like to run guard\_discovery? [Y/n], then it runs the guard\_discovery once with the --update-tap-flag to initially configure inspection engines. No matter what, it configures guard\_discovery --send-to-sqlguard-flag to run once every 24 hours.

5. For non-interactive mode, enter a command similar to this one, which uses the minimum parameters:

```
./guard-stap-guard-<release number>_<revision number>_1-rhel-5-linux-x86_64.sh -- --ni --dir
<guardium_installation_directory> --tapip <tap_ip or host_name> --sqlguardip <sqlguard_ip or host_name>
```

See the parameter description in [Linux-UNIX: S-TAP install script parameters](#).

## What to do next

---

Verify that the row of the S-TAP has a green status (first column) in Monitor > Maintenance > S-TAP Logs > S-TAP Status

## Linux-UNIX: S-TAP install script parameters

---

Understand the guard-stap-setup script for installing an S-TAP.

### Install script command line syntax

```
Usage guard-stap-setup [options]
```

Example

```
./guard-stap-guard-<release number>_<revision number>_1-rhel-5-linux-x86_64.sh -- --ni --dir <guardium_installation_directory>
--tapip <tap_ip or host_name> --sqlguardip <sqlguard_ip or host_name>
```

| Parameter               | Usage                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --?                     | Help - displays commands and their descriptions                                                                                                                                               |
| --ni                    | Non-interactive install.                                                                                                                                                                      |
| -k   -p                 | Specify whether to install with K-TAP (-k) or to not install K-TAP (-p) when K-TAP is not required (such as when using an Exit).                                                              |
| --ignore-compat         | Ignore script compatibility check.                                                                                                                                                            |
| -u                      | Update if a previous installation is found.                                                                                                                                                   |
| --user   --root         | Run S-TAP as user or root.<br>For more information about how to define these parameters, see <a href="#">Linux-UNIX: Before you start installing S-TAP</a> .                                  |
| --userinst   --rootinst | Install S-TAP as user or root.<br>For more information about how to define these parameters, see <a href="#">Linux-UNIX: Before you start installing S-TAP</a> .                              |
| --overwrite-existing    | Overwrite the existing installation if found. This parameter is disabled by default. If you specify it in an install or upgrade, it is disabled again after the install or upgrade completes. |
| --libdir <library>      | System library path. The library files must be located in a directory that is configured as trusted by the system. For example, /usr/lib on Linux, even on 64-bit systems. Default = /usr/lib |
| --tls force   none      | S-TAP TLS setting. The failover option is deprecated from v10.5.                                                                                                                              |
| --dir <dir>             | S-TAP install directory.                                                                                                                                                                      |

| Parameter                                     | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --ipfile <file>                               | <p>Text file that specifies a list of hostnames, IP addresses, and Guardium system addresses separated by a single space. For example:</p> <pre>database-01 10.10.10.1 gmachine-01 database-02 10.10.10.2 gmachine-01 database-03 10.10.10.3 gmachine-02</pre> <p>The command would look like:<code>/var/tmp/guard-stap-10.0.0_r103368_v10_5_1-rhel-5-linux-x86_64.sh --ni --dir /usr/local --ipfile /var/tmp/ipfile.txt</code></p> <p>GIM is a much easier way of configuring these parameters.</p> |
| --tapi <tapi>                                 | The IP of the machine S-TAP is being installed on.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --sqlguardip <sqlguardip>                     | The IP of the Guardium system this S-TAP should communicate with.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --presets <file>   <preset-options>           | Read installation settings or write them to a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| --no-discovery                                | Do not use the discovery utility to configure inspection engines. This parameter is disabled by default. If you specify it in an install or upgrade, it is disabled again after the install/upgrade completes.                                                                                                                                                                                                                                                                                       |
| --modules <module-bundles>                    | Specify an external K-TAP modules bundle.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| --ktap_allow_module_combos                    | Controls the FlexLoad mechanism: Allow inexact kernel match for K-TAP loading. If the bundle does not have an exact kernel match, it installs the best match. This parameter is disabled by default. If you specify it in an install or upgrade, it is disabled again after the install/upgrade completes.                                                                                                                                                                                           |
| --ktap_prevent_exact_match_build              | When specified, disables the K-TAP local build. It is <b>not recommended</b> to set this parameter; it increases the likelihood of not being able to find a matching module for the running kernel. This parameter is disabled by default. If you specify it in an install or upgrade, it is disabled again after the install/upgrade completes.                                                                                                                                                     |
| --ktap_log_rotate_file_size <file size in KB> | This parameter, together with KTAP_AIX_LOG_ROTATE_NFILES, configure the ktap.log rotation on AIX servers. When the file size reaches this threshold, in KB, it rotates. This parameter does not need modification. Valid values: >= 10. Default = 512                                                                                                                                                                                                                                                |
| --ktap_log_rotate_n_files                     | The ktap.log rotation on AIX servers is enabled, by default, during installation or upgrade from previous version. This parameter specifies the maximum number of files to keep. This parameter does not need modification. Valid values: >= 2. Default=2                                                                                                                                                                                                                                            |
| --load-balancer-ip <load_balancer_ip>         | The IP address of the central manager or managed unit this S-TAP uses for enterprise load balancing.                                                                                                                                                                                                                                                                                                                                                                                                 |
| --lb-app-group <app_group>                    | The application group name that this S-TAP belongs to for enterprise load balancing.<br>Attention: Group names with spaces or special characters are not supported.                                                                                                                                                                                                                                                                                                                                  |
| --lb-mu-group <mu_group>                      | The Managed Unit group name the app-group is associated with. Requires a defined LB-APP-GROUP. Define the MU group on the central manager before installing the S-TAP.<br>Attention: Group names with spaces or special characters are not supported.                                                                                                                                                                                                                                                |
| --lb-num-mus <number_of_mus>                  | The number of managed units the enterprise load balancer allocates for this S-TAP.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --fam-enable                                  | Enables or disables FAM. FAM rules must be defined in order for FAM to run. If rules are not defined, enabling this parameter opens a connection to the Guardium system on port 16022 (or 16023 if using encryption), but FAM remains essentially disabled.<br>Default value: 0<br><br>If this parameter is present in the script arguments, then the fam_enable is set to 1.                                                                                                                        |
| --fam-installed                               | Valid values: 0 and 1.<br>0: FAM module will not be installed.<br><br>1: FAM module will be installed<br><br>Default value: 0                                                                                                                                                                                                                                                                                                                                                                        |
| --skip-third-party-check                      | If Guardium detects a third-party conflict, K-TAP installation can fail during a shell installation. When this parameter is set, the S-TAP install process does not check for third-party applications, but sends the following warning:<br><br><code>KTAP MODULE WARNING OVERRIDE is enabled ... skipping third party kernel extension check</code>                                                                                                                                                 |

## Linux-UNIX: Upgrading the S-TAP agent using the shell installer

Use the shell installer, either in interactive mode or non-interactive mode, to upgrade the S-TAP agent on Linux, Solaris, HPUX, and AIX database servers.

### Before you begin

- Obtain the correct S-TAP bundle, from either [Fix Central](#), or your Guardium representative. The script name identifies the database server operating system.
- Certain Guardium® Data ProtectionS-TAP updates combined with certain sniffer patches do not support the ability to transfer DB\_USER in the event of a failover. Make sure that you have installed compatible patches, as described in [Determining whether Guardium Data Protection Linux/UNIX S-TAP and Sniffer patches are compatible](#).

### About this task

If any stage of the upgrade fails, undo all of the steps up to that point. Do not leave the S-TAP partially upgraded.

The S-TAP package name is in the format: `guard-stap-11.0.0.0_r123456_1-rhel-5-linux-x86_64.sh`, where the first three numbers are the release number, followed by the revision number, in this example r123456.

## Procedure

---

1. Log on to the database server using the `root` account.
2. Copy the S-TAP bundle to the installation directory, and run the command: `./guard-stap-guard-<release number>_<revision number>_1-rhel-5- linux-x86_64.sh`. If you want to enable the FlexLoad mechanism setting, include the parameter: `ktp_allow_module_combos`  
If you are running the script interactively, without the `-u` parameter, the system responds:  

```
Do you want to update the previous STAP installation? [y/N]
```

If you're running non-interactively (`-ni`) without the `-u` parameter, the system responds with this error:  

```
Detected previous STAP installation Run installer with '-u' flag to update previous installation
```
3. Confirm you want to upgrade. The script runs, and at completion you should see output similar to: Successfully updated from 10.6.0.0 105601 to 11.0.0.0 105854

## What to do next

---

Verify that the row of the S-TAP has a green status (first column) in Monitor > Maintenance > S-TAP Logs > S-TAP Status

## Linux-UNIX: Uninstalling S-TAP agents using the shell installer

---

Perform this procedure before installing a new version of S-TAP if you want to save the old configuration file.

### Before you begin

---

- If the database is using an exit library, disable the exit library, and then delete the exit library.
- If A-TAP is active, de-activate it before uninstalling the S-TAP. See [Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines](#).

### About this task

---

If you have installed A-TAP, you must deactivate it before attempting any upgrade/install operations; see the description of the A-TAP deactivation command, in [Linux-UNIX: Deactivating A-TAP](#).

If you are removing a previous version of S-TAP that used K-TAP, this procedure includes rebooting the database server. If K-TAP has been installed, you have a device file named: `/dev/guard_ktap`.

## Procedure

---

1. Log on to the database server system using the `root` account.
2. Optionally, copy the S-TAP configuration file to a safe location (a non-Guardium directory). By default, the full path name is: `/usr/local/guardium/guard_stap/guard_tap.ini`.  
You can use this file later if you have to re-install this version of the software, or you can refer to it when configuring an updated version of S-TAP. Do not ever use an older configuration file directly with a newer version of the software - newer properties may be missing, and the defaults taken may result in unexpected behavior when you start S-TAP.
3. Run the uninstall script. For example, if the default directory has been used: `[root@yourserver ~]# /usr/local/guardium/guard_stap/uninstall`
4. If your previous version of S-TAP included K-TAP, reboot the database server now.

## Linux-UNIX: Converting a shell managed S-TAP to a GIM managed S-TAP

---

An S-TAP that was installed by shell can be converted to a GIM-managed S-TAP.

### Before you begin

---

Verify that:

- S-TAP is up and running.
- K-TAP is loaded.
- Database activities are captured.
- Download the BUNDLE-GIM and save it on the database server.

### About this task

---

If you use the BUNDLE-GIM and BUNDLE-STAP that have the exact same version and revision number as the S-TAP, you do not need to reboot the database server. You can upgrade the S-TAP by installing a higher version or revision of the BUNDLE-STAP, but you need to reboot the database server.

## Procedure

---

1. Copy the GIM client installer on the database server in any folder.
2. Install the GIM client on database server where S-TAP is running by using the downloaded GIM client shell installer script.  
For example:  
If the GIM client reports to the same collector as the S-TAP:  

```
./guard-bundle-GIM-X.X.X_rXXXX_v1X_1-rhel-8-linux-x86_64.gim.sh -- -q
```

If the GIM client reports to the central manager:  

```
./ guard-bundle-GIM-X.X.X_rXXXX_v1X_1-rhel-8-linux-x86_64.gim.sh -- --sqlguardip <CM_IP> -q
```

The database responds:  

```
Installing modules
Installation completed successfully
```
3. Verify that the GIM and SUPERVISOR processes are running by entering the command:  

```
ps -ef|grep modules
```
4. Log in to the Guardium system that this S-TAP reports to. Go to Manage->Module Installation->Set up by Client.
5. In the Choose clients section, select the clients using check boxes in the table. Click Next to continue.
6. In the Choose bundle section, use the Select a bundle menu to select the bundle that is installed on the database.
7. Click Next, the click Install, and then click now or OK  
Allow about 5 minutes for installation to finish.
8. Verify the installation status in the GIM Events List report.  
If you used the exact same version and revision number of BUNDLE-GIM and BUNDLE-STAP as the currently running S-TAP on the database server, then S-TAP and K-TAP continue to monitor database activities but are managed by GIM. The Event description column in the GIM Events List report should show Status: OK
9. If you upgraded the S-TAP by installing a higher version or revision of BUNDLE-STAP, verify that the Event description column in the GIM Events List report is IP-PR.  
Reboot the database server as follows, depending on the operating system.
  - AIX: reboot
  - Linux® shutdown -r
  - SuSe: reboot
  - HP-UX: shutdown -r
  - Solaris: shutdown -i [6|0] (Note: '0' can be used only if shutdown is done from the terminal server)

## Linux-UNIX: Use native installers to install, upgrade, uninstall the S-TAP

---

The native installer provides a shell for the shell installer. The only advantage is that it ensures that S-TAP is registered in the operating system asset repository. This registration is not required by Guardium® for the installation of the S-TAP, but it might be a requirement at your company. Use the native installer only when necessary.

A native installer ensures that S-TAP is registered in the operating system asset repository. This registration is not required by Guardium for the installation of the S-TAP, but it might be a requirement at your company. There is a separate native installer for each OS type.

- [Linux-UNIX: Installing and uninstalling S-TAP with AIX native installer](#)
- [Linux-UNIX: Installing and uninstalling S-TAP with HP-UX native installer](#)
- [Linux-UNIX: Installing and uninstalling the S-TAP with Solaris native installer](#)

## Linux-UNIX: Installing and uninstalling S-TAP with AIX native installer

---

### Before you begin

---

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct native installer file (.bff file), from either [Fix Central](#), or your Guardium representative.

## Procedure

---

1. Obtain the IP address of the database server on which you are installing S-TAP. If virtual IPs are used, note those as well (you will need to configure those later, when completing the configuration).
2. Identify the IP address of the collector that will control this S-TAP, and to which this S-TAP will report and verify connectivity between the database server and the collector..
3. Copy the S-TAP installer to the local disk on the database server, typically to /tmp.
4. Enter the following command on a clean server (no previous S-TAP installation) to extract the shell installer for AIX®, substituting the appropriate file name with the appropriate .bff file:

```
installp -ax -d/var/tmp<filename> SqlGuardInstaller
Example:
installp -ax -d/var/tmp/guard-stap-guard-8.0.00rc1_r20934_1-aix-5.2-aix-powerpc.bff SqlGuardInstaller
```

The shell installer that is extracted, named guardium, is under /usr/local.

5. Continue with [running the interactive installer](#) of the installation procedure, running the generated installation script rather than the default installation script for the operating system version.

## Remove AIX S-TAP using Native Installer

---

### Procedure

To remove AIX S-TAP using the native installer:

```
/usr/lib/instl/sm_inst installp_cmd -u -f 'filename'
Example
/usr/lib/instl/sm_inst installp_cmd -u -f'SqlGuardInstaller'
```

## Linux-UNIX: Installing and uninstalling S-TAP with HP-UX native installer

### Before you begin

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct native installer file (.depot.gz file), from either [Fix Central](#), or your Guardium representative.

### Procedure

1. Obtain the IP address of the database server on which you are installing S-TAP. If virtual IPs are used, note those as well (you will need to configure those later, when completing the configuration).
2. Identify the IP address of the collector that will control this S-TAP, and to which this S-TAP will report and verify connectivity between the database server and the collector.
3. Copy the S-TAP installer to the local disk on the database server, typically to /tmp.
4. Extract the file with  

```
gzip -d <filename>.depot.gz
```
5. Enter the **swinstall** command as follows, supplying the selected file name (the appropriate native installer file) and your database server host name. This command starts an interactive program. Follow the prompts and use the appropriate controls to install the appropriate S-TAP installation program (.sh file), which is located in /var/spool/sw/var/tmp.  

```
swinstall -s /var/tmp/<filename>.depot @ ,hostname>:/var/spool/sw
```
6. Continue with [running the interactive installer](#) in the installation procedure, running the generated installation script rather than the default installation script for the operating system version.

## Remove HPUX S-TAP Using Native Installer

### Procedure

To remove HPUX S-TAP using the native installer, use the following command:

```
swremove @<hostname>:/var/spool/sw
```

## Linux-UNIX: Installing and uninstalling the S-TAP with Solaris native installer

### Before you begin

- Verify all [Linux-UNIX: S-TAP installation prerequisites](#).
- Obtain the correct native installer file (.pkg file), from either [Fix Central](#), or your Guardium representative.

### Procedure

1. Obtain the IP address of the database server on which you are installing S-TAP. If virtual IPs are used, note those as well (you will need to configure those later, when completing the configuration).
2. Identify the IP address of the collector that will control this S-TAP, and to which this S-TAP will report and verify connectivity between the database server and the collector.
3. Copy the S-TAP installer to the local disk on the database server, typically to /tmp.
4. Enter the **pkgadd** command to run the installer using the selected file:  

```
pkgadd -d <filename>.pkg
```

The shell installer is extracted under /usr/local/guardium
5. Continue with [running the interactive installer](#) of the installation procedure, running the extracted shell installer script rather than the default installation script for the operating system version.

## Remove AIX® S-TAP Using Native Installer

### Before you begin

- If A-TAP is active, de-activate it before uninstalling the S-TAP. See [Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines](#).

### Procedure

Enter to command:

## Linux-UNIX: S-TAP upgrade workflows per monitoring mechanism

The S-TAP upgrade workflow depends on your monitoring mechanism: K-TAP, exit library, A-TAP. Use these workflows together with the specific upgrade procedure.

### About this task

When upgrading S-TAP where K-TAP is also deployed, upgrade only the S-TAP in the global zone. (Without KTAP, there is no special procedure for upgrading S-TAP.)

- [Linux-UNIX: Upgrading S-TAP with databases that use A-TAP](#)  
Use this workflow when upgrading S-TAPs that use A-TAP monitoring.
- [Linux-UNIX: Upgrading S-TAP with databases that use an exit library](#)  
Understand the flow for upgrading an S-TAP whose databases use an exit library (Db2, Informix, Teradata).

### Related tasks

- [Linux-UNIX: Upgrading A-TAP in Zones and WPARs environment](#)

## Linux-UNIX: Upgrading S-TAP with databases that use A-TAP

Use this workflow when upgrading S-TAPs that use A-TAP monitoring.

### Procedure

1. Stop the databases.
2. De-instrument and de-activate all ATAPs (using guardctl).
3. Upgrade the S-TAP
4. Instrument and activate all A-TAPs.
5. Start the databases.

### Related reference

- [Linux-UNIX: guardctl utility commands for A-TAP](#)

## Linux-UNIX: Upgrading S-TAP with databases that use an exit library

Understand the flow for upgrading an S-TAP whose databases use an exit library (Db2, Informix, Teradata).

### About this task

If you are upgrading your S-TAP from v10.6.0.0 and later, all you need to do is to upgrade your S-TAP. The databases do not need to be stopped, and restart is not required. Database traffic continues to be monitored during the upgrade. After the upgrade the database continues to be fully monitored and fully operational, but using the previous version of the exit library. The next time the database is restarted, the newest version of exit library is automatically used. The restart can be performed at any time, even weeks later. If you have more than one database, or more than one instance of a database, they can be restarted individually; they do not need to be restarted at the same time. If there are any issues addressed in the new library that you are waiting for, however, you must restart the database.

If you are upgrading your S-TAP from pre-v10.6.0.0 to v10.6.0.0 and later, you must determine whether your exit library is copied or linked.

- If it is copied, then the library needs to be deleted. You'll create a linked library after upgrading the S-TAP.
- If it is linked, make sure it's linked to the library in the standard library paths. If not, you'll remove the link and create new links after you upgrade the S-TAP.

This procedure covers all of these scenarios.

### Procedure

1. Stop the database service.
  - Teradata
    - Enter:  

```
/etc/init.d/tpa stop
/etc/init.d/tgtw stop
```
    - Check that the Teradata database is stopped with your Teradata Administrator, or with the UNIX command:  

```
pdestate -a
```

The response should be:  

```
PDE state: DOWN/HARDSTOP
```

2. Verify if your exit library is copied or linked, and whether or not the link is correct. Depending on your database, these are the commands and expected responses if the library is linked to the standard library path:

Db2

```
ls -l $DB2_PATH/sqllib/security64/plugin/commexit/
lrwxrwxrwx 1 db2inst1 db2iadm1 34 Mar 13 18:24 libguard_db2_exit_64.so ->
/usr/lib64/libguard_db2_exit_64.so
```

Informix

```
ls -l $INFORMIXDIR/lib/libguard_informix_exit_64.so
lrwxrwxrwx 1 informix informix 39 May 22 18:31 libguard_informix_exit_64.so ->
/usr/lib64/libguard_informix_exit_64.so
```

Teradata

```
ls -l <Teradata_install_directory>/tdat/tgtw/site/
lrwxrwxrwx 1 teradata tdtrusted 39 Jun 25 13:51 libtgtwmonitoring.so ->
/usr/lib64/libguard_teradata_exit_64.so
```

If the library is linked to the standard library path, perform step [4](#).

If the response is anything else, perform steps [3](#), [4](#), and [5](#).

3. Remove the current link to libtgtwmonitoring.so:

Db2

Enter:

```
rm -rf $DB2_PATH/sqllib/security64/plugin/commexit/*
```

Informix

Enter:

```
rm -rf $INFORMIXDIR/lib/*
```

Teradata

a. Enter:

```
rm -rf <Teradata_install_directory>/tdat/tgtw/site/*
```

b. Verify the Link is removed by entering:

```
ls -ltr <teradata_install_directory>/tdat/tgtw/site/
```

The response should not include libtgtwmonitoring.so, indicating the link was successfully removed.

4. Upgrade the S-TAP. If the database has a link to the standard library path, the S-TAP automatically updates the link for the new (later) version.

5. Link libtgtwmonitoring.so to /usr/lib64/libguard. Execute the appropriate command for your database:

Db2

As Db2 OS user, create the linked library by running one of these commands, depending on the OS:

- ln -fs /usr/lib64/libguard\_db2\_exit\_64.so \$DB2\_PATH/sqllib/security64/plugin/commexit/libguard\_db2\_exit\_64.so
- ln -fs /usr/lib/64/libguard\_db2\_exit\_64.so \$DB2\_PATH/sqllib/security64/plugin/commexit/libguard\_db2\_exit\_64.so
- ln -fs /usr/lib/libguard\_db2\_exit\_64.so \$DB2\_PATH/sqllib/security64/plugin/commexit/libguard\_db2\_exit\_64.so

Informix

As Informix OS user, create the linked library by running one of these commands, depending on the OS:

- ln -fs /usr/lib64/libguard\_informix\_exit\_64.so \$INFORMIXDIR/lib/libguard\_informix\_exit\_64.so
- ln -fs /usr/lib/64/libguard\_informix\_exit\_64.so \$INFORMIXDIR/lib/libguard\_informix\_exit\_64.so
- ln -fs /usr/lib/libguard\_informix\_exit\_64.so \$INFORMIXDIR/lib/libguard\_informix\_exit\_64.so

Teradata

a. As Teradata OS user, create the linked library by running one of these commands, depending on the OS:

- ln -fs /usr/lib64/libguard\_teradata\_exit\_64.so /opt/teradata/tdat/tgtw/site/libtgtwmonitoring.so
- ln -fs /usr/lib/64/libguard\_teradata\_exit\_64.so /opt/teradata/tdat/tgtw/site/libtgtwmonitoring.so
- ln -fs /usr/lib/libguard\_teradata\_exit\_64.so /opt/teradata/tdat/tgtw/site/libtgtwmonitoring.so

b. Confirm the link was created by entering:

```
ls -l <Teradata_install_directory>/tdat/tgtw/site/
```

The response should be similar to:

```
lrwxrwxrwx 1 teradata tdtrusted 39 Jun 25 13:51 libtgtwmonitoring.so -> /usr/lib64/libguard_teradata_exit_64.so
```

6. Start the database service:

Teradata

a. Enter:

```
/etc/init.d/tpa start
/etc/init.d/tgtw start
```

b. Verify that the Teradata database is started with your Teradata Administrator, or with the UNIX command:

```
pdestate -a
```

The response should be:

```
PDE state is RUN/STARTED.
DBS state is 5: Logons are enabled - The system is quiescent
```

## Results

---

Your exit library will upgrade the next time you restart your database.

## Linux-UNIX: Working with K-TAP

K-TAP is a kernel module that is installed into the database server operating system during S-TAP installation. After it is installed, it can be enabled or disabled with a configuration file setting. When enabled, it observes access to a database server by hooking the mechanisms used to communicate between the database client and the server. With K-TAP you do not need to change how database clients connect to the server.

Important: K-TAP does not support Ksplice or any other live kernel patching mechanism. To use K-TAP in your Linux environment, you must disable live kernel patching, including Ksplice extensions and similar mechanisms, such as Ubuntu Linux livepatch or SUSE Linux Live Patching.

Note: If K-TAP fails to load properly during installation, possibly caused by hardware or software compatibility, P-CAP is installed as the default collection mechanism. See [Linux-UNIX: Enable K-TAP after installation if P-CAP was installed by default](#).

- [Linux-UNIX: Preparing to install K-TAP](#)  
The S-TAP installation process checks the database kernel to determine whether a K-TAP has been created to work with that kernel. If not, the K-TAP Loader can create the K-TAP by compiling it, or by using the FlexLoad mechanism. For Linux databases, you can check in advance using the [Finding the correct K-TAP version for your Linux kernel](#) database, if there is a matching K-TAP.
- [Linux-UNIX: S-TAP compilation of K-TAP](#)  
There are hundreds of Linux distributions available, and the list is growing. This means that there might not be a K-TAP already available for your Linux distribution. If the correct K-TAP is not available, the S-TAP installation process can build it for you.

## Linux-UNIX: Preparing to install K-TAP

---

The S-TAP installation process checks the database kernel to determine whether a K-TAP has been created to work with that kernel. If not, the K-TAP Loader can create the K-TAP by compiling it, or by using the FlexLoad mechanism. For Linux databases, you can check in advance using the [Finding the correct K-TAP version for your Linux kernel](#) database, if there is a matching K-TAP.

This flow is relevant for S-TAP installation with both GIM and non-GIM.

FlexLoad mechanism guidelines:

- SUSE requires that the primary kernel version (for example, 4.12.14 of the version 4.12.14-23.1) matches and the vendor specific version falls within range of a release: the digits following 4.12.14 have to be higher than the existing module in the list.
  - All others require that the primary kernel version (X.Y.Z) matches in addition to the major vendor specific version number (A in X.Y.Z-A.B.C). The digits following X.Y.Z in the OS kernel version have to be higher than the module to be flex loaded. For example, kernel 3.10.0-514.6.1.el7.ppc64le would accept a flex match for a module built for 3.10.0-514.2.2.el7.ppc64le.
  - In all cases, the kernel module representing the most recent kernel that matches the rules, and also is older than the kernel version installed, is chosen. Module families also need to match, for example, el5, el6, el7, pae, x86\_64, and so on.
1. For Linux databases only: Check if your database operating system-kernel version has a K-TAP module match.
    - a. On your database, as user root, run the command: `uname -r` to output only the kernel version. The kernel version is similar to: 2.6.18-164.10.1.el5.
    - b. Open the [Finding the correct K-TAP version for your Linux kernel](#) database.
    - c. Paste in your kernel version, select your Guardium version and operating system, and click Search. The database filters to show the relevant K-TAP version. There are three possibilities:
      - The Match column displays either **Exact**. There is an exact match. You can proceed with the S-TAP installation.
      - The Match column displays either **Flex**. Enable the FlexLoad mechanism when installing S-TAP, (step 4), or have the S-TAP compile the K-TAP during installation (step 3).

- There is no match at all. In this case you can either have S-TAP compile the K-TAP, or you can order a custom build (step 6).
2. For non-Linux databases: Look at the list of supported kernels in the fix pack of the target S-TAP install version , for example Guardium\_10.6\_KTAP\_List.zip, from [Fix Central](#).
- If there is a match, You can proceed with the S-TAP installation.
  - If there is no match, you can either compile the K-TAP during S-TAP installation (step 3), you can try to Flex Load (step 4), or you can order a custom K-TAP ([Linux-UNIX: Requesting a K-TAP module](#)).
3. If K-TAP Loader did not find an exact match or a close match, AND if FlexLoad mechanism is OFF, AND if the database system has the required packages installed (see [Linux-UNIX: S-TAP compilation of K-TAP](#)), it attempts to build one to match your Linux kernel. All you need to build the K-TAP is the S-TAP installer.
4. If K-TAP Loader cannot find the correct kernel module, AND if FlexLoad mechanism is ON, K-TAP Loader finds the closest matching kernel module and loads it. The FlexLoad mechanism is controlled by:
- GIM installation: KTAP\_ALLOW\_MODULE\_COMBO
  - shell installation: --ktap\_allow\_module\_combo
  - RPM: --set-flexload
5. If you ordered a custom K-TAP build, after two weeks you'll have a custom modules-xxx.tgz file. You specify that file during the shell install with the --modules flag, or with the GIM \_ALLOW\_CUSTOMED\_BUNDLES flag when installing with GIM.
6. If K-TAP cannot load the kernel module by any of these three modes, it informs you with a "Failed to load" message. It either installs the S-TAP without the K-TAP (and with PCAP instead), or fails the S-TAP installation. If you reach this point, you'll need to order a custom K-TAP build.
7. If you have several systems running the same Linux distribution, you can build a K-TAP on one system and copy it to the others. For example, you might build a K-TAP on a test system and then copy it to one or more production database servers after testing. If you use GIM to install the S-TAP, GIM can automatically copy the bundle containing the new K-TAP to a Guardium® system from which you can distribute it to other database servers.

## Linux-UNIX: S-TAP compilation of K-TAP

---

There are hundreds of Linux distributions available, and the list is growing. This means that there might not be a K-TAP already available for your Linux distribution. If the correct K-TAP is not available, the S-TAP installation process can build it for you.

Most of the K-TAP code is independent of the kernel. The installer enables the code to interact with your kernel. This layer is delivered as proprietary source code. The installer builds the complete K-TAP by compiling this proprietary source code against your Linux kernel. This produces a K-TAP specific to your Linux distribution.

This process requires that the standard kernel development utilities, provided with Linux distribution, are present on the database server where the K-TAP is to be built. The development package must be an exact match for the kernel. The required packages are:

- RedHat based servers:
  - kernel-devel- `uname -r` for booted kernel
  - gcc compiler package
- Suse based servers:
  - kernel-devel or kernel-source(if available) for booted kernel
  - kernel-default-devel for booted kernel
  - gcc compiler package
- Ubuntu/Debian based servers:
  - linux-headers for booted kernel image
  - gcc compiler package

Important: Ensure that the server has the minimum required GNU Compiler Collection (GCC) version or a newer version installed, as supported by the kernel. When the installer attempts to build a K-TAP module, you see messages issued by guard-ktap-loader. These messages can include:

- It is attempting to build
- The build has completed
- The K-TAP has been loaded
- The build cannot be attempted because the kernel development package is not found
- [Linux-UNIX: Copying a K-TAP module from the command line](#)
- [Linux-UNIX: Copying a K-TAP module with GIM](#)

## Linux-UNIX: Enrolling a K-TAP signing key

---

Use the following procedure to enroll the Guardium® signing key on any database server that requires secure boot and uses the K-TAP that is supplied by Guardium. The Guardium key must be enrolled on any servers before you install S-TAP.

## Before you begin

---

Enrolling the key requires that you have root privileges and system console access. The modules are signed by IBM, but you need to enroll the Guardium signing key on to the secure boot-enabled system.

Use the following command to determine whether secure boot is enabled on the server:

```
mokutil --sb-state
```

Response,

- **Secure boot disabled** - The procedure is not needed.
- **Secure boot enabled** - Complete this procedure to enroll the Guardium key.

## About this task

You need to enroll the key the first time that you install a K-TAP with kernel signing. Subsequent upgrades use the same key.

## Procedure

1. Obtain the correct installer script from either [Fix Central](#) or from your Guardium representative, and extract guardium\_module\_signing.der from the compressed file (located under a folder named **Kernel\_Signing**).
2. Copy the file with Guardium signing key guardium\_module\_signing.der to a server where secure boot is enabled.  
Note: Check that the signing key file is correct for your server. For example, for SUSE 15, the key is called guardium\_module\_signing\_suse15.der.
3. On the server, log in as root and enter the following command to enroll the key:

```
mokutil --import guardium_module_signing.der
```

Note: Specify a password to enter when the system restarts. You are prompted for the password after the BIOS POST, but before the kernel starts (in the EFI shim).

4. Verify that you have access to the system console.
5. Restart the system when possible.
  - a. During the start-up process, press any key when the system returns the following prompt, Press any key to perform MOK management.
  - b. Under **Perform MOK Management**, select Enroll MOK.
  - c. Click View key to see the certificate details, and then press Enter (or choose Continue).
  - d. At the system prompt **Enroll the key(s) ?**, click Yes.
  - e. Enter the enrollment password (the password that you used with the **mokutil --import** command in step 3).
  - f. Select Reboot.

## What to do next

Enter the following command to confirm the key's presence in the system keyring.

```
cat /proc/keys | grep Guardium
```

Example output,

```
06dd7037 I----- 2 perm 1f010000 0 0 asymmetri IBM Guardium Secure Boot Signing:
d0609780bff59335919e575279c9b20b6728ca93: X509.RSA 6728ca93
```

## Linux-UNIX: Signing and enrolling a locally built K-TAP

Use the following procedure to sign and enroll a signing key on any database server that requires secure boot and uses a locally built K-TAP. The Guardium® key must be enrolled on the server before you install S-TAP.

## Before you begin

If your site uses secure boot, and you want to use a local K-TAP build, then you can use the **kernelModuleSigning.sh** script to sign the locally built K-TAP module before you install S-TAP and K-TAP. The **kernelModuleSigning.sh** script helps automate upgrading or installing a new K-TAP.

To check whether secure boot is enabled on the server, run the following command :

```
mokutil --sb-state
```

Response:

- **Secure boot disabled** - The procedure is not needed.
- **Secure boot enabled** - Complete this procedure to enroll the Guardium key.

Note: 12.0 and later **kernelModuleSigning.sh** is included as part of your S-TAP package starting with versions 12.0.

## Procedure

1. If your company already has a public/private signing key, use that signing key. If you do not already have a signing key, use the following example to generate one. Enter the following code.

```
cat <<EOF >signfile.config
[req]
distinguished_name = req_distinguished_name
x509_extensions = v3
string_mask = utf8only
prompt = no
[req_distinguished_name]
O =<Key - Example>
CN = Secure Boot Signing
emailAddress = <example@yourcompany.com>

[v3]
subjectKeyIdentifier = hash
```

```
authorityKeyIdentifier = keyid
basicConstraints = critical,CA:FALSE
keyUsage = digitalSignature
extendedKeyUsage = codeSigning
```

```
EOF
```

Note: Replace the **organization (O)** and **emailAddress** lines with your own information.

```
openssl req -config ./signfile.config -new -x509 -newkey rsa:4096 -nodes -days 3650 -outform DER -keyout signfile.priv -
out signfile.der

openssl x509 --inform der --in signfile.der --text --noout > signfile.crt
```

2. Use **mokutil** to enroll your new key in the secure boot cache on database server and follow the instructions in the script.

For example:

```
mokutil --import ./signfile.der
```

3. Verify that you have access to the system console.

4. Restart the system when possible.

- a. During the start-up process, press any key when the system returns the following prompt, Press any key to perform MOK management.

- b. Under **Perform MOK Management**, select Enroll MOK.

- c. Click View key to see the certificate details, and then press Enter (or choose Continue).

- d. At the system prompt **Enroll the key(s) ?**, click Yes.

- e. Enter the enrollment password (the password that you used with the **mokutil --import** command in step).

- f. Select Reboot.

5. Proceed with your standard shell or bundle S-TAP fresh installation. You might need to upgrade afterward. When the installation starts, an error that is similar to the following displays:

```
<13>Dec 5 16:25:37 guard_ktap_loader: Custom module ktap-112810-rhel-8-linux-x86_64-xCUSTOMxrh8u5x64t-4.18.0-
372.26.1.e18_6.x86_64-x86_64-SMP.ko built for kernel 4.18.0-372.26.1.e18_6.x86_64.

<13>Dec 5 16:25:46 guard_ktap_loader: Cannot install ktap at this time, please contact IBM.
Could not start KTAP

<13>Dec 5 16:25:46 guard_ktap_loader: ktap module is not loaded at this time.
```

6. Don't panic! Run the **kernelModuleSigning.sh** utility on the database server where the S-TAP is running. Follow the instructions that display on the screen to sign your locally built K-TAP module (**ktap\*xCUSTOM\*.ko**) with the public and private signing keys.

After signing the keys, the script walks you through the next steps to finish the installation.

## Results

Enter the following code to confirm that the key is available in the system keyring:

```
cat /proc/keys | grep -i <key_word_of_key>
```

A successful response is similar to the following example:

```
cat /proc/keys | grep -i 'Key-Example'
0c113cc5 I----- 1 perm 1f010000 0 0 asymmetric Key-Example: Secure Boot Signing:
6c0351ef68bb6fd1d24501d461008d9813b3ca: X509.rsa 8d13b3ca []
```

## Linux-UNIX: Copying a K-TAP module with GIM

If you build a custom K-TAP module for a Linux database server, you can use GIM to copy that module to other servers that are running the same Linux distribution. For example, you can build a K-TAP on a test system and then copy it to one or more production database servers after testing.

### Before you begin

- Verify that STAP\_UPLOAD\_FEATURE=1 on the database on which you are going to build the custom module. By default, the parameter STAP\_UPLOAD\_FEATURE is 1. The default enables automatic upload of the newly built K-TAP module to the Guardium® system that hosts the GIM server that manages the S-TAP bundle. This setting does not affect S-TAP diagnostic files. They are uploaded to the Guardium system that the S-TAP is registered with.
- Set GIM\_ALLOW\_CUSTOMED\_BUNDLES=1 on each DB server that you want to copy the K-TAP module to. For security reasons, this parameter must be set manually on each DB server. GIM\_ALLOW\_CUSTOMED\_BUNDLES=1 cannot be changed from 0 to 1 in the GUI or the API. Only the operating system admin can change the value from 0 to 1 after GIM is installed. This parameter can be set to either 1 or 0 when you use the configurator utility on the DB server. This functionality is checked during the K-TAP installation (on the DB server). It is not checked while you are assigning or scheduling a bundle installation or a parameter update (like all the other parameters are validated). (You can set GIM\_ALLOW\_CUSTOMED\_BUNDLES=0 from the Guardium system.)
- The GIM client is installed and points to the central manager.

Note: The S-TAP bundle is always visible in the GIM GUI. However, the S-TAP console displays only the S-TAP agent if **sqlguard\_tapip** (in **guard\_tap.ini**) points to the same IP that is listed in the GIM configuration 'gim\_url'.

If **sqlguard\_tapip** points to a different IP address, then the S-TAP agent does not display in the S-TAP console.

### About this task

The custom K-TAP module is built when you install the S-TAP on a Linux server for which no pre-built K-TAP exists for the current kernel, but only if the kernel-devel package is installed. The S-TAP bundle is visible in the GIM GUI, regardless of which appliance the S-TAP agent points to. Uploading this module initiates creation of a custom S-TAP bundle. Bundle numbers have an appended suffix that starts with \_800 and increases by 1 with each additional bundle, for example BUNDLE\_STAP (10.1.4\_r102728\_800).

## Procedure

---

1. Use GIM to install the S-TAP on the Linux database server. Set the parameter STAP\_SQLGUARD\_IP=IP of the MU. The installer determines that a custom K-TAP module is required and builds it.
2. Transfer this bundle to other managed units:
  - a. On the central manager, go to **Manage > Central Management > Central Management**
  - b. In the table of managed units, select the managed units that you want to copy the bundle to.
  - c. Click Distribute GIM bundles.
3. Use [Set up by Client](#) to install the bundle on the managed units.
  - [Linux-UNIX: Copying a K-TAP module from the command line](#)

## Linux-UNIX: Copying a K-TAP module from the command line

---

Use the command line to copy a new K-TAP module from one Linux database server to other database servers that run the same Linux distribution.

### Before you begin

---

Use this procedure after you have built and tested a K-TAP module on a Linux database server.

### Procedure

---

1. Log in to the database server with the tested K-TAP module.
2. Change directory to /usr/local/guardium/guard\_stap/ktap/current/ and run **./guard\_ktap\_append\_modules** to add the locally built modules to modules.tgz.
3. Repeat step 1.
4. Copy the updated modules.tgz file to the target database server.
5. Log in to the target database server and change the directory to /usr/local/guardium/guard\_stap/ktap/current/.
6. Resolve any issues with the K-TAP, such as submitting a module request to IBM or installing kernel development packages.

Note: If you installed a GIM S-TAP bundle, set export GIM\_CONTEXT=Y. For example:

```
export GIM_CONTEXT=Y
```

7. Run the **guard\_ktap\_loader retry** script from the ktap directory. For example:

- shell/RPM installation:

```
guardium/guard_stap/ktap/current/guard_ktap_loader retry
```

GIM installation:

```
export GIM_CONTEXT=Y; modules/KTAP/current/guard_ktap_loader retry
```

8. Restart the S-TAP to connect it to the new K-TAP module.

### Results

---

The custom K-TAP module is ready to use on the target system. Repeat this procedure for each matching Linux system to which you want to deploy the K-TAP module.

- [Linux-UNIX: Copying a K-TAP module with GIM](#)
- [Linux-UNIX: K-TAP parameters](#)

## Linux-UNIX: Enable K-TAP after installation if P-CAP was installed by default

---

If, during the installation process, K-TAP fails to load properly, possibly caused by hardware or software incompatibility, P-CAP is installed as the default collection mechanism. To switch to K-TAP, after compatibility issues are resolved, follow these steps.

### Procedure

---

1. Resolve any issues with the K-TAP, such as submitting a module request to IBM or installing kernel development packages.

Note: If you installed a GIM S-TAP bundle, set export GIM\_CONTEXT=Y. For example:

```
export GIM_CONTEXT=Y
```

2. Run the script **guard\_ktap\_loader retry** from the ktap directory:

- shell/RPM installation: guardium/guard\_stap/ktap/current
- GIM installation: modules/KTAP/current

If K-TAP loads successfully, the guard\_tap.ini parameter ktap\_installed is automatically set to 1 (yes).

## Linux-UNIX: Requesting a K-TAP module

---

Perform this procedure before upgrading your Linux operation system to determine if there is a matching K-TAP module for the new kernel level, and if not to request the K-TAP module from Technical Support.

## Procedure

1. Access [Fix Central](#) and select the product and version per your need, and click Continue.

Type the product name to access a list of product choices.

When using the keyboard to navigate the page, use the **Tab** or **down arrow** key to move between fields.

| 2.6.18-128.1.1.el5                                                                         | 2.6.18-128.1.1.el5-x86_64-SMP.ko                                                                           |
| 2.6.18-128.1.6.0.1.el5                                                                     | 2.6.18-128.1.6.0.1.el5-x86_64-SMP.ko                                                                       |
| 2.6.18-128.1.6.el5                                                                         | 2.6.18-128.1.6.el5-x86_64-SMP.ko                                                                           |

6. If your kernel is not listed or not listed in the K-TAP list, open a Support Case: <https://www.ibm.com/mysupport/s/createrecord/NewCase>.

For each database server system you need the KTAP module for, you must provide these details:

- Kernel version (output of `uname -a`)
- Operating System version (output of `cat /etc/redhat-release` or, depending on the release `ls /etc/*release*` and then cat the output, or `cat /etc/issue`)
- CPU Info (output of `cat /proc/cpuinfo`)
- Database type and version
- Which version of S-TAP the K-TAP module needs to be compiled for

It typically takes up to 14 days to fulfill a new K-TAP module request. Guardium informs the customer when the new K-TAP module is available, ready to download.

## Linux-UNIX: K-TAP FAQs

Find answers to commonly asked questions about K-TAP.

Does K-TAP support Ksplice (or other live patching mechanisms)?

K-TAP does not support Ksplice or any other live kernel patching mechanism. To use K-TAP in your Linux environment, you must disable live kernel patching, including Ksplice extensions and similar mechanisms, such as Ubuntu Linux livepatch or SUSE Linux Live Patching.

Can one database server be used to build different custom K-TAP versions?

Yes. The module is created for the currently installed kernel on the server, so you must set the correct kernel and restart the server.

Do you need to regenerate and reinstall the custom K-TAP each time that the server receives a new kernel?

Yes.

What happens if the K-TAP is not up to date?

If the KTAP does not match the running kernel, it does not load.

Does a custom K-TAP need to have the same version as the S-TAP, or can a Guardium system have K-TAP and S-TAP that are running different versions?

K-TAPs and S-TAPs must run the same version.

When you install K-TAP by using the Flex method, Guardium determines which precompiled K-TAP is the most suitable for the installation. How is this procedure performed by Guardium?

See [Linux-UNIX: S-TAP compilation of K-TAP](#).

## Linux-UNIX: Special environments configuration

Use these procedures for as relevant for systems with Zones, RAC, WPAR, clusters.

## Linux-UNIX: Solaris Zones configuration

Install and configure S-TAP in the Solaris global Zones (kernel zones). Non-global zones (local zones) share the resource with global zone.

### About this task

This procedure covers both Solaris global Zones (kernel zones) and Non-global zones (local zones).

Solaris versions 10 and later implement virtualized operating environments called Zones. Each zone is self-contained and has its own hostname, IP address, storage, and process space. Processes running in one zone are disassociated from the other zones. There is an over-arching zone called the global Zone and every other zone is called a non-global or local zone.

S-TAP requires special configuration when it's installed in a zoned Solaris operating environment, since K-TAP, a kernel module, has to be installed in the global Zone, and it is shared between the local zones. This specific requirements are:

- S-TAP requires the **IP address of the database server host to which it connects**.

By default, S-TAP connects to the loopback address 127.0.0.1. This loopback address refers to the "local host", which is the global zone. Instead, obtain the IP address of the non-global zone using **ifconfig -a**. For example, in the zone dbserver01:

```
#ifconfig -a
....
....
*hme0:1: flags=1000843 mtu 1500 index 2
zone dbserver01inet 192.168.1.201 netmask ffffff00 broadcast 192.168.1.255*
....
....
```

The IP address of the zone "dbserver01" is 192.168.1.201. S-TAP must connect to this IP address rather than 127.0.0.1, in order to intercept database traffic to and from the zone dbserver01. Assuming that dbserver01 is DB\_0 is the guard\_tap.ini file, you would change:

```
[DB_0]
connect_to_ip=127.0.0.1

to

[DB_0]
connect_to_ip=192.168.1.201
```

You must edit the file guard\_tap.ini itself. You cannot update this configuration in the GUI.

- S-TAP requires the **path of the database server executable**.

Each zone is a self-contained operating environment. The path inside a particular zone is specific to that zone. For example, /opt/IBM/informix/11.70.UC3 can exist in each zone and yet each zone has a unique path.

S-TAP is installed in the global zone, therefore the database executable in the non-global zone must be accessible from the global zone. If the file system in the non-global zone is externally mounted via mechanisms like NFS, it is important that the mounted location has the required permission to be accessed from the global zone. Otherwise, the S-TAP cannot access the database executable: the S-TAP status is initially green in the collector GUI, but then turns red and stays red.

Since each non-global zone is a virtualized environment, paths inside a non-global zone are accessible from the global zone via a zone path prefix, which is the local zone. The syntax for the path to a particular zone is: <localzone>/root/<database server installation location>. Use the Solaris command **zoneadm** to obtain the prefixes for the various zones. For example, from the global zone:

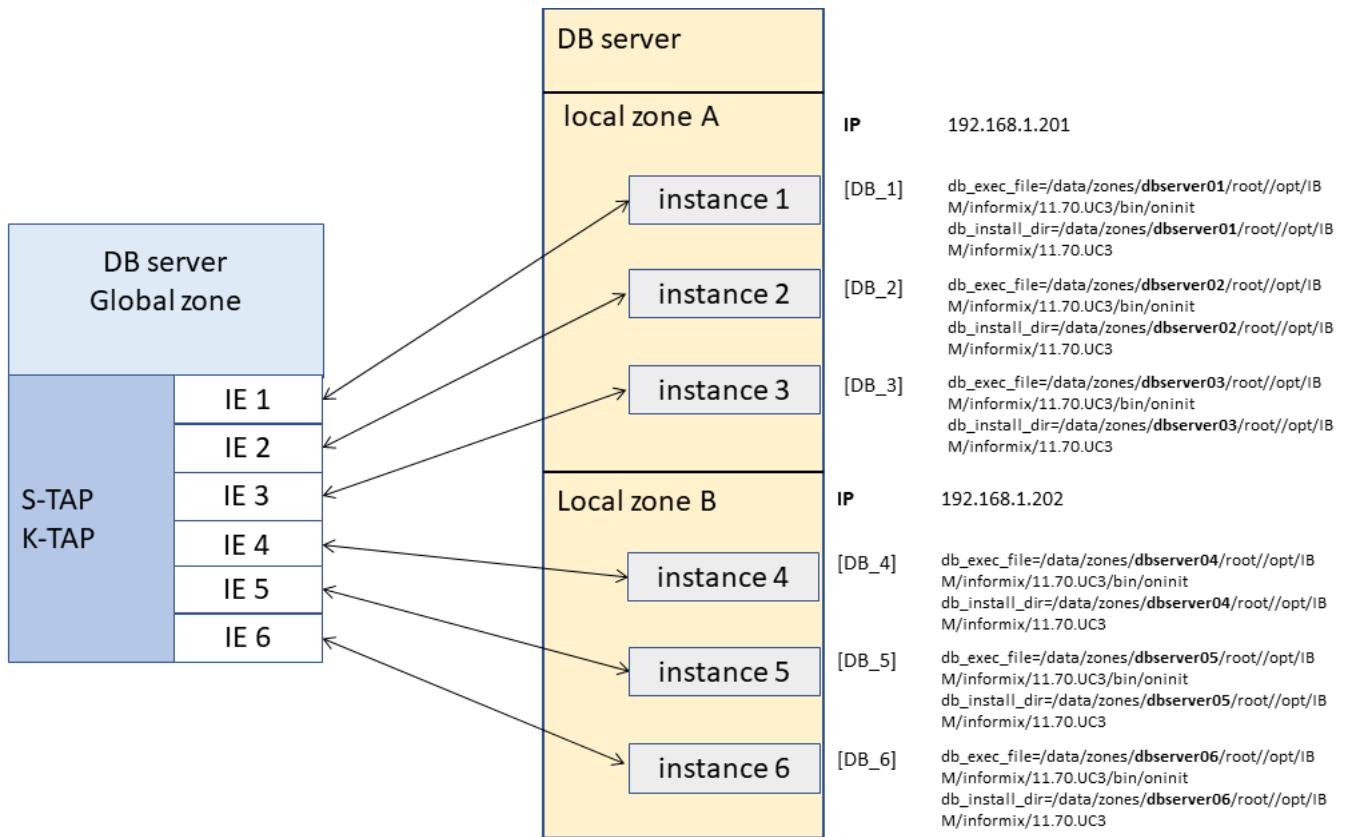

```
#zoneadm list -cv
ID NAME STATUS PATH
0 global running /
2 dbserver01 running /data/zones/dbserver01
3 dbserver02 running /data/zones/dbserver02
```

In this example output, there are two non-global zones: dbserver01 and dbserver02. The file structure inside each zone can be accessed from the global zone via /data/zones/dbserver01 and /data/zones/dbserver02 for the zones dbserver01 and dbserver02 respectively. Assuming that the database server is installed in /opt/IBM/informix/11.70.UC3 in the zone dbserver01, then the full path to that directory from the global zone would be:

/data/zones/dbserver01/root/opt/IBM/informix/11.70.UC3

When specifying the path to the database server executable and the install path to S-TAP, you must use this full zone relative path from the global zone. Using the IP address, the database server executable, and installation path, the guard\_tap.ini looks like:

```
[DB_1]
connect_to_ip=192.168.1.201
...
...
Path to the database server executable
db_exec_file=/data/zones/dbserver01/root//opt/IBM/informix/11.70.UC3/bin/oninit
Path to the database server installation
db_install_dir=/data/zones/dbserver01/root//opt/IBM/informix/11.70.UC3
...
```

**Multiple zones:** To monitor multiple non-global zones, create a DB section for each zone in the guard\_tap.ini file. To monitor dbserver02, add another section that includes:

```
[DB_2]
connect_to_ip=192.168.1.202
...
#
Path to the database server executable
db_exec_file=/data/zones/dbserver02/root//opt/IBM/informix/11.70.UC3/bin/oninit
Path to the database server installation
db_install_dir=/data/zones/dbserver02/root//opt/IBM/informix/11.70.UC3
...
...
```

## Procedure

1. Install S-TAP on the master zone (global zone) or kernel zone regardless of the zone in which the database runs, since the local zones share information from the master/kernel zone.
  2. Manually set S-TAP parameter connect\_to\_ip in the guard\_tap.ini file to the IP address of the non-global zone.
  3. When configuring the Inspection Engine, use the global/kernel zone values for the db\_install\_dir path and db\_exec\_file. These are the GUI parameters DB Install Dir, and Process Name, respectively. (From the global/kernel zone, S-TAP monitors access to databases in all zones.)
  4. Add the IP addresses of all zones that you want to monitor to the alternate\_ips parameter in the guard\_tap.ini file on the Solaris database server or use the S-TAP Control page to configure Alternate IPs.
- Typical parameter configuration:
- db\_exec\_file=/home/oracle18/app/oracle/product/18.0.0.0/dbhome\_1/bin/oracle (the full path to oracle executable)
  - db\_install\_dir=/home/oracle18/

## Results

- K-TAP is not loaded in the local zone as it is only loaded on the global zone. It is visible on the local zones.
- S-TAP does not run in the local zones.

## Related tasks

- [Linux-UNIX: Installing and activating A-TAP in Solaris zones](#)

## Linux-UNIX: Oracle RAC S-TAP configuration

Oracle RAC (Real Application Clusters) allows multiple computers to run Oracle RDBMS software simultaneously while accessing a single database, thus providing clustering.

## About this task

---

In a non-RAC Oracle database, a single instance accesses a single database. The database consists of a collection of data files, control files, and redo logs located on disk. The instance comprises the collection of Oracle-related memory and operating system processes that run on a computer system.

In an Oracle RAC environment, two or more computers (each with an Oracle RDBMS instance) concurrently access a single database. This allows an application or user to connect to either computer and have access to a single coordinated set of data.

## Procedure

---

1. Install S-TAP on all nodes. In case GIM is used, install the GIM client on all nodes, then install the bundle S-TAP on all nodes.

2. Configure the S-TAP parameters. All of the parameters can be configured through the GIM UI.

- STAP\_TAP\_IP: public IP configured for the node
- STAP\_ALTERNATE\_IPS: comma separated list of VIPs (virtual IPs) configured for the node, and the scan listener

Tip: Use this command to retrieve the value for virtual hostnames to put in STAP\_ALTERNATE\_IPS:

```
su - grid -c 'cat $ORACLE_HOME/network/admin/*.ora' |grep -i host
```

For example:

```
[root@racvm121 ~]# su - grid -c 'cat $ORACLE_HOME/network/admin/*.ora' |grep -i host
LISTENER_RACVM121=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP) (HOST=<hostname>) (PORT=1521)) (ADDRESS=(PROTOCOL=TCP) (
```

- Configure S-TAP inspection engine parameter: unix\_domain\_socket\_marker=<key>, where <key> value can be found in listener.ora in the IPC protocol definition

Tip: Command to retrieve value for unix\_domain\_socket\_marker:

```
su - grid -c 'cat $ORACLE_HOME/network/admin/*.ora' |grep -i KEY
```

- Example: If the following is a description in the listener.ora

```
LISTENER=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=IPC) (KEY=ORCL)))
```

then

```
unix_domain_socket_marker=ORCL
```

- Example: If there is more than one IPC line in listener.ora, use a common denominator of all the keys:

```
su - grid -c 'cat $ORACLE_HOME/network/admin/*.ora' |grep -i KEY
LISTENER=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=IPC) (KEY=LISTENER)))
LISTENER_SCAN1=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=IPC) (KEY=LISTENER_SCAN1)))
LISTENER_SCAN2=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=IPC) (KEY=LISTENER_SCAN2)))
LISTENER_SCAN3=(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=IPC) (KEY=LISTENER_SCAN3)))
```

Guardium uses a string search in the path. In this case LISTENER works for all four and should be used: unix\_domain\_socket\_marker=LISTENER

- Example: If there is no common denominator, create additional inspection engines with unix\_domain\_socket\_marker corresponding to the specific IPC key(s). For example the guard\_tap.ini may look similar to this example in the end:

```
[DB_0]
...
unix_domain_socket_marker=EXTPROC1522
...
[DB_1]
...
unix_domain_socket_marker=LISTENER
```

3. If the Oracle database is encrypted (ASO/SSL), activate A-TAP on all nodes (active and standby). This example shows an Oracle setup with two users: grid and oracle.

- a. Authorize users grid and oracle.

- b. Stop the instance on the node that is part of RAC environment using the grid environment by entering the command:

```
srvctl stop instance -db database_name -node node_name -force
```

- c. Verify that the instance on the node is stopped by entering the command from the grid environment:

```
srvctl status instance -db database_name -node node_name
```

- d. Configure A-TAP by entering the command:

```
/usr/local/guardium/guard_stap/guardctl --db-user=oracle --db-type=oracle --db-instance=oracle --db-home=$ORACLE_HOME
--db-version=18.0 store-conf
```

- e. Activate A-TAP by entering the command:

```
/usr/local/guardium/guard_stap/guardctl --db-instance=oracle activate
```

- f. Restart the instance on the node that is part of RAC environment using the grid environment by entering the command:

```
srvctl start instance -db database_name -node node_name
```

- g. Repeat steps [3.a](#) through [3.f](#) on all nodes of the RAC environment.

# Linux-UNIX: Configure S-TAP for Db2 WPAR

Learn to configure S-TAP for Db2 WPAR

## About this task

There are two methods of determining the shmem parameters:

- If your output to `db2 get dbm cfg | grep ASLHEAPSZ` is in English, use the script `find_db2_shmem_parameters.sh` ([1](#)). Its output lists the Db2 shared memory parameters defined in the Inspection Engines. You can run it from any directory. It requires the db2 instance name as parameter.
- If your output to `db2 get dbm cfg | grep ASLHEAPSZ` is not in English, compute the client I/O area offset (step [2](#)), then find the Db2 shared memory size (step [3](#)).

When `ktap_fast_shmem` set to 1, if there are multiple Db2 instances that are configured for a single WPAR in `guard_tap.ini` file and they have the same `db2_shmem_size`, then the `db2_fix_pack_adjustment` and `db2_shmem_client_position` are taken from the first Db2 section for that WPAR. So in cases where there are multiple Db2 instances running on the WPAR:

- If all Db2 instances have the same `db2_shmem_size`, `db2_fix_pack_adjustment`, and `db2_shmem_client_position`, the packets from all instances are collected even if only one instance is configured.
- If all Db2 instances have the same `db2_shmem_size`, but different `db2_fix_pack_adjustment` or `db2_shmem_client_position`, then only packets from the first configured Db2 instance are collected.

## Procedure

1. Run the script `find_db2_shmem_parameters.sh` from any directory, using the syntax: `find_db2_shmem_parameters.sh <instance name>`. Its output lists the Db2 shared memory parameters defined in the Inspection Engines.
2. (Perform only if output to `db2 get dbm cfg | grep ASLHEAPSZ` is not in English). Compute the client I/O area offset (`db2_shmem_client_position`).
  - a. Open a new bash shell as the db2 instance user.
  - b. Run the `ps -x` command to verify that the db2bp command processor is not currently running for this shell. You should not see a command called db2bp running. If it is running, either kill it or run a new shell.
  - c. Run the following:

```
db2 get database manager configuration | awk '/ASLHEAPSZ/{print $9 * 4096}'
```

The output is the required value for `db2_shmem_client_position`

3. (Perform only if output to `db2 get dbm cfg | grep ASLHEAPSZ` is not in English). To find the Db2 shared memory segment size (`db2_shmem_size`), perform one of:
  - This method gives the most accurate results.
    - Start a Db2 shared memory connection and keep it open.
    - Run this command to get the process ID for db2sysc: `ps -efaf | grep db2sysc`. The output looks like:

```
db2inst1 5309370 5505772 0 Nov 11 - 1232:12 db2sysc 0
```

In this example, the process ID is 5309370.

- Run this command to retrieve information about shared-memory processes: `ipcs -ma`. The output looks like:

```
IPC status from /dev/mem as of Wed Nov 20 13:21:45 CST 2013
T ID KEY MODE OWNER GROUP CREATOR CGROUP NATTCH SEGSZ CPID
m 2097152 0xffffffff D-rw----- pconsole system pconsole system 1 536870912 4522088

m 201326613 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 1 163905536 5309370
m 103750230 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 1 134217280 5309370
```

The output contains several columns beyond those shown here, but they do not affect this procedure. Find the line that contains the process ID that was identified in step [3.b](#) and also has a value of 2 under NATTCH. The Db2 shared-memory segment size is the value in the SEGSZ column. In this example, it is 131072.

- Tip: if the list returned in step [3.c](#) is too long, you can filter it by using the process ID. In this case, you would enter `ipcs -ma | grep 5309370`. The results do not contain the column headers, but you can look at the previous results to see the column headers and identify the correct line and column. In this example, it is the last line.

```
m 131072014 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 1 1342177280 5309370
m 763363344 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 1 268435456 5309370
m 227541013 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 1 163905536 5309370
m 106353238 0xffffffff D--rw----- db2inst1 db2iadml db2inst1 db2iadml 2 131072 5309370
```

- Alternatively, use this method, which is easier but less accurate:  
ATAP and KTAP rely on the size for identification of the Application/Agent shared memory segments. These segments are then tapped for C2S and S2C packets. The segments are equal to the sum of the ASLHEAPSZ and RQRIOLBK parameters. DB2® allocates much larger segments. In most cases, the size is

equal to (ASLHEAPSZ + 1) \* 2 pages, or (ASLHEAPSZ + 1) \* 8192 bytes. Exact size can be determined by observation of the shared memory segments in the system before and after new Db2 local connection is created. Use this sequence of commands to determine the shared memory segment size. ipcs command parameters and output format differ from platform to platform. The following script is based on the AIX® version.

```
ipcs -ma | sort -n -2 +3 > /tmp/before.txt
db2 connect to <some_existing_database>ipcs -ma | sort -n -2 +3 > /tmp/after.txt
db2 terminate
diff /tmp/before.txt /tmp/after.txt | awk '{if ($10 == 2) print $11}'
```

4. Set these parameters in order to capture the Db2 shared memory traffic.

Table 1. Db2 Parameters

| Parameter                      | STAP Name                 | ATAP Name         |
|--------------------------------|---------------------------|-------------------|
| Packet header size             | db2_fixed_pack_adjustment | db2_header_offset |
| Client I/O area offset         | db2_shmem_client_position | db2_c2soffset     |
| Db2 shared memory segment size | db2_shmem_size            | db2_shmsize       |

## Linux-UNIX: Configure S-TAP for SELinux

Learn to configure S-TAP for Red Hat Security Enhanced Linux (SELinux).

### About this task

Installing aGuardium®S-TAP with SELinux requires a few extra installation steps.

Note: Make sure that your S-TAP version matches the version of the Guardium appliance.

### Procedure

1. Install the S-TAP, using one of the methods described in [Linux-UNIX: Install S-TAP agents installation flow](#).

2. After you install the S-TAP, log into the Guardium server as root run the following commands.

Set the *enforce* environment variable to 0 and open the *guard\_tap.ini* file:

```
[root@mycompany guard_stap]# setenforce 0
[root@mycompany guard_stap]# ps -ef|grep stap
root 9955 1 0 10:32 ? 00:00:00 /guardium/guardium/guard_stap/guard_stap
/guardium/guardium/guard_stap/guard_tap.ini
root 10038 1889 0 10:32 pts/0 00:00:00 grep --color=auto stap
```

3. Run the following commands to enable required Guardium policies:

```
[root@mycompany guard_stap]# sealert -a /var/log/audit/audit.log
[root@mycompany guard_stap]#ausearch -c 'guard_discovery' --raw | audit2allow -M my-guarddiscovery
[root@mycompany guard_stap]# semodule -i my-guarddiscovery.pp

[root@mycompany guard_stap]# ausearch -c 'guard_stap' --raw | audit2allow -M my-guardstap
[root@mycompany guard_stap]# semodule -i my-guardstap.pp

[root@mycompany guard_stap]# ausearch -c 'guard_ktap_load' --raw | audit2allow -M my-guardktapload
[root@mycompany guard_stap]# semodule -i my-guardktapload.pp
```

4. Set the *enforce* environment variable back to 1.

```
[root@mycompany guard_stap]# setenforce 1
```

5. Restart the S-TAP.

## Linux-UNIX: Activating and deactivating A-TAP on all nodes of a Db2 Cluster

Learn how to activate and deactivate A-TAP on the nodes of a Db2 cluster that share a Db2 cluster.

### About this task

Activate A-TAP to capture encrypted traffic and shared memory traffic in Linux.

### Procedure

1. Authorize Db2 user on all nodes by running the following command.

```
<guardium_base>/xxx/guardctl authorize-user <user-name>
```

In the following example, user *db2inst1* is authorized.

```
/usr/local/guardium/bin/guardctl authorize-user db2inst1
/usr/local/guardium/bin/guardctl is_userAuthorized db2inst1
```

2. Configure A-TAP on all nodes.

3. Shut down the active node (node 1).

4. Activate A-TAP on node 1 by running the following command.

```
<guardium_base>/xxx/guardctl db_instance=<instance> activate
```

In the following example, `db2inst1` is node 1 and it is activated.

```
/usr/local/guardium/guard_stap/guardctl db_instance=db2inst1 activate
/usr/local/guardium/guard_stap/guardctl list-active
```

5. After you activate A-TAP on the original db2 server on node 1, do the following tasks:

- Restore the original Db2 server on node 1 so that other nodes can activate A-TAP. (All nodes share the executable).
- In the Db2 adm directory, copy `db2sysc-guard-original` over `db2sysc` (make a copy of each first and set them aside) by running the following command.

```
> cp db2sysc-guard-original db2sysc
```

6. Delete `db2sysc-guard-original` (otherwise, it fails activation on node 2) by running the following command.

```
rm -rf db2sysc-guard-original
```

7. Move cluster resources to node 2 by running the following command.

```
pcs resource move resource_id <destination node>
```

8. Activate A-TAP on node 2. This step creates the libraries on node 2 and replaces `db2sysc-guard-original`.

The following examples show the status for each node:

Node 1:

```
/usr/local/guardium/guard_stap/guardctl list-active
db2inst1
```

Node 2:

```
/usr/local/guardium/guard_stap/guardctl list-active
db2inst1
```

## Deactivating A-TAP on the nodes of a Db2 Cluster

Deactivate A-TAP on the active and passive nodes of a Db2 cluster when you upgrade the database or an S-TAP agent.

### Procedure

- Log in to the active node (node1).
- Shutdown the Db2 instance.
- Deactivate A-TAP on node 1.

For example:

```
/usr/local/guardium/guard_stap/guardctl db_instance=db2inst1 deactivate
```

- Deactivate A-TAP on all passive nodes by using the `force` option.

For example:

```
/usr/local/guardium/guard_stap/guardctl db_instance=db2inst1 --force-action=yes deactivate
```

## Linux-UNIX: Configure delayed cluster disk mounting

Configure S-TAP for delayed loading for Oracle, Informix® and DB2® database servers only.

When the S-TAP starts it must have access to the database home. If your environment uses a clustering scheme in which multiple nodes share a single disk that is mounted on the active node, but not on the passive node, the database home is not available on the passive node until failover occurs.

S-TAP can be configured for delayed loading by setting a configuration file property, `WAIT_FOR_DB_EXEC`. When S-TAP restarts, either from a system reboot or user initiated S-TAP stop / start commands, S-TAP polls all databases that have been configured to be monitored and begins monitoring all valid configurations. Any configuration anomalies (either on the database side or the S-TAP side) that limits S-TAP ability to monitor a database does not limit the S-TAP from monitoring other databases with valid configurations. This parameter determines the S-TAP response, and its status in the S-TAP Control page, if a DB instance is not available (`db_install_dir` or `db_exec_file` is not accessible) during IE validation, after an S-TAP or DB restart.

- 0 and less: S-TAP logs an event message with the event type `CONF_ERROR` when a DB instance is detected as unavailable for certain DB(PROTOCOL) during the S-TAP starting time. S-TAP also logs a `CONF_ERROR` if a DB changes its status from available to unavailable during the periodic check (every 15 minutes). These event messages change the S-TAP status in the GUI to yellow with the instruction to correct the parameter or set `WAIT_FOR_DB_EXEC > 0`. When a DB instance status changes from unavailable to available, a `WARNING` message is sent to the sniffer, but the GUI status does not change automatically. You need to click  to open the S-TAP event log and click Accept.
- greater than 0: A `WARNING` is logged for any unavailable database during S-TAP startup time or during a periodic check. The time interval of the periodic check is the value of `wait_for_db_exec`, in minutes. A warning message is also sent when an unavailable DB instance becomes available. Since the periodic check needs to get status of the database file configured for each inspection engine, and it consumes the CPUs, the value should not be less than the number of inspection engines.

Before setting this property to a positive value, be sure to set all other necessary configuration properties and test that the S-TAP starts and collects data correctly. This property can be modified using GIM GUI (`STAP_WAIT_FOR_DB_EXEC`), and the `guard_tap.ini` configuration file. It cannot be modified in the S-TAP Control UI page.

## Linux-UNIX: What to restart or reboot on the database server after installing or updating S-TAP

This topic details what needs to be rebooted or restarted after you install or upgrade your UNIX or Linux S-TAP. Restart and reboot requirements are the same for GIM and non-GIM implementations.

### Installing S-TAP when using EXIT

Db2 and Teradata: No restart needed.

Informix: No restart needed. If ifxserver is running, then restart it. If ifxserver is not running, then you do not need to restart anything.

### Installing S-TAP when using A-TAP

The database must be restarted when using A-TAP.

Deactivate and de-instrument the A-TAP before any database software updates.

### Installing S-TAP when using K-TAP with TCP/IPC or shared memory connections (SHM)

| OS/Database | Oracle  |     | Db2     |     | Sybase  |     | Mysql   |     | Informix |     |
|-------------|---------|-----|---------|-----|---------|-----|---------|-----|----------|-----|
|             | TPC/IPC | SHM | TPC/IPC | SHM | TPC/IPC | SHM | TPC/IPC | SHM | TPC/IPC  | SHM |
| Linux       | NR      | NR  | NR      | REQ | NR      | NR  | NR      | NA  | NR       | REQ |
| AIX *       | REQ     | NR  | REQ     | NR  | REQ     | NR  | REQ     | NA  | REQ      | NR  |
| Solaris     | NR      | NR  | NR      | NR  | NR      | NR  | NR      | NA  | NR       | NR  |
| HP-UX       | NR      | NR  | NR      | NR  | NR      | NR  | NR      | NA  | NR       | NR  |

Where:

- NR = No restart/reboot required (based on utilizing live update mechanism and referencing live update link if you have one)
- REQ = Restart required
- NA = Not applicable

\* On AIX, a database restart is always required after you install S-TAP in order to capture TCP traffic. When you install an S-TAP on AIX, AIX updates the system calls. When you restart the database server, K-TAP intercepts and updates the system call to ensure the server can access the most current system call.

### What to restart after a live upgrade of UNIX/Linux S-TAP

No restarts are necessary at all for live upgrades that do not include A-TAP or exit libraries.

Deactivate and de-instrument the A-TAP prior to any S-TAP upgrades.

#### When using Exit libraries:

- If you upgrade from v10.6.0.0 and higher, you do not need to restart the database. You can upgrade the S-TAP while the database is running; the next time the database is restarted, the updated exit library is used.
- If you upgrade from any release before 10.6.0.0: Restart any databases that use an exit library.

### Reboot guidelines

Rebooting the database server is only required when uninstalling K-TAP (whether or not K-TAP is in use).

## Linux-UNIX: Managing a GIM-, RPM-, and shell-installed S-TAP during a database upgrade

Only the A-TAP needs handling when you upgrade a database with a GIM, RPM, or shell-installed UNIX S-TAP. If a system is running multiple databases, the S-TAP can continue to run and monitor all other databases not being upgraded.

## Procedure

1. De-instrument, and de-activate the A-TAP, by using the guardctl utility.
2. Upgrade your database.
3. Instrument, activate, and restart the A-TAP, by using the guardctl utility.
4. If the system uses exit libraries, make sure that the exit library is in the appropriate place (for example if the DB location directory changed).
5. Verify that the inspection engine is correct, because paths may have changed.

When the DBA upgrades the database with a different installation path than the previous version, traffic is not captured unless you update with the correct installation path and restart the S-TAP. If the installation path is not updated, the database might not be monitored. Look in the S-TAP Events report for a message:  
DB instance stops running, please make sure DB under db\_install\_dir is still available, and restart the relevant S-TAP. If found, update db\_install\_dir in the guard\_tap.ini or DB Install Dir in the S-TAP control page.

6. Check that the inspection engine for the database is correct (for example, the version number).
7. If you modified the inspection engine configuration, including the DB installation path, restart the S-TAP.

# Linux-UNIX: Managing GIM clients during a major upgrade of the database server operating system

When you upgrade the operating system on your database server, use the GIM client to automatically upgrade itself and the GIM bundles (for example, GIM, S-TAP, CAS) installed on the Linux-UNIX database. However, most operating systems do not support a major upgrade, for example from RHEL7 to RHEL8.

## Before you begin

The target upgrade GIM bundles must be available on the GIM server. The build number of each bundle must be the same or greater than the bundle that is installed. Download from [Fix Central](#).

## About this task

This procedure is only relevant for databases whose operating system can be upgraded. If you cannot upgrade the operating system, you must uninstall the S-TAP, install the new operating system, and install the S-TAP bundle that is compatible with the newly installed operating system.

GIM bundles are OSType/OsVersion/Processor specific. When the OS version changes (for example, from RHEL7 to RHEL8), all the bundles need to be upgraded.

The GIM parameter auto\_install\_on\_db\_server\_os\_upgrade controls GIM's ability to auto-upgrade all bundles. If enabled, when the database server boots up after an operating system upgrade, GIM automatically downloads and installs these bundles. This parameter is disabled by default, to prevent unintentional bundle upgrades.

If the parameter is disabled when you upgrade the database operating system, the GIM client detects that the operating system changed, and it changes the \_x suffix of the version to \_0. You can see the version in the Set up by Client, for example, 10.6.1.4\_r123456\_0. To resolve the mismatch between the GIM client and the database operating system, do one of:

- Enable the GIM global parameter auto\_install\_on\_db\_server\_os\_upgrade, which automatically upgrades all the GIM clients with the latest bundle of the operating system they support.
- Do not enable auto\_install\_on\_db\_server\_os\_upgrade, and upgrade the GIM clients manually.

It is best to update all your GIM-installed modules as soon as possible after the upgrade, whether manually or automatically. K-TAP is not loaded after an operating system upgrade.

## Procedure

1. Log in to the CLI of the Guardium system that is the GIM server
2. Enable auto\_install\_on\_db\_server\_os\_upgrade by entering:

```
grdapic gim_set_global_param paramName="auto_install_on_db_server_os_upgrade" paramValue="1"
```

3. Upgrade the operating system on your database server.

## Results

At first boot after OS upgrade, the GIM client recognizes that the operating system was upgraded and:

1. Changes the configuration files for all GIM-installed modules to support the new operating system attributes.
2. Registers all the modules to the GIM server with the updated attributes. This change triggers the GIM server to look for a bundle that has the same build number as the previously installed bundle, but is compatible with the upgraded operating system. If it does not find such a bundle, it looks for the latest bundles that support the new operating system attributes. When the server finds appropriate bundles, it schedules them for upgrade and runs the upgrade process immediately. If the server cannot find appropriate bundles, it issues an error message.
3. Records an alert in the GIM\_EVENTS report, that an operating system upgrade occurred and lists the actions that should be taken.

## What to do next

Review the messages in the GIM\_EVENTS report. If the GIM server reports that the modules were upgraded successfully, verify the proper operation of the modules as you would do after any update.

If error messages were written to the GIM\_EVENTS report, indicating that the upgrade was not successful, review the error messages for guidance.

When the operating system upgrade is complete, disable the automatic update option on the GIM server to prevent a GIM client from erroneously starting an update process.

```
grdapic gim_set_global_param paramName="auto_install_on_db_server_os_upgrade" paramValue="0"
```

# Linux-UNIX: Managing an RPM- or shell-installed S-TAP during a major upgrade of the database server operating system

When you upgrade the operating system on your database server, you need to uninstall the S-TAP, and install a new version. However, most operating systems do not support a major upgrade, for example, from RHEL7 to RHEL8.

## Before you begin

The appropriate target upgrade shell or RPM bundles must be available on the database. The build number of each bundle must be the same or greater than the bundle that is installed. Download from [Fix Central](#).

## About this task

---

If you cannot upgrade the operating system, you must uninstall the S-TAP, install the new operating system, and install the S-TAP bundle that is compatible with the newly installed operating system.

## Procedure

---

1. Log in to the database.
2. If the system uses A-TAP: Disable and deinstrument the A-TAP by using the `guardctl` utility.
3. Uninstall the S-TAP, which also uninstalls the K-TAP.
4. Upgrade the operating system on your database server. (Upgrading includes at least one reboot of the operating system.)  
Note: Before you reboot, make sure to set the `ktap_installed` parameter to 1.
5. Install the S-TAP and the K-TAP with the appropriate installer.  
For example, if you are upgrading from RHEL7 to RHEL8, you used the RHEL7 to uninstall the S-TAP in step 3, but you need the RHEL8 installer to install the new S-TAP.
6. If the system uses A-TAP: Instrument and enable the A-TAP by using the `guardctl` utility.

# Linux-UNIX: Managing a GIM-, RPM-, or shell-installed S-TAP during a minor or kernel upgrade of the database server operating system

A minor database operating system upgrade can include a new operating system kernel. Use this task for both a minor upgrade or a kernel upgrade.

## Before you begin

---

- The loader automatically picks the right K-TAP at boot time.
- If the new kernel is already supported by a K-TAP module, the K-TAP installs as part of the S-TAP installation.
- If the new kernel is not supported by a K-TAP module, then you must install the development packages that support a local K-TAP module build. You might need to request a new K-TAP module from IBM Support. Save the appropriate K-TAP module locally on the database. For more information, see [Linux-UNIX: Preparing to install K-TAP](#).
- The parameter `auto_install_on_db_server_os_upgrade` is not relevant in this scenario.

## Procedure

---

1. If the system uses A-TAP: Use the `guardctl` utility to disable and deinstrument the A-TAP.
2. Upgrade the operating system or the kernel on your database server (upgrading includes rebooting the operating system.).  
Note: Before you reboot, make sure that the `ktap_installed` parameter in `guard_tap.ini` is set to 1.
3. If the system uses A-TAP: Use `guardctl` to instrument and enable the A-TAP.

## Linux-UNIX: Configuring S-TAP

Learn to configure the S-TAP.

To configure an S-TAP, you need to make changes to the guard\_tap.ini file that resides in the S-TAP default directory under /usr/local/guardium.

When you make changes to an S-TAP, Guardium updates the following files:

- guard\_tap.ini - The current working S-TAP configuration file.
- guard\_tap.ini.default\_orig - The default guard\_tap.ini file
- guard\_tap.ini.save\_default - The default file saved before you make any configuration changes.
- guard\_tap.ini.err - S-TAP configuration error log file.
- guard\_tap.ini.bak - This file is updated with the last successfully saved S-TAP configuration that passes parameters validation.
- guard\_tap.ini.prev - This file is updated with the last successfully saved S-TAP configuration that passes parameters validation and starts the S-TAP without error.

In general, you never need to touch the guard\_tap.ini files. You can configure the S-TAP either in the GUI or by using the **guard\_config\_update** command.

- [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#)

In the S-TAP Control page you can view all S-TAPs managed by this Guardium system, manage individual S-TAPs, and perform a few operations on all S-TAPs.

- [Linux-UNIX: Scheduling S-TAP diagnostics](#)

12.1 and later You can schedule S-TAP diagnostics by using the S-TAP Diagnostic Scheduler user interface.

- [Linux-UNIX: Configure S-TAP with guard-config-update](#)

You can use the guard-config-update script to update your S-TAP configuration (without using the GUI), whether S-TAP was installed with GIM, RPM, or shell.

- [Linux-UNIX: Discover database instances](#)

Enable S-TAP to periodically discover database instances and send the results to the current active S-TAP system.

- [Linux-UNIX: Configuring an Inspection Engine](#)

Configure or modify an inspection engine in the S-TAP Control pane.

- [Linux-UNIX: Inspection engine verification](#)

S-TAP verification confirms that the S-TAPs and their inspection engines in your environment are running and actively monitoring database activity. Understand verification, and define a schedule to regularly verify S-TAPs.

- [Linux-UNIX: S-TAP load-balancing models and configuration guidelines](#)

Understand the S-TAP load-balancing models, and choose the one appropriate to your setup.

- [Linux-UNIX: Kerberos-authenticated database traffic](#)

Kerberos is a network authentication protocol that eliminates the transmission of unencrypted passwords across the network.

- [Linux-UNIX: A-TAP management](#)

A-TAP is an application-level tap. It sits in the application layer to support monitoring of encrypted database traffic, which cannot be done in the kernel by K-TAP.

- [Linux-UNIX: Configure a public and private address for an S-TAP](#)

For an S-TAP deployed in a private network, Guardium® can refer to the S-TAP with a public IP address that is not visible from the database server on which S-TAP is installed, while the database uses a private address for the S-TAP.

- [Linux-UNIX: Configure S-TAP log and dump locations when /root partition size is limited](#)

S-TAP agents are installed in a partition with root privileges; by default they are installed into the /root partition based directories. For customers with limited root file systems size, follow these best practice recommendations to prevent the S-TAP agent from generating logs or dumps on the /root partition.

- [Linux-UNIX: Editing the S-TAP configuration parameters](#)

You can modify the S-TAP configuration after it is installed using GIM, the UI, or for advanced users, the configuration file on the database.

## Linux-UNIX: Configuring S-TAP in the S-TAP Control page

In the S-TAP Control page you can view all S-TAPs managed by this Guardium system, manage individual S-TAPs, and perform a few operations on all S-TAPs.

### Before you begin

You must be logged in to the Guardium system that is the active host for the S-TAP.

### About this task

Sometimes a user is unable to decide during the process of installing an S-TAP or can make the wrong decision and it goes undetected until after the installation process is complete. For instance, a user can forget to type in or use the wrong IP address for the SQL Guard IP. These types of mistakes can be remedied by modifying the S-TAP configurations.

Parameters in the GUI can be safely changed. Parameters that are not in the GUI rarely need changing and should normally be left unmodified; they are for use by Guardium Technical Support or advanced users.

All configuration changes require that the S-TAP agent be restarted. If you modify parameters in the GUI or with GIM, the S-TAP is restarted transparently. If you need to restart the S-TAP manually (for example after modifying the configuration by API or directly in the guard\_tap.ini), use the [Send Command](#) or follow the direction in [Linux-UNIX: Start and stop S-TAP and GIM processes for various OS types/versions](#) or [Linux-UNIX: Using guard-config-update to start, restart, and stop S-TAP, and view status](#).

If you installed your S-TAP by using the Guardium Installation Manager (GIM), you can update some parameters through the GIM GUI.

S-TAP status can be one of:

- Green: Online
- Yellow: one of:
  - Configuration error: When you modify S-TAP parameters in the GUI or GuardAPI, S-TAP checks the values before saving the parameters. When the S-TAP identifies an erroneous value, it does not save it and it creates an error in the S-TAP event log. The S-TAP uses default values so that it can keep sending

traffic. The S-TAP creates a backup guard\_tap.ini.bak under the S-TAP directory when it corrects the configuration. Click  to open the S-TAP event log, and evaluate the LOG\_CONF\_ERR error. Click one of the options:

- Accept to save the value the S-TAP assigned to the parameter
- Modify to open the Modify Configuration dialog and change the value.
- Close to close the window without making any changes or accepting the value.

(Parameters that do not have defaults, such as DB Install Dir and Process Name, do not have the accept option.) After you either accept or modify to a valid value, the status becomes green and the timestamp is updated. The S-TAP creates a backup guard\_tap.ini when it corrects the configuration. It is saved as guard\_tap.ini.bak under the S-TAP directory.

- Warning: After an S-TAP restart either db\_install\_dir or db\_exec\_file is not accessible during inspection engine validation. Guardium periodically checks for S-TAP status.

- Red: Offline

## Procedure

1. Go to Manage > Activity Monitoring > S-TAP Control to open S-TAP Control.
2. Perform operations on all S-TAPs in the page.
  - Refresh: refresh display of S-TAPs.
  - Add All to Schedule: add all displayed S-TAPs to the S-TAP verification schedule. See [Linux-UNIX: Inspection engine verification](#).
  - Remove All from Schedule: remove all displayed S-TAPs from the S-TAP verification schedule.
  - Comments: add comments. See [Comments](#).
3. Identify the S-TAP to be configured by its IP address or the symbolic hostname of the database server on which it is installed. View and perform operations on individual S-TAPs.

| Option                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|    | <p>Click Delete to remove an S-TAP.</p> <p>Delete an S-TAPs if you know that an S-TAP is inactive, or when the Guardium unit is no longer listed as a host in the S-TAPs configuration file. In either of these cases, the S-TAP displays indefinitely with an offline status if you do not delete it. (See also <a href="#">Linux-UNIX: Deleting inactive S-TAPs in a centralized environment</a>.)</p> <p>You cannot delete an active S-TAP from the list.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|    | Click Refresh to fetch a copy of the latest S-TAP configuration from the agent. (The S-TAP display does not auto-refresh.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|  | <p>Opens the S-TAP Commands pop-up, where you can run various commands on the S-TAP host.</p> <ul style="list-style-type: none"> <li>• Restart. Action depends on the Restart Mode.</li> <li>• Restart. Retsarts the S-TAP in the mode you select.           <ul style="list-style-type: none"> <li>• 0: Restarts the S-TAP. Use this mode in environments without enterprise load balancing.</li> <li>• 1: Restarts the S-TAP process while preserving the data in the S-TAP buffer. (The S-TAP picks up the new configuration from the enterprise load balancer without flushing the buffers.) Used in the enterprise load balancer environment.</li> </ul> </li> <li>• S-TAP logging: Starts S-TAP logging for debugging purposes, at the log level you enter in Level and for the duration you enter in Duration Sec. See tap_debug_output_level in <a href="#">Linux-UNIX: Debug parameters</a>.</li> <li>• Reinitialize buffer: Reset the K-TAP statistics along with deleting the S-TAP buffer.</li> <li>• K-TAP logging: Similar to S-TAP Logging; increases the debug output from K-TAP.</li> <li>• Push Guardium Insights Trust: To use an S-TAP to stream data from Guardium® Data Protection to Guardium Insights, you must first make establish trust. Use Push Guardium Insights Trust to paste in a signed, trusted Guardium Insights certificate . The certificate must be in PEM format and include the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- tags. From the CLI, you can use the <a href="#">push_insights_trust</a> API to push the certificate.</li> <li>• Run Diagnostics: Run the S-TAP diagnostics script (and upload the results to the Guardium system)</li> <li>• Upload Linux Modules: Linux only. Uploads the local custom build module of K-TAP.</li> <li>• Store SQL credentials: Saves the username - password pair on the selected S-TAP. (The password is encrypted on the S-TAP.) The S-TAP uses these credentials to access a database. See <a href="#">Linux-UNIX: Configuring S-TAP interception using Oracle Unified Audit</a>.</li> <li>• Revoke Ignore: All sessions that are ignored by a revocable ignore policy become unignored, and S-TAP starts capturing the traffic for those sessions.</li> <li>• Run Database Instance Discovery: Runs the discovery process once, immediately. (If enabled to run automatically, it runs, by default, every 24 hours.) You can specify rules to manage database instance discovery. To use discovered instance rules, clear the Replace Inspection Engines checkbox. For more information, see <a href="#">Database discovered instances rules</a>.</li> </ul> |
|  | <p>Opens the S-TAP configuration window. Parameters that do not appear in the GUI are advanced parameters. Do not modify them unless you are an advanced user, or Guardium Technical Support instructs you to modify them. See GUI parameters:</p> <ul style="list-style-type: none"> <li>• <a href="#">Linux-UNIX: S-TAP Control: Details</a></li> <li>• <a href="#">Linux-UNIX: S-TAP Control: Change auditing parameters</a></li> <li>• <a href="#">Linux-UNIX: S-TAP Control: Application server user identification parameters</a></li> <li>• <a href="#">Linux-UNIX: S-TAP Control: Guardium Hosts parameters</a></li> <li>• <a href="#">Linux-UNIX: S-TAP Control: Firewall parameters</a></li> <li>• <a href="#">Linux-UNIX: S-TAP Control: Inspection engine parameters</a></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|  | <p>Click to open the S-TAP event log, where you can see events such as connect, disconnect, GIM server configuration. This log is useful for troubleshooting. As described in <a href="#">S-TAP status</a>, use the event log to identify configuration errors (LOG_CONF_ERR).</p> <p>You can:</p> <ul style="list-style-type: none"> <li>• Accept to save the value the S-TAP assigned to the parameter</li> <li>• Modify to open the Modify Configuration dialog and change the value.</li> <li>• Close to close the window without making any changes or accepting the value.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|  | Adds the individual S-TAP to the scheduled verification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|  | A database might be running many sessions, some of which are currently ignored. Clear this option to stop ignoring traffic from ignored sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- [\*\*Linux-UNIX: S-TAP Control: Details\*\*](#)

These parameters define basic properties of the S-TAP. This topic lists the full set of parameters that can display under Details. Not all parameters display for every type of database server.

- [\*\*Linux-UNIX: S-TAP Control: Change auditing parameters\*\*](#)

These parameters affect the behavior of CAS.

- [\*\*Linux-UNIX: S-TAP Control: Application server user identification parameters\*\*](#)

These parameters affect the behavior of the S-TAP when an application user name needs to be bounded with database activities.

- [\*\*Linux-UNIX: S-TAP Control: Guardium Hosts parameters\*\*](#)

These parameters describe a Guardium system to which this S-TAP can connect.

- [\*\*Linux-UNIX: S-TAP Control: Firewall parameters\*\*](#)

These parameters affect the behavior of the S-TAP with respect to the firewall.

- [\*\*Linux-UNIX: S-TAP Control: Inspection engine parameters\*\*](#)

These parameters affect the behavior of the inspection engine that the S-TAP uses to monitor a data repository on a DB server. You can define up to 50 inspection engines per S-TAP.

---

## Linux-UNIX: S-TAP Control: Details

These parameters define basic properties of the S-TAP. This topic lists the full set of parameters that can display under Details. Not all parameters display for every type of database server.

Table 1. S-TAP Control: Details parameters

| Name                            | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Load balancing                  | 0             | <p>Controls load balancing to Guardium® systems. Valid values:</p> <ul style="list-style-type: none"> <li>• 0: No load balancing.</li> <li>• 1: Load balancing. Traffic is balanced between the primary and secondary servers, which are defined in the SQLGuard section.</li> <li>• 2: Redundancy. Fully mirrored S-TAP sends all traffic to all primary and secondary servers, which are defined in the SQLGuard section.</li> <li>• 3: Hardware load balancing. Guardium uses a load balancer such as F5 or Cisco. S-TAP sends the traffic to the load balancer, which forwards it to one of the collectors in the pool.</li> <li>• 4: Multiple KTAP buffer and S-TAP threads are used to split the traffic.</li> </ul> <p>Use the primary parameter in the SQLGUARD section to specify primary, secondary, tertiary or more, servers. If this parameter is set to 0, and you have more than one Guardium system monitoring traffic, then the non-primary Guardium systems are available for failover.</p> <p>This parameter is also used in enterprise load balancing. For more information, see <a href="#">Enabling enterprise load balancing and associating an S-TAP with a central manager</a>.</p> |

| Alternate ips                   | NULL          | Comma-separated list of alternate or virtual IP addresses used to connect to this database server. The alternate_ips parameter is only used when your server has multiple network cards with multiple IPs, or virtual IPs. S-TAP only monitors traffic when the destination IP matches either the S-TAP Host IP defined for this S-TAP, or one of the specified alternate IPs. It's recommended that you specify all virtual IPs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Discovery interval                            |                                     | The interval at which the S-TAP reports database instance discovery results to the collector. Select only if you want to change the discovery interval from its default of 24 hours. When you select this option, the UI updates with two radio buttons: Hour and Minute. Type in any positive integer to set the discovery interval in either hours or minutes. Clear the Enable discovery interval checkbox to disable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Wait for DB exec                              |                                     | When S-TAP restarts, either from a system reboot or user initiated S-TAP stop / start commands, S-TAP polls all databases that have been configured to be monitored and begins monitoring all valid configurations. Any configuration anomalies (either on the database side or the S-TAP side) that limits S-TAP ability to monitor a database does not limit the S-TAP from monitoring other databases with valid configurations. This parameter determines the S-TAP response, and its status in the S-TAP Control page, if a DB instance is not available (db_install_dir or db_exec_file is not accessible) during IE validation, after an S-TAP or DB restart. <ul style="list-style-type: none"> <li>0 and less: S-TAP logs an event message with the event type CONF_ERROR when a DB instance is detected as unavailable for certain DB(PROTOCOL) during the S-TAP starting time. S-TAP also logs a CONF_ERROR if a DB changes its status from available to unavailable during the periodic check (every 15 minutes). These event messages change the S-TAP status in the GUI to yellow with the instruction to correct the parameter or set WAIT_FOR_DB_EXEC &gt; 0. When a DB instance status changes from unavailable to available, a WARNING message is sent to the sniffer, but the GUI status does not change automatically. You need to click  to open the S-TAP event log and click Accept.</li> <li>greater than 0: A WARNING is logged for any unavailable database during S-TAP startup time or during a periodic check. The time interval of the periodic check is the value of wait_for_db_exec, in minutes. A warning message is also sent when an unavailable DB instance becomes available. Since the periodic check needs to get status of the database file configured for each inspection engine, and it consumes the CPUs, the value should not be less than the number of inspection engines.</li> </ul> |
| Kerberos plugin directory                     |                                     | Location of the Kerberos file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| QRW default state                         | 0             | Sets the query rewrite activation trigger. Must be 0 if firewall_default_state=1. Valid values: <ul style="list-style-type: none"><li>• 0: QRW activated per session when triggered by a rule in the installed policy</li><li>• 1: QRW activated for every session regardless of the installed policy.</li><li>• 2: All traffic is watched by default for QRW policy violations, but if no event triggers the watch in the first PRIORITY_COUNT packets, query rewrite is turned off for the session.</li></ul> When set to 2, the QRW operation can be modified by the following commands: <b>Watch</b> , <b>Drop</b> , <b>Watch &amp; Drop</b> and <b>Unwatch</b> . When a <b>Watch</b> command is received while state 2 is in effect, it changes the state from 2 to 1 so that the connection is permanently subject to firewall or query rewrite operations. When a <b>Drop</b> or <b>Watch &amp; Drop</b> is received, the connection is immediately terminated. When an <b>Unwatch</b> command is received while state 2 is in effect, it changes the state from 2 to 0 so the connection is no longer subject to firewall or query rewrite operations. |
| QRW force watch                           | NULL          | Comma-separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1.2.2.2.2/2.2.2.2) to watch automatically. Valid when qrw_installed is 1, and qrw_default_state is 0. Cannot be configured to the same IP range as firewall_force_unwatch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| QRW force unwatch                         | NULL          | Comma separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1.2.2.2.2/2.2.2.2) to exclude from watching. Valid when qrw_installed is 1, and qrw_default_state is 1. Cannot be configured to the same IP range as firewall_force_unwatch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Hunter trace                              | ✗             | Turns on the collection of UID chains. When enabled, captures the UID but without IP in the string. Use this setting for local TCP/IP connections including Solaris zones and AIX WPARs, and remote TCP/IP connections when appserver_installed = 1. <ul style="list-style-type: none"><li>• ✗: Disabled.</li><li>• ✓: Enabled.</li></ul> See more information in <a href="#">Linux-UNIX: UID chains</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Load balancer node affinity               | ✗             | Whether the S-TAP connects to more than one managed unit, for enterprise load balancing. Some scenarios need all traffic to go to the same collector. With Oracle ATAP, for example, the analyzed client IP only shows if both the encrypted and unencrypted sessions go to the same managed unit. <ul style="list-style-type: none"><li>• ✗: Disabled. The S-TAP traffic goes to, at a maximum, the number of managed units specified by Managed Units.</li><li>• ✓: Enabled. The S-TAP traffic goes to one managed unit, and has, at a maximum, the number of connections (to that managed unit) specified by Managed Units.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Name                      | Default value | Description                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Discovery use port ranges | ✗             | Enable S-TAP discovery of Oracle databases to combine discovered instances based on port ranges. This setting works with a single unix_domain_socket_marker. Multiple unix_domain_socket_marker configurations require separate instances.<br>Valid values: <ul style="list-style-type: none"><li>• ✗: Disabled.</li><li>• ✓: Enabled.</li></ul> |

## Linux-UNIX: S-TAP Control: Change auditing parameters

These parameters affect the behavior of CAS.

Table 1. CAS parameters for UNIX/Linux

| Name                      | Default value     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Task checkpoint           | task_checkpoint   | Internal handle program machine state in case of host failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client checkpoint         | client_checkpoint | File used to restart processing. A series of files is created. Each version of the file ends with a unique number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Checkpoint period         | 60                | Interval time, in seconds, for the check.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Fail over file            | fail_over_file    | Name of the outgoing messages buffer. The database writes to this file when the Guardium® system cannot be reached. During this time, the file can grow to the maximum size specified. When the limit is reached, a second file is created, with the same name with the digit 2 appended to the end of the name. (At this point CAS begins trying to connect to a secondary server.) If that file also reaches the maximum size, the first file is overwritten. If the first file fills again, the second file is overwritten. Thus, following an extended outage, you might lose data, but an amount of data up to twice the size of the Failover File Size Limit is stored. |
| Fail over file size limit | 50000             | Failover file maximum size, in KB. The disk space requirement is twice what you specify here because the system maintains two failover files. If you specify -1, the file size is unlimited, but it is recommended that you cap the file size.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Max rec. attempts         | 5000              | Number of reconnect attempts when connection is lost. The maximum number of times CAS attempts to reconnect to the Guardium system. Set this value to -1 for unlimited reconnection attempts. The default cas_max_reconnect_attempts and cas_reconnect_interval define an interval of about 3.5 days. After reaching the maximum, CAS continues to run, writing to the failover files, but it does not attempt to reconnect with a Guardium host.                                                                                                                                                                                                                             |
| Reconnect interval        | 60                | Wait time, in seconds, between reconnect attempts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Raw data limit            | 1000              | Maximum number of KB written for an item when the Keep data checkbox is marked in the item template. If you specify -1, the size is unlimited.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Md5 data limit            | 1000              | Maximum size of a data item, KB, on which the MD5 checksum calculation is performed. If you specify -1, there is no limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Linux-UNIX: S-TAP Control: Application server user identification parameters

These parameters affect the behavior of the S-TAP when an application user name needs to be bounded with database activities.

For more information, see [Linux-UNIX: Application server S-TAP configuration](#).

| Name               | Default value | Description                                                                                                                                                                                                                        |
|--------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session timeout    |               |                                                                                                                                                                                                                                    |
| Ports              | 8080          | Comma-separated list of ports, or hyphens for inclusive ranges of ports, on which the Java™ application is accessed by a web browser.                                                                                              |
| Login pattern      |               | Comma-separated list of strings specifying the login pattern that is passed to the application. This pattern is passed to the Java application to identify a user login.                                                           |
| Username prefix    |               | Comma-separated list of strings specifying the prefix to the username for a specific session. This is the pattern the Java application uses to indicate the username of the given session.                                         |
| Username postfix   |               | Comma-separated list of strings specifying the postfix to the username for a specific session. This pattern is passed to the Java application to indicate the end of the value for the given variable that indicates the username. |
| Session pattern    |               | Comma-separated list of strings specifying the start of an end-user session, using a particular database session. This pattern specifies the [change of] end-user session for a specific database connection.                      |
| Session prefix     |               | Comma-separated list of strings specifying the session identifier.                                                                                                                                                                 |
| Session postfix    |               | Comma-separated list of strings specifying where the session ends.                                                                                                                                                                 |
| Session ID pattern |               | Comma-separated list of strings specifying the identifier for marking which end-user session a specific connection is continuing with.                                                                                             |
| Session ID prefix  |               | Comma-separated list of strings specifying what identifies or precedes the session_id in a specific users indicator packet.                                                                                                        |
| Session ID postfix |               | Comma-separated list of strings specifying where the session ID ends.                                                                                                                                                              |

## Linux-UNIX: S-TAP Control: Guardium Hosts parameters

These parameters describe a Guardium system to which this S-TAP can connect.

| Name          | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Guardium Host |               | IP address or hostname of the Guardium system that acts as the host for the S-TAP. You can add Guardium systems for failover or load balancing..                                                                                                                                                                                                                                                                                                                                                                   |
| Main threads  | 1             | The number of threads that are used between the S-TAP and a Guardium® host.<br>Valid values: 1-10 (maximum total of 10 for all defined Guardium hosts)<br>Note: Enterprise load balancing does not support multiple threads for a single managed unit. Set this parameter to 1 if you are using enterprise load balancing.                                                                                                                                                                                         |
| Pool Size     |               | The number of connections to open between the S-TAP and the sniffer process on a Guardium host. Increasing the value provides more throughput that might be required when encryption such as TLS is enabled. The maximum number of pooled connections is 50. The total is the sum of (connection_pool_size x num_main_thread) in all of the [SQLGuard_n] sections in the guard_tap.ini. Valid values: <ul style="list-style-type: none"><li>• 0: Disable pooling</li><li>• 1-10: (for each defined host)</li></ul> |
| Active        |               | <ul style="list-style-type: none"><li>• <input checked="" type="checkbox"/> connection is active.</li><li>• <input type="checkbox"/> connection is not active.</li></ul> <p>You can change the primary S-TAP by clicking Modify, and opening the Guardium Hosts section.</p>                                                                                                                                                                                                                                       |

## Linux-UNIX: S-TAP Control: Firewall parameters

These parameters affect the behavior of the S-TAP with respect to the firewall.

| Name                   | Default value                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Firewall installed     |                                     | Firewall feature enabled. Valid values: <ul style="list-style-type: none"><li>• <input type="checkbox"/> disabled.</li><li>• <input checked="" type="checkbox"/> enabled.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Firewall timeout       | 2                                   | Time, in seconds, to wait for a verdict from the Guardium® system. If the firewall times out, the value of the parameter Firewall fail close determines whether to block or allow the connection.<br>Valid values: 0-10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Firewall default state | 0                                   | Valid values: <ul style="list-style-type: none"><li>• 0: Firewall is activated per session when triggered by a rule in the installed policy.</li><li>• 1: All traffic is watched for firewall policy violations</li><li>• 2: All traffic is watched for firewall policy violations for the initial priority_count packets (guard_tap.ini parameter). S-TAP watches the initial part of every new session to your DB. This is useful when you have session based policies, firewall rules based on the user, or some other information that is passed early in the session. It limits the impact of firewall on the performance. Instead of watching every bit of the session (Firewall default state=1) and waiting for an UNWATCH verdict, S-TAP simply unwatches automatically if no WATCH or DROP is sent.</li></ul> |
| Firewall fail close    | <input checked="" type="checkbox"/> | The action when the verdict cannot be set by the policy rules, for example the Firewall timeout expires. Valid values: <ul style="list-style-type: none"><li>• <input type="checkbox"/> the connection goes through.</li><li>• <input checked="" type="checkbox"/> the connection is blocked.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Firewall force watch   |                                     | When Firewall default state, then Firewall force watch specifies the network/mask of the IPs you want the firewall to watch, overriding the default (off).<br>Valid value: comma separated list of IP/mask values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Firewall force unwatch |                                     | When Firewall default state=1 (on), then Firewall force unwatch specifies the network/mask of the IPs you want the firewall to ignore, overriding the default (on).<br>Valid value: comma separated list of IP/mask values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Linux-UNIX: S-TAP Control: Inspection engine parameters

These parameters affect the behavior of the inspection engine that the S-TAP uses to monitor a data repository on a DB server. You can define up to 50 inspection engines per S-TAP.

| Name | Default value | Description |
|------|---------------|-------------|
|      |               |             |

| Name                     | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol                 |               | Required. The type of data repository that is monitored.<br>ASTERDB, Cassandra, CockroachDB, CouchDB, DB2®, Db2 Exit, ElasticSearch, exclude IE, FTP, GreenplumDB, HADOOP, HIVE, HP-Vertica, HTTP, HUE, IMPALA, Informix®, Informix Exit, KERBEROS, MariaDB, MemSQL, MongoDB, MySql, Netezza®, Oracle, PostgreSQL, REDIS, SAP Hana, Sybase, Teradata, Teradata Exit, WebHDFS, Windows File Share<br>If Protocol is one of the Exit libraries, only DB Install Dir and Intercept Types are needed.                                                                                                                                                                                                                                             |
| Port range               |               | For monitoring network traffic only, the port range over which to listen for database traffic. For a Kerberos inspection engine, set the start and end values to 88-88. If a range is used, do not include extra ports in the range, as this might result in excessive resource consumption while the S-TAP attempts to analyze unwanted traffic.<br>Examples:<br>To monitor range 1521-1525 (5 ports) with no port forwarding: <ul style="list-style-type: none"> <li>• Port range = 1521-1525</li> <li>• DB Real Port =1521</li> </ul> To monitor range 2000-2004 (5 ports) where network port 2000 is mapped to local port 1521: <ul style="list-style-type: none"> <li>• Port range = 2000-2004</li> <li>• DB Real Port = 1521</li> </ul> |
| DB Real Port             | 4100          | With K-TAP and PCAP, identifies the database port or range of ports to be monitored. For exit libraries, use its value for db_home.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Client Ip/Mask           |               | Restricts S-TAP to monitor traffic only from the specified sets of IP address and mask pairs, by using a list of addresses in IP address/mask format: n.n.n.n/m.m.m.m. If an improper IP address/mask is entered, the S-TAP does not start. Valid values: <ul style="list-style-type: none"> <li>• User-defined list</li> <li>• 0.0.0.0/0.0.0.0::/0: select all clients.</li> <li>• 127.0.0.1/255.255.255.255::1/0: local traffic only</li> </ul> Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously.<br>If the value of this parameter is not configured correctly, the value is replaced by the default value.                                                                      |
| Exclude Client Ip/Mask   |               | A list of client IP addresses and corresponding masks that are excluded from monitoring. Use this option to configure the S-TAP to monitor all clients, except for a certain client or subnet (or a collection thereof). Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Connect To Ip            | 127.0.0.1::1  | IP address for S-TAP to use to connect to the database. When K-TAP is enabled, this parameter is used for Solaris Zones and AIX WPARs and it should be the zone IP address in order to capture traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB User                  | NULL          | OS username (case-sensitive) of the owner of the DB server process (for example, oracle). This parameter specifies which user is allowed to use the db_request_handler socket. It is required if you are not using the user root. If set to an invalid value, A-TAP cannot access the socket to retrieve permission for accessing K-TAP. In this case, it requires authorization with a group membership to log decrypted traffic to K-TAP (by using the guardctl <b>authorize-user</b> command). You can define a comma-separated string of multiple users.                                                                                                                                                                                  |
| DB Install Dir           | NULL          | Db2, Informix, and Oracle: Enter the full path name for the database installation directory. For example: /home/oracle10. All other database types enter: NULL. For Db2 exit and Informix exit, db_install_dir must be exactly the same as the \$HOME value in the database (or \$DB2_HOME for Db2 Exit); otherwise tap_identifier does not function properly.                                                                                                                                                                                                                                                                                                                                                                                |
| Process Name             | NULL          | The value of this parameter depends on whether it's in an exit, and whether there is A-TAP. <ul style="list-style-type: none"> <li>• Exit libraries: see <a href="#">Linux-UNIX: Configuring Exit libraries</a></li> <li>• With A-TAP: see <a href="#">Linux-UNIX: Database-specific guardctl parameters</a></li> <li>• Without A-TAP: The full path name for the database executable. For example: <ul style="list-style-type: none"> <li>◦ Oracle: /\$ORACLE_HOME/bin/oracle</li> <li>◦ Informix: /INFORMIXTMP/.inf.sqlexec. Applies to all Informix platforms but Linux®.</li> <li>◦ Informix with Linux, example: /home/informix11/bin/oninit</li> <li>◦ MYSQL: mysql</li> </ul> </li> </ul>                                              |
| DB2 Shared Mem. Adjust   | 20            | Required when Db2® is selected as the database type, and shared memory connections are monitored. The offset to the server's portion of the shared memory area. Offset to the beginning of the Db2 shared memory packet, depends on the Db2 version: 32 in pre-8.2.1, and 80 in 8.2.1 and higher.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DB2 Sh. Mem. Client pos. | 61440         | The offset to the client's portion of the shared memory area. Required when Db2 is selected as the database type, and shared memory connections are monitored. Use the script find_db2_shmem_parameters.sh to find the value. The script is located in stap_directory/bin, and outputs what the Db2 shared memory parameters that are defined in the Inspection Engines should be. Run it either as root or Db2 user, by using the syntax: find_db2_shmem_parameters.sh <instance name>. You can run it from any directory.                                                                                                                                                                                                                   |
| DB2 Shared Mem. Size     | 131072        | Db2 shared memory segment size. Required when Db2 is selected as the database type, and shared memory connections are monitored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Name               | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

For Oracle11 SSL, instrument on AIX.</p> <p>For any Oracle requiring instrumentation, if you are using encryption=1 in the guard_tap.ini (which is not supported on Linux), you must instrument before setting that parameter.</p> <p>Some DBs require restart after enabling encryption.</p> <p>When using GIM to configure the S-TAP, GIM_ROOT_DIR must be set to the absolute path to the modules, for example /usr/local/guardium/modules</p> |
| Intercept Types    | NULL          | DO NOT change this parameter unless it is absolutely necessary. Protocol types that are intercepted by the IE. Valid values: <ul style="list-style-type: none"> <li>• NULL: auto intercepts all protocols the Database supports</li> <li>• Comma-separated list: IE intercepts these protocol types only.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Identifier         | NULL          | Used to distinguish inspection engines from one another. If unspecified, Guardium® auto-populates the field with a unique name that uses the database type and sequence number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DB Version         | 9             | The database version. The string must start with a numeral and not a letter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Unix Socket Marker | Null          | Specifies UNIX domain sockets marker for Oracle, MySQL, and Postgres. Usually the default is correct, but when the named pipe or UNIX domain socket traffic does not work then you need to make sure that this value is set correctly. For example, for Oracle, set unix_domain_socket_marker to the KEY of IPC defined in tnsnames.ora. If it is NULL or not set, the S-TAP uses defined default markers identified as: * MySQL - "mysql.sock" * Oracle - "./oracle/" * Postgres - ".s.PGSQL.5432"                                                                                                                                                                                                                                                                                                                                                          |

## Linux-UNIX: Scheduling S-TAP diagnostics

12.1 and later You can schedule S-TAP diagnostics by using the S-TAP Diagnostic Scheduler user interface.

### Before you begin

You must be logged in to the Guardium system that is the active host for the S-TAP®.

### Procedure

1. Browse to [Manage > Activity Monitoring > S-TAP Diagnostic Scheduler](#).  
You can see all the UNIX S-TAP hosts that are listed under the S-TAP Hosts column that are managed by the Guardium system. This is the same list that is present on the S-TAP Control page.
2. Select one or more S-TAP hosts and click Add to schedule. The following options are available to run the diagnostics:
  - Click Create Schedule to create a schedule to run the diagnostics and enter the details.
  - Click Run Once to run the diagnostic immediately.  
Important: After you run the diagnostics, click refresh to view the diagnostic results in the grid.
3. To remove the S-TAP hosts from the diagnostic schedule, select one or more S-TAP hosts from the S-TAP Hosts list and click Remove from schedule.
4. Optional: Click edit icon to edit the following S-TAP host details:
  - Participate in scheduled diagnostics
  - Level
  - Duration

## Linux-UNIX: Configure S-TAP with guard-config-update

You can use the guard-config-update script to update your S-TAP configuration (without using the GUI), whether S-TAP was installed with GIM, RPM, or shell.

### About this task

### Procedure

1. Log in to the database server as `root` and change the directory to `/opt/guardium`.
2. Run the script `guard-config-update` using the relevant options and actions from this list:

Table 1. guard-config update parameters

| Parameter  | Description                                                            |
|------------|------------------------------------------------------------------------|
| --stap-dir | S-TAP install directory if not default (default: /usr/local/guardium). |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --migrate-to-insights [tenant ID] [routeName] | Migrate an S-TAP to Guardium® Insights. Parameters:<br><br>tenant ID<br>The Guardium Insights tenant ID, including the <i>TNT_</i> prefix.<br>routeName<br>The DNS hostname for the Guardium Insights deployment. The DNS hostname is the same as the URL for the UI (without the https:// prefix).<br><br>Note: Before migrating the S-TAP, Guardium Insights must have a signed, trusted certificate that the S-TAP can locate. Store the certificate either in the default location ( <code>INSTALL_DIR/etc/pki/certs/trusted/ca.cert.pem</code> , where <code>INSTALL_DIR</code> is the Guardium Data Protection installation directory or configure a different location in the <code>guard_tap.ini</code> by using the <code>guardium_ca_path</code> parameter. If you specify a custom location, you must manually store the certificate (that is, you cannot use the <a href="#">push_insights_trust API</a> ).<br>You can also use the <a href="#">migrate_stap_config API</a> to migrate S-TAPS. |
| --set-tap-ip [IP or hostname]                 | Set <code>tap_ip</code> in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> (default: <code>rh5u9x64t.guard.swg.usma.ibm.com</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --set-sqlguard-ip [IP or hostname]            | Set <code>sqlguard_ip</code> in SQLGuard_0 section in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> (default: <code>127.0.0.1</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| --add-sqlguard-[ID] [IP or hostname]          | Add SQLGuard_ID section to S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| --remove-sqlguard [ID]                        | Remove SQLGuard_ID section from the S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --modify-sqlguard [ID] [parameter] [value]    | Set SQLGuard_ID section parameter to value in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> . Parameters:<br><br><code>sqlguard_ip</code><br>IP address or hostname of SQLGuard unit<br><code>sqlguard_port</code><br>Port used to connect to SQLGuard unit (default: 16016)<br><code>primary</code><br>Order of preference (1=primary, 2=secondary, 3=tertiary, and so on)<br><code>num_main_thread</code><br>Number of main connections to use for this SQLGuard, used with <code>participate_in_load_balancing = { 1, 4 }</code> (default: 1)<br><code>connection_pool_size</code><br>Number of data connections per main connection to SQLGuard unit (default: 0)                                                                                                                                                                                                                                                                                                        |
| --modify-tap [parameter] [value]              | Set TAP section parameter to value in S-TAP config file <code>/usr/local/guardium/guard_stap/guard_tap.ini</code> . For the list of <code>guard_tap.ini</code> parameters, see <a href="#">guard_tap.ini parameters</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| --help-config [option]                        | Show information about an option in the ini, if available (show all available if none specified).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| --set-flexload [0 or 1]                       | Controls the K-TAP FlexLoad mechanism: 0: disable, 1: enable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| --retry-ktap-load                             | Retry K-TAP loading (useful after installing dev packages, updating after K-TAP request, or changing flexload; automatically restarts S-TAP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| --discover-ies                                | Run discovery and replace all Inspection Engines with those discovered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --stop [service]                              | Stop service (S-TAP, or monitor) temporarily (Solaris services and inittab treat this as permanent disable, does not auto-start on boot until re-enabled).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --start [service]                             | Start service (S-TAP, or monitor) if not already running (implies enable).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --restart [service]                           | Restart service (S-TAP, or monitor) if already running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --disable [service]                           | Prevent service (S-TAP, or monitor) from running again.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| --enable [service]                            | Configure service (S-TAP, or monitor) for automatic start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| --status                                      | Show which services are started and if they are configured to start automatically.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| --show-tap [option]                           | Shows the value that is currently stored for a parameter in the TAP section of the <code>guard_tap.ini</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| --show-ies                                    | Shows the currently configured inspection engines in the <code>guard_tap.ini</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| --set-ktap-prevent-exact-match-build          | Enable or disable the K-TAP local build. It is recommended to leave the KTAP local build enabled, which is the default setting when installing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

3. Restart the S-TAP. For example, `/opt/guardium/guard_stap/guard-config-update --restart stap`.

## Linux-UNIX: Discover database instances

Enable S-TAP to periodically discover database instances and send the results to the current active S-TAP system.

The Guardium® Discovery Agent is a software agent that is automatically installed with the S-TAP package on a database server. The instance discovery agent reports database instances, listener, and port information to the Guardium system. Discovery does not find and report on every detail of the database instances on the server.

Auto-discovery is enabled by default during installation. It runs once daily. When discovery runs, it identifies the user modifications in the `guard_tap.ini`, and does not overwrite them with the discovered database details.

Guardium recommends that you leave the parameter values at their defaults. The parameters are described in [Linux-UNIX: Discovery parameters](#).

Database types that are supported by S-TAP discovery are listed in the [Guardium support matrix](#).

You can define rules to manage inspection engine creation on discovered databases. For more information, see [Database discovered instances rules](#).

The discovery bundle is not installed in a worker zone or WPAR; the discovery agent that is running on the global zone collects information from other zones. Limitation: On Solaris zones architecture, when Db2 instances are running on worker zones, Discovery does not discover the Db2 shared memory parameters.

Newly discovered database instances can be seen in the Discovered Instances report. From this report, datasources and inspection engines can quickly be added to Guardium using the Actions menu.

If databases on the database server are not operational (started) or are added later, the Discovery Agent can still discover these instances. Go to [Manage > Activity Monitoring > S-TAP Control](#), click , and select Run Database Instance Discovery.

S-TAP Discovery can be run manually but this action is not suggested. The main reason to run it manually is for debugging purposes. If a new request comes in from the user interface while a scheduled discovery is running, the new request is ignored.

Note: Once you activate A-TAP, you no longer need to run the S-TAP Discovery instance as it is already replaced by A-TAP.

You can run Discovery from a local command line on the database server (`/usr/local/guardium/guard_stap/guard_discovery`) by using one of these flags:

- `--update-tap` flag: edits the `guard_tap.ini` to add or update inspection engines
- `--send-to-sqlguard` flag (or with no flag, which is the default): sends the found changes to the Guardium system, where they appear in the Discovered Instances report
- `--print-output` flag: prints the found changes to `stdout` (for debugging)

If the S-TAP is running as "user" (and not guardium), the discovery functionality is limited. The following message displays:

WARNING: Discovery is enabled and STAP is running as user guardium.  
The discovery function is limited when STAP runs as user guardium.  
Discovery is most effective when '`tap_run_as_root=1`'

Note: To avoid an instance where S-TAP discovery does not open the Informix database, it is recommended to start Informix databases by using the full path to the executable.

Discovery also uses these parameters:

- `tap_ip`: the S-TAP with which the database instance is associated.
- `sqlguard_ip`: S-TAP discovery results are sent to this IP. (The Guardium system with `primary=1` in the SQLguard parameters.)

## Using Exit discovery

The Exit discovery feature allows database auto-discovery to discover any databases that have Exit protocols and add those instances to Discovered Instances report. By default, Exit discovery is disabled.

Guardium provides several ways to enable or disable Exit discovery.

- From the S-TAP Configuration page in the Guardium GUI - Select or clear Use exit db type to enable or disable Exit discovery .
- From GIM - To enable Exit discovery, set the `STAP_USE_EXIT_DB_TYPE` GIM parameter to 1. When `STAP_USE_EXIT_DB_TYPE` GIM is enabled, set `KTAP_ENABLED=0` to disable KTAP.  
To disable Exit discovery, set `STAP_USE_EXIT_DB_TYPE` GIM=0 (the default).
- By using the `update_stap_config` GuardAPI or REST API - For example, to enable Exit discovery for Informix, use the following command:  
`grdapic update_stap_config stapHost=2.2.2.2 updateValue=TAP.USCE_EXIT_DB_TYPE:1,TAP.DB_EXIT_LIST:Informix`

Setting up Exit discovery:

- When you install an S-TAP, you can set the `STAP_USE_EXIT_DB_TYPE` parameter to 1. In this case, K-TAP is disabled and Guardium discovers the Exit inspection engine and adds it to `guard_tap.ini` file as `use_exit_db_type=1`.
- You can also update an existing S-TAP to use Exit discovery. Update the S-TAP configuration through the GIM GUI to set `STAP_USE_EXIT_DB_TYPE` to 1.
- When `STAP_USE_EXIT_DB_TYPE` is set to 1, you can also set `STAP_DB_EXIT_LIST` to specify which database Exits to discover. For more information, see [STAP DB EXIT LIST](#) in [Linux-UNIX: General parameters](#).

You can also run discovery from the S-TAP control page in the UI, which updates the inspection engine immediately if the Replace Inspection Engines box is selected. For more information, see [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#).

Note: When Exit discovery is on, you can monitor only databases that support Exit protocols.

## Linux-UNIX: Configuring an Inspection Engine

Configure or modify an inspection engine in the S-TAP Control pane.

### Before you begin

You must be logged in to the Guardium system that manages the S-TAP.

### About this task

Do not configure an S-TAP inspection engine to monitor network traffic that is also monitored directly by a Guardium system that is hosting the S-TAP, or by another S-TAP reporting to the same Guardium system. That would cause the Guardium system to receive duplicate information: it would not be able to reconstruct sessions, and it would ignore that traffic.

You can also add inspection engines directly in the `guard_tap.ini` file, see [Linux-UNIX: Editing the S-TAP configuration parameters](#).

You can define up to 50 inspection engines per S-TAP.

## Procedure

---

1. Navigate to `Manage > Activity Monitoring > S-TAP Control`.
2. In the row of the S-TAP, click .  
The S-TAP Configuration window opens.
3. Scroll to the bottom of the inspection engines, and click next to Add Inspection Engine....  
Note: You can add a maximum of 50 Inspection Engines only. If you exceed this limit, then the additional engines are truncated.
4. Select the protocol and enter the port range. The window refreshes with the relevant parameters, some with their default values.
5. Configure all the required parameters, and click Add. If you are missing parameters, the system informs you what is missing.

## Linux-UNIX: Inspection engine verification

---

S-TAP verification confirms that the S-TAPs and their inspection engines in your environment are running and actively monitoring database activity. Understand verification, and define a schedule to regularly verify S-TAPs.

Verification checks the sniffer operation and communication between the Guardium system and the inspection engines. You can enable verification for all S-TAP clients on your system, or individual S-TAP clients, or individual inspection engines.

Verification is supported for these database types:

- Db2
- Greenplum
- Informix
- MSSQL (for cluster configuration supports only advanced verification)
- MySQL
- Netezza
- Oracle
- PostgreSQL
- Teradata (advanced verification only)

There are two types of verification:

### Standard verification

Checks the sniffer operation, and the communication between the S-TAP and the inspection engine. During standard verification, Guardium® attempts to log in to database defined in the inspection engine with user `resutlfd`, based on the assumption that no such user exists on the target system. (If that user exists, use advanced verification instead.) Depending on the installed policy, failed login alerts might be triggered for that login attempt. Next, the verification process checks whether it can connect to the selected inspection engine on the database server. It expects to receive a response that indicates a failed login. If a different response is received, you might have to investigate further.

Some error messages from individual databases do not indicate a specific problem. For example, on several supported databases, the error code that is returned for a wrong port can also mean that the database itself is not started.

### Advanced verification

Use advanced verification to avoid failed login requests, and manage individual inspection engines. During advanced verification, Guardium logs into the database that is defined in the configured datasource. It runs `select * from non_existent_table`. Depending on the installed policy, this SQL might appear in reports or alerts.

- [Linux-UNIX: S-TAP verification](#)

The S-TAP verification process checks several configuration parameters and attempts to connect to the inspection engines.

- [Linux-UNIX: Configure standard verification](#)

Use this task to add all inspection engines on a specific S-TAP client host to the verification schedule.

- [Linux-UNIX: Configure advanced verification](#)

Use this task to run advanced verification on individual inspection engines on a specific S-TAP client host, and to add individual inspection engines to advanced verification.

- [Linux-UNIX: Configuring the S-TAP verification schedule](#)

The default schedule for verifying S-TAPs is once per hour, every day. You can change this schedule.

---

## Linux-UNIX: S-TAP verification

The S-TAP verification process checks several configuration parameters and attempts to connect to the inspection engines.

Before connecting to the database, the verification process checks whether the sniffer process is running on the Guardium® system. The sniffer is responsible for communicating with each S-TAP and processing the data that is received. If the sniffer is not running, responses from the S-TAP are not recognized.

The verification process attempts to log in to your database's STAP client with an erroneous user ID and password, to verify that this attempt is recognized and communicated to the Guardium system.

Next the verification process checks whether it can connect to the selected inspection engine on the database server. It expects to receive a response that indicates a failed login. If a different response is received, you might have to investigate further.

Some error messages from individual databases do not indicate a specific problem. For example, on several supported databases, the error code returned for a wrong port can also mean that the database itself is not started.

## Linux-UNIX: Configure standard verification

Use this task to add all inspection engines on a specific S-TAP client host to the verification schedule.

### About this task

As an alternative to this procedure, you can:

- use the GRDAPI command `verify_stap_inspection_engine_with_sequence`.
- Use the procedure in [Linux-UNIX: Configure advanced verification](#) to configure verification on individual inspection engines, by clicking Verify in step 3. The system immediately outputs results. Failed checks are shown first, with recommendations for next steps. Checks that succeeded are shown in a collapsed section at the end of the list. In some situations, it might be useful to review the successful checks in order to choose among possible next steps.

### Procedure

- Access [Manage > Activity Monitoring > S-TAP Control](#).
- Use these options:
  - Add All to Schedule: add all inspection engines for all displayed S-TAPs to verification.
  - Remove All from Schedule: remove all inspection engines for all displayed S-TAPs from verification.
  - Add to Schedule: add all inspection engines of the selected S-TAP client to the schedule.
- If an S-TAP does not have the option All Can Control enabled, you can only change its status if your Guardium system is the primary system for this S-TAP.
- Click Refresh.
- To verify now, go to [Manage > Activity Monitoring > S-TAP Verification Scheduler](#) and click Run Once Now.
- By default, the system waits five seconds before displaying verification results. If your network latency is high, this might not be enough time to receive the expected response from the database server. If you need to allow more time, you can use the `store stap network_latency` CLI command to change the period.

### What to do next

View the verification results in the S-TAP Verification page ([Manage > Reports > Activity Monitoring > S-TAP Verification](#) page).

## Linux-UNIX: Configure advanced verification

Use this task to run advanced verification on individual inspection engines on a specific S-TAP client host, and to add individual inspection engines to advanced verification.

### Procedure

- Access [Manage > System View > S-TAP Status Monitor](#).
- Click anywhere in the row of the S-TAP.  
The window refreshes with the individual inspection engines of this host.
- To output immediate verification results, take the following steps:
  - Click one inspection engine, and click Advanced Verify.
  - 12.0 Optionally, under Datasource, select Show only matching S-TAP host or select a name from the Name list to search for a specific inspection engine.  
12.1 and later Optionally, under Datasource, make sure that Show only matching S-TAP host and host is selected. If you select a datasource for which the IP address or port does not match the datasource, then an error message is returned.
  - Click Verify.
- The S-TAP Verification Results opens. Failed checks are shown first, with recommendations for next steps. Checks that succeeded are shown in a collapsed section at the end of the list. In some situations, it might be useful to review the successful checks in order to choose among possible next steps.
- By default, the system waits five seconds before it displays verification results. If your network latency is high, five seconds might not be enough time to receive the expected response from the database server. If you need to allow more time, you can use the `store stap network_latency` CLI command to change the period.
- To add to or remove individual inspection engines to the verification schedule:
  - Select one or more inspection engines.
  - Click Add to Schedule or Remove from Schedule

### What to do next

View the results of schedules verification in the S-TAP Verification page ([Manage > Reports > Activity Monitoring > S-TAP Verification](#)).

## Linux-UNIX: Configuring the S-TAP verification schedule

The default schedule for verifying S-TAPs is once per hour, every day. You can change this schedule.

### About this task

The same schedule is used for all S-TAPs that are scheduled for verification.

Once a schedule is defined, you can click the Pause button in the S-TAP Verification Scheduler to temporarily stop the verification process while keeping it active. Use the Run Once Now button to run the verification once in real-time.

### Procedure

1. Click [Manage > Activity Monitoring > S-TAP Verification Scheduler](#) to open the S-TAP Verification Scheduler.
2. In the S-TAP Verification Scheduler portion of the page, click [Modify Schedule](#).
3. In the Schedule Definition dialog, use the drop-down lists and check boxes to schedule when verification runs.  
This schedule is applied to all S-TAPs that are scheduled for verification.
4. Click [Save](#) to save your changes.

## Linux-UNIX: S-TAP load-balancing models and configuration guidelines

Understand the S-TAP load-balancing models, and choose the one appropriate to your setup.

The two main reasons for using load balancing:

- To improve reliability. If one collector fails, the traffic is rerouted to another collector so that no traffic is lost.
- To increase throughput. Load-balancing shares your high-volume traffic between a few collectors.

### Failover

S-TAP sends traffic to one collector (primary) and fails over to one or more collectors (secondary, tertiary, and so on) as needed. The S-TAP agents are configured with a primary and at least one secondary collector IP. If the S-TAP agent cannot send the traffic to the primary collector, the S-TAP agent automatically fails over to the secondary. It continues to send data to the secondary host until either the secondary host system becomes unavailable, the primary host becomes available again, or until the S-TAP is restarted (at which point it attempts to connect to its primary host first). If the secondary host system becomes unavailable, it fails over to the tertiary if there is one defined. In the second case S-TAP fails over from the secondary Guardium® host back to the primary Guardium host.

Set up a primary and up to two secondary collectors. You can either define one collector as a standby failover collector only, or a few failover collectors. When you use one standby failover, one collector is usually sufficient for 4-5 collectors. When you use a few failover collectors, each one should run at a maximum 50% capacity, so that there are always resources for extra load. Choose the setup that works best with your architecture, database, and data center layout.

The S-TAP restarts each time configuration changes are applied from the active host.

1. In the S-TAP Control window, Details section: set Load balancing to 0; In the Guardium Hosts section: add at least one secondary Guardium Host.

Note: If you are not an advanced user, do not update the default failover configuration default values.

2. Before you designate a Guardium system as a secondary host for an S-TAP, verify these items.

- The Guardium system must have connectivity to the database server where S-TAP is installed. When multiple Guardium systems are used, they are often attached to disjointed branches of the network.
- The Guardium system must not have a security policy that will ignore session data from the database server where S-TAP is installed. In many cases, a Guardium security policy is built to focus on a narrow subset of the observable database traffic, ignoring all other sessions. Make sure that the secondary host will not ignore session data from S-TAP or modify the security policy on the Guardium system as necessary.

#### Enhanced failover mechanism to avoid data loss

12.1 and later

The main goal of failover mechanism is to preserve the session parameters when switching the S-TAP to the secondary collector. The regular failover mechanism saves session parameters as 'failover messages' that are received from the primary collector over the network. If a failover occurs, the mechanism forwards the failover messages to the secondary collector. In rare cases, the failover messages are lost. To address this, the enhanced failover mechanism, also saves session parameters in the form of several raw database protocol packets. If a failover is required and the failover messages are lost, the failover mechanism forwards the raw database packets to the secondary collector.

### Load balancing

This configuration balances traffic from one database onto multiple collectors based on the client ports. This option is useful when you must monitor all traffic (comprehensive monitoring) of an active database. (Note that for outliers detection, the collectors must be under the same aggregator and central manager so that the aggregator can process all related data.) When the generated traffic is large and you need to house the data online on a collector for an extended period, use this method because it performs session-based load balancing across multiple collectors. An S-TAP can be configured in this manner with up to 10 collectors.

Complete the following configuration procedure in the Details section of the S-TAP Control window.

- Set the Value of the Load balancing parameter to 1 for load balancing.

### Internal load balancing

12.1 and later

The Internal Load Balancer (ILB) helps avoid data loss caused due to collector overload.

The ILB evaluates the data load and helps avoid the data loss by proactively forecasting the load on the collector and redirecting the traffic to another collector to balance this load.

On the sniffer, ILB dynamically determines the number of sessions that a sniffer can accept from the S-TAP. This value is based on the collector's capacity for session information and processing collector load.

ILB sends two values to the S-TAP: the total number of allowed sessions on the appliance and the total number of sessions currently opened in the sniffer.

Note: The calculation of current sessions includes all the connected S-TAPs.

Each S-TAP keeps count of open sessions and uses the allowed session count to determine whether it can send new session data to the existing collector.

If number of open sessions is more than the allowed session count, then the S-TAP redirects new sessions to another collector.

If the number of open sessions do not exceed the allowed session count then the S-TAP may send the new sessions to existing collector.

## Enabling internal load balancer

---

12.1 and later

Enabling on UNIX

1. To enable the internal load balancer feature on S-TAP, set the INTERNAL\_LOAD\_BALANCER\_ENABLED parameter to 1. Default value = 0. Value range = 0, 1.
2. Also, set the PARTICIPATE\_IN\_LOAD\_BALANCING to 4.  
Default value = 0. Valid values = 0 - 4

Enabling on collector

1. Create a session-level policy. For more information on creating session-level policy, see [Creating session-level policies](#).
2. In the Rule action field, select CONFIGURE.
3. In the Option field, select ILB and click OK.

## Grid

---

With Grid, the S-TAP communicates to the collector through a load balancer, such as f5 and Cisco. The S-TAP agent is configured to send traffic to the load balancer. The load balancer forwards the S-TAP traffic to one of the collectors in the pool of collectors. You also can configure failover between load balancers for continuous monitoring if the load balancer should fail.

S-TAP attempts to write to the buffer at an interval of tap\_min\_heartbeat\_interval. If it fails 5 times consecutively it fails over. Also, if it detects that the buffer is half full, it fails over.

1. In the Details section of the S-TAP Control window, set the value of the Load balancing parameter to 3 for the grid model. For more information, see [S-TAP Control: Details](#).
2. Set all can control = 1.
3. Guardium Host = <the IP of the Virtual IP of the balancer, to which all S-TAP database clients point to>.

## Redundancy

---

In redundancy, the S-TAP communicates its entire payload to multiple collectors. The S-TAP is configured with more than one collector (often only two) and communicates the identical content to both. This option provides full redundancy of the same logged data across multiple collectors. It can also be used for logging data and alert on activity at different levels of granularity.

In the Details section of the S-TAP Control window, set the value of the Load balancing parameter to 2 for redundancy. For more information, see [S-TAP Control: Details](#).

### Multiple K-TAP buffers

This mode works the same as when Load balancing is set to 1 but utilizes extra threads and K-TAP buffers to increase throughput. In the Details section of the S-TAP Control window, set the value of the Load balancing parameter to 4. See [Linux-UNIX: Multi-threading S-TAP to increase S-TAP throughput](#).

Note: If there is no K-TAP being used and Load balancing is set to 4, the behavior is the same as with Load balancing set to 1.

## Linux-UNIX: Kerberos-authenticated database traffic

---

Kerberos is a network authentication protocol that eliminates the transmission of unencrypted passwords across the network.

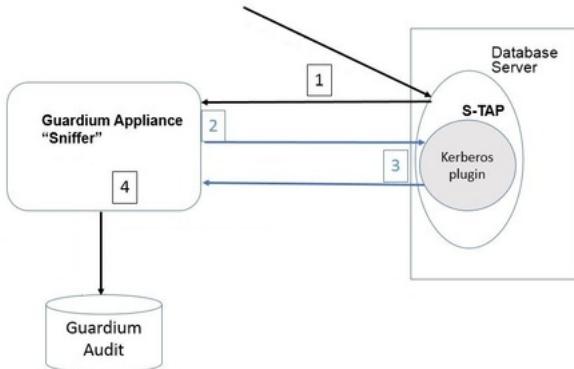

It works in a mutual authentication mode, verifying both the identity of the user that is requesting authentication as well as the server providing the requested authentication. The Kerberos authentication mechanism issues tickets for accessing network services. These tickets contain encrypted data, including an encrypted password, that confirms the user's identity to the requested service.

For auditing and alerting, it's important to know which database user performed an action. When login is done with a Kerberos ticket, determining the database user is not always straightforward.

Guardium S-TAP only sees network traffic and passes it on to the sniffer on the Guardium appliance. When a Kerberos ticket is used for login, S-TAP passes that Kerberos ticket along to the sniffer. For some database server types, the sniffer can determine the database user from the Kerberos login traffic and no additional information is required. For other database server types, the sniffer needs some assistance. That function is performed by the S-TAP Kerberos plugin.

The S-TAP Kerberos plugin is not enabled by default; it requires additional configuration.

If you use Kerberos at all, configure the plugin. There is no performance implication or other downside to configuring the plugin, just in case you need it.

The data flow between the database, the Guardium® sniffer and the Guardium audit data is:

1. S-TAP captures the Kerberized database login packet (along with other activity) and sends it to the Guardium appliance.
2. If the sniffer can determine the user name from the Kerberos ticket, it parses it.
3. If the sniffer cannot determine the user name from the Kerberos ticket, it sends the Kerberos ticket, along with a request for the database user, to the S-TAP. S-TAP checks to see if there is a Kerberos plugin configured. If there is a Kerberos plugin configured, S-TAP gives the ticket to the plugin and the plugin attempts to figure out DB\_USER from the ticket. It returns the database user name to S-TAP. (If not, then the database user name is not supplied and you do not see database user names in your reports.)
4. The sniffer can now populate the database user for that ticket, and correlate it with the rest of the database activity for that user in the Audit.

- [\*\*Linux-UNIX: Kerberos authentication supported databases\*\*](#)

View the list of database servers that are supported for Kerberos authentication, and whether they require the Kerberos plugin.

- [\*\*Linux-UNIX: Configuring Kerberos by using the setup\\_kerberos.sh script\*\*](#)

Run the setup\_kerberos.sh script to configure and activate Kerberos on your Oracle, Sybase and DB2 databases. The script makes all of the configuration updates in both the database and the S-TAP.

- [\*\*Linux-UNIX: Enabling the Kerberos plugin\*\*](#)

To enable the plugin, edit the guard\_tap.ini configuration file and change the **kerberos\_plugin\_dir** entry to point to the directory where the plugin itself (libguardkerbplugin.so) and the configuration file (guardkerbplugin.conf) are located.

- [\*\*Linux-UNIX: Configuring the Kerberos plugin\*\*](#)

To monitor database traffic on a server that uses Kerberos authentication, including identifying the DB\_USER, you must configure the guardtap.ini and guardkerbplugin.conf files appropriately.

- [\*\*Linux-UNIX: Finding the Kerberos configuration parameters for Oracle\*\*](#)

For Oracle Kerberos, locate the Kerberos keytab and configuration file locations in sqlnet.ora.

- [\*\*Linux-UNIX: Finding the Kerberos configuration parameters for Sybase\*\*](#)

Use the Sybase environment variables to get the Kerberos information.

- [\*\*Linux-UNIX: Merging keytab files\*\*](#)

If you have multiple keytab files (for multiple databases on one host), you can merge the keys. After combining the keytabs, configure the Kerberos plugin to point to the one new combined keytab. Each database continues to use its own individual keytab, not the combined one.

## Linux-UNIX: Kerberos authentication supported databases

View the list of database servers that are supported for Kerberos authentication, and whether they require the Kerberos plugin.

| Database   | Kerberos plugin required? |
|------------|---------------------------|
| Db2        | No                        |
| Oracle     | Yes                       |
| Cassandra  | Yes                       |
| Sybase ASE | Yes                       |
| HBase      | Yes                       |
| MongoDB    | No                        |
| HDFS       | No                        |
| Big SQL    | No                        |
| Hive       | Yes                       |
| Impala     | No                        |

## Linux-UNIX: Configuring Kerberos by using the setup\_kerberos.sh script

Run the setup\_kerberos.sh script to configure and activate Kerberos on your Oracle, Sybase and DB2 databases. The script makes all of the configuration updates in both the database and the S-TAP.

### Before you begin

- Make sure you know the database username.
- Inspection engines must be configured on the databases before you run the script because it scans the database environments.

### About this task

- The setup\_kerberos.sh script is part of the S-TAP installation, and is located in the S-TAP installation directory.
- This script is an alternative to the Kerberos configuration tasks described in [Linux-UNIX: Enabling the Kerberos plugin](#), [Linux-UNIX: Configuring the Kerberos plugin](#), [Linux-UNIX: Finding the Kerberos configuration parameters for Oracle](#), [Linux-UNIX: Finding the Kerberos configuration parameters for Sybase](#).
- The script has these flags:
  - d: disable plugin
  - e: enable plugin
  - s: scan
  - S: scan and update configuration
  - v: verbose
  - h: print this help

## Procedure

---

- Log in to the database server as `root`, and access the S-TAP installation directory.
  - To enable, scan the databases, and enable the configuration, run `setup_kerberos.sh -e enable plugin -s scan -S scan and update configuration`. The script starts to run, and prompts you for the required details.
  - When the script completes without errors, restart the S-TAP.
- 

## Linux-UNIX: Enabling the Kerberos plugin

To enable the plugin, edit the `guard_tap.ini` configuration file and change the `kerberos_plugin_dir` entry to point to the directory where the plugin itself (`libguardkerbplugin.so`) and the configuration file (`guardkerbplugin.conf`) are located.

## Procedure

---

- For a default shell install: `kerberos_plugin_dir=/usr/local/guardium/guard_stap`
  - For a default GIM install: (exact path varies with software release in use)  
`kerberos_plugin_dir=/usr/local/IBM/modules/STAP/current/10.1.3_r101299_1-1495145548`
  - Default (plugin is disabled): `kerberos_plugin_dir=NULL`
- 

## Linux-UNIX: Configuring the Kerberos plugin

To monitor database traffic on a server that uses Kerberos authentication, including identifying the DB\_USER, you must configure the `guardtap.ini` and `guardkerbplugin.conf` files appropriately.

## About this task

---

All customization settings for the Kerberos plugin are located in the file `guardkerbplugin.conf`. The default contents of this file are:

```
Kerberos values
KRB5RCACHETYPE=none
KRB5_KTNAME=/path/to/kerberos/krb5.keytab
KRB5_CONFIG=/path/to/kerberos/krb5.conf
Plugin values
KRB5_PLUGIN_CCACHE=/path/to/kerberos/krb5cc_*
KRB5_PLUGIN_GSSAPI_LIBRARY=/path/to/lib/libgssapi_krb5.so
#KRB5_PLUGIN_DEBUG=0
```

Lines beginning with a #, as well as blank lines, are treated as comments and ignored. Invalid entries cause errors and prevent the Kerberos plugin from running.

When any configuration entry is changed, the S-TAP must be restarted for the updated values to take effect.

Configuration entries are:

**KRB5RCACHETYPE**  
KRB5RCACHETYPE=none  
**KRB5\_KTNAME**  
This is the path to the keytab file; this can either be a keytab file already in use by the system, or one generated by Kerberos utilities specifically for use by the plugin. In general this file will have the name `krb5.keytab`, for example:  
KRB5\_KTNAME=/home/oracle11/krb5/keytab KRB5\_KTNAME=/home/sybase15/kerberos/keytab  
**KRB5\_CONFIG**  
This is the path to the Kerberos configuration file in use by the system. In general this file is named `krb5.conf`, for example:  
KRB5\_CONFIG=/home/oracle11/krb5/krb5.conf KRB5\_CONFIG=/home/sybase15/kerberos/krb5.conf  
**KRB5\_PLUGIN\_CCACHE**  
This is a wildcard path to where the Kerberos system cache files are located. For example:  
KRB5\_PLUGIN\_CCACHE=/tmp/krb5cc\*  
The value can also be a name if it is on the standard lib path, for example:  
KRB5\_PLUGIN\_CCACHE=<library name>.so  
Multiple paths can be specified, separated by a colon (:), for example:  
KRB5\_PLUGIN\_CCACHE=/home/sybase16/krb5cc\*: /tmp/krb5cc\*  
Note: Specifying more files than needed (for instance, specifying `/tmp/*`) impacts performance.  
**KRB5\_PLUGIN\_GSSAPI\_LIBRARY**  
This is the location of the Kerberos GSSAPI dynamic library. On most systems this is named `libgssapi_krb5.so`.  
The location can be specified by a full path, for example:  
KRB5\_PLUGIN\_GSSAPI\_LIBRARY=/usr/lib64/libgssapi\_krb5.so KRB5\_PLUGIN\_GSSAPI\_LIBRARY=/opt/freeware/lib64/libgssapi\_krb5.so  
Alternately, if the library is located on the standard library search path for the system, you can specify only the file name, for example:

KRB5\_PLUGIN\_GSSAPI\_LIBRARY=libgssapi\_krb5.so  
 Note: Any libraries that are needed by the GSSAPI library (typically libkrb5.so, libk5crypto.so, libkrbsupport.so) must also be on the system.  
 Important: If the Kerberos libraries are NOT in the standard library paths, you need to use the parameter KRB5\_PLUGIN\_GSSAPI\_LIBRARY. Uncomment it and update its value with full path of libgssapi\_krb5.so.

KRB5\_PLUGIN\_DEBUG  
 This parameter is used for debugging the plugin only. For normal operation this line must be commented out, or plugin performance is impacted.

## Procedure

---

1. In the guard\_tap.ini file, change the value of kerberos\_plugin\_dir parameter to the full path to the Guardium S-TAP, since that is where the plugin is located.
    - GIM installation: kerberos\_plugin\_dir=<guardium\_base>/modules/STAP/current
    - S-TAP shell installation: kerberos\_plugin\_dir=<guardium\_base>/guard\_stap
  2. Configure these in the guardkerbplugin.conf file that is also located in S-TAP installation directory:
    - KRB5\_KTNAME=<full path to kerberos krb5.keytab file>
    - KRB5\_CONFIG=<full path to kerberos krb5.conf file>
    - Optional parameters as described above. This configuration parameter for ticket cache might be required if the Kerberos plugin does not recognize the user. This parameter accepts wild cards as there is usually more than one cache file. You can specify multiple paths, separated by colons.
    - KRB5\_PLUGIN\_CCACHE=<full path to kerberos krb5cc\_\* files:additional full path to kerberos krb5cc\_\* files:etc>
- Note: In Guardium releases previous to V. 10.1.2, the parameters allow\_weak\_crypto = 1 and clockskew = 600 were required. In most cases these parameters are no longer required

## Linux-UNIX: Finding the Kerberos configuration parameters for Oracle

---

For Oracle Kerberos, locate the Kerberos keytab and configuration file locations in sqlnet.ora.

### About this task

---

## Procedure

---

1. Enter: **grep -i KERBEROS \$ORACLE\_HOME/network/admin/sqlnet.ora**  
 Output is similar to:  

```
SQLNET.AUTHENTICATION_KERBEROS5_SERVICE = oracle
SQLNET.KERBEROS5_CONF = /home/oracle11/krb5/krb5.conf
SQLNET.KERBEROS5_REALMS = /home/oracle11/krb5/krb.realms
SQLNET.AUTHENTICATION_SERVICES= (BEQ,KERBEROS5)
SQLNET.KERBEROS5_CLOCKSKW = 600
SQLNET.KERBEROS5_KEYTAB = /home/oracle11/krb5/keytab
SQLNET.KERBEROS5_CONF_MIT = TRUE
```
2. To find the Kerberos cache parameter, enter: **oklist|grep -i cache**  
 Output is similar to:  

```
Ticket cache: /tmp/krb5cc_500
```

## Linux-UNIX: Finding the Kerberos configuration parameters for Sybase

---

Use the Sybase environment variables to get the Kerberos information.

## Procedure

---

1. Enter: **klist -k**  
 Output is similar to:  

```
env|grep -i KRB
KRB5_KTNAME=/home/sybase15/kerberos/keytab
KRB5_CONFIG=/home/sybase15/kerberos/krb5.conf
```
2. To find the Kerberos cache parameter, enter: **klist -c**  
 Output is similar to:  

```
Ticket cache: FILE:/tmp/krb5cc_533
```

## Linux-UNIX: Merging keytab files

---

If you have multiple keytab files (for multiple databases on one host), you can merge the keys. After combining the keytabs, configure the Kerberos plugin to point to the one new combined keytab. Each database continues to use its own individual keytab, not the combined one.

## Procedure

---

1. Open the MIT Kerberos **ktutil** on your database server.
2. Write the 3 keytabs (filename 1, 2, 3) into the Kerberos V5 keytab file keytab, by entering, for example:

```

> ktutil
ktutil: read_kt <filename 1>
ktutil: read_kt <filename 2>
ktutil: read_kt <filename 3>
ktutil: write_kt krb5.keytab
ktutil: quit

```

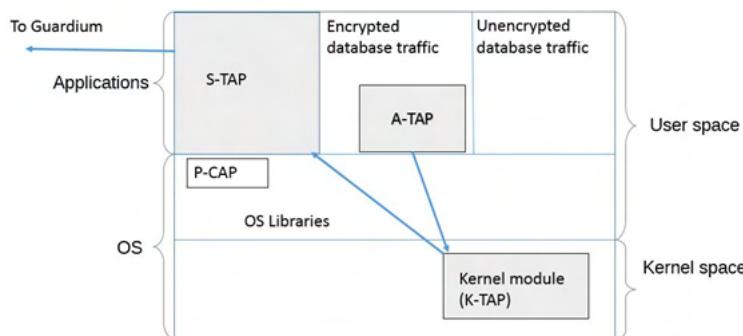

- Configure the Kerberos plugin to point to the one new combined keytab, in this example, **keytab**.

## Linux-UNIX: A-TAP management

A-TAP is an application-level tap. It sits in the application layer to support monitoring of encrypted database traffic, which cannot be done in the kernel by K-TAP.

The A-TAP mechanism monitors communication between internal components of the database server. The data is unencrypted in the application layer, where A-TAP picks it up and sends to K-TAP. K-TAP is a proxy to pass data to S-TAP, and from there it is then sent to the Guardium collector.

This figure shows where A-TAP fits in with the overall architecture on the database server.

A-TAP is included in every S-TAP but must be specifically configured for each database that requires it.

### When to use A-TAP

A-TAP is required when DBMS encryption in motion is used, but there may be other internal database implementation details such as shared memory that require it.

If you have the option, use an exit library instead of A-TAP.

### Limitations:

- A-TAP is not supported in an environment where a 32-bit database is located on a 64-bit server
- For ASO traffic, CLIENT\_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP.
- For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations.
- For SSL traffic, CLIENT\_IP is not the actual client IP and there is no ANALYZED\_CLIENT\_IP.
- If CLIENT\_HOST\_NAME cannot be mapped to one specific network, it cannot be used to differentiate between multiple networks. In this case, ANALYZED\_CLIENT\_IP will not be available. Due to this limitation, use CLIENT\_HOST\_NAME to identify the actual client session.

Attention: The Exit interfaces for Db2® and Informix® are preferred to using A-TAP for Db2 and Informix. The Exit interfaces offer several advantages:

- No need to install or use kernel modules (K-TAP).
- Lower CPU utilization.
- New database versions are supported sooner.

A-TAP for Db2 and Informix are no longer supported starting with Guardium 12.0.

For information about using Db2 Exit, see [Linux-UNIX: Configuring Db2 Exit](#).

For information about using Informix Exit, see [Linux-UNIX: Configuring Informix Exit](#).

**Monitoring restrictions:** See [Guardium support matrix](#) for complete details on what is supported for the various databases and operating systems.

Zones, WPARs, Teradata, and Oracle require additional configuration.
- [Linux-UNIX: Troubleshooting A-TAP configuration issues](#)  
This section summarizes common mistakes made during A-TAP configurations, their symptoms, and how to avoid them.

# Linux-UNIX: Preparing for A-TAP configuration and maintenance

Configuring and maintaining A-TAP requires coordination with both the database and system administrators.

To configure and activate A-TAP, the following authorities are needed:

- Either root access on the database server, or the database user.
- Authority to stop and restart the database

In addition, you must work with the DBA to get the required parameters to input into the utility. Details of the needed parameters are in [Linux-UNIX: Database-specific guardctl parameters](#). For ongoing maintenance, your organization must have documented procedures in place to handle the activation and deactivation of A-TAP during OS and database upgrades. See [Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines](#). For clustered environments, you need to configure and activate A-TAP on all nodes.

In most cases, use the Guardium guardctl utility to activate, upgrade, or deactivate A-TAP. See [Linux-UNIX: guardctl utility commands for A-TAP](#) for details on the syntax and options of the guardctl utility.

Before you begin:

- Make sure that the S-TAP is installed and K-TAP is enabled.
- Ensure that you have the root privileges on the database server.
- Consult [Linux-UNIX: Database-specific guardctl parameters](#) for your database to ensure you have the parameters you need to run the utility.

## Linux-UNIX: A-TAP configuration and activation

Configure and activate each A-TAP.

### About this task

Prerequisite:

- S-TAP and K-TAP are installed.
- If the software is installed with GIM, verify that GIM\_ROOT\_DIR is the absolute path to the modules, for example /usr/local/guardium/modules.
- The user must be authorized for the guardium group. If the guardium group was created in LDAP, then create a local group called guardium with the same group ID (when authorizing the DB user it is added to this group), OR add the guardium group ID (GID) to the DB user in /etc/passwd. For a shell installation, if the inspection engine db\_user is specified, then you don't need to authorize the user even in an LDAP environment.

There are two methods of managing your A-TAPs: either as user root for all functions, or as a db user. The db user option can configure, activate, deactivate, and instrument A-TAP, but cannot perform all functions. This means that the non-root user can handle day to day activities of the A-TAP, without requiring the root user. The guardctl help window lists the permitted commands for the logged-in user. The functionality is:

- When activating an A-TAP instance not as root, the current user must be the db\_user specified in the instance configuration, and must be specified as the db\_user for the matching inspection engine in the S-TAP configuration.
- A non-root user cannot manage (configure, active, deactivate, and instrument) an A-TAP instance that was initially configured by the root user.
- The root user can activate and deactivate a non-root created A-TAP instance, but must specify the instance name as \${DB\_USER}/\${DB\_INSTANCE}

Authorizing the user is optional. If you have db\_user specified in the guard\_tap.ini, you don't need to authorize the user, but you still may. If db\_user is not specified in the guard\_tap.ini, you must authorize the user and cannot perform any actions as non-root with guardctl.

### Procedure

1. Verify ktp\_installed=1 in the guard\_tap.ini file.
2. Log off from all active database sessions and stop the database. It is very important that all processes with database admin user are stopped. For example, on oracle, issue **ps -ef | grep oracle**

3. As root user, authorize the database administrative user to log traffic using the guardctl utility with the authorize-user command:  
`<guardium_base>/xxx/guardctl authorize-user <user-name>`

```
shell installer with postgres authorize user
/usr/local/guardium/guard_stap/guardctl authorize-user postgres Authorizing user 'postgres' to log traffic
shell installer with postgres verify authorization
/usr/local/guardium/guard_stap/guardctl is_user_authorized postgres User 'postgres' is authorized.
GIM installation with postgres authorize user
/usr/local/guardium/modules/ATAP/current/files/bin/guardctl authorize_user postgres Authorizing user 'postgres' to log traffic
shell installer example with Greenplum authorize user
/usr/local/guardium/guard_stap/guardctl authorize-user <gpadmin> Authorizing user '<gpadmin>' to log traffic
```

Note: If you're using MongoDB, restart the **mongod-mms-auto** process.

4. Store the configuration parameters:

- a. See [Linux-UNIX: Database-specific guardctl parameters](#) to determine the parameters needed for your database type and platform.
- b. Store configuration for the database instance using the store-conf command of the guardctl utility as follows.

```
<guardium_base>/xxx/guardctl db_instance=<instance> [<name>=<value> ...] store-conf
```

For example:

```
shell installer Oracle on Linux store-conf
/usr/local/guardium/guard_stap/guardctl --db-user=oracle11 --db-type=oracle --db-instance=on12rh60 --db-home=/home/oracle11/product/11.1.0/db_1 --db-version=11.2 store-conf
GIM installation Oracle on Linux store-conf
```

```

/usr/local/guardium/modules/ATAP/current/files/bin/guardctl db_instance=$ORACLE_SID db_home=$ORACLE_HOME db_type=oracle
db_user=oracle12 db_version=12 store-conf
shell installer Greenplum on Linux store-conf
/usr/local/guardium/guard_stap/guardctl --db-user=<gpadmin> --db-type=greenplum -db-home=<db_user home directory> --db-
instance=<greenplum> --db-base=<db_user home directory> store-conf

```

Note: Instrumentation is done automatically during activate; there is no explicit instrumentation.

#### 5. Activate A-TAP.

a. Enter <guardium\_base>/xxx/guardctl db\_instance=<instance> activate

```

shell installer Oracle on Linux activate
/usr/local/guardium/guard_stap/guardctl --db-instance=onrh60x activate
GIM installation Oracle on Linux activate
/usr/local/guardium/modules/ATAP/current/files/bin/guardctl --db-instance=onrh60x activate
shell installer Greenplum on Linux activate
/opt/guardium/guard_stap/guardctl --db-type=greenplum --db-home=/usr/local/greenplum-db-4.3.4.0 --db-user=gpadmin
--db-instance=greenplum --db-base=<db_user home directory> activate

```

You can activate and deactivate A-TAP by using the Encryption checkbox of the inspection engine configuration in the Guardium GUI, though there are no advantages to activating it in the GUI. This option is not available for Linux platforms.

b. Confirm that the instances are activated using the list-active command of the guardctl utility: <guardium\_base>/xxx/guardctl list-active

Example: <guardium\_base>/xxx/guardctl list-active oracle

#### 6. Start the database server.

#### 7. For SAP IQ (Sybase) 16.1 SP04 and higher, take the following steps to enable retrieval of the database user before you activate the A-TAP.

a. Create a stored procedure that calls the function 'guard' in the SybaseIQ ATAP library:

```
(DBA)> create or replace procedure CGuard (in p1 long varchar, in p2 long varchar) external name
'guard@/usr/lib64/libguard-atap-sybaseiq-any-64.so'
```

If the GNU C library (glibc) is lower than version 2.34, test that the call succeeds by executing the following command and verifying that it doesn't report an error. You can ignore the error messages if glibc is equal to or greater than version 2.34.

```
(DBA)> call CGuard(connection_property('UserID'),connection_property('Number'))
```

b. Create a login procedure:

```
(DBA)> create or replace procedure dba.login_msg_user() begin call dbo.sp_login_environment; call
CGuard(connection_property('UserID'),connection_property('Number')); end
```

c. Grant execute permissions to PUBLIC for the login procedure:

```
(DBA)> grant execute on DBA.login_msg_user to PUBLIC
```

d. Set the login procedure to execute for PUBLIC:

```
(DBA)> set option PUBLIC.login_procedure='DBA.login_msg_user'
```

Tip: After you activate the A-TAP, use the `ps -ef | grep dataserver` command to report on the running Sybase process (rather than `showserver`).

## Linux-UNIX: A-TAP activate, deactivate and DB stop, restart guidelines

Understand when to activate and deactivate A-TAP, and stop or restart the DB.

Restart/load/activated requirements for A-TAP.

| Scenario                                                       | Instructions                                                                    |
|----------------------------------------------------------------|---------------------------------------------------------------------------------|
| After installation of UNIX A-TAP in Oracle cluster environment | All database instances as well as all inter-cluster processes must be restarted |
| Before activating A-TAP                                        | Stop database                                                                   |
| After activating A-TAP                                         | Restart database                                                                |
| Before deactivating A-TAP                                      | Stop database                                                                   |
| Before upgrading database (for example applying Fixpack)       | Deactivate A-TAP                                                                |
| Before upgrading S-TAP                                         | Deactivate A-TAP                                                                |
| Before uninstalling S-TAP                                      | Deactivate A-TAP                                                                |

## Linux-UNIX: guardctl utility commands for A-TAP

The guardctl utility is the A-TAP management tool. Understand these commands before starting to work with A-TAPs.

### guardctl utility

There are two methods of managing your A-TAPs: either as user root for all functions, or as a db user. The db user option can configure, activate, deactivate, and instrument A-TAP, but cannot perform all functions. This means that the non-root user can handle day to day activities of the A-TAP, without requiring the root user. The guardctl help window lists the permitted commands for the logged-in user. The functionality is:

- When activating an A-TAP instance not as root, the current user must be the db\_user specified in the instance configuration, and must be specified as the db\_user for the matching inspection engine in the S-TAP configuration.
- A non-root user cannot manage (configure, active, deactivate, and instrument) an A-TAP instance that was initially configured by the root user.

- The root user can activate and deactivate a non-root created A-TAP instance, but must specify the instance name as \${DB\_USER}/\${DB\_INSTANCE}

Authorizing the user is optional. If you have db\_user specified in the guard\_tap.ini, you don't need to authorize the user, but you still may. If db\_user is not specified in the guard\_tap.ini, you must authorize the user and cannot perform any actions as non-root with guardctl.

The guardctl utility is installed under <guardium\_base>/guard\_stap directory where <guardium\_base> is the directory where Guardium® software is installed. In the case of a GIM installation guardctl it is installed under <guardium\_base>/modules/ATAP/current/files/bin.

#### Syntax

```
<guardium_base>/xxx/guardctl [<parameter>=<value>] [<parameter>=<value> ...] <command> [-q | -v | -qv]
```

See parameters in [Linux-UNIX: Database-specific guardctl parameters](#).

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

## -q, -v, -qv flags

Use these flags to manage the output:

- q (quiet): suppress all output except name/value pairs
- v (value pairs): add name/value pairs related to each command
- qv: outputs name/value pairs only

The output depends on the type of command.

- Commands that take action across all configured instances
  - Print all name/value pairs for each instance except overall\_rv and overall\_msg
  - Print overall\_rv name/value pair at end where value is
    - 0 (success) if and only if all report success
    - 1 (failure) if any report any failure
  - Print overall\_msg name/value pair at end
  - Returns the value reported in the "overall\_rv" name/value pair
- Commands that take action on a single instance
  - Print all name/value pairs except overall\_rv and overall\_msg
  - Returns the value reported in the "rv" name/value pair
- Commands that store parameters, print parameters, or check status
  - Does not print name/value pairs

Name/Value pairs output looks like:

```
db_instance: ${db_instance}
db_user: ${db_user}
db_base: ${db_base}
db_home: ${db_base}
db_version: ${db_version}
db_type: ${db_type}
is_active: ${is_active} ("yes" or "no")
is_instrumented: ${is_db_instrumented} ("yes" or "no")
msg: some string
rv: ${retval}
overall_rv: ${retval}
overall_msg: (string)
```

## commands

| Command        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| activate       | Activates A-TAP for the specified database instance using the stored parameters. Outputs Name/Value pairs if -v or -qv specified. Activating an instance that's already active (whether DB is running or not) does not generate an error.                                                                                                                                                                                                                                     |
| authorize-user | Adds the user to 'guardium' authorization group.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| db_console_log | Enables the A-TAP console log. Valid values: <ul style="list-style-type: none"> <li>0: disable, log only error level info</li> <li>1: enable</li> </ul> Default = 0                                                                                                                                                                                                                                                                                                           |
| deactivate     | Deactivates the A-TAP for the specified, single database instance. Outputs Name/Value pairs if -v or -qv specified. Deactivating an instance that's already inactive (whether DB is running or not) does not generate an error.                                                                                                                                                                                                                                               |
| deactivate-all | Deactivates A-TAP for a specified list of database instances. If no database instances are specified, all active A-TAPs are deactivated. Outputs Name/Value pairs for each instance, if -v or -qv specified. You can optionally specify the db-type to deactivate a group (e.g. all Oracle). For additional name/value pair, specify "overall_rv={0,1}" at end. Returns success (0) if rv=0 for every instance. Returns failure (1) if at least one instance reports rv != 0. |
| deinstrument   | Removes instrumentation for the specified Oracle DB. Not required from v10.1 and higher. If deinstrumentation is required, it is done automatically during deactivate. Outputs Name/Value pairs if -v or -qv specified. Deinstrumenting an instance that is not instrumented does not generate an error, even if the is DB running, regardless of activation status.                                                                                                          |
| dump-params    | Dumps current values of parameters                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| get-statistics | Get A-TAP statistics. Statistics includes information about which ATAPs are active, which are inactive, and which are in an incorrect in-between state (this shouldn't happen, it usually occurs when someone updates the DB while ATAP is active).                                                                                                                                                                                                                           |
| help           | Default command, prints the list of supported commands, parameters and their default values. Use this to see which commands you can execute, depending on your user type.                                                                                                                                                                                                                                                                                                     |
| instrument     | Explicitly creates relinked instrumented Oracle. If instrumentation is required, it is usually done automatically during activate. Manual instrumentation is only required for Oracle versions <= 10 on AIX. Instrumenting an already instrumented instance returns an error. Outputs Name/Value pairs if -v or -qv specified.                                                                                                                                                |

| Command              | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| is-active            | Returns 1 if there is at least one A-TAP activated instance. Otherwise, returns 0.                                                                                                                                                                                                                                                                                                 |
| is-user-authorized   | Checks whether the db-user (running A-TAP) is authorized to the guardium group, and can log database traffic to K-TAP/S-TAP.                                                                                                                                                                                                                                                       |
| list-active          | Lists database instance user names of all active A-TAP database instances. Outputs Name/Value pairs if -v or -qv specified.                                                                                                                                                                                                                                                        |
| list-configured      | Lists database instances with configured but inactive A-TAPs. Outputs Name/Value pairs if -v or -qv specified.                                                                                                                                                                                                                                                                     |
| oracle-relink        | Calls the utility provided by oracle to relink the DB binary.                                                                                                                                                                                                                                                                                                                      |
| prepare-libs         | Prepares libraries for use in Zone/WPAR installation                                                                                                                                                                                                                                                                                                                               |
| repair               | Run this command if the DB is (accidentally) upgraded while the A-TAP is active. It renames the -guard-original and -guard-instrumented files. Returns success on successful repair or if repair is not necessary. Does not touch the current DB executable. Outputs Name/Value pairs if -v or -qv specified. From v10.1.4, it is called automatically on activate and deactivate. |
| restore-active-ataps | Restores the active state of the A-TAPs previously saved via save-active-ataps. If an instance fails to activate (due to DB running or some other error), then the remaining instances still attempt to activate. This command can be run multiple times without problem, since activating an already active instance is not an error.                                             |
| save-active-ataps    | Saves the configurations for the currently active A-TAPs in a single file so that they can be restored later to an active state. Useful prior to deactivate-all when preparing to upgrade DBs.                                                                                                                                                                                     |
| store-conf           | Stores the configuration for a particular database instance                                                                                                                                                                                                                                                                                                                        |
| store-system-conf    | Stores the system configuration parameters                                                                                                                                                                                                                                                                                                                                         |

## Linux-UNIX: guardctl return codes

The guardctl error codes clarify error conditions that occur, in particular, when you are call the guardctl script to manage ATAP instances via another script.

| Code | Description                                                                                                   | Usage                                                                                                                                                                                                                                                              |
|------|---------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | success                                                                                                       | Returned by every command.<br>When returned in response to deactivate, all instances are deactivated<br>When returned in response to is-active, there are no active instances                                                                                      |
| 1    | bad parameter                                                                                                 | Returned by every command when a parameter is invalid or missing                                                                                                                                                                                                   |
| 2    | is-active called on unrecognized instance                                                                     | Returned by is-active when a db-instance specified is not known to guardctl and as such cannot be determined to be active or not                                                                                                                                   |
| 20   | attempted to activate instance while database was running, but not yet active                                 | Returned by activate to indicate that the DB instance is running, so activation could not take place                                                                                                                                                               |
| 21   | attempted to deactivate instance while database was running, but not yet inactive                             | Returned by deactivate to indicate that the DB instance is running, so deactivation could not take place                                                                                                                                                           |
| 22   | user is not authorized                                                                                        | Returned by instrument and activate to indicate that the db-user specified is not authorized as a member of the 'guardium' group. Run authorize-user to correct.                                                                                                   |
| 23   | db-home parameter doesn't match db_install_dir parameter in guard_tap.ini                                     | Returned by store-conf and activate to indicate that the current guard_tap.ini doesn't have an IE configured with a db_home that matches the db_install_dir ATAP parameter. One of those needs to be adjusted to the correct value or STAP may not run.            |
| 24   | attempt to deactivate an instance where the executable is neither an ATAP executor or the instrumented binary | Returned by deactivate. This instance looks like it should be activated, but the binary isn't what it should be if it is. DB executable could have been updated while ATAP was active. Run the repair command to fix the issue and activate again.                 |
| 25   | attempt to activate atap when encryption=1 set in guard_tap.ini                                               | Returned by activate when the encryption parameter is set to 1 in the IE. Do not activate with guardctl and use the encryption parameter in the ini.                                                                                                               |
| 26   | db executable file not found                                                                                  | Returned by activate, deactivate, instrument, deinstrument, store-conf, prepare-libs, and repair. The DB executable is missing (e.g. the oracle binary itself is not in the path specified). Check the path parameters used when configuring the instance.         |
| 27   | instrumentation required but not done                                                                         | Returned by activate and store-conf when instrumentation is required, but has not already been done. Oracle instrumentation is now automatically done in most cases, but still needs to be manually specified for AIX and Oracle versions <= 10.                   |
| 28   | is-active reports instance is not active                                                                      | Returned by is-active. Informational only. The db-instance specified is not active or if no instances were specified, no instances are active.                                                                                                                     |
| 29   | deactivate-all not complete success                                                                           | Returned by deactivate-all when at least one active instance could not be deactivated.                                                                                                                                                                             |
| 30   | is-instrumented reports instance is not instrumented                                                          | Not exported via command.                                                                                                                                                                                                                                          |
| 40   | internal instrumentation error                                                                                | Returned by instrument when instrumentation couldn't be completed.                                                                                                                                                                                                 |
| 41   | internal instrumentation error                                                                                | Returned by instrument when instrumentation couldn't be completed.                                                                                                                                                                                                 |
| 42   | internal instrumentation error                                                                                | Returned by instrument when instrumentation couldn't be completed.                                                                                                                                                                                                 |
| 43   | instrumentation error, cannot save original binary                                                            | Returned by instrument when the -guard-original file already exists. Either A-TAP is currently active with instrumentation, or A-TAP is inactive but the instrumentation is still active. Deactivate and deinstrument before subsequent instrument and activate.   |
| 44   | attempt to instrument while instance running and not already instrumented                                     | Returned by instrument when DB instance is currently running. Stop DB instance before attempting to instrument again.                                                                                                                                              |
| 45   | attempt to instrument while A-TAP is active and not already instrumented                                      | Returned by instrument when A-TAP is already active, but instrumentation is not active. This can happen when switching from an Oracle configuration that doesn't require instrumentation to one that does. Deactivate A-TAP before attempting to instrument again. |
| 46   | attempt to instrument and already instrumented instance                                                       | Returned by instrument while instance is already instrumented. If instrumentation needs to be redone, deinstrument first.                                                                                                                                          |

| Code | Description                                                                                                                | Usage                                                                                                                                                                                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 93   | unspecified error due to DB running not when activating, deactivating, or instrumenting (e.g. when running repair command) |                                                                                                                                                                                                                                                                          |
| 94   | no atap library supporting this db                                                                                         | Returned by instrument, deinstrument, prepare-libs, activate, deactivate, repair, list-active, and list-configured. Usually indicates that an unknown error occurred.                                                                                                    |
| 95   | system error, cannot find group                                                                                            | Returned by activate. The guardium group doesn't appear to be known to this system.                                                                                                                                                                                      |
| 96   | system error, cannot create group                                                                                          | Returned by authorize-user. The guardium group did not exist and an attempt to create the group failed.                                                                                                                                                                  |
| 97   | filesystem error, cannot create directory or file, or insufficient space detected                                          |                                                                                                                                                                                                                                                                          |
| 98   | platform unsupported                                                                                                       | Returned by instrument, deinstrument, prepare-libs, activate, deactivate, repair, list-active, list-configured, store-conf. The DB you're trying to use with ATAP is not supported on this platform (e.g. DB2, Informix, teradata, or mongo on anything but Linux, etc). |
| 99   | other unspecified error                                                                                                    |                                                                                                                                                                                                                                                                          |

## Linux-UNIX: Database-specific guardctl parameters

Each database type has specific guardctl requirements.

- [Linux-UNIX: Db2-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Db2 database, Linux only.
- [Linux-UNIX: Informix-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Informix database.
- [Linux-UNIX: Greenplum-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Greenplum database.
- [Linux-UNIX: Mongo-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a MongoDB database.
- [Linux-UNIX: Oracle-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for an Oracle database.
- [Linux-UNIX: Postgres-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Postgres database.
- [Linux-UNIX: Sybase-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Sybase database.
- [Linux-UNIX: Sybase IQ-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Sybase database.
- [Linux-UNIX: Teradata-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Teradata database.
- [Linux-UNIX: Vertica-specific guardctl parameters](#)  
Use these guardctl parameters when configuring A-TAP for a Vertica database.

## Linux-UNIX: Db2-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Db2 database, Linux only.

### Db2 (Linux only) required parameters

**Example:**

```
/usr/local/guardium/guard_stap/guardctl --db-user=db2inst1 --db-type=db2 --db-instance=dn0rh7x6 --db-version=10.5 store-conf
```

The script **find\_db2\_shmem\_parameters.sh**, located in `stap_directory/bin`, outputs what the Db2 shared memory parameters defined in the Inspection Engines should be. Execute it either as root or Db2 user, using the syntax: **find\_db2\_shmem\_parameters.sh <instance name>**. You can run it from any directory.

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                | How to determine                    |
|--------------------|----------------------|-------------------------------------|
| db_user            | Db2 username         | Points to the DB instance user name |
| db_instance        | Db2 instance name    | \$ db2 LIST DATABASE DIRECTORY      |
| db_type            | db2                  |                                     |
| db_version         | The database version | As Db2 user: \$ db2level            |

### Db2 (Linux only) optional parameters

| Optional Parameter | Value                                  | How to determine                                                                                      | When is it required                                               |
|--------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| db_home            | Path where the DB version is installed | Same as db_base                                                                                       |                                                                   |
| db_base            | Database instance user home directory  | Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Where db_base is not same as db_home                              |
| db_bits            | 32 or 64                               | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                               | Required only if A-TAP is not able to recognize the architecture. |

| Optional Parameter | Value  | How to determine                     | When is it required                          |
|--------------------|--------|--------------------------------------|----------------------------------------------|
| db2_shmsize        | 131072 | Db2 shared memory size               | When the value is different than the default |
| db2_c2soffset      | 61440  | Db2 shared memory client area offset | When the value is different than the default |
| db2_header_offset  | 20     | Db2 shared memory header offset      | When the value is different than the default |

## Linux-UNIX: Informix-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Informix database.

### Informix required parameters

**Example:**

```
/usr/local/guardium/guard_stap/guardctl --db-user=informix --db-type=informix --db-instance=in17rh7x --db-version=11.70 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                  | How to determine                    |
|--------------------|------------------------|-------------------------------------|
| db_user            | Informix username      | Points to the DB instance user name |
| db_instance        | Informix instance name | Informix Server instance name       |
| db_type            | informix               |                                     |
| db_version         | The database version   | As Informix user: dbaccess -V       |

### Informix optional parameters

| Optional Parameter | Value                                       | How to determine                                                                                                                       | When is it required                  |
|--------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| db_home            | Points to where the DB version is installed | Same as db_base                                                                                                                        |                                      |
| db_base            | Home directory of db_user                   | DB instance user home directory. Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Where db-base is not same as db-home |
| db_bits            | 32 or 64                                    | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                |                                      |

## Linux-UNIX: Greenplum-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Greenplum database.

Important: When A-TAP is configured, blocking (S - GATE) and redaction are not supported.

### Greenplum required parameters

**Example:**

```
/opt/guardium/guard_stap/guardctl --db-type=greenplum --db-home=/usr/local/greenplum-db-4.3.4.0 --db-user=gpadmin --db-instance=greenplum --db-base=/usr/local/greenplum-db-4.3.4.0 activate
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                                 | How to determine                                                                                                                                                                                           |
|--------------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_base            | Database instance user home directory | Required when db_user is different than the OS user for the DB. In this case, the db_base value should be set also in the guard_tap.ini parameter db_install_dir, for the corresponding Inspection Engine. |
| db_home            | Path where the database is installed. |                                                                                                                                                                                                            |
| db_instance        | Greenplum instance name               | User-defined string that identifies this instance                                                                                                                                                          |
| db_type            | Greenplum                             |                                                                                                                                                                                                            |
| db_user            | Greenplum user name                   | OS user for the database .or user that owns the process for the database executable                                                                                                                        |

## Linux-UNIX: Mongo-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a MongoDB database.

Important: When A-TAP is configured, blocking (S - GATE) and redaction are not supported.

### Mongo required parameters

**Example:**

```
/opt/guardium/guard_stap/guardctl --db-type=mongodb --db-instance=mongodb36 --db-user=mongodb36 --db-base=/home/mongodb36 --db-home=/home/mongodb36/mongodb-linux-x86_64-enterprise-rhel62-3.6.5 activate
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                                                                                                                         | How to determine                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_base            | Database instance user home directory                                                                                         | Required when db_user is different than the OS user for the DB. In this case, the db_base value should be set also in the guard_tap.ini parameter db_install_dir, for the corresponding Inspection Engine. |
| db_home            | Path where the database is installed.                                                                                         |                                                                                                                                                                                                            |
| db_instance        | MongoDB instance name                                                                                                         | User-defined string that identifies this instance                                                                                                                                                          |
| db_type            | <ul style="list-style-type: none"> <li>• Servers running mongod: mongodb</li> <li>• Servers running mongos: mongos</li> </ul> |                                                                                                                                                                                                            |
| db_user            | MongoDB user name                                                                                                             | OS user for the database .or user that owns the process for the database executable                                                                                                                        |

## Linux-UNIX: Oracle-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for an Oracle database.

**Example:**

```
/usr/local/guardium/guard_stap/guardctl --db-user=oracle11 --db-type=oracle --db-instance=on12rh60 --db-home=/home/oracle11/product/11.1.0/db_1 --db-base=/home/oracle11 --db-version=11.2 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

## Oracle required parameters

| Required Parameter | Value                                                                 | How to determine                                                                                                                       |
|--------------------|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| db_user            | Oracle user name                                                      | Use the database instance user name.                                                                                                   |
| db_instance        | Oracle instance name                                                  | Use the value from \$ORACLE_SID                                                                                                        |
| db_type            | Oracle                                                                |                                                                                                                                        |
| db_home            | DB HOME. for example \$ORACLE_HOME                                    | DB admin has these details.                                                                                                            |
| db_base            | Database instance user home directory (Database owner home directory) | DB owner \$HOME (~DB_USER), and must match db_install_dir in the corresponding Inspection Engine. See <a href="#">db_install_dir</a> . |
| db_version         | The database version                                                  | Run SQL > SELECT * FROM V\$VERSION                                                                                                     |

## Oracle optional parameters

| Optional Parameter  | Value    | How to determine                                                                                                   | When is it required                                                                                                                                                                                                                                                                                                                                     |
|---------------------|----------|--------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_relink           | No/yes   | A-TAP activation method                                                                                            |                                                                                                                                                                                                                                                                                                                                                         |
| db_use_instrumented | No/yes   | A-TAP activation uses a relinked version of Oracle previously created with the <b>guardctl instrument</b> command. | <p>Instrumentation is required for:</p> <ul style="list-style-type: none"> <li>• Oracle 12 and later SSL for all non-Windows platforms</li> <li>• Oracle SSL on AIX</li> <li>• Oracle ASO prior to Oracle 11.2 on AIX</li> </ul> <p>Instrumentation is automatic when Oracle is linked from the <b>activate</b> command or through the Guardium UI.</p> |
| db_bits             | 32 or 64 | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                            | Required only if A-TAP is not able to recognize the architecture.                                                                                                                                                                                                                                                                                       |

## Linux-UNIX: Postgres-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Postgres database.

## Postgres required parameters

**Example:**

```
/usr/local/guardium/guard_stap/guardctl --db-user=postgres --db-type=postgres --db-instance=guardium_qa --db-version=9.4 --db-base=/home/postgres94 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value             | How to determine                    |
|--------------------|-------------------|-------------------------------------|
| db-user            | Postgres username | Points to the DB instance user name |

| Required Parameter | Value                  | How to determine                      |
|--------------------|------------------------|---------------------------------------|
| db_instance        | Postgres instance name | Postgres Server instance name         |
| db_type            | postgres               |                                       |
| db_version         | The database version   | As Postgres user:<br>pg_ctl --version |

## Postgres optional parameters

| Optional Parameter | Value                                       | How to determine                                                                                                                       | When is it required                  |
|--------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| db_home            | Points to where the DB version is installed | Same as db_base                                                                                                                        |                                      |
| db_base            | Home directory of db_user                   | DB instance user home directory. Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Where db-base is not same as db-home |
| db_bits            | 32 or 64                                    | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                |                                      |
| db_tcp_min_port    | 0 to any integer                            | Low end of TCP port range to intercept                                                                                                 | Using Real IPs                       |
| db_tcp_max_port    | 0 to any integer                            | High end of TCP port range to intercept                                                                                                | Using Real IPs                       |

## Linux-UNIX: Sybase-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Sybase database.

## Sybase required parameters

### Example:

```
/usr/local/guardium/guard_stap/guardctl --db-user=sybase15 --db-type=sybase --db-instance=sn57rh7x --db-version=15 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                                     | How to determine                                                                               |                                                                                                                                                                                                           |
|--------------------|-------------------------------------------|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_home            | Points to where the database is installed | Same as db_base                                                                                | The basis for how we look for the DB binary. It can usually use the value of db_base, though it's immediately apparent when activating if it's wrong (guardctl complains about not finding the DB binary) |
| db_instance        | Sybase instance name                      | Sybase Server instance name. This parameter is used to name the ATAP instance within guardctl. |                                                                                                                                                                                                           |
| db_tcp_max_port    | 0 to any integer                          | High end of TCP port range to intercept. Use real IPs.                                         |                                                                                                                                                                                                           |
| db_tcp_min_port    | 0 to any integer                          | Low end of TCP port range to intercept. Use real IPs.                                          |                                                                                                                                                                                                           |
| db_type            | sybase                                    |                                                                                                |                                                                                                                                                                                                           |
| db_user            | Sybase user name                          | The database instance user name. Use the value of the guard_tap.ini parameter: db_user         |                                                                                                                                                                                                           |
| db_version         | The database version                      | As Sybase user:<br>> select @@version<br>> go                                                  |                                                                                                                                                                                                           |

## Sybase optional parameters

| Optional parameter           | Value                                 | How to determine                                                                                                                                                  | When is it required                                                                                                                                                                                                                                                                                                                        |
|------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_base                      | Database instance user home directory | DB instance user home directory. this needs to match db_install_dir in some IE in the guard_tap.ini. Do not use the ~DB_USER shortcut, use the full path instead. | If you aren't specifying db_home separately, use the value for db_base as the value for db_home.                                                                                                                                                                                                                                           |
| db_bits                      | 32 or 64                              | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                                           | Required only if A-TAP is not able to recognize the architecture.                                                                                                                                                                                                                                                                          |
| -db-tcp-intercepted-ports    | 0 to any integer                      | TCP ports to intercept                                                                                                                                            | Specifies whether you want the real IP reported for encrypted sessions. There are potential performance impacts in this mode, and an added complication to the A-TAP setup by specifying this port. Leave blank to use the non-specific IP mode. This parameter is mutually exclusive with db_tcp_min_port and db_tcp_max_port parameters. |
| db-tcp-max-associate-time-ms | 1 to any integer                      |                                                                                                                                                                   | Ensure this parameter has a value. Otherwise it might drop some database connections for concurrent sessions. Default = 2500                                                                                                                                                                                                               |

## Linux-UNIX: Sybase IQ-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Sybase database.

### Sybase IQ required parameters

#### Example:

```
/usr/local/guardium/guard_stap/guardctl --db-user=sybase --db-type= sybaseiq --db-instance= sybaseiq --db-version=16.1 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                | How to determine                                                                                                                                                                             |
|--------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_instance        | Sybase instance name | Sybase Server instance name (could be any name to identify the environment)                                                                                                                  |
| db_type            | sybaseiq             |                                                                                                                                                                                              |
| db_user            | Sybase user name     | The Sybase IQ account owner                                                                                                                                                                  |
| db_version         | The database version | As Sybase user:<br><br><pre>\$ start_iq -v<br/>SAP IQ/16.1.040.1175/12886/P/SP04.02/Linux/Linux64 - x86_64 - 3.10.0-327/64bit/2019-09-24<br/>17:40:48<br/>[sybiq16@rh7u5x64t-ktap ~]\$</pre> |
| db_tcp_max_port    | 0 to any integer     | High end of TCP port range to intercept. Use real IPs.                                                                                                                                       |
| db_tcp_min_port    | 0 to any integer     | Low end of TCP port range to intercept. Use real IPs.                                                                                                                                        |

### Sybase IQ optional parameters

| Optional Parameter           | Value                                     | How to determine                                                                                                                       | When is it required                                                                                                                                                                                                                                                                                                                        |
|------------------------------|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_home                      | Points to where the database is installed | <b>echo \$SYBASE</b> or <b>echo \$SYBROOT</b> from Sybase IQ user environment                                                          | Where db-home is not in the same path as DB user HOME directory                                                                                                                                                                                                                                                                            |
| db_base                      | Home directory of db_user                 | DB instance user home directory. Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Should match value for db_install_dir for corresponding Inspection Engine in guard_tap.ini                                                                                                                                                                                                                                                 |
| db_bits                      | 32 or 64                                  | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                |                                                                                                                                                                                                                                                                                                                                            |
| -db-tcp-intercepted-ports    | 0 to any integer                          | TCP ports to intercept                                                                                                                 | Specifies whether you want the real IP reported for encrypted sessions. There are potential performance impacts in this mode, and an added complication to the A-TAP setup by specifying this port. Leave blank to use the non-specific IP mode. This parameter is mutually exclusive with db_tcp_min_port and db_tcp_max_port parameters. |
| db-tcp-max-associate-time-ms | 1 to any integer                          |                                                                                                                                        | Ensure this parameter has a value. Otherwise it might drop some database connections for concurrent sessions. Default = 2500                                                                                                                                                                                                               |

## Linux-UNIX: Teradata-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Teradata database.

### Examples of commands

Store A-TAP configuration:

```
/usr/local/guardium/guard_stap/guardctl --dbinstance=teradata --tdc_gtwgateway=/usr/tgtw/bin/gtwgateway --db-type=teradata --db-home=/opt/teradata/tdat/pde/15h.00.00.07 --dbuser=teradata store-conf
```

Activate A-TAP:

```
/usr/local/guardium/guard_stap/guardctl -db instance=teradata activate
```

Start Teradata instance:

```
/etc/init.d/tpa start
Teradata Database Initiator service is starting...
Teradata Database Initiator service started successfully.
/etc/init.d/tgtw start
tgtw Startup complete
```

### Teradata required parameters

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                                                                                                                                                         | How to determine                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| db_instance        | typically teradata                                                                                                                                            | Teradata Server instance name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| db_home            | Points to where the DB version is installed, one of: <ul style="list-style-type: none"><li>• /opt/teradata/tdat/pde/15h.00.00.07</li><li>• /usr/pde</li></ul> | Determine the path to pdomain. | tdc_gtwgateway     | /usr/tgtw/bin/gtwgateway                                                                                                                                      | Default path to gtwgateway is /usr/tgtw/bin/gtwgateway, otherwise the tdc_gtwgateway parameter should be configured: --tdc_gtwgateway=/usr/tgtw/bin/gtwgateway                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Teradata optional parameters

| Optional Parameter | Value                     | How to determine                                                                                                                       | When is it required                  |
|--------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| db_base            | Home directory of db_user | DB instance user home directory. Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Where db_base is not same as db_home |
| db_bits            | 32 or 64                  | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                |                                      |

## Linux-UNIX: Vertica-specific guardctl parameters

Use these guardctl parameters when configuring A-TAP for a Vertica database.

## Vertica required parameters

### Example:

```
/usr/local/guardium/guard_stap/guardctl --db-user=vertica --db-type=vertica --db-instance=guardium_qa --db-version=9.4 --db-base=/home/vertica94 store-conf
```

Note: Hyphen and underscore are interchangeable in the guardctl parameters.

| Required Parameter | Value                 | How to determine                     |
|--------------------|-----------------------|--------------------------------------|
| db_user            | vertica username      | Points to the DB instance user name  |
| db_instance        | Vertica instance name | Vertica Server instance name         |
| db_type            | vertica               |                                      |
| db_version         | The database version  | As Vertica user:<br>pg_ctl --version |

## Vertica optional parameters

| Optional Parameter | Value                                       | How to determine                                                                                                                       | When is it required                  |
|--------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| db_home            | Points to where the DB version is installed | Same as db_base                                                                                                                        |                                      |
| db_base            | Home directory of db_user                   | DB instance user home directory. Value for db_base must match the correct path DB instance user home directory. It cannot be ~DB_USER. | Where db-base is not same as db-home |
| db_bits            | 32 or 64                                    | DB instance architecture (32 for 32-bit, 64 for 64-bit)                                                                                |                                      |
| db_tcp_min_port    | 0 to any integer                            | Low end of TCP port range to intercept                                                                                                 | Using Real IPs                       |
| db_tcp_max_port    | 0 to any integer                            | High end of TCP port range to intercept                                                                                                | Using Real IPs                       |

## Linux-UNIX: Deactivating A-TAP

You must deactivate A-TAP before upgrading the database OS. You also need to deactivate the ATAPs before upgrading or uninstalling STAP (whether or not it's installed via GIM, RPM, or shell installer).

## About this task

---

### Procedure

---

1. Make sure the database is stopped. Log off from all active database sessions.
2. Deactivate A-TAP for the database:

```
general example
 <guardium_base>/xxx/guardctl -db-instance=<instance-name> deactivate
Greenplum example
 /opt/guardium/guard_stap/guardctl --db-instance=<instance-name> deactivate
```

3. Alternately, deactivate all active instances by running:  
`<guardium_base>/xxx/guardctl deactivate-all`

## Linux-UNIX: Configuring and Activating A-TAP in Special Environments

---

Zones, WPARs, Teradata, and Oracle require additional configuration.

- [Linux-UNIX: Activating A-TAP for Oracle on a Veritas Cluster](#)

S-TAP includes an A-TAP feature required for Oracle deployments which use encryption. This task describes activating A-TAP in this Oracle Veritas Clustering nodes.

- [Linux-UNIX: Installing and activating A-TAP in Solaris zones](#)

Installing A-TAP in Solaris zones requires additional configuration.

- [Linux-UNIX: Installing and activating A-TAP in WPARs environment](#)

Installing A-TAP in WPARs requires additional configuration.

- [Linux-UNIX: Deactivate and uninstall A-TAP in Zones and WPARs environment](#)

- [Linux-UNIX: Upgrading A-TAP in Zones and WPARs environment](#)

- [Linux-UNIX: Configure and activate A-TAP steps for Teradata database](#)

- [Linux-UNIX: Oracle considerations for A-TAP](#)

## Linux-UNIX: Activating A-TAP for Oracle on a Veritas Cluster

---

S-TAP includes an A-TAP feature required for Oracle deployments which use encryption. This task describes activating A-TAP in this Oracle Veritas Clustering nodes.

### About this task

---

This procedure uses typical file paths for a shell installation. The GIM procedure is the same, but with different paths. For example:  
`/opt/guardium/modules/ATAP/current/files/bin/guardctl`.

### Procedure

---

1. Set up A-TAP on all nodes without activation. For example:

```
/opt/guardium/guard_stap/guardctl --db-user=oracle --db-type=oracle --db-instance=oracle --db-home=
/dbarepzb/db/oracle/product/11.2.0.4 --db-version=11.2 store-conf
```

And

```
/opt/guardium/guard_stap/guardctl --db-instance=oracle authorize-user
```

2. Stop all Oracle processes. This ensures that `ORACLE_HOME` will still mount on primary.

3. Activate A-TAP on the primary node. For example:

```
/opt/guardium/guard_stap/guardctl --db-instance=oracle activate
```

4. Copy the `guard_tap.ini` file from the active node to all passive nodes, and change the `tap_ip` parameters appropriately. Then restart the S-TAP on the passive nodes.

5. Copy the A-TAP executer from the active node to all passive nodes. For example:

```
scp /opt/guardium/etc/guard/executor/root/* root@server:/opt/guardium/etc/guard/executor/root/
```

6. Restart the Oracle Services and verify that encrypted traffic is captured on the primary server.

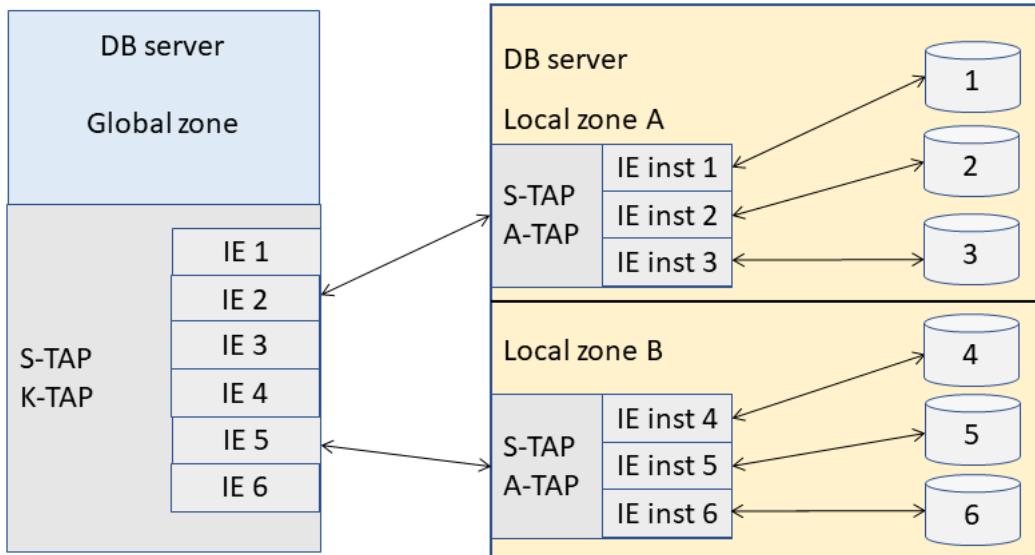

## Linux-UNIX: Installing and activating A-TAP in Solaris zones

---

Installing A-TAP in Solaris zones requires additional configuration.

### About this task

---

## Procedure

1. Install S-TAP/K-TAP on the global zone using GIM or shell installation and verify that inspection engines are configured for all local zones databases. If discovery did not find database instances running on the local zones, configure them manually for all available databases running in the local zones either in the `guard_tap.ini` file or the GUI.
2. In the local zone, install the same S-TAP version that is already installed in the global zone. (The S-TAP installer automatically detects the local zone environment and disables K-TAP by default).
3. Verify that inspection engines are configured in the S-TAPs in the local zones (installed in step 2) for all databases that require A-TAP. If discovery did not find database instances running on the local zones, manually create inspection engines for these databases using the `guard_tap.ini` file or the GUI.
4. Verify that the group ID (GID) for the group "guardium" is the same as the group ID for this group in the global zone. If the group IDs do not match, change the group ID in the local zones using command `groupmod -g <NEW_GID> guardium`. For example:

```
bash-3.2# groupmod -g 105 guardium
bash-3.2#
```

5. For each local zone where Oracle is installed, make sure the Guardium® device is mapped. Use these commands in the global zone environment.
  - a. Find the zone\_name by executing `zoneadm list`
  - b. `zoneadm -z <zone_name> halt`
  - c. `zonecfg -z <zone_name>`
  - d. `add device`
  - e. `set match=/dev/guard_ktap`
  - f. `end`
  - g. `verify`
  - h. For Solaris 11 devices `guard_ktap1`, `guard_ktap2`, `guard_ktap3`, `guard_ktap4`, `guard_ktap5`, repeat steps 5.d to g for each device. For example:

```
root@sys-sol11u3:~# zoneadm list
global
sys-sol11u3z2
sys-sol11u3z1
root@sys-sol11u3:~# zonecfg -z sys-sol11u3z2
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap1
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap2
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap3
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap4
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> add device
zonecfg:sys-sol11u3z2:device> set match=/dev/guard_ktap5
zonecfg:sys-sol11u3z2:device> end
zonecfg:sys-sol11u3z2> verify
zonecfg:sys-sol11u3z2> exit
root@sys-sol11u3:~#
```

- i. For Solaris 10, the device names are different. To find the correct string for the devices, execute this command in the Global Zone environment:

```
ls /dev/ktap*|awk -F "-" '{print $1}'
```

Typical output looks like:

```
/dev/ktap_106844_0
/dev/ktap_106844_1
/dev/ktap_106844_2
/dev/ktap_106844_3
/dev/ktap_106844_4
/dev/ktap_106844_5
bash-3.2#
```

After mapping the devices, go to the relevant local zone dev directory and create links for mapped devices to /dev/guard\_ktap\*, for example:

```
bash-3.2# cd /zones/sol110z2/dev
bash-3.2# ln -fs ktap_106844_0 guard_ktap
bash-3.2# ln -fs ktp_106844_1 guard_ktp1
bash-3.2# ln -fs ktp_106844_2 guard_ktp2
bash-3.2# ln -fs ktp_106844_3 guard_ktp3
bash-3.2# ln -fs ktp_106844_4 guard_ktp4
bash-3.2# ln -fs ktp_106844_5 guard_ktp5
bash-3.2# ls -lrt *ktp*
crw-rw-rw- 1 root guardium 336, 5 Jul 15 12:36 ktp_106844_5
crw-rw-rw- 1 root guardium 336, 4 Jul 15 12:36 ktp_106844_4
crw-rw-rw- 1 root guardium 336, 3 Jul 15 12:36 ktp_106844_3
crw-rw-rw- 1 root guardium 336, 2 Jul 15 12:36 ktp_106844_2
crw-rw-rw- 1 root guardium 336, 1 Jul 15 12:36 ktp_106844_1
crw-rw-rw- 1 root guardium 336, 0 Jul 15 12:36 ktp_106844_0
lrwxrwxrwx 1 root root 13 Jul 19 10:58 guard_ktp -> ktp_106844_0
lrwxrwxrwx 1 root root 13 Jul 19 10:58 guard_ktp1 -> ktp_106844_1
lrwxrwxrwx 1 root root 13 Jul 19 10:59 guard_ktp2 -> ktp_106844_2
lrwxrwxrwx 1 root root 13 Jul 19 10:59 guard_ktp3 -> ktp_106844_3
lrwxrwxrwx 1 root root 13 Jul 19 10:59 guard_ktp4 -> ktp_106844_4
lrwxrwxrwx 1 root root 13 Jul 19 10:59 guard_ktp5 -> ktp_106844_5
```

j. Set the permissions so that `guard_ktp` and `ktp_xxxxx` are accessible by everyone, using the command: `chmod 0666 *ktp*`. For example:

```
bash-3.2# chmod 0666 *ktp*
```

#### k. exit

6. Verify that all devices are properly mapped by executing this command in the Global Zone environment:

```
zonecfg -z <zone_name> info|grep match
```

For example:

```
root@sys-sol11u3:~# zonecfg -z sys-sol11u3z2 info|grep match
match: /dev/guard_ktp4
match: /dev/guard_ktp3
match: /dev/guard_ktp2
match: /dev/guard_ktp1
match: /dev/guard_ktp
match: /dev/guard_ktp5
```

7. Boot the local zone by executing the command:

```
zoneadm -z <zone_name> boot
```

8. Note: A-TAP only needs to be activated in the global zone for encrypted databases running in the global zone. If required, activate it with the `guardctl` command option `activate`. It cannot be enabled with the encryption checkbox in the inspection engine section in GUI interface or by setting `encryption=1` in the `guard_tap.ini` file. If the database is not used on the global zone, then A-TAP activation in the global zone is not required. To activate A-TAP in the global zone, use the DB OS user. Activate A-TAP in the local zones using `guardctl`. Activation in local zones can only be performed by the root user with DB OS user authorization.

## Related reference

- [Linux-UNIX: guardctl utility commands for A-TAP](#)

## Linux-UNIX: Installing and activating A-TAP in WPARs environment

Installing A-TAP in WPARs requires additional configuration.

## About this task

### Procedure

- Install S-TAP/K-TAP in the AIX global environment using GIM or shell installation.
- In the WPAR, install the same S-TAP version that is already installed in the AIX global environment, with K-TAP disabled, since the kernel is shared in the WPAR.
- If discovery did not find database instances running on the WPAR, manually create inspection engines for these databases using `guard_tap.ini` or the GUI.
- Activate A-TAP using `guardctl` with user root. It cannot be done through enabling the encryption box in the inspection engine section in GUI interface or by setting `encryption=1` in the `guard_tap.ini` file. A-TAP (`guardctl`) activation may complain and issue warnings about errors installing libraries under `/usr/lib` (since that directory belongs to the AIX Global environment)
- Restart the S-TAP.

## Linux-UNIX: Deactivate and uninstall A-TAP in Zones and WPARs environment

## Procedure

---

1. On every sub-Zone/sub-WPAR with A-TAP installed/active:
  - a. Deactivate (and deinstrument if necessary, for Oracle on AIX) all A-TAPs using guardctl following the steps in [Linux-UNIX: Deactivating A-TAP](#).
  - b. Manually remove (`rm -rf`) the installation directory
  - c. Manually remove the ATAP libraries: `find /usr/lib -type f -name 'libguard-*.*' | xargs rm -f`

Note: Removing the libraries may give errors; these can be ignored.
2. Uninstall STAP/KTAP using the normal method
  - a. Remove the libraries: `find /usr/lib -type f -name 'libguard-*.*' | xargs rm -f o`
  - b. On Solaris, remove the ktap device from each zone's configuration:

```
zoneadm -z <zonenumber> halt
zonecfg -z <zonenumber>
<zonenumber>> info
```

If a ktap device is found, remove it:

```
<zonenumber> remove device match=/dev/ktap_xxxx (FOR SOLARIS 10)
<zonenumber> remove device match=/dev/guard_ktap (FOR SOLARIS 11)
<zonenumber>> verify
<zonenumber>> exit
zoneadm -z <zonenumber> boot
```
  - c. Remove the ktap device file and link from each sub-Zone/sub-WPAR device directory, for example:

```
/export/home2/zones/iris3/dev cd /export/home2/zones/iris3/dev
rm -f ktap_xxxx guard_ktap
```
  - d. With multiple KTAP devices, repeat the steps for each KTAP device by using the name ktap\_xxxx (Solaris 10) or guard\_ktap\_x (Solaris 11).

---

## Linux-UNIX: Upgrading A-TAP in Zones and WPARs environment

## Procedure

---

1. For Solaris Zone:
  - a. On the master/global-zone, remove the previously installed K-TAP device.

```
zoneadm -z <zonenumber> halt
zonecfg -z <zonenumber>
<zonenumber>> info
```
  - b. If a K-TAP device is found, remove it.

```
<zonenumber> remove device match=/dev/ktap_xxxx (for Solaris 10)
<zonenumber> remove device match=/dev/guard_ktap (for Solaris 11)

<zonenumber>> verify
<zonenumber>> exit
zoneadm -z <zonenumber> boot
```
  - c. For Solaris sub-zones, remove the previous K-TAP device file and link from sub-zone device directory. Go to the sub-zone device directory, for example `/export/home2/zones/iris3/dev`.

```
cd /export/home2/zones/iris3/dev
rm -f ktap_xxxx guard_ktap
```
2. For Solaris Zone:
  - a. On the master/global-zone, add the new K-TAP device to the zone configuration.

```
zoneadm -z <zonenumber> halt
zonecfg -z <zonenumber>
<zonenumber>> add device

<zonenumber>device> set match=/dev/ktap_xxxx (for Solaris 10)
<zonenumber>device> set match=/dev/ktap_xxxx (for Solaris 11)

<zonenumber>device> end
<zonenumber>> verify
<zonenumber>> exit
zoneadm -z <zonenumber> boot
```
  - b. Add the `guard_ktap` link and change permission. Go to the sub-zone device directory, for example: sub-zone device directory=`/export/home2/zones/iris3/dev`

```
cd /export/home2/zones/iris3/dev
ln -fs ktap_xxxx guard_ktap
chmod 0666 ktap_xxxx
chmod 0666 guard_ktap
```
  - c. Since there are multiple ktap devices, repeat steps for each K-TAP device by using the name ktap\_xxxx\_x(solaris 10) or guard\_ktap\_x (solaris 11)
3. For AIX WPARs: on WPARs, change permission on K-TAP devices. Go to the WPARs device directory, for example: wpar device directory=`/wpar/odin3/dev`

```
ln -fs ktap_xxxx guard_ktap
chmod 0666 ktap_xxxx
chmod 0666 guard_ktap
```

## Linux-UNIX: Configure and activate A-TAP steps for Teradata database

Step 1: Determine the user running gtwgateway and the path

For Example:

```
su11u1x64-tera:~ # ps -ef | grep gtwgateway
teradata 5000 4608 0 Jan03 ? 00:00:05 /usr/tgtw/bin/gtwgateway
root 20128 20063 0 12:35 pts/0 00:00:00 grep gtwgateway
```

gtwgateway runs as user teradata

Set parameter `--db-user=teradata` to guardctl

Path to gtwgateway is `/usr/tgtw/bin/gtwgateway`. This is the default value for the parameter `tdc_gtwgateway` and as such does not need to be specified.

Otherwise, the parameter should be `--tdc_gtwgateway=/usr/tgtw/bin/gtwgateway`

Step 2: Determine the path to pdemain

Typically, this will be `/usr/pde/bin/pdemain`

For Example:

```
su11u1x64-tera:~ # ps -ef | grep pdemain
root 4608 1 0 Jan03 ? 00:00:25 pdemain -debug
su11u1x64-tera:~ # ls -l /proc/4608/exe
lrwxrwxrwx 1 root tdtrusted 0 2015-01-03 01:20 /proc/4608/root 20620 20063
0 12:40 pts/0 00:00:00 grep pdemain/exe ->
/opt/teradata/tdat/pde/15h.00.00.07/bin/pdemain
```

Checking the inodes for this file and `/usr/pde/bin/pdemain`, we see that they are the same.

```
su11u1x64-tera:~ # ls -li /opt/teradata/tdat/pde/15h.00.00.07/bin/pdemain
1638875 -r-xr-xr-x 1 teradata tdtrusted 1294666 2014-01-22 01:40
/opt/teradata/tdat/pde/15h.00.00.07/bin/pdemain
su11u1x64-tera:~ # ls -li /usr/pde/bin/pdemain
1638875 -r-xr-xr-x 1 teradata tdtrusted 1294666 2014-01-22 01:40
/usr/pde/bin/pdemain
```

Since the inodes are the same and the default value for `--db-home=/usr/pde`, the parameter in this case does not need to be specified. Otherwise, you can specify `--db-home=/opt/teradata/tdat/pde/15h.00.00.07` or `--db-home=/usr/pde` since `bin/pdemain` in both paths is the same file hardlinked in this case.

Step 3: Stop the Teradata instance

For Example:

```
su11u1x64-tera:~ # /etc/init.d/tgtw stop
tgtw Shutdown complete
su11u1x64-tera:~ # /etc/init.d/tpa stop
PDE stopped for TPA shutdown
```

Step 4: Authorize the DB user to the Guardium group

For Example:

```
/usr/local/guardium/guard_stap/guardctl --db-instance=teradata authorize-user
```

Step 5: Store the configuration for A-TAP using the parameters determined in steps 1 and 2.

For Example:

```
/usr/local/guardium/guard_stap/guardctl --db-instance=teradata
--tdc_gtwgateway=/usr/tgtw/bin/gtwgateway --db-type=teradata
--db-home=/opt/teradata/tdat/pde/15h.00.00.07 --db-user=teradata store-conf
```

Step 6: Activate A-TAP

For Example:

```
/usr/local/guardium/guard_stap/guardctl --db-instance=teradata activate
```

#### Step 7: Restart the Teradata instance

For Example:

```
su11u1x64-tera:~ # /etc/init.d/tpa start
Teradata Database Initiator service is starting...
Teradata Database Initiator service started successfully.

su11u1x64-tera:~ # /etc/init.d/tgtw start
tgtw Startup complete
```

---

## Linux-UNIX: Oracle considerations for A-TAP

### A-TAP Procedure when working with Oracle Patch Installations

---

Oracle patches may invoke **relink** and will replace the Oracle executable, causing the A-TAP to stop functioning.

The correct procedure is:

1. Make sure all A-TAP instances are deactivated and deinstrumented.
2. Apply Oracle patch(es).
3. Instrument and activate all A-TAP instances

However, in case A-TAP was not properly deactivated prior to Oracle patch installation, DO NOT try to deactivate it after patch installation. Instead follow these steps:

1. Check if A-TAP IS OK.

```
grep guardium ${ORACLE_HOME}/bin/oracle >& /dev/null && echo "ATAP IS OK"

a. If ATAP IS OK is displayed, the A-TAP is still active and there is no need to do anything.
b. If ATAP IS OK is NOT displayed, remove ${ORACLE_HOME}/bin/oracle-guard and activate the A-TAP.
```

In case everything else fails:

- Remove \${ORACLE\_HOME}/bin/oracle-guard
- Run **relink all**

### A-TAP Problems And Solutions associated with Oracle Permissions

---

Several problems may occur that have to do with user and group permissions.

- In 'BEQUEATH' access from the user other than the one that installed the database the permissions have to be set manually:
  - add user running sqlplus to group 'guardium'
  - open the read permissions 'chmod a+r' on the following two directories:  

```
/usr/local/guardium/xxx/etc/guard
/usr/local/guardium/xxx/etc/guard/executor
```

    - make sure that the SUID and SGID bits are on \${ORACLE\_HOME}/bin/oracle.
      - If not, run the command **chmod ug+s \${ORACLE\_HOME}/bin/oracle**
- If the UID or EUID are not members of OWNER group GID, the reason for permission denied is that the user matching UID or EUID does not belong to group matching OWNER GID.
- To make it easier, not having to handle different OS syntaxes for adding users and groups, while disabling the automatic addition to group Guardium, two commands are available within guardctl which can be used irrespective of the method you use to activate ATAP (i.e. guardctl or guard\_tap.ini):
  - #/path/to/guardium/bin/guardctl is-user-authorized
  - #/path/to/guardium/bin/guardctl authorize-user ...

Note: Group Guardium can be removed on most OS's with **groupdel guardium**. However, after removal, only the **guard\_ktap\_loader** parameter can correctly re-create it and change the K-TAP device permissions.

---

## Linux-UNIX: Troubleshooting A-TAP configuration issues

This section summarizes common mistakes made during A-TAP configurations, their symptoms, and how to avoid them.

Table 1. A-TAP configuration issues and recommendations

| Symptoms                                        | Mistake                                                          | Platform | How to Avoid                                                                                                                                                  |

| Error during A-TAP activation. | Insufficient disk space, install exits |          | Clean up disk space and retry. If that does not help, change db_space=8 to db_space=1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Linux-UNIX: Configure a public and private address for an S-TAP

For an S-TAP deployed in a private network, Guardium® can refer to the S-TAP with a public IP address that is not visible from the database server on which S-TAP is installed, while the database uses a private address for the S-TAP.

### About this task

Typical scenarios where the Guardium system cannot recognize the S-TAPs IPs, and the IPs that can be validated by system are not the IPs you want to report data with:

- Cloud deployment with internal and external IPs.
- S-TAP clients are using private IPs, for example when running OpenStack and creating VMs.

You can modify the S-TAP configuration in the:

- S-TAP Control page, Details section: Force server IP
- Manage > Module Installation > Set up by Client page.
- S-TAP configuration file `guard_tap.ini`: `force_server_ip`.

For example, you create a database system in the cloud. Internal to that system (if you're logged in), the server identifies with the IP address 1.1.1.1. But from the outside world (from any other machine), it responds to the IP 2.2.2.2. This makes it difficult to identify servers in report. If you set the `tap_ip` to 2.2.2.2, and set the `private_tap_ip` to 127.0.0.1 (default if it is a local IP), everything works smoothly, but there are inconsistencies between reports. To resolve this, set `force_server_ip=1`, then the server only identifies with the external, public IP (TAP IP), and all reports from this database use the IP 2.2.2.2 (one single consistent IP address).

### Procedure

- Specify `tap_ip` in the `guard_tap.ini`, or `STAP_TAP_IP` in the Set up by Client page to the external, public IP address (virtual IP). This is the IP reported as the S-TAP host in the S-TAP Control page. If `tap_ip` is set to a name, it has to be resolvable by `getservername()`.
- Specify `private_tap_ip` in the `guard_tap.ini`, or `STAP_PRIVATE_TAP_IP` in the Set up by Client page, to an IP address that the database host can recognize (physical IP).
- Optional: If you want the collector to record the server IP address to be the address specified in `tap_ip`, set `force_server_ip=1` in the `guard_tap.ini`, or `STAP_FORCE_SERVER_IP` in the Set up by Client page or from the S-TAP Control page, Details section.

### Results

When the S-TAP registers with the collector, the S-TAP appears as having the external IP address.

## Linux-UNIX: Configure S-TAP log and dump locations when /root partition size is limited

S-TAP agents are installed in a partition with root privileges; by default they are installed into the `/root` partition based directories. For customers with limited root file systems size, follow these best practice recommendations to prevent the S-TAP agent from generating logs or dumps on the `/root` partition.

### Procedure

- Redirect the S-TAP debug log to a partition whose size is larger than `/root`. By default the S-TAP log writes to the `/tmp` directory. Change the write directory using one of the following:
  - Use the GuardAPI command `update_stap_config`. This example redirects the logs to `/var`: `xxx.xxx.xxx.com> grdapi update_stap_config stapHost=xxxx updateValue=TAP.tap_log_dir:/var`
  - In the `guard_tap.ini` file, change the parameter `tap_log_dir` value to the new target directory. For example, `tap_log_dir=/var`. Restart the S-TAP.
- Redirect the core dumps to a partition outside of `/root` that is larger in size. (By default the cores are generated in the `<guard install dir>`.) On Linux systems:

- a. Open the file /etc/abrt/abrt.conf
  - b. Set DumpLocation = <desired location>
  - c. Restart the service with: **restart abrt.service**
3. Rotate the log files using one of the following options:
- Use the guard\_monitor tool that is part of Guardium S-TAP agent to redirect and rotate Guardium logs. See:[Linux-UNIX: S-TAP Monitor \(guard\\_monitor\)](#). Specifically, use these parameters:

```
; maximum file size of monitor log file (KB)
monitor_log_rotate_size=1024
; number of rotated monitor logs to keep
monitor_log_rotate_num_kept=5
; maximum file size of log files (KB)
log_rotate_size=4096
; number of rotated logs to keep
log_rotate_num_kept=5
; logs to rotate
logs_to_rotate=/tmp/guard_stap.stderr.txt,/tmp/guard_stap.stdout.txt,/usr/local/guardium/guard_stap/ktap/ktap_install.log,/usr/local/guardium/guard_stap/guard_discovery.stderr.log
```

Note:

Set logs\_to\_rotate to include any redirected log files as described in [1](#). For example, if you redirected logs to /var, then logs\_to\_rotate would be:logs\_to\_rotate=/var/guard\_stap.stderr.txt,/var/guard\_stap.stdout.txt,/usr/local/guardium/guard\_stap/ktap/ktap\_install.log

On some OS other log files may get used and can therefore be included for rotation. For example:

```
logs_to_rotate=/tmp/guard_stap.stderr.txt,/tmp/guard_stap.stdout.txt,/var/log/ktap_install.log,/opt/guardium/guard_stap/guard_discovery.stderr.log,/var/log/ktap.log,/var/guard_stap.stderr.txt,/var/guard_stap.stdout.txt,/usr/local/guardium/guard_stap/ktap/ktap_install.log,/usr/local/guardium/guard_stap/guard_discovery.stderr.log,/var/tmp/ktap-trace.txt
```

- Use the Unix native Log rotation **logrotate** or any comparable software, to manage logs on the DB server.

## Linux-UNIX: Editing the S-TAP configuration parameters

You can modify the S-TAP configuration after it is installed using GIM, the UI, or for advanced users, the configuration file on the database.

Note: Parameters in the GUI may be safely changed. Parameters that are not in the GUI are advanced, and rarely need changing. They are for use by Guardium support or advanced users.

**CAUTION:**

Do not modify advanced parameters unless you are an expert user or you have consulted with IBM Technical Support.

You can some modify parameters in the GUI. See [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#).

GIM is an easy method for modifying parameters, if the S-TAP bundle was installed with GIM. See [Set up by Client](#).

Configuration Change Alerting: When the S-TAP sends an updated configuration to the collector, the collector checks the new configuration against the last stored configuration on the collector and an alert is generated detailing what has changed. This alert appears in the S-TAP event log. If a section is added or removed, the parameters of that section are listed. If a section parameter is changed, it displays the section name, parameter name, old value, and new value. If a parameter is added or removed from a section, the section name, parameter name, and value are displayed. For example:  

```
UTAP 'rh7-docker1' configuration changed,
differences: Section 'TAP' parameter
'discovery_debug' changed from '0' to '1' Section 'TAP' parameter 'stap_statistic' changed from '1'
to '0' Section 'SQLGuard_1' added Section 'SQLGuard_1' parameter 'connection_pool_size'='0' added
Section 'SQLGuard_1' parameter 'num_main_thread'='1' added Section 'SQLGuard_1' parameter
'primary'='2' added Section 'SQLGuard_1' parameter 'sqlguard_ip'='gimb39' added Section 'SQLGuard_1'
parameter 'sqlguard_port'='16016' added
```

If it is necessary to modify the configuration file from the database server, follow the procedure described in this section. The guard\_tap.ini file contains comments that explain many of the parameters.

The S-TAP needs restarting after you modify the guard\_tap.ini file. Either restart it in the S-TAP Control page with the [Send command](#) or using one of: [Linux-UNIX: Start and stop S-TAP and GIM processes for various OS types/versions](#), [Linux-UNIX: Using guard-config-update to start, restart, and stop S-TAP, and view status](#).

The guard\_tap.ini file has a [Proxy] section that is only used for the Guardium External S-TAP containers. Do not modify any parameters in this section.

**CAUTION:**

Parameters must be added to their relevant section: [TAP], [SQLGuard], [DB\_<name>].

1. Log on to the database server system using the root account.
2. Stop the S-TAP.
3. Make a backup copy of the configuration file: guard\_tap.ini. The default file locations is /usr/local/guardium/guard\_stap/guard\_tap.ini
4. Open the configuration file in a text editor.
5. Edit the file as necessary.
6. Save the file.
7. Restart the S-TAP and verify that your change has been incorporated.

- [Linux-UNIX: Guardium Hosts \(SQLGuard\) parameters](#)

These parameters describe a Guardium system to which this S-TAP can connect. All parameters in this section are basic, and appear in the [SQL\_GUARD] section.

- [Linux-UNIX: General parameters](#)

These parameters define basic properties of the S-TAP running on a database server and the server on which it is installed, and do not fall into any of the other categories.

- [Linux-UNIX: Inspection engine parameters](#)

These parameters affect the behavior of the inspection engine that the S-TAP uses to monitor a data repository on a DB server.

- [Linux-UNIX: Oracle Unified Auditing parameters](#)

These parameters define the Oracle Unified Auditing connection between the S-TAP and the SQL server.

- [Linux-UNIX: Firewall parameters](#)

These parameters affect the behavior of the S-TAP with respect to the firewall.

- [Linux-UNIX: Query rewrite parameters](#)

The query rewrite parameters affect the behavior of the S-TAP with respect to discovery.

- [Linux-UNIX: Server-side masking \(SSM\) parameters](#)  
The server-side masking parameters affect the behavior of the S-TAP with respect to discovery.
- [Linux-UNIX: Discovery parameters](#)  
The discovery parameters define the behavior of the auto-discovery feature, for discovering database instances and sending the results to the current active S-TAP.
- [Linux-UNIX: Application server parameters](#)  
These parameters affect the behavior of the S-TAP when an application user name needs to be bounded with database activities.
- [Linux-UNIX: Hadoop parameters](#)  
Guardium supports Hadoop integration using HDFS, Hortonworks with Apache Ranger, and Cloudera Navigator. Understand the S-TAP configuration required for these integrations.
- [Linux-UNIX: Configuration Auditing System \(CAS\) parameters](#)  
These parameters affect the behavior of CAS.
- [Linux-UNIX: Debug parameters](#)  
These parameters affect the behavior of S-TAP debugging.
- [Linux-UNIX: K-TAP parameters](#)  
These parameters affect the behavior of the K-TAP.

## Linux-UNIX: Guardium Hosts (SQLGuard) parameters

These parameters describe a Guardium system to which this S-TAP can connect. All parameters in this section are basic, and appear in the [SQL\_GUARD] section.

| GUI                                                                        | GIM              | guard_tap.ini        | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------|------------------|----------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pool size                                                                  |                  | connection_pool_size | 0             | The number of connections to open between the S-TAP and the sniffer process on a Guardium® host. Increasing the value provides more throughput that might be required when encryption such as TLS is enabled. The maximum number of pooled connections is 50. The total is the sum of (connection_pool_size x num_main_thread) in all of the [SQLGuard_n] sections in the guard_tap.ini.<br>Valid values: <ul style="list-style-type: none"><li>• 0: Disable pooling</li><li>• 1-10: (for each defined host)</li></ul> |

In guard_tap.ini: 1=Primary, 2=Seconday, 3=tertiary, and so on                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                            |                  | sqlguard_port        | 16016         | Read only. Port used for S-TAP to connect to Guardium system.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Guardium Host                                                              | STAP_SQLGUARD_IP | sqlguard_ip          | NULL          | IP address or hostname of the Guardium system that acts as the host for the S-TAP. You can define multiple hosts by adding sections [SQLGuard_1], [SQLGuard_2], and so on.                                                                                                                                                                                                                                                                                                                                             |

## Linux-UNIX: General parameters

These parameters define basic properties of the S-TAP running on a database server and the server on which it is installed, and do not fall into any of the other categories.

These parameters are stored in the [TAP] section of the S-TAP properties file. **DB2\_SHMEM\_DRIVER\_INSTALLED**

Table 1. S-TAP configuration parameters in the [TAP] section

| GUI             | GIM         | guard_tap.ini                                   | Default value | Description                                                                                                                                                                                                     |
|-----------------|-------------|-------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|----------------------|-----------------------|-----------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wait for DB exec     | STAP_WAIT_FOR_DB_EXEC | wait_for_db_exec            | 0             | <p>When S-TAP restarts, either from a system reboot or user initiated S-TAP stop / start commands, S-TAP polls all databases that have been configured to be monitored and begins monitoring all valid configurations. Any configuration anomalies (either on the database side or the S-TAP side) that limits S-TAP ability to monitor a database does not limit the S-TAP from monitoring other databases with valid configurations. This parameter determines the S-TAP response, and its status in the S-TAP Control page, if a DB instance is not available (db_install_dir or db_exec_file is not accessible) during IE validation, after an S-TAP or DB restart. Valid values:</p> <ul style="list-style-type: none"> <li>• 0 and less: S-TAP logs an event message with the event type CONF_ERROR when a DB instance is detected as unavailable for certain DB(PROTOCOL) during the S-TAP starting time. S-TAP also logs a CONF_ERROR if a DB changes its status from available to unavailable during the periodic check (every 15 minutes). These event messages change the S-TAP status in the GUI to yellow with the instruction to correct the parameter or set WAIT_FOR_DB_EXEC &gt; 0. When a DB instance status changes from unavailable to available, a WARNING message is sent to the sniffer, but the GUI status does not change automatically. You need to click  to open the S-TAP event log and click Accept.</li> <li>• greater than 0: A WARNING is logged for any unavailable database during S-TAP startup time or during a periodic check. The time interval of the periodic check is the value of wait_for_db_exec, in minutes. A warning message is also sent when an unavailable DB instance becomes available. Since the periodic check needs to get status of the database file configured for each inspection engine, and it consumes the CPUs, the value should not be less than the number of inspection engines.</li> </ul> <p>See <a href="#">Linux-UNIX: Configuring S-TAP in the S-TAP Control page</a> for more details on the S-TAP Status page. Before setting this property to a positive value, be sure to set all other necessary configuration properties and test that the S-TAP starts and collects data correctly. This property can be modified using GIM GUI (STAP_WAIT_FOR_DB_EXEC), and the guard_tap.ini configuration file.</p> |
| Dynamic ring buffers |                       | enable_dynamic_ring_buffers | 0             | <p>Dynamically adds and removes S-TAP buffers for each main connection during peak traffic, to prevent an overflow in the S-TAP buffer. If S-TAP failover happens, data in all buffers is moved to the new buffers.</p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>• 0: Disabled</li> <li>• 1: Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                      | STAP_RUN_AS_ROOT      | tap_run_as_root             | 1             | <p>Run S-TAP as user root or as user guardium. Valid values:</p> <ul style="list-style-type: none"> <li>• 0: Run as guardium user</li> <li>• 1: Run as root</li> </ul> <p>In some cases you need to run the S-TAP as guardium (and not root). This can cause other issues and should only be used when necessary. Running S-TAP as the guardium user can cause a database or protocol to stop working because of permission levels. Verify that the database path or exec file gives the Guardium user read permission. Depending on your environment, typical limitations are:</p> <ul style="list-style-type: none"> <li>• <b>wait_for_db_exec</b> might not work. For cluster, check the database path or exec file for Guardium user read permission.</li> <li>• Database on AIX® WPAR and Solaris Zones may not work, check the permission to access the install path or exec file</li> <li>• For Oracle BEQ, restart S-TAP after starting or restarting the database.</li> <li>• For Informix® shared memory, restart S-TAP after starting or restarting the database.</li> <li>• For DB2 shared memory, if <b>shmctl</b> failed because of permission issue, then in most cases S-TAP should be changed to run as root. <ul style="list-style-type: none"> <li>◦ If shared memory segment has read permission by group, then make sure the DB2 instance has been added to user (Guardium) group. But still on each server, only one set of configuration of DB2® can be supported.</li> <li>◦ If shared memory segment has read permission by db2 user only, then S-TAP has to run as root. (open a DB2 shared memory session, run command <b>ipcs -ma</b>, check MODE on the output)</li> </ul> </li> </ul> <p>Can be set when pushing to a group of DB servers via GIM.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                           |                                | exit_lib_num_threads      |               | Hidden parameter. The number of shared memory segments created by the S-TAP. The number of requests for shared memory segments (from the exit library) is equal to the number of instances on the database. The value of this parameter should be equal to or greater than the number of database instances. The default is 10, the maximum is 20. |

## Linux-UNIX: Inspection engine parameters

These parameters affect the behavior of the inspection engine that the S-TAP uses to monitor a data repository on a DB server.

These parameters are stored in the individual [DB\_<name>] inspection engine section of the S-TAP properties file, guard\_tap.ini, with the name of a data repository. There can be multiple sections in a properties file, each describing one inspection engine used by this S-TAP.

| GUI                       | guard_tap.ini    | Default value       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Protocol                  | db_type          |                     | Required. The type of data repository that is monitored.<br>ASTERDB, Cassandra, CockroachDB, CouchDB, DB2®, Db2 Exit, ElasticSearch, exclude IE, FTP, GreenplumDB, HADOOP, HIVE, HP-Vertica, HTTP, HUE, IMPALA, Informix®, Informix Exit, KERBEROS, MariaDB, MemSQL, MongoDB, Mysql, Netezza®, Oracle, PostgreSQL, REDIS, SAP Hana, Sybase, Teradata, Teradata Exit, WebHDFS, Windows File Share                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Port range                | port_range_start |                     | For monitoring network traffic only, the lowest numbered port on which to listen for database traffic. Together with port_range_end, this parameter defines the range of ports that are monitored for this database instance. Usually the range contains only a single port. For a Kerberos inspection engine, set the start and end values to 88-88. If a range is used, do not include extra ports in the range. Extra ports might result in excessive resource consumption while the S-TAP attempts to analyze unwanted traffic.<br>Examples:<br>To monitor range 1521-1525 (five ports) with no port forwarding: <ul style="list-style-type: none"> <li>• port_range_start=1521</li> <li>• port_range_end=1525</li> <li>• real_db_port=1521</li> </ul> To monitor range 2000-2004 (five ports) where network port 2000 is mapped to local port 1521: <ul style="list-style-type: none"> <li>• port_range_start=2000</li> <li>• port_range_end=2004</li> <li>• real_db_port=1521</li> </ul> |
| Port range                | port_range_end   |                     | For monitoring network traffic only, the highest numbered port on which to listen for database traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| KTAP DB Real Port         | real_db_port     | 4100                | With K-TAP and PCAP, identifies the database port or range of ports to be monitored. For exit libraries, use its value for db_home.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Client Ip/Mask            | networks         | 0.0.0.0/0.0.0.0::/0 | Restricts S-TAP to monitor traffic only from the specified sets of IP address and mask pairs, by using a list of addresses in IP address/mask format: n.n.n.n/m.m.m.m. If an improper IP address/mask is entered, the S-TAP does not start. Valid values: <ul style="list-style-type: none"> <li>• User-defined list</li> <li>• 0.0.0.0/0.0.0.0::/0: select all clients.</li> <li>• 127.0.0.1/255.255.255.255::1/0: local traffic only</li> </ul> Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously. If the value of this parameter is not configured correctly, the value is replaced by the default value.                                                                                                                                                                                                                                                                                                                          |
| Exclude Client Ip/Mask    | exclude_networks |                     | A list of client IP addresses and corresponding masks that are excluded from monitoring. Use this option to configure the S-TAP to monitor all clients, except for a certain client or subnet (or a collection thereof). Client Ip/Mask (networks) and Exclude Client Ip/Mask (exclude networks) cannot be specified simultaneously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| TEE Listen Port-Real Port | tee_listen_port  |                     | Deprecated. Replaced by the parameter real_db_port when the K-TAP monitoring mechanism is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Connect To Ip             | connect_to_ip    | 127.0.0.1::1        | IP address for S-TAP to use to connect to the database. Some databases accept local connection only on the real IP address of the Guardium® system, and not on the default (127.0.0.1::1). When K-TAP is enabled, this parameter is used for Solaris zones and AIX® WPARs. Set it to the zone IP address to capture traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| GUI                | guard_tap.ini             | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|---------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB User            | db_user                   | NULL          | OS username (case-sensitive) of the owner of the DB server process (for example, oracle). This parameter specifies which user is allowed to use the db_request_handler socket. It is required if you are not using the user root. If set to an invalid value, A-TAP cannot access the socket to retrieve permission for accessing K-TAP. In this case, it requires authorization with a group membership to log decrypted traffic to K-TAP (by using the <b>guardctl authorize-user</b> command). You can define a comma-separated string of multiple users.                                                                                                                                                                                                                                                                                               |

| Intercept Types    | intercept_types           | NULL          | <p>DO NOT change this parameter unless it is absolutely necessary. Protocol types that are intercepted by the IE.</p> <p>Valid values:</p> <ul style="list-style-type: none"> <li>NULL: auto intercepts all protocols the Database supports</li> <li>Comma-separated list: IE intercepts these protocol types only.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Identifier         | tap_identifier            | NULL          | Used to distinguish inspection engines from one another. If unspecified, Guardium auto-populates the field with a unique name that uses the database type and sequence number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DB Version         | db_version                | 9             | The database version. The string must start with a numeral and not a letter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Unix Socket Marker | unix_domain_socket_marker | Null          | Specifies UNIX domain sockets marker for Oracle, MySQL, and Postgres. Usually the default is correct, but when the named pipe or UNIX domain socket traffic does not work then you need to make sure that this value is set correctly. For example, for Oracle, set unix_domain_socket_marker to the KEY of IPC defined in tnsnames.ora. If it is NULL or not set, the S-TAP uses defined default markers identified as: * MySQL - "mysql.sock" * Oracle - "./oracle/" * Postgres - ".s.PGSQL.5432"                                                                                                                                                                                                                                                                                                                                                        |

## Parameters used with IBM Db2 databases

The script **find\_db2\_shmem\_parameters.sh**, located in `stap_directory/bin`, outputs what the Db2 shared memory parameters defined in the Inspection Engines should be. Execute it either as root or Db2 user, using the syntax: **find\_db2\_shmem\_parameters.sh <instance name>**. You can run it from any directory.

Table 1. Additional S-TAP configuration parameters for a Db2 inspection engine

| GUI                     | guard_tap.ini           | Default value | Description                                                                                                                                                                                                                                                                                      |
|-------------------------|-------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB2 Shared Mem. Adjust. | db2_fix_pack_adjustment | 20            | Required when Db2 is selected as the database type, and shared memory connections are monitored. The offset to the server's portion of the shared memory area. Offset to the beginning of the Db2 shared memory packet, depends on the Db2 version: 32 in pre-8.2.1, and 80 in 8.2.1 and higher. |

| GUI                      | guard_tap.ini             | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------|---------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB2 Sh. Mem. Client Pos. | db2_shmem_client_position | 61440         | The offset to the client's portion of the shared memory area. Required when Db2 is selected as the database type, and shared memory connections are monitored. Use the script find_db2_shmem_parameters.sh to find the value. The script is located in <code>stap_directory/bin</code> , and outputs what the Db2 shared memory parameters that are defined in the Inspection Engines should be. Run it either as root or Db2 user, by using the syntax: <code>find_db2_shmem_parameters.sh &lt;instance name&gt;</code> . You can run it from any directory. |
|                          | db2bp_path                | Null          | Relevant only when using A-TAP on Db2. If the program 'db2bp' (part of Db2) is in the standard location, db2bp_path does not need to be set. If it is non-standard, then this parameter points to its location. Set this parameter to the full path of the relevant db2bp as seen from the global zone or WPAR. For example, if the file is /data/db2inst1/sqllib/bin/db2bp and the zone is installed in /data/zones/oracle2nd/root/ then set the full path (db2bp_path) as /data/zones/oracle2nd/root/data/db2inst1/sqllib/bin/db2bp                         |
| DB2 Shared Mem. Size     | db2_shmem_size            | 131072        | Db2 shared memory segment size. Required when Db2 is selected as the database type, and shared memory connections are monitored.                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Linux-UNIX: Oracle Unified Auditing parameters

These parameters define the Oracle Unified Auditing connection between the S-TAP and the SQL server.

These parameters are stored in the individual [SQLC\_<integer>] sections of the S-TAP properties file, guard\_tap.ini. There can be multiple sections in a properties file, each describing one connection for pulling data from a database, which is used by this S-TAP.

Note: The password can be defined only with the API command [store\\_sql\\_credentials](#).

| GUI                       | guard_tap.ini      | Default value | Description                                                                                                                                                                                                                                                                                                                        |
|---------------------------|--------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB type                   | db_type            |               | Required. The type of data monitored repository. Valid value: <ul style="list-style-type: none"><li>• Oracle</li></ul>                                                                                                                                                                                                             |
| Instance name             | instance           |               | Required. service_name that specifies the connection identifier in the tnsnames.ora that is used to connect to the database.                                                                                                                                                                                                       |
| Data pull interval (sec.) | data_pull_interval | 30            | Frequency, in seconds, of S-TAP polls of the audit table that looks for new data.                                                                                                                                                                                                                                                  |
| User name                 | username           |               | Required. User name of a user with access to the database and permission to read entries in the unified audit table.                                                                                                                                                                                                               |
| User role                 | role               |               | Role for user with access to the database and permission to read entries in the audit table, for example, for a user name "sys", you might specify a user role of "sysdba"                                                                                                                                                         |
| Data pull number of rows  | data_pull_rows     | 100           | The number of rows to attempt to pull in one iteration. Each check interval, S-TAP attempts to pull the full amount of new data to the collector. Use this parameter to tune the amount of memory that is used by the S-TAP versus impact on the database for collecting data. It is recommended to leave it at the default value. |
| Timeout (sec.)            | timeout            | 300000        | Time, in seconds, to allow the database to respond.                                                                                                                                                                                                                                                                                |

## Linux-UNIX: Firewall parameters

These parameters affect the behavior of the S-TAP with respect to the firewall.

These parameters are stored in the [TAP] section of the S-TAP properties file.

| GUI                | GIM                     | guard_tap.ini      | Default value | Description                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------|--------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Firewall installed | STAP_FIREWALL_INSTALLED | firewall_installed | 0             | Firewall feature enabled. Valid values: <ul style="list-style-type: none"><li>• 0: Disabled.</li><li>• 1: Enabled.</li></ul><br>Note: firewall_installed and qrw_installed cannot be enabled at the same time. If qrw_installed is set to 1, then firewall_installed is disabled.                                                                                     |
| Firewall timeout   | STAP_FIREWALL_TIMEOUT   | firewall_timeout   | 2             | Time to wait for a verdict from the Guardium® system. If the firewall times out, the value of the parameter firewall_fail_close determines whether to block or allow the connection.<br>Valid values: -1 to -999, 1 to 10.<br>Negative values represent milliseconds and positive values represent seconds. For example, -50 is 50 milliseconds while 3 is 3 seconds. |

| Firewall fail close    | STAP_FIREWALL_FAIL_CLOSE    | firewall_fail_close    | 0             | The action when the verdict cannot be set by the policy rules, for example the Firewall timeout expires. Valid values: <ul style="list-style-type: none"><li>• 0: the connection goes through.</li><li>• 1: the connection is blocked.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Firewall default state | STAP_FIREWALL_DEFAULT_STATE | firewall_default_state | 0             | Sets the firewall activation trigger. Must be 0 if <a href="#">qrw_default_state=1</a> or 2. Valid values: Valid values: <ul style="list-style-type: none"><li>• 0: Firewall is activated per session when triggered by a rule in the installed policy.</li><li>• 1: All traffic is watched for firewall policy violations</li><li>• 2: All traffic is watched for firewall policy violations for the initial priority_count packets (guard_tap.ini parameter). S-TAP watches the initial part of every new session to your DB. This is useful when you have session based policies, firewall rules based on the user, or some other information that is passed early in the session. It limits the impact of firewall on the performance. Instead of watching every bit of the session (Firewall default state=1) and waiting for an UNWATCH verdict, S-TAP simply unwatches automatically if no WATCH or DROP is sent.<br/>To reduce the possibility that short sessions evade firewall and redaction rules, if either firewall_default_state or qrw_default_state is set to 2, create a session-level policy. S-TAP watches all priority packets and sends them to collector, which reduces the chance of avoiding firewall or redaction rules.</li></ul> |
| Firewall force watch   | STAP_FIREWALL_FORCE_WATCH   | firewall_force_watch   | NULL          | When firewall_default_state=0 (off), then firewall_force_watch specifies the network/mask of the IPs you want the firewall to watch, overriding the default (off).<br>Valid value: comma separated list of IP/mask values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Firewall force unwatch | STAP_FIREWALL_FORCE_UNWATCH | firewall_force_unwatch | NULL          | When firewall_default_state=1 (on), then firewall_force_unwatch specifies the network/mask of the IPs you want the firewall to ignore, overriding the default (on).<br>Valid value: comma separated list of IP/mask values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Linux-UNIX: Query rewrite parameters

The query rewrite parameters affect the behavior of the S-TAP with respect to discovery.

| GIM                    | guard_tap.ini     | Default Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|-------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_QRW_INSTALLED     | qrw_installed     | 0             | Enable or disable the query rewrite feature. When set to 0, all other parameters in this group are ignored. Valid values: <ul style="list-style-type: none"><li>• 0: Disabled</li><li>• 1: Enabled</li></ul><br>Note: firewall_installed and qrw_installed cannot be enabled at the same time. If qrw_installed is set to 1, then firewall_installed is disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| STAP_QRW_DEFAULT_STATE | qrw_default_state | 0             | Sets the query rewrite activation trigger. Must be 0 if <a href="#">firewall_default_state=1</a> or 2. Valid values: <ul style="list-style-type: none"><li>• 0: QRW is activated per session when triggered by a rule in the installed policy.</li><li>• 1: Watch all packets. QRW is activated for every session regardless of the installed policy. S-TAP watches all priority packets and sends them to collector, which reduces the chance of avoiding firewall or redaction rules.</li><li>• 2: Priority packets are watched by default. If event is not triggered by the priority packets, then query rewrite stops watching after priority packets until the policy is triggered. To reduce the possibility that short sessions evade firewall and redaction rules, when either qrw_default_state or firewall_default_state is set to 2, create a session-level policy. Firewall/QRW is initially activated for a limited number of the first packets (priority packets) of each session. If not triggered by the rule of the installed SLP policy, then Firewall/QRW is automatically deactivated.<br/>When set to 2, the QRW operation can be modified by the following commands:<ul style="list-style-type: none"><li>◦ <b>Watch</b> - S-TAP changes the state from 2 to 1 so that the connection is permanently subject to firewall or query rewrite operations.</li><li>◦ <b>Drop</b> - Terminate the connection immediately.</li><li>◦ <b>Watch &amp; Drop</b> - Terminate the connection immediately.</li><li>◦ <b>Unwatch</b> - S-TAP changes the state from 2 to 0 so the connection is no longer subject to firewall or query rewrite operations.</li></ul></li></ul> |
| STAP_QRW_FORCE_WATCH   | qrw_force_watch   | NULL          | Comma-separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1,2.2.2.2/2.2.2.2) to watch automatically. Valid when qrw_installed is 1, and qrw_default_state is 0. Cannot be configured to the same IP range as firewall_force_unwatch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| STAP_QRW_FORCE_UNWATCH | qrw_force_unwatch | NULL          | Comma separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1,2.2.2.2/2.2.2.2) to exclude from watching. Valid when qrw_installed is 1, and qrw_default_state is 1. Cannot be configured to the same IP range as firewall_force_watch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Linux-UNIX: Server-side masking (SSM) parameters

The server-side masking parameters affect the behavior of the S-TAP with respect to discovery.

These parameters are stored in the [TAP] section of the S-TAP properties file.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

| Parameter                         | Default value | Description                                                                                                                                                                                                                                                                  |
|-----------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| server_side_masking_installed     | 0             | Enables the server-side masking feature. Valid values: <ul style="list-style-type: none"><li>• 0=No</li><li>• 1=Yes</li></ul>                                                                                                                                                |
| server_side_masking_default_state | 0             | Sets the server-side masking activation trigger. Valid values: <ul style="list-style-type: none"><li>• 0=SSM activated per session when triggered by a rule in the installed policy</li><li>• 1=SSM activated for every session regardless of the installed policy</li></ul> |
| server_side_masking_force_watch   | NULL          | Comma separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1,2.2.2.2/2.2.2.2) whose sessions are watched automatically. Valid when server_side_masking_installed=1 and qrw_default_state=0. Cannot be configured to the same range as firewall_force_watch.         |
| server_side_masking_force_unwatch | NULL          | Comma separated list of client IP/MASKs (for example, 1.1.1.1/1.1.1.1,2.2.2.2/2.2.2.2) whose sessions are not watched. Valid when server_side_masking_installed is 1 and firewall_default_state is 1. Cannot be configured to the same range as firewall_force_unwatch.      |

## Linux-UNIX: Discovery parameters

The discovery parameters define the behavior of the auto-discovery feature, for discovering database instances and sending the results to the current active S-TAP.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

| GIM                                | guard_tap.ini                 | Default value                                                             | Description                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|-------------------------------|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_DISCOVERY_INTERVAL            | discovery_interval            | 24                                                                        | The time interval at which auto-discovery runs. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• &lt; 0: interval in minutes</li><li>• &gt; 0: interval in hours</li></ul> Default = 24 (hours)                                                                                                                                  |
| STAP_DISCOVERY_DBs                 | discovery_dbs                 | oracle:db2:informix:mysql:pos:tgres:sybase:hadoop:teradata:netezza:memsql | Colon (':') separated list of database types to attempt to discover. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                              |
| STAP_DISCOVERY_DEBUG               | discovery_debug               | 0                                                                         | Output debug information from discovery. The log is guard_discovery.stderr.log located in the directory specified by the parameter tap_log_dir (by default: /tmp/guard_stap). <ul style="list-style-type: none"><li>• 0: disable (errors only)</li><li>• 1: errors and debug statements</li></ul> Can be set when pushing to a group of DB servers via GIM. |
| STAP_DISCOVERY_ORA_ALT_LOCATIONS   | discovery_ora_alt_locations   |                                                                           | Alternate locations to look for listener.ora files. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                               |
| STAP_DISCOVERY_ORA_USE_PORT_RANGES | discovery_ora_use_port_ranges | 0                                                                         | Enable S-TAP discovery of Oracle databases to combine discovered instances based on port ranges. This setting works with a single unix_domain_socket_marker. Multiple unix_domain_socket_marker configurations require separate instances. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• 1: enabled</li></ul>                 |
| STAP_DISCOVERY_PORT                | discovery_port                | 8443                                                                      | S-TAP Discovery uses this port to connect to the Guardium® system.                                                                                                                                                                                                                                                                                          |

## Linux-UNIX: Application server parameters

These parameters affect the behavior of the S-TAP when an application user name needs to be bounded with database activities.

These parameters are in the [TAP] section on the guard\_tap.ini file.

For more information, see [Linux-UNIX: Application server S-TAP configuration](#).

| GUI                             | GIM                          | guard_tap.ini           | Default value | Description                                                                                                                                                              |
|---------------------------------|------------------------------|-------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| App. Server User Identification | STAP_APPSERVER_INSTALLED     | appserver_installed     | 0             |                                                                                                                                                                          |
| Ports                           | STAP_APPSERVER_PORTS         | appserver_ports         | 8080          | Comma-separated list of ports, or hyphens for inclusive ranges of ports, on which the Java™ application is accessed by a web browser.                                    |
| Login pattern                   | STAP_APPSERVER_LOGIN_PATTERN | appserver_login_pattern |               | Comma-separated list of strings specifying the login pattern that is passed to the application. This pattern is passed to the Java application to identify a user login. |

| GUI                | GIM                             | guard_tap.ini              | Default value | Description                                                                                                                                                                                                                        |
|--------------------|---------------------------------|----------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username prefix    | STAP_APPSERVER_USERNAME_PREFIX  | appserver_username_prefix  |               | Comma-separated list of strings specifying the prefix to the username for a specific session. This is the pattern the Java application uses to indicate the username of the given session.                                         |
| Username postfix   | STAP_APPSERVER_USERNAME_POSTFIX | appserver_username_postfix |               | Comma-separated list of strings specifying the postfix to the username for a specific session. This pattern is passed to the Java application to indicate the end of the value for the given variable that indicates the username. |
| Session pattern    | STAP_APPSERVER_SESSION_PATTERN  | appserver_session_pattern  |               | Comma-separated list of strings specifying the start of an end-user session, using a particular database session. This pattern specifies the [change of] end-user session for a specific database connection.                      |
| Session prefix     | STAP_APPSERVER_SESSION_PREFIX   | appserver_session_prefix   |               | Comma-separated list of strings specifying the session identifier.                                                                                                                                                                 |
| Session postfix    | STAP_APPSERVER_SESSION_POSTFIX  | appserver_session_postfix  |               | Comma-separated list of strings specifying where the session ends.                                                                                                                                                                 |
| Session ID pattern | STAP_APPSERVER_USERSESS_PATTERN | appserver_usersess_pattern |               | Comma-separated list of strings specifying the identifier for marking which end-user session a specific connection is continuing with.                                                                                             |
| Session ID prefix  | STAP_APPSERVER_USERSESS_PREFIX  | appserver_usersess_prefix  |               | Comma-separated list of strings specifying what identifies or precedes the session_id in a specific users indicator packet.                                                                                                        |
| Session ID postfix | STAP_APPSERVER_USERSESS_POSTFIX | appserver_usersess_postfix |               | Comma-separated list of strings specifying where the session ID ends.                                                                                                                                                              |

## Linux-UNIX: Hadoop parameters

Guardium supports Hadoop integration using HDFS, Hortonworks with Apache Ranger, and Cloudera Navigator. Understand the S-TAP configuration required for these integrations.

- [Parameters for HDFS](#)
- [Parameters for Hortonworks with Apache Ranger](#)
- [Parameters for Cloudera Navigator using Kafka messaging](#)

### Parameters for HDFS

Table 1. Parameters for HDFS integration

| GUI                              | GIM                                   | guard_tap.ini                    | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|---------------------------------------|----------------------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ranger HDFS audit directories    | STAP_RANGER_HDFS_AUDIT_DIRS           | ranger_hdfs_audit_dirs           | NULL    | Comma-separated list of directories where Ranger logs the service audits. Include one directory that contains the daily log directories, for each service you want to monitor. Usually the paths are located under /ranger/audit.<br><br>Example service directories for CDP 7:<br>/ranger/audit/hive/hiveServer2,/ranger/audit/kafka/kafka,/ranger/audit/hbase/hbaseMaster,/ranger/audit/hbase/hbaseRegional,/ranger/audit/atlas/atlas,/ranger/audit/hdfs/hdfs<br><br>Example service directories for HW 3:<br>/ranger/audit/hbaseMaster,/ranger/audit/hbaseRegional,/ranger/audit/hdfs,/ranger/audit/hiveServer2,/ranger/audit/kafka,/ranger/audit/solr,/ranger/audit/storm |
| Ranger HDFS audit history length | STAP_RANGER_HDFS_AUDIT_HISTORY_LENGTH | ranger_hdfs_audit_history_length | 30      | The length of the audit history. <ul style="list-style-type: none"> <li>A value of 0 means that the S-TAP will read audits from the beginning of time.</li> <li>A positive value (max = 2147483647) is the history length in days. The default is 30 days.</li> <li>A negative value (min = -2147483648) is the history length in hours.</li> </ul>                                                                                                                                                                                                                                                                                                                           |
| Ranger HDFS keytab               | STAP_RANGER_HDFS_KEYTAB               | ranger_hdfs_keytab               | NULL    | Required for Kerberos. Location of the Kerberos keytab that contains the principal used to connect to HDFS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ranger HDFS lib location         | STAP_RANGER_HDFS_LIB_LOCATION         | ranger_hdfs_lib_location         | NULL    | Locate libhdfs.so provided by Hadoop cluster (for example, /usr/hdp/3.1.0.141-1/usr/lib/libhdfs.so) and set ranger_hdfs_lib_location to the directory that contains libhdfs.so (for example, /usr/hdp/3.1.0.141-1/usr/lib).                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| HDFS name node                   | STAP_RANGER_HDFS_NAMENODE             | ranger_hdfs_namenode             | NULL    | IP or hostname of the HDFS NameNode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Ranger HDFS poll (milliseconds)  | STAP_RANGER_HDFS_POLL_MS              | ranger_hdfs_poll_ms              | 100     | Time interval, in milliseconds, the S-TAP waits between checking for new Ranger audits in HDFS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| HDFS port                        | STAP_RANGER_HDFS_PORT                 | ranger_hdfs_port                 | 8020    | The HDFS NameNode port the S-TAP connects to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                  | STAP_RANGER_HDFS_READER_ENABLED       | ranger_hdfs_reader_enabled       | 0       | Whether the Ranger HDFS reader is enabled. Valid values: <ul style="list-style-type: none"> <li>0: Disabled</li> <li>1: Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| GUI              | GIM                   | guard_tap.ini    | Default | Description                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------|------------------|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ranger HDFS user | STAP_RANGER_HDFS_USER | ranger_hdfs_use  | NULL    | The user with which S-TAP connects to HDFS. if the HDFS setup is using Kerberos, set the parameter to the Kerberos principal.                                                                                                                                                                   |
| LD library path  | STAP_LD_LIBRARY_PATHS | ld_library_paths | NULL    | Locate libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server/libjvm.so) and set ld_library_paths to the directory that contains libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server). |

## Parameters for Hortonworks with Apache Ranger

Some parameters are configurable through the Guardium user interface or through the Guardium Installation Manager. All parameters are configurable using the Guardium API.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

Table 2. Parameters for Hortonworks with Apache Ranger integration

| GIM                                        | guard_tap.ini                         | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------|---------------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STAP_LOG4J_READER_ENABLED                  | log4j_reader_enabled                  | 0             | Enable log4j listening mode for Ranger traffic. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• 1: enabled</li></ul>                                                                                                                                                                                                                                                                                                                 |
| STAP_LOG4J_PORT                            | log4j_port                            | 5555          | The port where the Guardium S-TAP listens for Ranger audits (integer value). Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                                                                                           |
| STAP_LOG4J_LISTEN_ADDRESS                  | log4j_listen_address                  | 0.0.0.0       | IP Address for log4j listener, for Ranger plug ins. The default value of 0.0.0.0 is recommended, as this enables the S-TAP to receive traffic from any host. Use localhost if configuring the system for high availability (indicates the loopback address of the system). If you choose to restrict access to a specific address, be sure you are not excluding any necessary traffic for monitoring. Can be set when pushing to a group of DB servers via GIM. |
| STAP_LOG4J_NUM_CONNECTIONS                 | log4j_num_connections                 | 20            | The number of concurrent connections (integer) to expect from the service or services defined for this S-TAP. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                                                          |
| STAP_RANGER_DYNAMIC_POLICY_PORT            | ranger_dynamic_policy_port            | 5556          | Port that Ranger plugins connect to. S-TAP listens here for the Ranger dynamic policy. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                                                                                 |
| STAP_RANGER_DYNAMIC_POLICY_LISTEN_ADDRESS  | ranger_dynamic_policy_listen_address  | 0.0.0.0       | Ranger dynamic policy reader listener port. <ul style="list-style-type: none"><li>• 0.0.0.0 indicates any IP address of the system</li><li>• Use localhost for HA</li></ul> Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                            |
| STAP_RANGER_DYNAMIC_POLICY_NUM_CONNECTIONS | ranger_dynamic_policy_num_connections | 20            | Maximum allowed connections for Ranger dynamic policy reader. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                                                                                                          |
| STAP_RANGER_DYNAMIC_POLICY_TIMEOUT         | ranger_dynamic_policy_timeout         | 10            | Timeout, in seconds, for Ranger dynamic policy reader policy verdicts. Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                                                                                                 |
| STAP_RANGER_DYNAMIC_POLICY_DEFAULT_VERDICT | ranger_dynamic_policy_default_verdict | 1             | Default policy verdict for Ranger dynamic policy reader when the verdict times out. Valid values: <ul style="list-style-type: none"><li>• 0: block</li><li>• 1: pass</li></ul> Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                         |
| STAP_RANGER_DYNAMIC_POLICYREADER_ENABLED   | ranger_dynamic_policy_reader_enabled  | 0             | Enable Hortonworks dynamic policy reader. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• 1: enabled</li></ul> Can be set when pushing to a group of DB servers via GIM.                                                                                                                                                                                                                                                             |

## Parameters for Cloudera Navigator using Kafka messaging

Guardium supports Cloudera Navigator for collecting audit data using the Kafka messaging system.

Some parameters are configurable through the Guardium user interface or through the Guardium Installation Manager. All parameters are configurable using the Guardium API.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

Table 3. guard\_tap.ini parameters for Cloudera Navigator using Kafka messaging integration

| GUI | GIM                      | guard_tap.ini        | Default | Description                                                                                                                                                              |
|-----|--------------------------|----------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|     | STAP_KAFKAREADER_ENABLED | kafka_reader_enabled | 0       | Enables Cloudera Navigator integration using Kafka publish and consume. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• 1: enabled</li></ul> |

| GUI                 | GIM                          | guard_tap.ini           | Default              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------|-------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bootstrap servers   | STAP_KAFKA_BOOTSTRAP_SERVERS | kafka_bootstrap_servers |                      | Required. The comma separated list of host_name:port pairs is used to establish the initial connection to the Kafka cluster. After the initial connection is established, all servers in the cluster are used. Consider specifying more than one bootstrap in case one is down. Example: hostnameofbroker1:9092,hostnameofbroker2:9092                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Enable TLS          | STAP_KAFKA_USE_TLS           | kafka_use_tls           | 0                    | Whether the Kafka cluster uses TLS. Valid values: <ul style="list-style-type: none"><li>• 0: disabled</li><li>• 1: enabled</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Topic name          | STAP_KAFKA_TOPIC_NAME        | kafka_topic_name        | NavigatorAuditEvents | Required. The topic name in the Kafka cluster that Cloudera publishes audits to, and that S-TAP reads audits from.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Principal           | STAP_KAFKA_PRINCIPAL         | kafka_principal         | NULL                 | The Kerberos principal name for the S-TAP, which is used when the Kafka cluster requires Kerberos authentication.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                     | STAP_KAFKA_MESSAGE_MAX_BYTES | kafka_message_max_bytes | 65536                | The maximum number of bytes of messages to attempt to fetch for each topic-partition in each fetch request. The fetch request size must be at least as large as the maximum message size that the Kafka broker(s) that is connected to the S-TAP allows. Otherwise the Cloudera Navigator Audit server that is publishing audits to the Kafka cluster can send messages larger than the S-TAP can fetch. If there is a message larger than the value of this parameter, S-TAP skips that audit and continues.<br>There is no maximum size for this parameter. Best practice is to set it to the same value as the Kafka broker's message.max.bytes. This ensures that the S-TAP can handle the same maximum message size as the broker. Increase the S-TAP buffer size if needed. If you increase kafka_message_max_bytes, the S-TAP allocates more memory, in order to hold the maximum message size. |
| Path to keytab file | STAP_KAFKA_KEYTAB            | kafka_keytab            | NULL                 | The path to the Kerberos keytab file on the S-TAP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Group name          | STAP_KAFKA_GROUP_NAME        | kafka_group_name        | NULL                 | Required. Assigns the S-TAP to this Kafka consumer group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SSL CA path         | STAP_KAFKA_SSL_CA_LOCATION   | kafka_ssl_ca_location   | NULL                 | Required if kafka_use_tls = 1. Path to the certificate authority (CA) for verifying the Kafka cluster certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| LD library path     | STAP_LD_LIBRARY_PATHS        | ld_library_paths        | NULL                 | Required. A colon delimited list of paths to search for Kafka libraries. Kafka libraries are located in the stap install directory. Set this parameter to the directory containing the guard_stap binary. (Examples: /usr/local/guardium/guard_stap, /usr/local/modules/STAP/current, /opt/guardium/modules/STAP/current.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Linux-UNIX: Configuration Auditing System (CAS) parameters

These parameters affect the behavior of CAS.

Table 1. CAS parameters for UNIX/Linux

| GUI                       | guard_tap.ini                 | Default value     | Description                                                                 |
|---------------------------|-------------------------------|-------------------|-----------------------------------------------------------------------------|
| Task checkpoint           | cas_task_checkpoint           | task_checkpoint   |                                                                             |
| Client checkpoint         | cas_client_checkpoint         | client_checkpoint |                                                                             |
| Checkpoint period         | cas_checkpoint_period         | 60                |                                                                             |
| Fail over file            | cas_fail_over_file            | fail_over_file    |                                                                             |
| Fail over file size limit | cas_fail_over_file_size_limit | 50000             |                                                                             |
| Max rec. attempts         | cas_max_reconnect_attempts    | 5000              |                                                                             |
| Reconnect interval        | cas_reconnect_interval        | 60                |                                                                             |
| Raw data limit            | cas_raw_data_limit            | 1000              |                                                                             |
| Md5 data limit            | cas_md5_size_limit            | 1000              |                                                                             |
|                           | cas_command_wait              | 300               | Wait time in seconds before killing a long-running data collection process. |
|                           | cas_server_failover_delay     | 60                | Wait time in minutes before trying to connect to another Guardium system.   |

## Linux-UNIX: Debug parameters

These parameters affect the behavior of S-TAP debugging.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

These parameters are in the [TAP] section on the guard\_tap.ini file.

Table 1. S-TAP configuration parameters for debugging

| GUI | GIM | guard_tap.ini | Default value | Description |
|-----|-----|---------------|---------------|-------------|
|-----|-----|---------------|---------------|-------------|

| GUI             | GIM                  | guard_tap.ini          | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------------------|------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Logs are stderr.txt, guard_stap.fam.txt located in the directory specified in tap_log_dir parameter (by default: /tmp/guard_stap). Valid values:</p> <ul style="list-style-type: none"> <li>• 0: Disable</li> <li>• 1: Basic debug</li> <li>• 4: Verbose debug</li> <li>• 6: Appserver debug</li> <li>• 10: Exit engine debug. Debug information is logged in both S-TAP log and db2_exit log (db2diag.log).</li> <li>• 11: exit engine debug. Debug information is only logged in db2_exit log (db2diag.log).</li> </ul> |
| Messages Remote | STAP_REMOTE_MESSAGES | remote_messages        | 1             | <p>Send messages to the active Guardium host. Valid values:</p> <ul style="list-style-type: none"> <li>• 0: Do not send messages</li> <li>• 1: Send messages to the active Guardium system.</li> </ul>                                                                                                                                                                                                                                                                                                                                         |

## Linux-UNIX: K-TAP parameters

These parameters affect the behavior of the K-TAP.

These parameters are located in the [TAP] section of the S-TAP properties file: guard\_tap.ini.

Attention: These are advanced parameters and should be modified only by IBM Technical Support.

Table 1. K-TAP configuration parameters

| GIM                         | guard_tap.ini          | Default value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | ktap_installed         | 1             | <p>Whether or not the Kernel Monitor module is installed. ## Linux-UNIX: S-TAP configuration per database type

This section provides detailed instructions or example for configuring monitoring on various databases.

- [Linux-UNIX: Configuring Apache Cassandra and S-TAP for auditing interception](#)  
Configure Apache Cassandra and S-TAP to monitor encrypted traffic on Apache Cassandra. Monitoring includes authorization messages for login, normal SQLs, prepared statements, batch statements, bind variables, and bound values. This configuration does not require an inspection engine or K-TAP.
- [Linux-UNIX: Application server S-TAP configuration](#)  
Application Server S-TAP is a very easy way to identify application users for Java Application Server applications when built-in functionality is not available. It doesn't require any changes to existing applications which makes it a very attractive solution. Nevertheless some considerations need to be taken into account.
- [Linux-UNIX: CockroachDB inspection engine configuration](#)  
View a typical Cockroach database inspection engine configuration. Guardium supports unencrypted connections with a cockroach database. This configuration required K-TAP.
- [Linux-UNIX: Couchbase auditing configuration](#)  
Use a double proxy to capture couchbase traffic with real client IPs.
- [Linux-UNIX: Using SAP-HANA with encrypted connections](#)  
When SAP-HANA is configured with SSL/TLS encryption, S-TAP requires configuring two proxies using NGINX.

- [Linux-UNIX: Datastax Cassandra auditing configuration](#)  
Configure logging to a file appender for monitoring encrypted traffic on Datastax Cassandra. This supports the audits provided by the built-in audit logging, for example: queries, data manipulation language, data definition language, data control syntax, authentication. This configuration does not require an inspection engine or K-TAP.
- [Linux-UNIX: Db2 IE configuration](#)  
View a typical inspection engine configuration, and flows for enabling and disabling A-TAP, and opening the SSL console for an Db2 inspection engine.
- [Linux-UNIX: Elastic Search configuration](#)  
Encrypted Elastic Search is supported via SSL termination.
- [Linux-UNIX: Configuring Exit libraries](#)  
Exit libraries embed a Guardium library into the database, using the exit mechanism. The exit library, or module, communicates directly with the Guardium S-TAP to forward database traffic.
- [Linux-UNIX: Hadoop configuration](#)  
This topic introduces fundamental concepts and processes for monitoring Hadoop data with Guardium.
- [Linux-UNIX: MongoDB IE configuration](#)  
View a typical inspection engine configuration, and flows for enabling and disabling A-TAP, and opening the SSL console for a MongoDB inspection engine.
- [Linux-UNIX: Neo4J auditing configuration](#)  
Use a double proxy together with either K-TAP or PCAP to capture encrypted Neo4J traffic.
- [Linux-UNIX: Oracle Connection Manager configuration to monitor encrypted traffic](#)  
You can use the Oracle Connection Manager to monitor encrypted traffic, without A-TAP.
- [Linux-UNIX: Oracle IE configuration](#)  
View a typical configuration for an inspection engine on an Oracle database.
- [Linux-UNIX: Configuring S-TAP interception using Oracle Unified Audit](#)  
Use Oracle Unified Auditing (OUA) to capture user activities in Oracle database environments based on Oracle Unified Audit policies. All captured activities are stored in specific tables. Linux S-TAP x86\_64 can dynamically load and use Oracle-provided libraries to connect to the configured Oracle services. The S-TAP can then pull data from the unified auditing tables, and send data to Guardium collectors.
- [Linux-UNIX: Redis configuration](#)  
Redis TCP protocol is supported by an S-TAP installed on a Redis server. If Redis is set up with SSL/TLS encryption, you need two proxies using HAProxy Load Balancer.

## Linux-UNIX: Configuring Apache Cassandra and S-TAP for auditing interception

Configure Apache Cassandra and S-TAP to monitor encrypted traffic on Apache Cassandra. Monitoring includes authorization messages for login, normal SQLs, prepared statements, batch statements, bind variables, and bound values. This configuration does not require an inspection engine or K-TAP.

### About this task

Limitations: Apache auditing does not include SOURCE\_PROGRAM, SERVER\_OS, CLIENT\_OS, DB\_PROTOCOL\_VERSION, or OS\_USER.

To configure Apache Cassandra and S-TAP for auditing, configure a logback to write to the S-TAP Cassandra audit reader in the same directory as the `guard_stap.cassandra_audit` executable. The logback is created when you enable Cassandra Audit in the S-TAP configuration. Specify the value for `cassandra_audit_delimiter` in the output string for logback.

The following jar files for this configuration are part of the S-TAP installation. They are located in the directory where the S-TAP is installed, which is often, but not always, in /usr/local/guardium/guard\_stap.

- `guardium_cassandra_audit-3.4.jar` (for the query handler, versions 3.4 to 3.10)
- `guardium_cassandra_audit-3.11.jar` (for the query handler, version 3.11 only)
- `guardium_cassandra_audit-4.0.jar` (for the query handler, versions 4.0 and higher)

The user who runs the Cassandra database must be authorized to write to the `cassandra` pipe in the S-TAP directory. Use `guardctl authorize-user` to add the user to the `Guardium` group.

When you copy the JAR files to the `cassandra` directory, make sure that the `cassandra` user has the proper permissions to read them.

Apache Cassandra auditing supports multi-tenancy.

### Procedure

1. Copy the relevant JAR files to the Cassandra lib directory so that the database can find and use them.

For example,

- Non-GIM S-TAP:

```
cp -p /usr/local/guardium/guard_stap/guardium_cassandra_audit-4.0.jar /usr/share/cassandra/lib
```

- GIM S-TAP:

```
cp -p /usr/local/modules/STAP/current/guardium_cassandra_audit-4.0.jar /usr/share/cassandra/lib
```

2. Enable Cassandra auditing in S-TAP by setting the `cassandra_audit_enabled=1`. You can set this parameter from the GUI, by editing the `guard_tap.ini` file, or by using the `update_stap_config` grdapi function.

3. Authorize the `cassandra` user to write to the Cassandra pipe in the S-TAP directory.

For example,

- Non-GIM S-TAP:

```
/usr/local/guardium/guard_stap/guardctl --db-user=cassandra authorize-user
```

- GIM S-TAP:

```
/usr/local/guardium/modules/ATAP/current/files/bin/guardctl -db-user=cassandra authorize-user
```

4. Edit the `logback.xml` configuration file as shown in the following example.

```

<appender name="Guardium" class="ch.qos.logback.core.FileAppender">
<file>/usr/local/guardium/guard_stap/.cassandra_audit</file>
<immediateFlush>true</immediateFlush>
<encoder>
<pattern>%msg{}GUARD_DELIM</pattern>
</encoder>
</appender>
<logger name="com.ibm.guardium" level="INFO">
<appender-ref ref="Guardium"/>
</logger>

```

- Non-GIM S-TAP:

```
<file>/usr/local/guardium/guard_stap/.cassandra_audit</file>
```

- GIM S-TAP:

```
<file>/usr/local/modules/STAP/current/.cassandra_audit</file>
```

5. Change jvm.options to enable the custom\_query\_handler\_class to call into the logging mechanism by setting JVM\_EXTRA\_OPTS to include the following line.

```
-Dcassandra.custom_query_handler_class=com.ibm.guardium.CassandraQueryHandler
```

6. To enable AUTH logging on, when users connect to the database, set a property in JVM\_EXTRA\_OPTS so that the logging mechanism can correctly redirect auth requests.

For example, if you use PasswordAuthenticate, add the following statement to JVM\_EXTRA\_OPTS.

```
-DGardiumBaseAuthenticator=org.apache.cassandra.auth.PasswordAuthenticator
```

Then, instead of specifying PasswordAuthenticator in cassandra.yaml, you can use com.ibm.guardium.CassandraAuthenticator.

7. The default role manager (CassandraRoleManager) explicitly checks for PasswordAuthenticator. Therefore, if you enable AUTH logging, you also need to change role\_manager in cassandra.yaml.

Set role\_manager to com.ibm.guardium.GuardCassandraRoleManager and specify an additional property in JVM\_EXTRA\_OPTS for the role manager to use.

For example, -DGardiumBaseRoleManager=org.apache.cassandra.auth.CassandraRoleManager

8. Set Java environment variables. For example,

```
JVM_OPTS="$JVM_OPTS $JVM_EXTRA_OPTS"
```

## What to do next

Optionally, you can choose to decode the username during a failed login. To add the decoding functionality, use a class that can understand the format that you are using. Since Cassandra can be extended to use custom authenticators, this format might differ from the base PasswordAuthenticator, which uses SASL. Guardium provides a decoder that works for PasswordAuthenticator. You can optionally switch out the decoder for PasswordAuthenticator for a different decoder, which must be provided by the implementor of the custom authenticator. To specify the replacement decoder, add the following to JVM\_EXTRA\_OPTS (default-included decoder for PasswordAuthenticator shown): -DGardiumBaseAuthenticatorDecoder=com.ibm.guardium.GuardPasswordAuthenticatorDecoder. The interface for the replacement authenticator is as follows,

```

package com.ibm.guardium;
import java.nio.ByteBuffer;
public interface IGuardAuthenticatorDecoder
{
 String getUsername(byte[] clientResponse);
}

```

## Linux-UNIX: Application server S-TAP configuration

Application Server S-TAP is a very easy way to identify application users for Java Application Server applications when built-in functionality is not available. It doesn't require any changes to existing applications which makes it a very attractive solution. Nevertheless some considerations need to be taken into account.

For Application Server S-TAP to work, the username needs to be transmitted in clear text in the HTTP stream. Some authentication mechanisms, for example, regular HTTP based authentication are hashed or Base64 encoded and are not supported. In general Form Logins transmit the username in clear text.

This method does not work with all applications. It depends on the way that connection pooling is used. For example, it requires that the access to the database is synchronous with the same process or thread that is handling the HTTP request. A good example is a servlet-based application where a servlet processes HTTP requests, and in the process receives a connection from a connection pool to access the database.

HTTPS connections are also not supported. This is normally not a crucial problem because the S-TAP is installed on the application server. In normal enterprise configurations, only traffic to the web server is HTTPS encrypted and the connection between web and application server is standard HTTP.

There are situations when it is not possible or desirable to change the application source code, so the Guardium Application Event API cannot be used. The application may also not use stored procedures to define user boundaries. In some of these cases the ability of the Guardium S-TAP to monitor network traffic can be used to identify application users. In this scenario the S-TAP is used to correlate application end users with database activity. An S-TAP is installed on the machine that hosts the application server; and is not installed on the machine that hosts the database server. It is then configured to monitor incoming HTTP traffic to the application server, filter out user names and correlate them through an application server session id with database activity. In Guardium this is called Application Server User Identification or Application Server S-TAP.

This approach is advantageous because it works without changing the application or reconfiguring the application server. It is therefore a very fast and easy solution. The disadvantages are that it also does not work with all enterprise applications. Possible problems include incompatible authentication mechanisms that encrypt or hash user names. Application Server S-TAP works best for standard Java Enterprise Applications using a type of Form Login authentication.

1. Analyze the application's web traffic to determine:

- The HTTP port of the application server.
- The application user name in the HTTP traffic during login.
- The Java Session ID that is correlated to the user name.

There are various tools you can use for this analysis. It is beyond the scope of the Guardium Knowledge Center.

## 2. Configure and save the Application server S-TAP. Typical parameter values specific for the application server settings:

- App. Server User Identification: 1
- App server user ID: 1
- Session timeout:1800
- Ports: 8081
- Login pattern: userid
- Username prefix: userid=
- Username postfix: &
- Session pattern: action=login
- Session prefix: JSESSIONID=
- Session postfix: ;
- Session ID pattern: Cookie
- Session ID prefix: USESESSIONID=
- Session ID postfix: ;

Guardium stores the application username in the field **Application User**, in the entity **Access Period**. You can add this field to reports.

## Linux-UNIX: Couchbase auditing configuration

Use a double proxy to capture couchbase traffic with real client IPs.

## About this task

This procedure requires two proxies of either Nginx or HAProxy type. Both must be located on the database.

### Guidelines:

- Incoming encrypted traffic from the Client is sent to the first proxy instance, Proxy1.
- Proxy1 terminates the SSL and adds the proxy protocol to ports.
- The second proxy instance, Proxy2, listens to intermediate ports and removes the proxy protocol.
- K-TAP intercepts traffic in between Proxy1 and Proxy2 to get decrypted traffic with real client IPs.
- Outgoing decrypted traffic from Proxy2 is sent to unencrypted Couchbase database ports.

## Procedure

### 1. Configure the database.

These ports must be open on each host for Couchbase Server to operate correctly. In addition, these ports must be available (not blocked by a firewall or other such mechanism):

- Between each node of a cluster
- Between nodes of multiple clusters connected by using XDCR
- Between application servers and nodes, and for administrative access

| Port Name                              | Default Port Number<br>Unencrypted /<br>Encrypted | Description                         | Node-to-node | Client-to-Node | Cluster admin | XDCR v1 (CAPI) | XDCR v2<br>(XMEM) |

| fts_http_port /<br>fts_ssl_port        | 8094 / 18094                                      | Search service<br>REST/HTTP traffic | Yes          | Yes            | No            | No             | No                |
| memcached_port /<br>memcached_ssl_port | 11210 / 11207                                     | Data Service                        | Yes          | Yes            | No            | No             | Yes               |

2. Proxy Configuration: There are two ways to setup Proxy configurations along with IPTABLE configurations.

- Proxy1 listens on port 1xxxx, so external ports are still the same to the user. For example, an encrypted connection still connects via the GUI as `http://COUCHBASE:1xxxx`. In this case the couchbase configuration needs to make sure it is not listening on 1xxxx. Couchbase configuration is in the `static_config` file. To avoid reconfiguring clients, the default ports must be modified so that the clients connect to the first proxy instance instead. For example:

```
{memcached_ssl_port, 11207}
{ssl_rest_port, 18091}
{ssl_capi_port, 18092}
{ssl_query_port, 18093}
{fts_ssl_port, 18094}
```

These ports need to be used in the first proxy instance and Couchbase would need to be configured to expect unencrypted connections and to move these ports to a different number so that they do not duplicate ports being listened on by the proxy instances.

- Proxy1 listens on port yxxxx where y is not 1, so the couchbase configuration can stay as the default, but external ports need to be changed to yxxxx.

3. Configure HAProxy. (Not required if you are using NGINX.)

To enable Proxy Protocol in HAProxy1, add the `send-proxy` keyword to the `/etc/haproxy/haproxy.cfg` file. To get the Real Client IP, strip the Proxy protocol in HAProxy2, and add `accept-proxy` to `/etc/haproxy/haproxy.cfg` file.

Added/Modify `haproxy.cfg` for all couchbase ssl ports, giving an example of ssl port(1xxxx), where xxxx is SSL port, such as 8091/8092, etc; yyy is service name such as rest/capi/query, etc.

Method1: Proxy1 listens on port 1xxxx and pass traffic to Proxy2, Proxy2 listens on port 2xxxx and send decrypted traffic to couchbase no ssl port (xxxx). By using this method, couchbase should not listen on port 1xxxx.

- frontend yyy\_in bind \*:

```
bind *:1xxxx ssl crt /etc/haproxy/ha_couchbase_cert_key.pem
default_backend send_pp_yyy
```

- backend send\_pp\_yyy

```
balance roundrobin
server intermediate_yyy 127.0.0.1:2xxxx send-proxy
```

- frontend strip\_pp\_yyy

```
bind 127.0.0.1:2xxxx accept-proxy
default_backend yyy_out
```

- backend yyy\_out

```
balance roundrobin
server yyyy 127.0.0.1:xxxx
```

Method2: Proxy1 listens on port 3xxxx and passes traffic to Proxy2. Proxy2 listens on port 2xxxx and sends decrypted traffic to couchbase no ssl port (xxxx). By using this method, the external port for user should be changed to 3xxxx.

- frontend yyy\_in bind \*:

```
bind *:3xxxx ssl crt /etc/haproxy/ha_couchbase_cert_key.pem
default_backend send_pp_yyy
```

- backend send\_pp\_yyy

```
balance roundrobin
server intermediate_yyy 127.0.0.1:2xxxx send-proxy
```

- frontend strip\_pp\_yyy

```
bind 127.0.0.1:2xxxx accept-proxy
default_backend yyy_out
```

- backend yyy\_out

```
balance roundrobin
server yyyy 127.0.0.1:xxxx
```

4. Configure NGINX. (Not required if you are using HAProxy.)

For a TCP stream, the PROXY protocol can be enabled for connections between NGINX and an upstream server. To enable the PROXY protocol in Nginx1, include the `proxy_protocol` directive in a server block at the stream {} level in `/etc/nginx/nginx.conf`. NGINX terminates HTTPS traffic (the `ssl_certificate` and `ssl_certificate_key` directives) and proxies the decrypted data to a backend server. In Nginx2, add listen with `proxy_protocol` to receive the client's real IP forwarded with Proxy Protocol.

- a. Make sure that your NGINX installation includes the HTTP and Stream Real IP modules:

```
nginx -V 2>&1 | grep -- 'http_realip_module'
nginx -V 2>&1 | grep -- 'stream_realip_module'
```

b. Add/modify nginx.cfg for all couchbase ssl ports, giving an example of ssl port(1xxxx), where xxxx is SSL port, such as 8091/8092, etc; yyy is service name such as rest/capi/query, etc.

- Method1: Proxy1 listens on port 1xxxx and pass traffic to Proxy2, Proxy2 listens on port 2xxxx and sends decrypted traffic to couchbase no ssl port (xxxx). When using this method, couchbase should not listen on port 1xxxx.

```
stream {
 server {
 listen 1xxxx ssl;
 proxy_pass 127.0.0.1:2xxxx;
 ssl_certificate /opt/couchbase/SSLCA/chain.pem;
 ssl_certificate_key /opt/couchbase/SSLCA/nodedir/pkey.key;
 ssl_session_cache shared:SSL:8m;
 proxy_protocol on;
 }

 server {
 listen 2xxxx proxy_protocol;
 proxy_pass 127.0.0.1:xxxx;
 }
}
```

- Method2: Proxy1 listens on port 3xxxx and pass traffic to Proxy2, Proxy2 listens on port 2xxxx and send decrypted traffic to couchbase no ssl port (xxxx). When using this method, the external port for user should be changed to 3xxxx.

```
stream {
 server {
 listen 2xxxx ssl;
 proxy_pass 127.0.0.1:3xxxx;
 ssl_certificate /opt/couchbase/SSLCA/chain.pem;
 ssl_certificate_key /opt/couchbase/SSLCA/nodedir/pkey.key;
 ssl_session_cache shared:SSL:8m;
 proxy_protocol on;
 }

 server {
 listen 3xxxx proxy_protocol;
 proxy_pass 127.0.0.1:xxxx;
 }
}
```

##### 5. Configure the network.

If the client is on the same server with the DB, verify that all traffic from the client is sent to Proxy1. Otherwise, all traffic that is not from Proxy2 to DB is dropped. This requires IPTABLE setup.

In order to support encrypted traffic for couchbase, it is necessary to configure a proxy service to terminate the encryption. The proxy solution that is used depends on your requirements, though NGINX and HAProxy both work well for this. [Example configurations are attached above]

Using this script to setup IPTABLES. The UID can vary depending on your system configuration. As with all firewall rules, order is important.

```
#!/bin/sh

Remove any existing jumps to our custom chains
iptables -D INPUT -j chain-couchbase-incoming
iptables -D OUTPUT -j chain-couchbase-outgoing

Clean any existing custom chains
iptables -F chain-couchbase-incoming
iptables -F chain-couchbase-outgoing
iptables -X chain-couchbase-incoming
iptables -X chain-couchbase-outgoing
iptables -N chain-couchbase-incoming
iptables -N chain-couchbase-outgoing

Define external(proxy1), proxy2, ssl and no ssl ports
external_port_prefix=0
ssl_port_prefix=0
proxy2_port_prefix=0
port_list=0

Pass in all arguments, please see bottom usage.
for i in "$@" ; do
 # set the port prefix
 if echo $i | grep '^-' > /dev/null; then
 if echo $i | grep '^external_port_prefix$' > /dev/null; then
 external_port_prefix=999
 elif echo $i | grep '^ssl_port_prefix$' > /dev/null; then
 ssl_port_prefix=999
 elif echo $i | grep '^port_list$' > /dev/null; then
 port_list=999
 fi
 elif ["X$external_port_prefix" = "x999"]; then
 external_port_prefix=$i
 elif ["X$proxy2_port_prefix" = "x999"]; then
 proxy2_port_prefix=$i
 elif ["X$ssl_port_prefix" = "x999"]; then
 ssl_port_prefix=$i
 elif ["X$port_list" = "x999"]; then
 port_list=$i
 fi
 # set ports
 if ["$i" = "11210"]; then
 external_port=${external_port_prefix}1207
 proxy2_port=${proxy2_port_prefix}1207
```

```

 ssl_port=${ssl_port_prefix}1207
else
 external_port=${external_port_prefix}${i}
 proxy2_port=${proxy2_port_prefix}${i}
 ssl_port=${ssl_port_prefix}${i}
fi

#####
INCOMING RULES

Allow loopback access to intermediate ports so that proxy1 can
route traffic to proxy2
iptables -A chain-couchbase-incoming -i lo -p tcp --dport ${proxy2_port} -j ACCEPT

Disallow external access to proxy2
iptables -A chain-couchbase-incoming -p tcp --dport ${proxy2_port} -j REJECT

Disallow direct access to encrypted ports
iptables -A chain-couchbase-incoming -p tcp --dport ${ssl_port} -j REJECT

Allow loopback access to unencrypted ports so that proxy2 can
route traffic to DB
iptables -A chain-couchbase-incoming -i lo -p tcp --dport ${i} -j ACCEPT

Disallow direct access to unencrypted ports
iptables -A chain-couchbase-incoming -p tcp --dport ${i} -j REJECT

Allow access to proxy1
iptables -A chain-couchbase-incoming -p tcp --dport ${external_port} -j ACCEPT

#####
OUTGOING RULES

Allow loopback access to unencrypted ports to allow routing from proxy2 to
DB (proxy2 runs under couchbase UID)
iptables -A chain-couchbase-outgoing -o lo -p tcp --dport $i -m owner --uid couchbase -j ACCEPT

Allow loopback access to intermediate ports to allow routing from proxy1 to
proxy2 (proxy1 runs under couchbase UID)
iptables -A chain-couchbase-outgoing -o lo -p tcp --dport ${proxy2_port} -m owner --uid couchbase -j ACCEPT

Disallow loopback access to unencrypted ports to prevent local clients from
skipping interception
iptables -A chain-couchbase-outgoing -o lo -p tcp --dport $i -j REJECT
fi
done

if ["${port_list}" = "0"]; then
 echo "usage: /root/set_firewall.sh -external_port_prefix [1-9] -proxy2_port_prefix[1-9] -ssl_port_prefix [1-9] -
port_list [servers's no SSL port list]"
 echo "for example /root/set_firewall.sh -external_port_prefix 2 -proxy2_port_prefix 3 -ssl_port_prefix 1 -port_list
8091 8092 8093 8094 11210"
fi

Firewall chains need to return at the end
iptables -A chain-couchbase-incoming -j RETURN
iptables -A chain-couchbase-outgoing -j RETURN

Hook the main rules up to the chains
iptables -A INPUT -j chain-couchbase-incoming
iptables -A OUTPUT -j chain-couchbase-outgoing

```

#### 6. Configure the S-TAP.

Use the first instance of the proxy to terminate the encryption and add proxy-protocol for Guardium to collect the traffic and be able to attribute the correct analyzed\_client\_ip. Use the second instance to remove proxy-protocol, in order to not break the connection to the database. Configure the inspection engine to collect the traffic between the two proxy instances. For example, if you are using the sample configurations above, then the ports to collect for Couchbase are 28091-28094, 11210, 21207. If local TCP connections are allowed, then iptables rules need to allow for the possibility that the UID can vary depending on your system configuration. And as with all firewall rules, order is important.

Edit the inspection engine for port\_range\_end, port\_range\_start and real\_db\_port. They should be set as proxy2 port or range and db\_type should be COUCHBASE. For example, when proxy2 port is 2xxxx:

- If you are using K-TAP, modify the IE parameters in the guard\_tap.ini file:

```
[DB_0]
db_type=COUCHBASE
port_range_end=28094
port_range_start=28091
real_db_port=28091
networks=127.0.0.1/255.255.255.255,9.70.165.199/255.255.255.255
```

- If you are using PCAP, modify the parameters in the guard\_tap.ini file:

```
devices=ens32,lo
ktap_installed=0

[DB_0]
db_type=COUCHBASE
port_range_end=28094
port_range_start=28091
real_db_port=28091
```

---

## Linux-UNIX: Using SAP-HANA with encrypted connections

When SAP-HANA is configured with SSL/TLS encryption, S-TAP requires configuring two proxies using NGINX.

## Before you begin

---

Verify the following prerequisites:

- S-TAP is installed and configured on the SAP-HANA server.
- NGINX is installed and configured for reverse-proxy connections.
- SAP-HANA is configured to use only SSL/TLS connections and the database global configuration enforces SSL/TLS. For example:

```
[communication]
ssl = on
sslEnforce = true
```

## Procedure

---

1. Identify the ports clients use to connect to the database.
2. Configure NGINX using the configuration file that is typically located at `/etc/nginx/nginx.conf`.

For example, assuming that the original port for client connections to the database is 30015 and the SSL certificate is `sap-hana.pem`:

```
worker_processes 1;

load_module lib64/nginx/modules/ngx_stream_module.so;

events {
 worker_connections 1024;
 use epoll;
}
stream {
 upstream saphana {
 server localhost:30015;
 }

 server {
 listen 31015 ssl;
 proxy_pass localhost:32015;
 proxy_protocol on;
 ssl_certificate /hana/shared/HXE/HDB00/su12u2ppc64le-hana/sec/sap-hana.pem;
 ssl_certificate_key /hana/shared/HXE/HDB00/su12u2ppc64le-hana/sec/sap-hana.key;
 }
 server {
 listen 32015 proxy_protocol;
 proxy_pass saphana;
 proxy_ssl on;
 proxy_ssl_certificate /hana/shared/HXE/HDB00/su12u2ppc64le-hana/sec/sap-hana.pem;
 proxy_ssl_certificate_key /hana/shared/HXE/HDB00/su12u2ppc64le-hana/sec/sap-hana.key;
 }
}
```

3. Restart the NGINX service using the following command: `sudo systemctl restart nginx`.

4. Configure the S-TAP for SAP-HANA using second proxy port.  
For example, in a typical inspection engine configuration:

```
[DB_0]
connect_to_ip=127.0.0.1,::1
db2_fix_pack_adjustment=20
db2_shmem_client_position=61440
db2_shmem_size=131072
db2bp_path=NULL
db_exec_file=NULL
db_install_dir=NULL
db_user=NULL
db_type=HANA
encryption=0
informix_inf_file=NULL
db_version=
instance_running=1
intercept_types=NULL
load_balanced=1
port_range_end=32050
port_range_start=32010
priority_count=20
real_db_port=32015
tap_identifier=SAP-HANA
tee_listen_port=0
unix_domain_socket_marker=NULL
networks=0.0.0.0/0.0.0.0,::/0
exclude_networks=
```

Note: If clients use multiple ports for database connections, the NGINX configuration file requires multiple reverse-proxy sections.

## Linux-UNIX: Datastax Cassandra auditing configuration

---

Configure logging to a file appender for monitoring encrypted traffic on Datastax Cassandra. This supports the audits provided by the built-in audit logging, for example: queries, data manipulation language, data definition language, data control syntax, authentication. This configuration does not require an inspection engine or K-TAP.

## Before you begin

---

See [Datastax online reference](#) for details about Datastax audit logging.

The user running the Cassandra database needs to be authorized to write to the cassandra pipe in the S-TAP directory. Use guardctl authorize-user to add the user to the group.

Before copying the jars to the Cassandra directory, make sure that the Cassandra user has appropriate permissions to read the jar files.

## About this task

---

Datastax Cassandra auditing can be configured concurrently with Apache Cassandra on the same host, since they have different setups on different files. The S-TAP handles both of them similarly, via a pipe.

Datastax Cassandra auditing supports multi-tenancy.

## Procedure

---

1. On the database, open the file dse.yaml in a text editor and update the Audit logging options section, with:

```
Audit logging options
audit_logging_options:
 enabled: true
 logger: SLF4JAuditWriter
```

2. Save and close the file.

3. Open the file logback.xml in a text editor and add this appender:

```
<appender name="GuardiumAuditWriterAppender" class="ch.qos.logback.core.FileAppender">
 <file>S-TAP location in your system</file>
 <encoder>
 <pattern>%msg{}GUARD_DELIM</pattern>
 <immediateFlush>true</immediateFlush>
 </encoder>
</appender>
```

Typical S-TAP locations are:

- non-GIM installations: /usr/local/guardium/guard\_stap/
- GIM installations: /opt/modules/STAP/current/

4. Add the new appender to audit logger:

```
<logger name="SLF4JAuditWriter" level="INFO" additivity="false">
 <appender-ref ref="SLF4JAuditWriterAppender"/>
 <appender-ref ref="GuardiumAuditWriterAppender"/>
</logger>
```

5. Save and close the file.

6. Verify that the guard\_tap.ini parameter cassandra\_audit\_enabled=1.

This creates the file appender pipe for Cassandra/Datastax with native audit logging.

7. If the guard\_tap.ini parameter cassandra\_audit\_delimiter if set to something other than the default, verify that the value "GUARD\_DELIM" in the logger configuration has the same value.

8. On your Guardium system, add the Cassandra user to the "guardium" group, by entering:

```
/usr/local/guardium/guard_stap/guardctl authorize-user <cassandra>
```

This allows the Cassandra user to write to the pipe file appender. The permissions on the pipe allow the S-TAP user to read/write and anyone in the guardium group to write.

9. Restart theS-TAP to create the Cassandra audit pipe.

10. Restart the Cassandra instance to pick up the logging changes. (The restart for Cassandra also ensures that the guardium group membership is picked up for the new Cassandra process.)

## Related reference

## Linux-UNIX: Db2 IE configuration

---

View a typical insepction engine configuration, and flows for enabling and disabling A-TAP, and opening the SSL console for an Db2 inspection engine.

## Typical Db2 inspection engine configuration

---

```
name =db24
type =db2
sequence =4
connect to IP=127.0.0.1
install dir = /home/db2inst1
exec file = /home/db2inst1/sqllib/adm/db2sysc
encrypted = no
port range = 50000 - 50000
ktap real port = 50000
identifier = db2_9.32.164.228(50000,50000,DB_3)
client = 0.0.0.0/0.0.0.0
```

## Activate and deactivate A-TAP for SSL traffic

---

Before activating A-TAP, you need to stop the Db2 instance:

```
systemctl stop db2
```

Activate A-TAP:

```
/usr/local/guardium/guard_stap/guardctl --db-user=db2 --db-type=oracle --db-instance=db2 --db-base=/home/ibmuser --db-home=/usr db2
```

Restart the Db2 instance:

```
systemctl start db2
```

## Set up Db2 with TLS/SSL certificate and key

---

For example, on an instance with SSL and kerberization:

### Deactivating A-TAP

---

Before deactivating A-TAP, you need to stop the Db2 instance.

```
systemctl stop db2
```

Deactivate A-TAP: Restart the Db2 instance:

```
systemctl start db2
```

---

## Linux-UNIX: Elastic Search configuration

Encrypted Elastic Search is supported via SSL termination.

Configuration guidelines:

- Elastic Search is configured to listen on the loopback device only, allowing the SSL termination to occur on the public interface.
- Elastic search uses a PKCS12 file that needs to be converted to PEM; and private key files for NGINX to use.
- In this example, the IE is configured to capture traffic on port 9201. The traffic enters the system encrypted on public port 9200, gets decrypted and routed to port 9201, then re-encrypted and passed to the loopback port 9200 where it is handled by Elastic Search.

An example configuration for Elastic Search for NGINX:

```
[root@<elasticsearch host> ~]# cat /etc/nginx/nginx.conf
user elasticsearch;
worker_processes 1;
error_log /var/log/nginx/error.log warn;
pid /var/run/nginx.pid;
events {
 worker_connections 1024;
}
http {
 server {
 listen 9201;
 server_name <elasticsearch hostname>;
 location / {
 proxy_ssl_certificate /usr/share/elasticsearch/config/<elasticsearch hostname>.crt;
 proxy_ssl_certificate_key /usr/share/elasticsearch/config/<elasticsearch hostname>.key;
 proxy_pass https://localhost:9200;
 proxy_http_version 1.1;
 }
 }
 server {
 listen <elasticsearch host>:9200 ssl;
 server_name <elasticsearch host>;
 ssl_certificate /usr/share/elasticsearch/config/<elasticsearch hostname>.crt;
 ssl_certificate_key /usr/share/elasticsearch/config/<elasticsearch hostname>.key;
 location / {
 proxy_pass http://<elasticsearch hostname>:9201;
 proxy_http_version 1.1;
 }
 }
}
[root@<elasticsearch hostname> ~]#
```

Typical inspection engine configuration:

```
[DB_0]
connect_to_ip=127.0.0.1::1
db2_fix_pack_adjustment=20
db2_shmem_client_position=0
db2_shmem_size=131072
db2bp_path=NULL
db_exec_file=NULL
db_install_dir=NULL
db_type=EL_SEARCH
db_user=elastic
encryption=0
```

```

db_version=9
instance_running=1
intercept_types=NULL
load_balanced=1
port_range_end=9201
port_range_start=9201
priority_count=20
real_db_port=9201
tap_identifier=el_search_9.98.176.129(9300,9300,DB_0)
tee_listen_port=0
unix_domain_socket_marker=NULL
networks=0.0.0.0/0.0.0.0,:::/0
exclude_networks=

```

## Linux-UNIX: Configuring Exit libraries

Exit libraries embed a Guardium library into the database, using the exit mechanism. The exit library, or module, communicates directly with the Guardium S-TAP to forward database traffic.

- [Linux-UNIX: Configuring Db2, Informix, and Teradata exit by using the setup\\_exit.sh script](#)  
Run the setup\_exit.sh script to configure and activate the Db2, Informix, and Teradata exit libraries. The script makes all of the configuration updates in both the database and the S-TAP.
- [Linux-UNIX: Configuring Db2 Exit](#)  
The Db2® Exit module enables S-TAP to monitor any Db2 database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.
- [Linux-UNIX: Configuring Informix Exit](#)  
The Informix exit module enables S-TAP to monitor any Informix database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.
- [Linux-UNIX: Configuring Teradata exit](#)  
The Teradata exit module enables S-TAP to monitor any Teradata database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.

## Related concepts

- [Embedded integrations](#)

## Linux-UNIX: Configuring Db2, Informix, and Teradata exit by using the setup\_exit.sh script

Run the setup\_exit.sh script to configure and activate the Db2, Informix, and Teradata exit libraries. The script makes all of the configuration updates in both the database and the S-TAP.

### Before you begin

- Make sure you know the database username.
- The inspection engine for the exit library must be configured on the database. Use one of the following methods:
  - During S-TAP installation, if auto-discovery is enabled, it auto-discovers databases and creates inspection engines for the discovered databases.
  - [Linux-UNIX: S-TAP Control: Inspection engine parameters](#)
  - [Linux-UNIX: Configuring an Inspection Engine](#)

### About this task

The setup\_exit.sh script is part of the S-TAP installation, and is located in the S-TAP installation directory. This script is an alternative to the exit configuration tasks described in [Linux-UNIX: Configuring Db2 Exit](#), [Linux-UNIX: Configuring Informix Exit](#), [Linux-UNIX: Configuring Teradata exit](#), which describe the full configuration of each exit.

If this database is the only one to monitor, then K-TAP is not required. Set ktap\_installed=0 in guard\_tap.ini, or with GIM set ktap\_enabled to no. However, if another database (DB\_TYPE is not EXIT) needs monitoring by S-TAP, then K-TAP is required.

### Procedure

1. Log in to the database server as **root**, and access the S-TAP installation directory.
2. Run `./setup_exit.sh [db2 | informix | teradata]`  
The script starts to run, and prompts you for the required details. When you complete the script, the system responds with a message similar to one of:
  - If the configuration is valid: DB <db user> has a GOOD setup for EXIT.
  - If you skipped something in the configuration: <xxx> is skipped, <yyy> will not work. This message indicates that the inspection engine is not properly configured for the type of exit library.
  - If the inspection engine is not an exit inspection engine, or not a specified DB type, the script skips the inspection engine, and a message is logged as Section \${db\_section} is not target IE, skip
  - If the script setup needs an S-TAP restart: To work with EXIT, please restart STAP!!.
  - If the script setup needs a database restart: Please restart the <db\_type> (<db\_user>) !!, for example a DB2 with db\_user of db2inst1 Please restart the DB2 (db2inst1) !!.
3. Optional: Set up Zone or WPARs.
  - a. In the secondary zone or WPAR, install the same version of S-TAP that is already installed in global, with K-TAP disabled.

- b. On the zone or WPAR, add the exit inspection engine in the guard\_tap.ini or configure by using the GUI.
- c. If discovery automatically created any inspection engines for zones or WPARs on the global zone, delete them.

## Linux-UNIX: Configuring Db2 Exit

The Db2® Exit module enables S-TAP to monitor any Db2 database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.

### About this task

Db2 Exit embeds a Guardium® library into the Db2 database and communicates with the S-TAP with a Guardium shared library.

By default, Guardium supports up to 10 total Exit inspection engines (combined total of all Exit types). If you use more than one type of Exit, the combined maximum is 10. For more information, see the [exit\\_libs\\_num\\_threads](#) parameter in [Linux-UNIX: General parameters](#).

Db2 Exit shared libraries are part of the Guardium UNIX S-TAP installation. S-TAP includes 64-bit and 32-bit.

- libguard\_db2\_exit\_64.so
- libguard\_db2\_exit\_32.so (available for RHEL6 on the i686 CPU only)

When you install the S-TAP, it copies libraries in the standard library paths, and creates links.

- The S-TAP copies libraries in the standard library paths:
  - Shell Installation - <guardium\_installation\_directory>/guard\_stap
  - GIM Installation - < guardium\_installation\_directory>/modules/STAP/current/files
- And then creates links. For example:
  - /usr/lib64/libguard\_db2\_exit\_64.so -> libguard\_db2\_64.so.<release number>
  - /usr/lib/libguard\_db2\_exit\_32.so -> libguard\_db2\_32.so.<release number>

The digits after `.so`, reflect the release number. These digits were introduced in V10.6. (In previous releases, Lib files do not include release numbers.)  
[Guardium support matrix](#) details exactly what Db2 Exit can monitor.

If you are not monitoring another database, then K-TAP is not required. Set ktap\_installed=0 in `guard_tap.ini`, or with GIM; set ktap\_enabled to no. You can upgrade the Linux OS and the S-TAP without being concerned about K-TAP module compatibility. However, if you are monitoring another database with S-TAP, then K-TAP is required. Ensure that a compatible K-TAP module is available when you upgrade your Linux version.

When you upgrade S-TAP from 10.6.0.0 and higher, database restart is not required. You can upgrade S-TAP while the database is running. The EXIT library from the previous version is used until you restart the database. When you restart the database, it starts by using the updated exit library on the S-TAP. However, if the new library addresses any issues you are waiting for, you must restart the database.

Use the Db2 Exit health check script to gather information from the Db2 server when you configure the Db2 inspection engines. The script is located in the `guard_stap/bin` directory. You can run it from anywhere with the full path. The script name is `./db2_exit_health_check.sh [ check | fix ]`. By default it outputs some of the IE parameters for each DB2\_EXIT inspection engine, and runs checks on the IE configuration. Use the fix option to fix the IE parameters.

**User authorization:** The user must be authorized for the `guardium` group. If the `guardium` group was created in LDAP, then take one of the following steps,

- Create a local group called `guardium` with the same group ID (when you authorize the DB user it is added to this group).
- Add the `guardium` group ID (GID) to the DB user in `/etc/passwd`.

In a shell installation, if the inspection engine `db_user` is specified, then you don't need to authorize the user even in an LDAP environment.

In a GIM installation, you still need to authorize the db user.

Note: If your site uses Db2 Warehouse, you can use the Db2 Warehouse integration. For more information, see [Embedded integrations](#).

## Procedure

1. Install and start the S-TAP agent on the database server and configure an Inspection engine for the `db2_exit` protocol. See [Linux-UNIX: Before you start installing S-TAP](#) and [Linux-UNIX: Inspection engine parameters](#).
2. If S-TAP is already installed and configured with A-TAP:
  - a. Stop the Db2 by entering `db2stop force; ipclean`
  - b. Deactivate the A-TAP by entering `/opt/IBM/guardium/module/modules/ATAP/current/files/bin/guardctl db_instance=<db_instance> deactivate`
  - c. Configure the IE (Inspection Engine) for DB2\_EXIT as usual either in the `guard_tap.ini` or from the GUI. (Make sure any previously configured IE for `db_type=DB2_EXIT` is removed.)
  - d. Verify that the parameter `db_install_dir` for DB2\_EXIT IE is set to the value of `$DB2_HOME` or `$HOME` of Db2 environment variable.
  - e. Restart the S-TAP with the new configuration.
3. Determine the bitwise of the Db2. Log in as `root` and run `db2level`. The output is similar to  
`DB21085I Instance db2inst1 uses 64 bits and DB2 code release SQL09070, with level identifier 08010107`
4. Locate the communication buffer exit library location (DB2PATH):
  - a. Log in to Db2 as user `trip`
  - b. In the Db2 CLP, run `get database manager configuration`
  - c. In the output, look for default database path:  
`Default database path (DFTDBPATH) = /DB2/trip`  
`DFTDBPATH` is the value that you need for the environment parameter DB2PATH.
5. The first time that you set up Db2 for exit, log in as Db2 OS user, and create the directory by entering one of these commands.
  - 64-bit environment: - `mkdir $DB2_PATH/sqllib/security64/plugin/commexit`
  - 32-bit environment: - `mkdir $DB2_PATH/sqllib/security/plugin/commexit`
6. As Db2 OS user, run the command: `ln -fs /usr/lib64/libguard_db2_exit_64.so $DB2_PATH/sqllib/security64/plugin/commexit/libguard_db2_exit_64.so`.  
 This allows Db2 to use the version-independent symbolic link that was created during S-TAP installation.
7. As `root` user, add the Db2 OS user to the `Guardium` group.  
 The `Guardium` group is created during S-TAP installation. This requirement increases the security of shared memory regions that are created by the S-TAP.
  - a. If Db2 user is 'trip', verify whether 'trip' is already authorized. Use `guardctl` under the A-TAP folder, as user `root`.

- ```
# /opt/IBM/guardium/module/modules/ATAP/current/files/bin/guardctl is-user-authorized trip
User 'trip' is authorized.
```
- b. If the user trip is not authorized, authorize it now:
- ```
/opt/IBM/guardium/module/modules/ATAP/current/files/bin/guardctl authorize-user trip
```
8. Enable Db2 Exit in Db2 (so it sends the database activity to the S-TAP).
- Log in as Db2 OS user and use the Db2 CLP commands to enable:  
`db2 UPDATE DBM CFG USING COMM_EXIT_LIST libguard_db2_exit_64`
  - Verify whether DB2\_Exit is successfully enabled by entering,  
`db2 get database manager configuration`  
If successful, the output includes,  
`Communication buffer exit library list (COMM_EXIT_LIST) = libguard_db2_exit_64`
9. Restart the Db2 database with the commands:
- ```
db2stop force
db2start
```
10. Set up Zone or WPARs,
- In the secondary Zone or WPAR, install the same version of S-TAP that is already installed in global, with K-TAP disabled.
 - On Zone or WPARs, add the DB2_EXIT IE in the guard_tap.ini or configure by using GUI.
 - If discovery automatically created any inspection engines, delete them.

Related tasks

- [Linux-UNIX: Upgrading S-TAP with databases that use an exit library](#)

Linux-UNIX: Configuring Informix Exit

The Informix exit module enables S-TAP to monitor any Informix database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.

About this task

Informix Exit embeds a Guardium® library into the Informix database and communicates with the S-TAP via a Guardium shared library.

By default, Guardium supports up to 10 total Exit inspection engines (combined total of all Exit types). If you use more than one type of Exit, the combined maximum is 10. For more information, see the [exit_libs_num_threads](#) parameter in [Linux-UNIX: General parameters](#).

Informix Exit shared libraries are part of the Guardium Unix S-TAP installation. S-TAP includes 64-bit Exit libraries for 64-bit OS version and 32-bit Exit libraries for 32-bit OS version.

- `libguard_informix_exit_64.so`
- `libguard_informix_exit_32.so` (available for RHEL6 on the i686 CPU only)

When you install the S-TAP, it copies libraries in the standard library paths, and creates links, for example:

- It copies libraries in the standard library paths:
 - Shell Installation: <guardium_installation_directory>/guard_stap
 - GIM Installation: < guardium_installation_directory>/modules/STAP/current/files
- It creates links, for example:
 - `/usr/lib64/libguard_informix_exit_64.so -> libguard_informix_exit_64.so.<release number>`
 - `/usr/lib/libguard_informix_exit_32.so -> libguard_informix_exit_32.so.<release number>`

The digits after `.so`, reflect the release number. These digits were introduced in V10.6. (In previous releases, Lib files do not include release numbers.)
[Guardium support matrix](#) details exactly what can be monitored by Informix Exit.

If there is no other database to monitor then K-TAP is not required. Set `ktap_installed=0` in `guard_tap.ini`, or with GIM: set `ktap_enabled` to no. You can upgrade the Linux OS and the S-TAP without being concerned about K-TAP module compatibility. However, if there is another database that needs monitoring by S-TAP, then K-TAP is required. You must ensure that a compatible K-TAP module is available when you upgrade your Linux version.

When upgrading S-TAP from **v10.6.0.0 and higher**, database restart is not required. You can upgrade S-TAP while the database is running. The EXIT library from previous version is used until you restart the database, When you restart the database, it starts using the updated exit library. If there are any issues addressed in the new library that you are waiting for, you must restart the database.

Procedure

- Install and start up the S-TAP agent on the database server and configure an inspection engine for the informix exit protocol. See [Linux-UNIX: Installing, upgrading and uninstalling S-TAP agents](#) and [Linux-UNIX: Inspection engine parameters](#).
- Log in as user `informix` to the database and locate its instance name (INFORMIXSERVER) and its installation directory (INFORMIXDIR) by running these Unix commands:
`$ echo $INFORMIXSERVER
INFORMIXSERVER=test117
$ echo $INFORMIXDIR
INFORMIXDIR=/home/informix`

3. As user `root`, make sure the user `informix` is in the `guardium` group. If the user is not in the group `guardium`, use the `guardctl` utility to add the user to the group, for example:
`/usr/local/guardium/bin/guardctl authorize-user informix`
or with UNIX (AIX only):
`# chgroup users=informix guardium`
4. Copy `libguard_informix_exit` to the system standard library PATH (`/usr/lib64` or `/usr/lib`).
5. As user `informix`, create a link to the `informix_exit` library by running the command:
`ln -fs /usr/lib64/libguard_informix_exit_64.so $INFORMIXDIR/lib/libguard_informix_exit_64.so`
This allows `Informix` to use the version-independent symbolic link that was created during S-TAP installation.
6. To enable `informix_exit` monitoring you must start the `ifxguard` process. To start this process for first time run this command as user `informix`:
`ifxguard -p $INFORMIXDIR/lib/libguard_informix_exit_64.so -l $INFORMIXDIR/tmp/ifxguard.msg.txt`
After the `ifxguard` process starts, it automatically creates two files: one for configuration and one for messaging. The configuration file is created under `$INFORMIXDIR/etc/ifxguard.$INFORMIXSERVER` with these lines:
`NAME in2rh5u7_guard`
`LOGFILE /home/informix12/tmp/ifxguard.msg.txt`
`WORKERS 4`
`LIBPATH /home/informix12/lib/libguard_informix_exit_64.so`
7. Set up Zones/WPARs.
 - a. In the secondary Zone or WPAR, install same version of S-TAP that is already installed in global, with K-TAP disabled.
 - b. On Zone or WPARs, add Db2 EXIT IE in the `guard_tap.ini` or configure using GUI.
 - c. If discovery automatically created any inspection engines, delete them.
8. To restart the process in case the exit was reconfigured, the process hangs, or is not responding:
 - a. Disable `ifxguard`, as user `informix`, run the command: `ifxguard -k`
The output prints: `ifxguard in2rh5u7_guard successfully shut down`
 - b. To restart `ifxguard` after successful setup, as user `informix`, run the command `ifxguard`.
The output prints: `ifxguard set instance name in2rh5u7_guard Starting ifxguard in2rh5u7_guard ...`
check log file: `/home/informix12/tmp/ifxguard.msg.txt`
9. Restart the S-TAP.

Related tasks

Linux-UNIX: Configuring Teradata exit

The Teradata exit module enables S-TAP to monitor any Teradata database activities, whether encrypted or not and whether local or remote. It does not require A-TAP or K-TAP.

About this task

Teradata Exit embeds a Guardium® library into the Teradata database and communicates with the S-TAP through a Guardium shared library.

By default, Guardium supports up to 10 total Exit inspection engines (combined total of all Exit types). If you use more than one type of Exit, the combined maximum is 10. For more information, see the `exit_libs_num_threads` parameter in [Linux-UNIX: General parameters](#).

Teradata Exit shared libraries are part of the Guardium UNIX S-TAP installation. The S-TAP includes 64-bit Exit libraries for 64-bit OS version and 32-bit Exit libraries for 32-bit OS version:

- `libguard_teradata_exit_64.so`
- `libguard_teradata_exit_32.so` (available for RHEL6 on the i686 CPU only)

When you install the S-TAP:

- It copies libraries in the standard library paths:
 - Shell and RPM installation: <guardium_installation_directory>/guard_stap
 - GIM installation: <guardium_installation_directory>/modules/STAP/current/files
- It creates links, for example:
 - `/usr/lib64/libguard_teradata_exit_64.so -> libguard_teradata_exit_64.so.<release number>`
 - `/usr/lib/libguard_teradata_exit_32.so -> libguard_teradata_exit_32.so.<release number>`

The digits after `.so` reflect the release number. These digits were introduced in V10.6. (In previous releases, Lib files do not include release numbers.) [Guardium support matrix](#) details exactly what can be monitored by Teradata Exit.

Teradata configuration

The `gtwcontrol` option `-u SendConnectRespNoSecurity` specifies whether the gateway sends connection responses encrypted or cleartext. Valid values are:

- YES: The logon response is in cleartext (unencrypted plain text).
- NO: The logon response is encrypted. This is the default setting.

Set this parameter to Yes to capture DB User (-u YES). (When set to No, the connection response is encrypted before it gets to the `gtwgateway`, the process that loads the Guardium Exit library, and therefore cannot be passed unencrypted to Guardium.)

For more information, see [Teradata documentation](#).

K-TAP considerations

If there is no other database to monitor, then K-TAP is not required. Set `ktap_installed=0` in `guard_tap.ini`, or with GIM: set `ktap_enabled` to no. You can upgrade the Linux® OS and the S-TAP without being concerned about K-TAP module compatibility. However, if there is another database that needs monitoring by S-TAP, and K-TAP is required you must ensure that a compatible K-TAP module is available when you upgrade your Linux version.

Upgrade

When you upgrade S-TAP from **v10.6.0.0 and higher**, database restart is not required. You can upgrade S-TAP while the database is running. The Exit library from the previous version is used until you restart the database. When you restart the database, it starts using the updated exit library. If there are any issues that are addressed in the new library that you are waiting for, this is only resolved when you restart the database.

Procedure

1. Install and start the S-TAP agent on the database server and configure an inspection engine for the teradata_exit protocol. See [Linux-UNIX: Before you start installing S-TAP](#) and [Linux-UNIX: Inspection engine parameters](#). Use these parameters and values:

| GUI | guard_tap.ini | GUI Value / guard_tap.ini value |
|----------------|----------------|---|
| Protocol | db_Type | Teradata Exit / TRD_EXIT |
| ClientIP/Mask | networks | 0.0.0.0/0 / 0.0.0.0/0.0.0.0 |
| DB Install Dir | db_install_dir | Home directory of the user that runs the main Teradata process (pdemain), (using the following command <echo \$HOME>) |
| Process Name | db_exec_file | Full path to the main Teradat process (pdemain) |
| DB User | db_user | NULL (not relevant for Teradata exit) |

A typical DB section in the guard_tap.ini file for the inspection engine is:

```
[DB_0]
connect_to_ip=127.0.0.1
db_exec_file=/opt/teradata/tdat/tgtw/16.20.07.01/bin/pdemain
db_install_dir=/root
db_type=TRD_EXIT
db_user=NULL
encryption=0
db_version=9
intercept_types=NULL
load_balanced=1
port_range_end=0
port_range_start=0
priority_count=20
real_db_port=NULL
tap_identifier=TRD_EXIT_dbatera1620 (0,0,DB_0)
unix_domain_socket_marker=NULL
networks=0.0.0.0/0.0.0.0
exclude_networks=
```

When you are defining the inspection engine with the GUI, it looks like:

When the inspection engine is configured, it look like:

| Protocol | Port Range | TEE Listen Port-Real Port | | |
|---------------|------------|---------------------------|---------|--|
| Teradata Exit | 0-0 | | | |
| Ip | Mask | Connect To Ip | DB User | |
| 0.0.0.0 | 0 | 127.0.0.1 | NULL | |

2. As user root enable teradata exit in the database, while the database is running, by entering:

```
/usr/tgtw/bin/gtwcontrol --monitorlib load=yes
```

3. Stop the Teradata service:

a. Enter:

```
/etc/init.d/tpa stop
/etc/init.d/tgtw stop
```

b. Check that the Teradata database is stopped with your Teradata Administrator, or with the UNIX command:

```
pdestate -a
```

The response should be:

PDE state: DOWN/HARDSTOP

4. Authorize the required users:

a. As user **root**, verify that the users **teradata**, **tdatuser**, and **root** are in the **guardium** group. If any of the users are not in the group **guardium**, use the **guardctl** utility to add the user to the group. (The **teradata** and **tdatuser** users are the primary operating system-native users used in running Teradata DBS/PDE where they are created during Teradata Database installation process. **root** is the user of pdmain process.) For example:

- For shell installation:

```
<guardium_installation_directory>/guard_stap/guardctl authorize-user teradata  
<guardium_installation_directory>/guard_stap/guardctl authorize-user tdatuser
```

- For GIM installation:

```
<guardium_installation_directory>/ATAP/current/files/bin/guardctl authorize-user teradata  
<guardium_installation_directory>/ATAP/current/files/bin/guardctl authorize-user tdatuser
```

b. Confirm that the user is authorized with the option **is-user-authorized** in the **guardctl** command.

- For shell S-TAP installation:

```
<guardium_installation_directory>/guard_stap/guardctl is-user-authorized teradata  
<guardium_installation_directory>/guard_stap/guardctl is-user-authorized tdatuser  
<guardium_installation_directory>/guard_stap/guardctl is-user-authorized root
```

- For GIM S-TAP installation:

```
<guardium_installation_directory>/ATAP/current/files/bin/guardctl is-user-authorized teradata  
<guardium_installation_directory>/ATAP/current/files/bin/guardctl is-user-authorized tdatuser  
<guardium_installation_directory>/ATAP/current/files/bin/guardctl is-user-authorized root
```

5. As user **root**, create the directory **<teradata_install_directory>/tdat/tgtw/site** by running:

```
mkdir <teradata_install_directory>/tdat/tgtw/site
```

6. Set the permissions and the ownership for the directory: site.

- a. Enter:

```
chown -R teradata:tdtrusted <teradata_install_directory>/tdat/tgtw/site  
chmod -R 755 <teradata_install_directory>/tdat/tgtw/site
```

Note: In some cases permissions for **root** **root** also work.

- b. Confirm that the permissions are set correctly. For example:

```
db-teradata1610:~ #  
db-teradata1610:~ # ls -la /opt/teradata/tdat/tgtw/  
total 16  
drwxr-xr-x 4 root      root      4096 Jan 27 22:08 .  
drwxr-xr-x 8 teradata  tdtrusted 4096 Dec  7  2017 ..  
dr-xr-xr-x 6 teradata  tdtrusted 4096 Oct 27  2017 16.10.00.00  
drwxr-xr-x 2 teradata  tdtrusted 4096 Jan 27 22:08 site  
db-teradata1610:~ #
```

7. Start the Teradata service:

- a. Enter:

```
/etc/init.d/tpa start  
/etc/init.d/tgtw start
```

- b. Verify that the Teradata database is started with your Teradata Administrator, or with the UNIX command:

```
pdestate -a
```

The response should be:

```
PDE state is RUN/STARTED.  
DBS state is 5: Logons are enabled - The system is quiescent
```

8. Link the Teradata Exit library to the **libtgtwmonitoring.so**.

- a. As Teradara OS user, create the link for the full path of the Teradata Exit library from the standard system library path, either **/usr/lib** or **/usr/lib64**, depending on the OS version of your database server. This allows Teradata to use the version-independent symbolic link that was created during S-TAP installation.

```
ln -fs <standard_system_library_path>/libguard_teradata_exit_64.so  
<teradata_install_directory>/tdat/tgtw/site/libtgtwmonitoring.so
```

- b. Verify that the link is created, for example:

```
db-teradata1610:~ # ls -lrt /opt/teradata/tdat/tgtw/site/  
total 0  
lrwxrwxrwx 1 teradata  tdtrusted 39 Jan 27 22:08 libtgtwmonitoring.so -> /usr/lib64/libguard_teradata_exit_64  
.so
```

9. Confirm that the Teradata Exit library is loaded into the database by verifying The Monitoring Library: **load=yes** in response to the command:

```
/usr/tgtw/bin/gtwcontrol -d
```

```
db-teradata1610:~ # /usr/tgtw/bin/gtwcontrol -d
gtwcontrol: gtwversion 16.10.00.00
gdo version: 6, created on Mon Jan 28 17:11:31 2019

systemname: db-teradata1610

Linux-UNIX: Disabling Teradata exit

Follow this procedure to disable the Teradata exit library.

Procedure

1. Verify that the "gtwgateway" process is running. Check that the Teradata database is running with your Teradata Administrator, or by using the UNIX command:

```
pdestate -a
```

The response should be:

```
PDE state is RUN/STARTED.
DBS state is 5: Logons are enabled - The system is quiescent
```

2. As root, unload the Teradata Exit library by entering:

```
/usr/tgtw/bin/gtwcontrol --monitorlib load=no
```

3. Stop the Teradata database:
 - a. Stop the Teradata service:

```
/etc/init.d/tpa stop  
/etc/init.d/tgtw stop
```

b. Verify that the Teradata database is stopped with your Teradata Administrator, or by using the UNIX command:

```
pdestate -a
```

The response should be:

```
PDE state: DOWN/HARDSTOP
```

4. If you are never going to enable the library again, delete the directory site by entering:

```
rm -f <teradata_install_directory>/tdat/tgtw/site
```

Linux-UNIX: Hadoop configuration

This topic introduces fundamental concepts and processes for monitoring Hadoop data with Guardium.

Capacity planning

The following sizing guidelines assume an average volume of audited traffic. Higher volumes of audited traffic may require additional resources.

- 10 management or server nodes per collector
- 20 or more data nodes per collector
- Possibly additional nodes per collector if physical appliances are used

It is also possible to size by the Processor Value Unit (PVU) of the nodes, but this may result in over-sizing if auditing low volumes of traffic. The capacity sizing guideline is 4000 PVU per collector.

There are a few options for integrating with Hadoop. The Ranger HDFS integration supports newer versions of Hortonworks and Cloudera (CDP 7.x). Use this integration when possible. Otherwise, choose your integration according to your cluster version. All integrations support SSL.

- [Linux-UNIX: Hadoop integration with Ranger HDFS for Hortonworks and Cloudera 7](#)

Hadoop services load a Ranger Audit Plugin. The Ranger Audit Plugin applies policies from the Ranger Policy Server. If an operation is covered by one of those policies and audit logging is enabled for the policy, the audit is logged to the Ranger Audit Server. The Ranger Audit Server can be configured to log audits to directories in HDFS. The S-TAP can consume Ranger audits from HDFS by connecting to the HDFS namenode, and reading Ranger audits for the services from the configured audit directory. S-TAP reads audits of each configured service from the oldest to the newest. This configuration uses the Cloudera Data Platform 7.x and Hortonworks 2.3 - 3.1 with Ranger HDFS.

- [Linux-UNIX: Hadoop integration with Cloudera Navigator](#)

Learn how to integrate Hadoop with Cloudera Navigator 5.8 - 6.3.x, Cloudera's native data governance solution.

- [Linux-UNIX: Hadoop integration using Hortonworks and Apache Ranger](#)

Apache Ranger, included with the Hortonworks Data Platform 2.3-2.6, offers fine-grained access control and auditing over Hadoop components such as Solr, Storm, Hive, HBASE, and HDFS by using policies.

Linux-UNIX: Hadoop integration with Ranger HDFS for Hortonworks and Cloudera 7

Hadoop services load a Ranger Audit Plugin. The Ranger Audit Plugin applies policies from the Ranger Policy Server. If an operation is covered by one of those policies and audit logging is enabled for the policy, the audit is logged to the Ranger Audit Server. The Ranger Audit Server can be configured to log audits to directories in HDFS. The S-TAP can consume Ranger audits from HDFS by connecting to the HDFS namenode, and reading Ranger audits for the services from the configured audit directory. S-TAP reads audits of each configured service from the oldest to the newest. This configuration uses the Cloudera Data Platform 7.x and Hortonworks 2.3 - 3.1 with Ranger HDFS.

Supported functions with Ranger HDFS for Hortonworks and Cloudera 7

You can use Ranger HDFS for Hortonworks and Cloudera 7 with the following functions:

- Audit SSL-encrypted activity
- Audit Kerberos authenticated traffic - By using Ranger integration, you do not need to propagate keytabs for Guardium.
- Audit Hive, HBASE, HDFS - HBASE deployment is simpler with Ranger, you do not need to deploy S-TAPs on data nodes.
- Audit SOLR
- Audit Kafka
- Audit Storm
- Audit Impala
- 12.1 and later Audit Atlas
- Audit exceptions - Ranger catches only "access denied" exceptions.

Limitations

Ranger integration supports the following policy rule actions:

- Alert daily
 - Alert only
 - Alert per match
 - Alert per time granularity
 - Log full details
 - Log full details with replaced values
 - Log masked details
 - Log only
 - No parse
 - Quick parse
 - Quick parse no fields
 - Record values separately
 - Skip logging

Linux-UNIX: Configuring S-TAPs: Ranger HDFS for Hortonworks and Cloudera 7

Learn how to configure the S-TAP for Ranger HDFS integration.

Before you begin

Verify the following before you start:

- A functional Hortonworks cluster with [Ranger installed](#) and properly configured or a Cloudera Data Platform 7.x cluster with Ranger installed and configured. Ranger should be configured with policies to log all desired operations. Ranger should be configured to log audits to HDFS.
- If HDFS uses Kerberos, you need to specify the path to a keytab and a corresponding principal (ranger_hdfs_user).
- S-TAP is installed on a cluster node that has the proper HDFS libraries.
- The user with which S-TAP connects to HDFS must have the necessary permissions to read the files in the Ranger audit directories.

Procedure

1. Install the S-TAP or S-TAPs using the standard procedure for the chosen installer (GIM, shell, or RPM).
2. Browse to [Manage](#) > [Module Installation](#) > [Set up by Client](#), select the S-TAP or S-TAPs that are and set **STAP_RANGER_HDFS_READER_ENABLED=1**. (You can also directly modify the parameter **ranger_hdfs_reader_enabled** in the **guard_tap.ini** and restart the S-TAPs.) This step ensures that only the relevant S-TAPs display in the GUI.
3. Browse to [Setup](#) > [Tools and Views](#) > [Hadoop Monitoring](#) and click  in the Add cluster information tile.
4. Select Ranger HDFS from the Hadoop distribution drop-down menu.
5. From the Host name/IP drop-down list, select the Ambari server where the S-TAP is installed.
6. Configure the following parameters.

Table 1. Parameters for HDFS integration

| GUI | Default | Description |
|---------------------------|---------|---|
| HDFS audit directories | NULL | Comma-separated list of directories where Ranger logs the service audits. Include one directory that contains the daily log directories, for each service you want to monitor. Usually the paths are located under /ranger/audit.

Example service directories for CDP 7: /ranger/audit/hive/hiveServer2,/ranger/audit/kafka/kafka,/ranger/audit/hbase/hbaseMaster,/ranger/audit/hbase/hbaseRegional,/ranger/audit/atlas/atlas,/ranger/audit/hdfs/hdfs

Example service directories for HW 3: /ranger/audit/hbaseMaster,/ranger/audit/hbaseRegional,/ranger/audit/hdfs,/ranger/audit/hiveServer2,/ranger/audit/kafka,/ranger/audit/solr,/ranger/audit/storm |
| HDFS lib location | NULL | Locate libhdfs.so provided by Hadoop cluster (for example, /usr/hdp/3.1.0.141-1/usr/lib/libhdfs.so) and set ranger_hdfs_lib_location to the directory that contains libhdfs.so (for example, /usr/hdp/3.1.0.141-1/usr/lib). |
| HDFS name node | NULL | IP or hostname of the HDFS NameNode. |
| HDFS poll (milliseconds) | 100 | Time interval, in milliseconds, the S-TAP waits between checking for new Ranger audits in HDFS. |
| HDFS port | 8020 | The HDFS NameNode port the S-TAP connects to. |
| HDFS user | NULL | The user with which S-TAP connects to HDFS. If the HDFS setup is using Kerberos, set the parameter to the Kerberos principal. |
| LD library path | NULL | Locate libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server/libjvm.so) and set ld_library_paths to the directory that contains libjvm.so (for example, /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.191.b12-1.el7_6.x86_64/jre/lib/amd64/server). |
| HDFS audit history length | 30 | The length of the audit history. <ul style="list-style-type: none"> • A positive value is the history length in days, maximum = 2147483647. The default is 30 (days). • A negative value is the history length in hours, maximum = -2147483648. • 0 - The S-TAP reads audits from the first audit that was written into the Ranger audit logs. |
| Use Kerberos | | Check to use Kerberos authentication. |
| Principal | | Required for Kerberos. The value of Ranger HDFS user. |

| GUI | Default | Description |
|-------------|---------|---|
| HDFS keytab | NULL | Required for Kerberos. Location of the Kerberos keytab that contains the principal used to connect to HDFS. |

7. Click Save.

Linux-UNIX: Upgrading and uninstalling S-TAPs: Ranger HDFS for Hortonworks and Cloudera 7

You can upgrade or uninstall the S-TAP using the standard method for your installation type (e.g. shell, GIM, package).

There are no special steps required for upgrading or uninstalling S-TAPs that are used in a Ranger HDFS integration.

Linux-UNIX: Ranger HDFS for Hortonworks and Cloudera 7 FAQs

Find answers to some basic issues with Ranger HDFS integration.

HDFS audits are not being processed and the following message is seen in the STAP logs:

```
2020.04.22 12:55:35 ranger_hdfs_integration/guard_hdfs.cc(78) HDFS: cannot load libhdfs, no path provided
Verify that ranger_hdfs_lib_location is set to the directory containing libhdfs.so on the server hosting S-TAP.
```

HDFS audits are not being processed and the following message is seen in the STAP logs:

```
2020.04.22 12:57:52 ranger_hdfs_integration/guard_hdfs.cc(111) HDFS: unable to open /tmp/libhdfs.so, error: /tmp/libhdfs.so: cannot open shared object file: No such file or directory
```

Verify that ranger_hdfs_lib_location is set to the directory containing libhdfs.so on the server hosting S-TAP.

HDFS audits are not being processed and the following message is seen in the STAP logs:

```
2020.04.22 12:59:20 ranger_hdfs_integration/guard_hdfs.cc(111) HDFS: unable to open /usr/hdp/3.1.0.0-78/usr/lib/libhdfs.so, error: libjvm.so: cannot open shared object file: No such file or directory
```

Verify that ld_library_paths is set to the directory containing libjvm.so on the server hosting S-TAP.

HDFS audits are not being processed and the following message is seen in the STAP logs:

```
hdfsExists: invokeMethod((Lorg/apache/hadoop/fs/Path;)Z) error: ConnectException: Connection refusedjava.net.ConnectException: Call From <STAP_HOSTNAME>/<STAP_IP> to <NN_HOSTNAME>/<PORT> failed on connection exception: java.net.ConnectException: Connection refused; For more details see: http://wiki.apache.org/hadoop/ConnectionRefused
For more details see: http://wiki.apache.org/hadoop/ConnectionRefused.
```

Verify that ranger_hdfs_namenode and ranger_hdfs_port are correct. Also, ensure that the HDFS NameNode is up and running.

HDFS audits are not being processed and the following message is seen in the STAP logs:

```
hdfsBuilderConnect(forceNewInstance=0, nn=hw3-cl1-01.swg.usma.ibm.com, port=8020,
kerbTicketCachePath=/usr/local/guardium/guard_stap/hdfs_reader_ticket, userName=foobar) error: LoginException: Unable to obtain password from user org.apache.hadoop.security.KerberosAuthException: failure to login: for principal: foobar using ticket cache file: /usr/local/guardium/guard_stap/hdfs_reader_ticket javax.security.auth.login.LoginException: Unable to obtain password from user
```

There is an issue with the keytab or principal S-TAP is configured to use. Verify that the ranger_hdfs_keytab and ranger_hdfs_user are correct for the environment.

HDFS audits are not being processed and a message similar to the following is seen in the STAP logs::

```
CannotObtainBlockLengthException: Cannot obtain block length for LocatedBlock {BP-475011667-9.32.164.237-1546906377615;blk_1074457421_717409; getBlockSize()=428; corrupt=false; offset=0; locs=[DataNodeInfoWithStorage[9.32.164.137:1019,DS-39fe5b73-f666-4285-bd50-805b4acc9250,DISK], DataNodeInfoWithStorage[9.32.164.148:1019,DS-fd105fa3-aa8e-44f5-a878-7d409ea6d24f,DISK]]}
```

ON an HDFS client for the HDFS cluster, enter the command **hdfs debug recoverLease** for the ranger audit log file whose name appears just before the **CannotObtainBlockLengthException** message, using the syntax:

```
hdfs debug recoverLease -path <path to audit file> -retries <number of times to try to recover the lease on the HDFS file>
```

For example:

```
hdfs debug recoverLease -path /ranger/audit/solr/20200623/solr_ranger_audit_hw3-cl1-02.log -retries 10
hdfs debug recoverLease -path /ranger/audit/storm/20200812/storm_ranger_audit_hw3-cl1-01.log -retries 10
```

For more information, see [Cannot obtain block length for LocatedBlock](#).

Linux-UNIX: Hadoop integration with Cloudera Navigator

Learn how to integrate Hadoop with Cloudera Navigator 5.8 - 6.3.x, Cloudera's native data governance solution.

Guardium provides the capability to subscribe to audit events when Cloudera Navigator is configured to publish audits to Kafka. Audited activity is sent to a Kafka cluster where the Guardium S-TAP consumes the events and sends them to the Guardium collector to be parsed and logged. The data is highly protected in the hardened Guardium system. All normal Guardium functions can be used, such as real-time alerting and integration with SIEM, reporting and workflow, and analytics.

Why integrate with Navigator? A key reason is the fact that many organizations are now using SSL encryption for their clients to access Hadoop data. By using this integration, events can be monitored even though the wire traffic is encrypted. Support for Kerberos and LDAP authentication is also easier with the Navigator integration since no special keytab configuration is required.

The Cloudera version that is referenced in this content is https://docs.cloudera.com/documentation/enterprise/6/6.3/topics/cn_iu_introduce_navigator.html

Guardium functions supported with Navigator

- Audit SSL-encrypted activity
- Audit Kerberos-authenticated traffic - With Navigator integration, you do not need to propagate keytabs for Guardium.
- Audit Hive, HBASE, HDFS, Impala
- Audit Solr
Note: For Navigator, only commands that are issued with **solrctl** are collected, not normal user activity.
- Audit Sentry
- Audit exceptions

Limitations and restrictions

- Guardium-based blocking does not support any Hadoop components with Cloudera Navigator integration.
- The supported policy rule actions are:
 - Alert per match
 - Log only
 - Skip logging
 - Alert daily
 - Alert only
 - Alert per time granularity
 - Log full details with replaced values
 - Log masked details
 - No parse
 - Record values separately
 - Quick parse
 - Quick parse no fields
- Capturing failed logins from Hue requires Cloudera Manager 5.8 or later.
- Access to “new projects and documents” from Hue are not captured by Navigator and thus are not captured by Guardium.
- In Hbase, Navigator access through Hue reports only the DB User of HBASE or HUE.
- In HBase, Navigator captures the Grant commands but not the user that is granted.
- When using Impala statements with Cloudera Navigator, statements across multiple lines are merged into a single-line statement. As a result, statements that use single-line comments (that is, comments that begin with two dashes [--]), can cause errors. To use comments with Impala statements, use one of the following techniques:
 - Use comments that begin with two dashes (--) only at the very end of the statements.
 - Wrap all comments in slash-asterisk format /* comment */. For example,

```
select * from user_table from all_users
/* comment appearing within the statement */
where user_age > 70 and user_location in ('TAIWAN', 'JAPAN');
```

Prerequisites

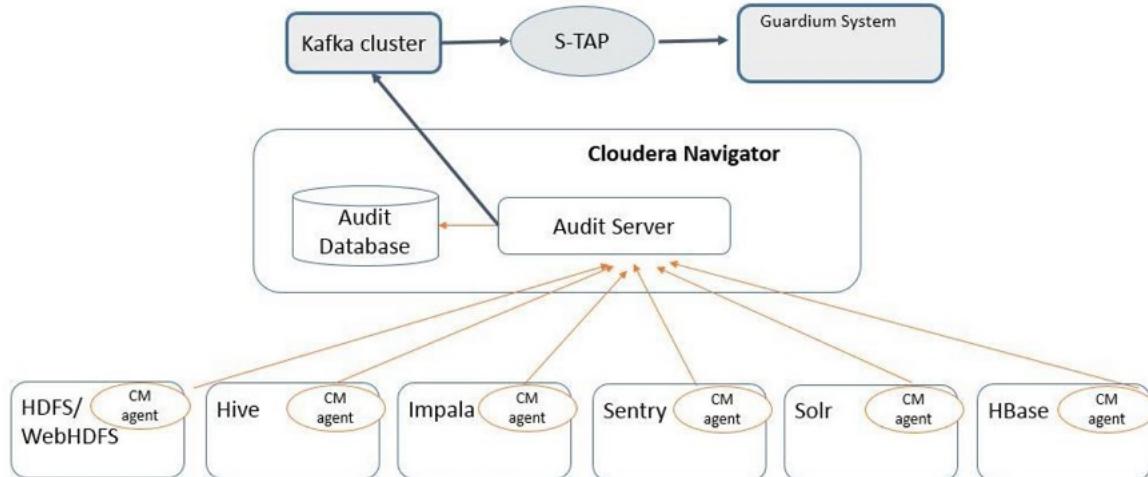

Guardium integration with Cloudera Navigator requires the following minimum software release levels:

- IBM Security Guardium and S-TAP at V10.1.2 or later.
- CDH 5.7, and Cloudera Manager 5.8, and the Kafka included with those versions.

Architecture and data flow

Instead of locating an S-TAP on the Hadoop servers, the Cloudera Manager agent sends audit events from the Hadoop component logs to the Navigator audit server. At that point, Navigator writes the audit events to its audit database. To integrate with Guardium, set up Navigator to publish. Guardium gathers the event records from Kafka.

Figure 1. S-TAP reads Navigator audit events off the Kafka cluster

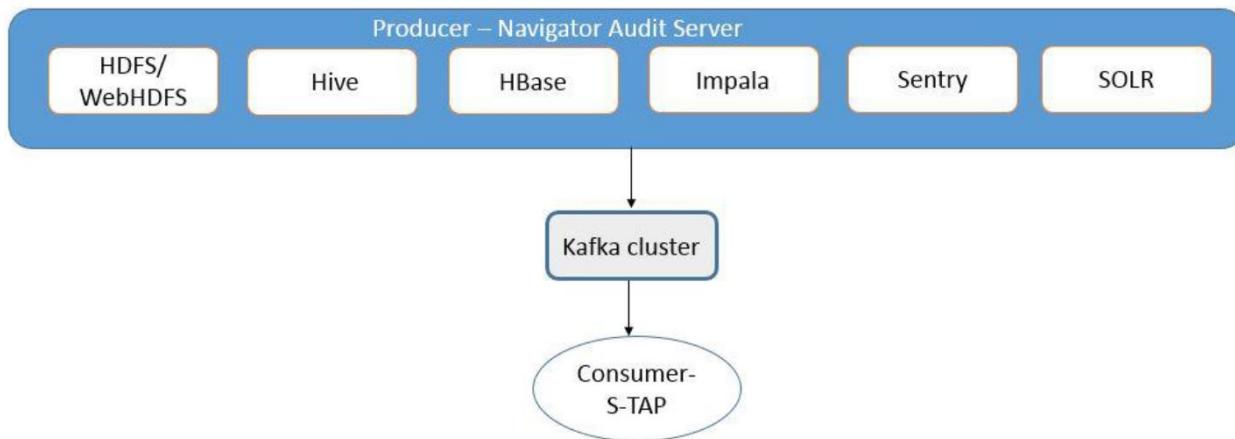

Configuration is flexible. You can install the S-TAP:

- On a node in the Hadoop cluster.
- On a separate server outside of the Hadoop cluster, if that server has network connectivity to the Kafka cluster and the Guardium appliance.

Configuring multiple STAPs for the same Kafka cluster and specifying the same kafka_group_name allows the Kafka cluster to balance the load of the topics and partitions over the S-TAPs.

In this configuration, Navigator produces the log events for each Hadoop component, and the S-TAP consumes those events. Using the Guardium user interface, you specify the message topic identifier that Navigator uses so that the Guardium S-TAP knows which events it is supposed to pick up.

Figure 2. Audit events are written to the Kafka cluster where S-TAP picks them up

Recommendation: Use a secure Kafka cluster to ensure that your audit events are protected.

A few words about Kafka. Apache Kafka is a distributed messaging system.

- A server in a Kafka cluster is a Broker.
- Message writers are called Producers.
- Message readers are called Consumers.
- A message category is called a Topic.

[Linux-UNIX: Planning the integration with Cloudera Navigator](#)

- [Hadoop parameters](#)

Linux-UNIX: Planning the integration with Cloudera Navigator

Integrating with Cloudera Navigator requires gathering some information from the administrators responsible for Cloudera and Kafka, as well as from the data security team responsible for Guardium. Gather the following information before you begin.

- Host and ports for the Kafka bootstrap servers.
- Whether TLS and Kerberos are used in the Kafka cluster. See [2 in Linux-UNIX: Preliminary configuration](#).
- The host and port for the server where the S-TAP is installed. Verify that there is network connectivity between this server and both the Kafka cluster and the Guardium collector.
- The operating system and version used on the S-TAP host so you can download and install the correct S-TAP.
- The host for the Guardium system. This is required for installing and configuring the S-TAP.

Linux-UNIX: Preliminary configuration

This section covers the preparatory configuration: the Navigator auditing component, verifying that TLS/SSL is configured correctly for Kafka, installing S-TAP on a server

Procedure

1. Configure the Navigator auditing component.
 - If you do not already have Navigator configured to audit the supported services as normal, without Guardium, refer to Cloudera documentation for more information about setting that up. Be aware that you may need to specifically enable the configuration for each service, depending on the level of Cloudera that you have. Solr auditing is disabled by default. You must enable it following the instructions in the Cloudera documentation.

Figure 1. Enabling Solr audit in Cloudera Manager

| Category | Property | Value | Description |
|--------------------|-------------------------|---|---|
| ▼ Service-Wide | Enable Audit Collection | <input checked="" type="checkbox"/> Reset to the default value: false | Enable collection of audit events from the service's roles. |
| Advanced | | | |
| Cloudera Navigator | | | |
| Logs | | | |

- To get Impala traffic, you need to enable Impala Daemon auditing as described in the Cloudera documentation. Here's a screenshot from the Impala service configuration in Cloudera Manager that shows Impala audit event generation is enabled.

Figure 2. Enabling audit events for Impala in Cloudera Manager

| Property | Value | Description |
|--------------------------------------|---|--|
| Enable Impala Audit Event Generation | <input checked="" type="checkbox"/> Reset to the default value: false | Enables audit event generation by Impala daemons. The audit log file will be placed in the directory specified by 'Impala Daemon Audit Log Directory' parameter. |
| enable_audit_event_log | Impala audit log is set when Navigator audit collection is enabled. | |

2. Verify that TLS/SSL is configured correctly for Kafka.

The Kafka cluster you use for producing Cloudera audit events must not be configured with required SSL client authentication. In Cloudera Manager, go to Kafka Configuration > SSL client authentication and choose the none or requested radio button.

3. Install the S-TAP on the designated server inside or outside of the Hadoop cluster.

- Use the appropriate procedure for your system. See [Linux-UNIX: Installing, upgrading and uninstalling S-TAP agents](#).
- Verify connectivity between the S-TAP and the Guardium system. The S-TAP status should be green in the S-TAP Status Monitor page. Go to Manage > System View > S-TAP Status Monitor.

Linux-UNIX: Configure publication of Navigator audit events to Kafka

The Navigator administrator or full administrator must do this task from Cloudera Manager.

Procedure

- Go to Cluster > Cloudera Management Service > Cloudera Management Service
- Click the Configuration tab. From the left navigation menu choose the category Publishing.
- For Kafka Service, select the Kafka radio button. The default topic name for Navigator event publishing is NavigatorAuditEvents. You can change this, but if you do, be sure to change it also in the S-TAP configuration to be a matching name. See [Linux-UNIX: Configuring the S-TAP for Cloudera](#).

Linux-UNIX: Configuring the S-TAP for Cloudera

Configure the S-TAP to establish communication between the Guardium system and Cloudera Navigator that uses a Kafka cluster.

About this task

You can also configure the S-TAP directly in the guard_tap.ini file. Restart the S-TAP for the configuration to take effect.

Procedure

- Browse to Setup > Tool and Views > Hadoop Monitoring and then click the add icon (+) in the Add cluster information tile.
- Select Cloudera as the Hadoop distribution.
- Select an S-TAP that is connected to the Guardium system in the S-TAP host name drop-down list.
- Enter the Kafka details.
 - Group name. The name of the Kafka consumer group you want this S-TAP to be a part of.
 - Topic name for the Kafka cluster. Unless this setting was changed in the Kafka cluster configuration settings, use the default NavigatorAuditEvents. For more information about configuring the Kafka cluster, see the Cloudera documentation.
 - Bootstrap servers. One or more Kafka nodes to take the initial connection from the Guardium S-TAP. Both host name and port are required for each server. Any nodes that are leaders of a partition for the topic can handle consumer requests. For the initial connections, it's best to specify more than one server to provide a failover in case one of the bootstrap servers is down.
 - LD library path. Path to the directory that contains the guard_stap binary, indicating to the S-TAP about which libraries to load. (For example, /usr/local/guardium/guard_stap or /usr/local/modules/STAP/current.)
- If your Kafka cluster is configured with TLS, check Enable TLS.

Restriction: Guardium does not support Kafka clusters that are configured to require SSL client authentication.

 - SSL CA path. Required parameter for TLS. Path to a file that contains the certificate to verify the Kafka broker's certificate, in PEM format. You can have a file that contains multiple certificates in a single file.
- If the Kafka cluster requires Kerberos authentication, check Use Kerberos, and enter the Kerberos details.
 - Principal. The Kerberos principal name for the S-TAP. For example, guardium/FullyQualifiedDomainName@kerberosDomain

- Path to keytab file, the full path to the Kerberos keytab file on the S-TAP server. For example, /etc/krb.keytab. Verify that the keytab is owned by the S-TAP user and group, and is only readable by the user.
7. Click Save.
The NavigatorAuditEvents pop-up opens, showing that monitoring is enabled. If the S-TAP status is not green, investigate its status.

Related reference

- [Linux-UNIX: Hadoop parameters](#)

Linux-UNIX: Validate and troubleshoot the Cloudera configuration

Check that the Cloudera configuration successfully captures traffic.

Procedure

1. Go to the S-TAP Status Monitor page and verify that the S-TAP is still green. (Inspection engine verification is not supported for Hadoop sources, so that is always Unverified.)
2. Install a Guardium policy, or use the default policy, then run some simple HDFS or Hive commands on the Cloudera cluster and see if you can see the traffic in a report or, after a bit of time, in the investigation dashboard.
3. Troubleshooting: If you are not seeing traffic from Navigator, check the following:
 - In Cloudera Manager, verify that auditing is enabled for each service you want to monitor.
 - Is integration enabled? Check the S-TAP configuration to make sure that the kafka_reader_enabled=1.
 - Is the Kerberos principal and path correct?
 - Are the Kafka bootstrap servers up and running?
 - If TLS is checked in the GUI, verify that Kafka is setup for TLS, and vice versa. Also verify that TLS on the Kafka is not configured with client authentication required.
 - Double check your Guardium policy to make sure you are logging the traffic you expect to see from Navigator.
 - Check your report to see if you have defined it correctly. (Server type group, now -n days, and so on.)

Linux-UNIX: Hadoop integration using Hortonworks and Apache Ranger

Apache Ranger, included with the Hortonworks Data Platform 2.3-2.6, offers fine-grained access control and auditing over Hadoop components such as Solr, Storm, Hive, HBASE, and HDFS by using policies.

The audit data is written to both HDFS and Solr. Guardium can integrate with Ranger in two ways:

- For auditing, Guardium acts as another logger source for Ranger Auditing. Audited activity is sent to the Guardium collector where it is parsed and logged. After the data is in Guardium, it is highly protected in the hardened appliance. You can use all normal Guardium functions, such as real-time alerting and integration with SIEM, reporting and workflow, and analytics.
- For blocking, Guardium extends Ranger access control policies, by using what is known in Ranger as dynamic policies.

With Ranger integration, the data is decrypted before it is sent to the Guardium system for auditing. In addition to SSL support, Ranger integration that uses dynamic policies enables blocking support for more components than is supported by standard S-TAP.

Supported functions with Ranger integration

You can use Ranger integration with the following functions:

- Audit SSL-encrypted activity
- Audit Kerberos authenticated traffic - By using Ranger integration, you do not need to propagate keytabs for Guardium.
- Audit Hive, HBASE, HDFS - HBASE deployment is simpler with Ranger, you do not need to deploy S-TAPs on data nodes.
- Audit SOLR
- Audit Kafka
- Audit Storm
- Audit exceptions - Ranger catches only "access denied" exceptions.
- Blocking of Hive, HDFS, and HBASE with dynamic policies.

Limitations

Ranger integration supports the following policy rule actions:

- Alert daily
- Alert only
- Alert per match
- Alert per time granularity
- Log full details
- Log full details with replaced values
- Log masked details
- Log only
- No parse
- Quick parse
- Quick parse no fields
- Record values separately

- Skip logging

Linux-UNIX: Hortonworks Ranger architecture and data flow

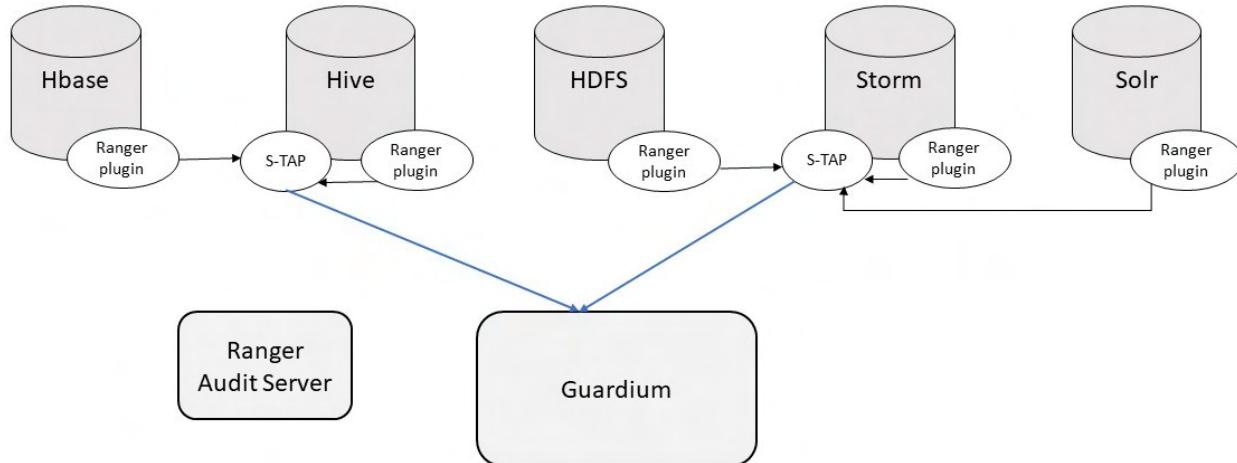

Learn how the monitoring and audit, and the blocking, are implemented.s

Monitor and Audit

The important difference with this architecture is that the S-TAP is not collecting audit data directly from the Hadoop component; instead the Ranger plugins write the audit messages to log4j, which forwards them to the S-TAP. The S-TAP then sends the messages to the Guardium collector for logging, alerting, reporting, and analytics.

The configuration is quite flexible in that you can install S-TAPs on more nodes. You can configure Ranger to send all component traffic to one S-TAP or you could specify, for example, that all HBase traffic goes to one S-TAP and Hive and HDFS goes to another.

Figure 1. Ranger plugin using log4j as an alternate logging source, forwarding audit data to Guardium

Blocking (Ranger Dynamic Policy integration)

Blocking is implemented by extending Ranger access control policies to honor blocking policy rules that are specified on the Guardium appliance. The actual implementation of blocking is performed as an access denial from Ranger. For more information about how blocking fits into the architecture and data flow and guidance for implementing blocking, see [IBM Security Monitoring and Blocking for Hortonworks Hadoop Using Apache Ranger Integration](#).

For blocking, you need an additional component called the Guardium plug-in for Ranger. This plug-in is called `guardium_evaluator.jar` and resides alongside the Ranger plugin on the Hadoop component nodes. You need this on the data/slave nodes as well if you want to block HBase.

S-TAPs required: You do not need any additional S-TAPs than what is already required for monitoring/auditing. It makes sense to use the same collector/S-TAP combinations for blocking as you do for auditing.

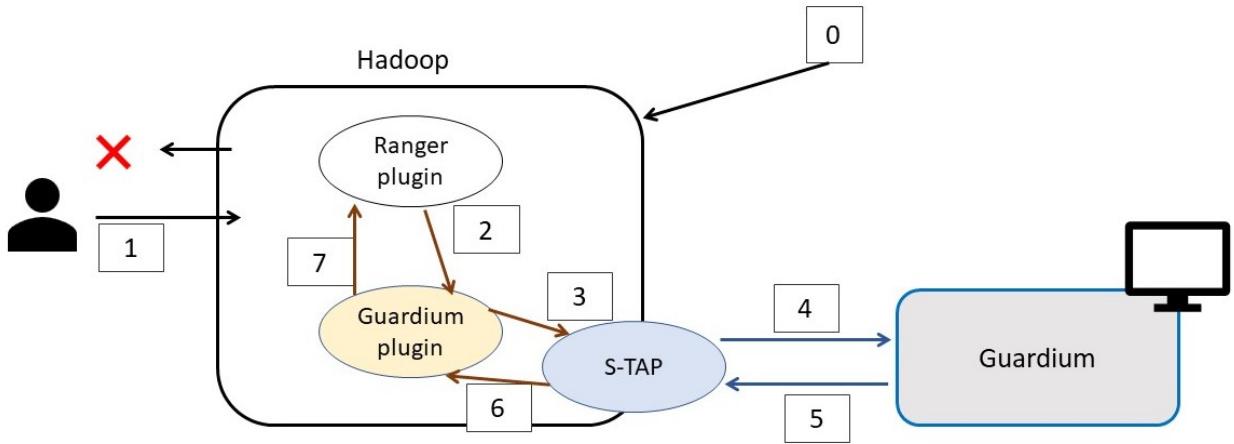

Prerequisite (**Step 0**): The administrator sets up filtering conditions on a Ranger policy based on resource, user or group or other conditions allowed by Ranger. For simplicity, let's call this the "watch" criteria. For example, the Ranger policy might specify Scott's activity against certain resources, because he's a privileged user. The policy also includes a condition to call the Guardium evaluator plugin. For more information about creating Ranger policies, see the Hortonworks documentation and Ranger tutorials.

The administrator sets up S-TAP to enable integration with the dynamic policies and the firewall. The S-TAP does not have to be directly co-located the Ranger or Guardium plugins.

On the Guardium appliance, install a policy that includes the rule action of S-GATE Terminate for inappropriate access to Hadoop. This rule could include additional criteria such as client IP address or other runtime information.

[Figure 2](#) illustrates the blocking flow, described by the following text.

Figure 2. Blocking flow with Guardium and Hortonworks Ranger

1. User tries to access a resource that meets the “watch” criteria.
2. Ranger plugin sends information about this access to the Guardium plugin.
3. Guardium plugin sends message to S-TAP.
4. S-TAP sends request to appliance about this access.
5. If Guardium blocking policy rule conditions are met, the Guardium appliance sends “block” response to S-TAP
6. S-TAP sends “block” to Guardium plugin
7. Guardium plugin tells Ranger not to match the original watching rule. This means that if there is no other Ranger policy that allows access to the resource, then access will not be allowed to the resource.

Linux-UNIX: Planning the integration with Hortonworks and Apache Ranger

Complete and verify the tasks in this topic before configuring the integration.

Topology of S-TAPs and collectors

Determine the required topology:

- Number of collectors needed
- Components monitored by each S-TAPs

Some customers prefer to have one S-TAP for each component. At a minimum, we recommend one S-TAP for HBase and one S-TAP for everything else.

Tip: An S-TAP is not required to sit on the same node as any particular component. It's possible--and even advisable if supporting Hadoop HA--to establish a dedicated Linux box for an S-TAP.

When configuring the number of connections for an S-TAP, use the following rule of thumb:

- HBase: one plus the number of region servers
- Everything else: one plus one for each component monitored

Attention:

- For blocking, verify access to all HBase region servers, since you will need to copy the Guardium plugin JAR file to each of these region servers.
- For configuring high availability failover scenarios, record the failover node IP addresses or host names.

High availability and failover

Hadoop uses secondary nodes for high availability to handle data requests should the primary node fail. There are several options for S-TAP deployment so that you can continue to collect audit data in a failover scenario.

Install the S-TAP and set it up on a system that is not part of the Hadoop cluster

This provides a simple configuration where, when the components fail over, the new node automatically uses the S-TAP as a remote logger. No changes are needed to any configurations or S-TAPs.

Hybrid approach (recommended)

Install an S-TAP for HDFS and Hive using `localhost` in the S-TAP host field, then use a separate system such as an edge node for HBase. This provides an alternative to installing S-TAPs on all nodes and region servers and is the recommended approach.

Install the S-TAP on the nodes in the cluster

In this model, you install an S-TAP on the primary and standby node for each component.

Using `localhost` in the S-TAP host field, install an S-TAP on every node in the cluster and every region server for HBASE. This is approach is not recommended.

Guardium load balancing

Guardium S-TAP and enterprise load balancing options are supported when Ranger integration is enabled.

Linux-UNIX: Hortonworks and Apache Ranger prerequisites

Verify these prerequisites before starting your integration.

- S-TAP and appliance are running Guardium V10.1 or later
- Hortonworks 2.3-3.1 with Ranger
- For Hive 3+, log4j libraries must be replaced by log4j 2.8 libraries for hiveserver2 in /usr/hdp/current/hive-server2/lib directory. The correct libraries are:
 - log4j-1.2-api-2.8.2.jar
 - log4j-api-2.8.2.jar
 - log4j-core-2.8.2.jar
 - log4j-slf4j-impl-2.8.2.jar
 - log4j-web-2.8.2.jar

You can download the libraries from <https://logging.apache.org/log4j/log4j-2.8/download.html>

- Solr Component is configured (mandatory Ranger component that enables display of user information in Guardium)
- Ambari and Ranger information. A significant portion of setup is done through Ambari, the Hadoop administrative interface. You need the following information:

Ambari

- A user ID and password who has privileges to update and save the *log4j* configuration, such as a Service Administrator account. For simplicity, refer to this as the admin account and password.
- Port and IP address or hostname.
- Cluster name.

Ranger

The details are only needed if configuring blocking. For more information about configuring blocking, see [IBM Security Monitoring and Blocking for Hortonworks Hadoop Using Apache Ranger Integration](#).

- A Service Administrator account that can update and save the *log4j* configuration.
- Port and IP address or hostname.

- These ports must be open (assuming use of default ports):

- For monitoring, open port 5555 between the node(s) that S-TAP is on and the Ranger server.
- For blocking, open port 5556 to allow communication between S-TAP and all nodes in the cluster that have the Guardium plugin.

Linux-UNIX: FAQs Hortonworks Ranger configuration

Read answers to the most asked questions about the Hortonworks Ranger configuration.

What Hadoop service components connect to the S-TAP?

https://docs.hortonworks.com/HDPDocuments/HDP2/HDP-2.6.4/bk_command-line-installation/content/installing_ranger_plugins.html lists where the Ranger plug-ins are installed for each Hadoop service. These plug-ins are what connect to the S-TAP.

Can multiple STAPs be configured per Hadoop service?

It depends. The Ranger plug-ins for the service connect to the S-TAP. If your HDFS service has only a single NameNode, there can be only one connection for that service. If there are multiple components with Ranger plug-ins (for example, HBASE, which has the Ranger plug-ins on the Master server, and on every Region server), multiple connections can be made. The main issue is that all components of the Hadoop service share one configuration. As a result, the remote host parameter of the Guardium® log4j logger is the same. One option is to put "localhost" as the host to log to and install an S-TAP on every node that has a Ranger plug-in for that service. Another option is to use DNS round robin to have each plug-in connect to a different S-TAP. Another option is to use configuration groups to specify different Guardium log4j logger remote hosts for the different Hadoop service components.

Why does the x service show up in reports for the y service?

Hadoop services often utilize each other for various functions. It is normal to see references to other Hadoop services in reports.

What is missing if the Ranger plug-in for x service is not configured?

All audits related to that service are not logged.

Can Ranger policies be configured in a way to filter audits to S-TAP while retaining audits in Ranger?

No. If actions match a Ranger policy and that policy has auditing enabled, the audit goes to all audit destinations.

Is an inspection engine needed for Hortonworks integration?

No. Inspection engines are not needed for Hadoop services that use the integration to send audits.

The Guardium UI is showing monitoring enabled, but the Ranger plug-ins are not installed yet. What is happening?

Guardium checks only that the Guardium log4j logger exists in the Hadoop service logging configuration. It does not check whether the Ranger plug-ins are installed, or if the Ranger repository and policies exist.

Linux-UNIX: Configure the solution for monitoring

This section describes how to configure the solution for monitoring.

1. [Linux-UNIX: Configure the Ranger plugins using Ambari](#)

Use this procedure to enable Ranger plug-ins for the Hadoop components you want to monitor. Refer to Hortonworks documentation for more details as needed or if you need to enable auditing on a non-Ambari cluster.

2. [Linux-UNIX: Configure Guardium and Ranger communication](#)

Learn how to establish communication between the Guardium system and Ranger.

3. [Linux-UNIX: Install and configure S-TAPs](#)

Install and configure S-TAPs for Ranger integration.

Linux-UNIX: Configure the Ranger plugins using Ambari

Use this procedure to enable Ranger plug-ins for the Hadoop components you want to monitor. Refer to Hortonworks documentation for more details as needed or if you need to enable auditing on a non-Ambari cluster.

Procedure

1. In Ambari, log in as the administrator. Go to Ranger > Configs > Ranger Plugin and enable the relevant Ranger plugins (HDFS, Hive, Kafka, HBase, Storm, Solr).
2. Create repositories for all the components to be audited.
3. Restart Ranger and the components.
4. Ensure Ranger auditing is turned on for each component's Ranger policies. By default, they are enabled, but you can verify in the Ranger console.

Next topic: [Linux-UNIX: Configure Guardium and Ranger communication](#)

Linux-UNIX: Configure Guardium and Ranger communication

Learn how to establish communication between the Guardium system and Ranger.

Before you begin

- If you are using SSL, add the certificate to the keystore with the CLI command **store certificate keystore trusted console**.

You can perform the equivalent procedure using the APIs [add_ranger_config](#) and [add_ranger_service](#).

Procedure

1. Go to Setup > Tools and Views > Hadoop Monitoring.
2. Click  in the Add cluster information section to begin defining a new configuration.
3. Select **Hortonworks** from the Hadoop distribution menu.
4. Host name/IP - Enter the host name or IP address of the Ambari server.
5. Port number - Enter the Ambari server port number.
If you leave this field blank, the configuration uses the default port of 8080.
6. Cluster name - Enter the Hadoop cluster name.
7. If you are using SSL, check the SSL Enabled checkbox.
8. User name - Enter an Ambari administrator user name.
9. Password - Enter the password for the Ambari administrator account.
10. Click Test Connection to verify the configuration.
11. Click Save to save the configuration.
12. **If you are using Hive 3+:** The Hadoop administrator must modify the configuration:
 - a. In the advanced configuration page in Ambari for Hive, remove any previous reference to the Guardium logger/appender from the log4j 2 configuration files (for example the beeline-log4j2, hive-exec-log4j2, hive-log4j2, and llap-cli-log4j2 files). Remove these lines:

```
# Configuration for Guardium integration with Ranger log4j logging.
log4j.appenders.guardlistener=org.apache.log4j.net.SocketAppender
log4j.appenders.guardlistener.Port=5555
log4j.appenders.guardlistener.RemoteHost=hw-cl4-01.guard.swg.usma.ibm.com
log4j.logger.xaaudit=ALL,guardlistener
```
 - b. Add these lines to the log4j 2 configuration files.

```
# audit logger
# Configuration for Guardium integration with Ranger log4j logging.
appender.guardlistener.type=Socket
appender.guardlistener.name=guardlistener
appender.guardlistener.port=5555
appender.guardlistener.host=9.32.164.237
appender.guardlistener.layout.type = SerializedLayout
logger.xaaudit.name=xaaudit
logger.xaaudit.level=INFO
logger.xaaudit.appenders.guardlistener.ref = guardlistener
```
 - c. Adjust the port and host for your environment. The host is the S-TAP you are using and the port is 5555 unless changed. If it is changed, it must match the log4j_port parameter value in the guard_tap.ini file.
 - d. Modify the log4j 2 configuration file with the same changes in four sections: beeline-log4j2, hive-exec-log4j2, hive-log4j2, and llap-cli-log4j2. The changes are:
 - add `guardlistener` to the list of appenders:
`appenders = console, DRFA, audittest, guardlistener`
 - add `xaaudit` to the list of loggers:
`NIOServerCnxn, ClientCnxnSocketNIO, DataNucleus, Datastore, JPOXgua, xaaudit`
 - e. Restart the HIVE service.
13. **If you are using version of Hive earlier than Hive 3+:** The Hadoop administrator must verify the configuration.

- a. # Configuration for Guardium integration with Ranger log4j logging.
`log4j.appenders.guardlistener=org.apache.log4j.net.SocketAppender
log4j.appenders.guardlistener.Port=5555
log4j.appenders.guardlistener.RemoteHost=<host name>
log4j.logger.xaaudit=ALL,guardlistener`
- b. Adjust the port and host for your environment. The host is the S-TAP you are using and the port is 5555 unless changed. If it is changed, it must match the log4j_port parameter value in the guard_tap.ini file.
- c. Verify the following settings in `custom`
`ranger-<service>-audit:`

```
xasecure.audit.destination.log4j=true  
xasecure.audit.destination.log4j.logger=xaudit
```

d. If any changes were made, restart the HIVE service.

14. If you are using Solr:

a. Register the Solr so that it can be monitored by using the script /usr/local/guardium/guard_stap/guard_log4j_listener_config.py. Enter this command, substituting your hostname:

```
./guard_log4j_listener_config.py -a <hostname> -b 8444 -u admin -p admin -c hw3cl1 -s solr -l 5555 -x enable --ssl
```

b. Install the ranger plugin and add the following lines to these files to enable log4j logging:

- /usr/cloudera-hdp-solr/xxx/cloudera-hdp-solr/solr/server/solr-webapp/webapp/WEB-INF/lib/ranger-solr-audit.xml
- /usr/cloudera-hdp-solr/xxx/cloudera-hdp-solr/solr/server/resources/ranger-solr-audit.xml

Lines to add to the files:

```
<!-- Log4j audit provider configuration -->  
    <property>  
        <name>xasecure.audit.destination.log4j</name>  
        <value>true</value>  
    </property>  
    <property>  
        <name>xasecure.audit.destination.log4j.logger</name>  
        <value>xaudit</value>  
    </property>  
    <property>  
        <name>xasecure.audit.log4j.is.enabled</name>  
        <value>true</value>  
    </property>
```

c. Restart the Solr.

Results

The new configuration is available from the Hadoop Monitoring page (marked with a green check mark icon). If the service does not display port information and the S-TAP status is **S-TAP not installed**, edit the configuration and specify a valid S-TAP.

Linux-UNIX: Install and configure S-TAPs

Install and configure S-TAPs for Ranger integration.

Before you begin

Review [Linux-UNIX: Planning the integration with Hortonworks and Apache Ranger](#) for information about S-TAP requirements and deployment options.

Procedure

1. Install S-TAPs and enable them for the Ranger integration.

You may need more than one S-TAP to handle the traffic, for example configure one S-TAP on the name node for HDFS, Hive and Kafka traffic and one S-TAP on the HBASE master node for all HBase traffic.

2. Configure guard_tap.ini for auditing.

a. Open guard_tap.ini in a text editor.

You must edit the file directly, as there is no UI or GIM support for these settings.

b. Add the parameters listed below.

Update the values to reflect your system.

```
; Settings for log4j  
logging.log4j_reader_enabled=1  
log4j_port=5555  
log4j_listen_address=0.0.0.0  
; Maximum number of connections to support from the log4j service  
log4j_num_connections=50
```

c. Restart the S-TAP after updating any settings.

What to do next

Install Guardium and Ranger policies. For monitoring and auditing, there is virtually no difference in policy rules when using Ranger than when using standard S-TAP monitoring for Hadoop. For more information, see [IBM Security Monitoring and Blocking for Hortonworks Hadoop Using Apache Ranger Integration](#).

Previous topic: [Linux-UNIX: Configure Guardium and Ranger communication](#)

Linux-UNIX: MongoDB IE configuration

View a typical insepction engine configuration, and flows for enabling and disabling A-TAP, and opening the SSL console for a MongoDB inspection engine.

Note: Redaction is not supported with or without SSL for Mongo 4.2 and higher.

MongoDB does not include OS_USER in the login packet, however you can use the UID chain to determine the DB_USER for reports. For more information, see [Linux-UNIX: UID chains](#).

Typical MongoDB inspection engine configuration

```
[DB_0]
connect_to_ip=127.0.0.1
db2_fix_pack_adjustment=20
db2_shmem_client_position=0
db2_shmem_size=131072
db2bp_path=NULL
db_exec_file=/usr/bin/mongod-guard-original
db_install_dir=/var/lib
db_type=MONGODB
db_user=mongod
encryption=0
db_version=9
instance_running=1
intercept_types=NULL
load_balanced=1
port_range_end=27017
port_range_start=27017
priority_count=20
real_db_port=27017
tap_identifier=MONGODB_mongo42-rhl7(27017,27017,DB_0)
tee_listen_port=0
unix_domain_socket_marker=NULL
networks=0.0.0.0/0.0.0.0
exclude_networks=
```

Activate and deactivate A-TAP for SSL traffic

Before activating A-TAP, you need to stop the MongoDB instance:

```
systemctl stop mongod
```

Activate A-TAP:

```
/usr/local/guardium/guard_stap/guardctl --db-user=mongod --db-type=mongodb --db-instance=mongo --db-base=/home/ibmuser --db-home=/usr activate
```

Restart the MongoDB instance:

```
systemctl start mongod
```

Set up mongo with TLS/SSL certificate and key

For example, on an instance with SSL and kerberization:

```
mongo --ssl --sslPEMKeyFile /etc/ssl/mongo40standalone-va.pem --sslPEMKeyPassword guardium --sslAllowInvalidCertificates --host <hostname> --port 27017 --authenticationMechanism=GSSAPI --authenticationDatabase='$external' --username <username>
```

Deactivating A-TAP

Before deactivating A-TAP, you need to stop the DB instance.

```
systemctl stop mongod
```

Deactivate A-TAP:

```
/usr/local/guardium/guard_stap/guardctl --db-user=mongod --db-type=mongodb --db-instance=mongo --db-base=/var/lib --db-home=/usr deactivate
```

Restart the MONGO DB instance:

```
systemctl start mongod
```

Linux-UNIX: Neo4J auditing configuration

Use a double proxy together with either K-TAP or PCAP to capture encrypted Neo4J traffic.

About this task

This procedure requires two proxies of either NGINX or HAProxy type. Both must both be located on the database.

The first proxy instance terminates the SSL and adds a proxy protocol to ports 7687 and 7473. The second proxy instance listens to the intermediate ports (17687 and 17473) and removes the proxy protocol. K-TAP or PCAP intercepts the traffic between the two proxy instances. Outgoing decrypted traffic from Proxy2 is sent to unencrypted Neo4j database ports (27687, 7474).

Procedure

1. Configure the database.

Neo4J advertises the ports it uses. The ports need to be changed to avoid conflicting with the proxy ports: Neo4J needs to have its port configuration changed and the proxy entry point ports need to be configured for advertising (requires version 3.5.0 or newer). In the neo4j configuration file: /home/neo4j/neo4j/conf/neo4j.conf, add/edit these lines. In this example the DB server is rh7u3x64t-ktap.databaseserver.

```
dbms.connector.bolt.listen_address=127.0.0.1:27687
dbms.connector.bolt.advertised_address=rh7u3x64t-ktap:7687
dbms.connector.http.listen_address=127.0.0.1:7474
dbms.connector.https.listen_address=127.0.0.1:27473
dbms.connector.https.advertised_address=rh7u3x64t-ktap:7473
```

2. Configure HAProxy. (Not required if you are using NGINX.)

In the HAProxy configuration file /etc/haproxy/haproxy.cfg:

- Enable the Proxy Protocol in Proxy1(HAProxy1) by adding the send-proxy keyword to the backend.
- Strip the Proxy protocol in Proxy2(HAProxy2) by adding accept-proxy to the frontend.

```
frontend main
    bind *:7687 ssl crt /home/neo4j/neo4j/certificates/neo4j.pem
    mode tcp
    default_backend send_proxy_protocol

backend send_proxy_protocol
    balance roundrobin
    server app1 127.0.0.1:17687 send-proxy

frontend strip_proxy_protocol
    bind 127.0.0.1:17687 accept-proxy
    mode tcp
    default_backend neo4j

backend neo4j
    balance roundrobin
    server app1 127.0.0.1:27687
```

3. Configure NGINX. (Not required if you are using HAProxy.)

For a TCP stream, the PROXY protocol can be enabled for connections between NGINX and an upstream server. To enable the PROXY protocol in Proxy1(Nginx1), include the proxy_protocol directive in a server block at the stream{} level in /etc/nginx/nginx.conf. NGINX terminates HTTPS traffic (the ssl_certificate and ssl_certificate_key directives) and proxies the decrypted data to a backend server. In Proxy2(Nginx2), add listen with proxy_protocol to receive the client's real IP forwarded with Proxy Protocol.

- Make sure that your NGINX installation includes the HTTP and Stream Real IP modules:

- nginx -V 2>&1 | grep -- 'http_realip_module'
- nginx -V 2>&1 | grep -- 'stream_realip_module'

- In the file /etc/nginx/nginx.conf, add:

```
stream {
    upstream neo4jweb {
        server localhost:7474;
    }
    upstream neo4jbolt {
        server localhost:27687;
    }

    server {
        listen 7473      ssl;
        proxy_pass      localhost:17473;
        proxy_protocol  on;
        ssl_certificate /home/neo4j/neo4j/certificates/neo4j.cert;
        ssl_certificate_key /home/neo4j/neo4j/certificates/neo4j.key;
    }
    server {
        listen 7687      ssl;
        proxy_pass      localhost:17687;
        proxy_protocol  on;
        ssl_certificate /home/neo4j/neo4j/certificates/neo4j.cert;
        ssl_certificate_key /home/neo4j/neo4j/certificates/neo4j.key;
    }
    server {
        listen 17473     proxy_protocol;
        proxy_pass      neo4jweb;
    }
    server {
        listen 17687     proxy_protocol;
        proxy_pass      neo4jbolt;
    }
}
```

4. Configure the network.

Verify that all traffic from the client is sent to Proxy1. Any traffic that does not go from Proxy2 to DB is dropped. This requires IPTABLE setup. Use this script neo4j_firewall.sh to set up the IPTABLES:

```

#!/bin/sh

# Remove any existing jumps to our custom chains
iptables -D INPUT -j chain-neo4j-incoming
iptables -D OUTPUT -j chain-neo4j-outgoing

# Clean any existing custom chains
iptables -F chain-neo4j-incoming
iptables -F chain-neo4j-outgoing
iptables -X chain-neo4j-incoming
iptables -X chain-neo4j-outgoing
iptables -N chain-neo4j-incoming
iptables -N chain-neo4j-outgoing

# Define external(proxy1), proxy2, ssl and no ssl ports
no_ssl_port_prefix=2
proxy2_port_prefix=1
port_list=0

# Pass in all arguments, please see bottom usage.
for i in "$@" ; do
    # set the port prefix
    if echo $i | grep '^-' > /dev/null; then
        if echo $i | grep '^--port_list$' > /dev/null; then
            port_list=999
        fi
    elif [ "X${port_list}" = "X999" ]; then
        external_port=${i}
        proxy2_port=${proxy2_port_prefix}${i}
        no_ssl_port=${no_ssl_port_prefix}${i}
        if [ "${external_port}" = "7473" ]; then
            no_ssl_port=7474
        fi
    ######
    # INCOMING RULES

    # Allow loopback access to intermediate ports so that proxy1 can
    # route traffic to proxy2
    iptables -A chain-neo4j-incoming -i lo -p tcp --dport ${proxy2_port} -j ACCEPT

    # Disallow external access to proxy2
    iptables -A chain-neo4j-incoming -p tcp --dport ${proxy2_port} -j REJECT

    # Allow loopback access to unencrypted ports so that proxy2 can
    # route traffic to DB
    iptables -A chain-neo4j-incoming -i lo -p tcp --dport ${no_ssl_port} -j ACCEPT

    # Disallow direct access to unencrypted ports
    iptables -A chain-neo4j-incoming -p tcp --dport ${no_ssl_port} -j REJECT

    # Allow access to proxy1
    iptables -A chain-neo4j-incoming -p tcp --dport ${external_port} -j ACCEPT
    ######
    # OUTGOING RULES

    # Allow loopback access to unencrypted ports to allow routing from proxy2 to
    # DB (proxy2 runs under neo4j UID)
    iptables -A chain-neo4j-outgoing -o lo -p tcp --dport ${no_ssl_port} -m owner --uid neo4j -j ACCEPT

    # Allow loopback access to intermediate ports to allow routing from proxy1 to
    # proxy2 (proxy1 runs under neo4j UID)
    iptables -A chain-neo4j-outgoing -o lo -p tcp --dport ${proxy2_port} -m owner --uid neo4j -j ACCEPT

    # Disallow loopback access to unencrypted ports to prevent local clients from
    # skipping interception
    iptables -A chain-neo4j-outgoing -o lo -p tcp --dport ${no_ssl_port} -j REJECT
fi
done

if [ "${port_list}" = "0" ]; then
    echo "usage: /root/set_firewall.sh -port_list [external port list]"
    echo "for example /root/set_firewall.sh -port_list 7473 7687"
fi

# Firewall chains need to return at the end
iptables -A chain-neo4j-incoming -j RETURN
iptables -A chain-neo4j-outgoing -j RETURN

# Hook the main rules up to the chains
iptables -A INPUT -j chain-neo4j-incoming
iptables -A OUTPUT -j chain-neo4j-outgoing

```

5. Configure the S-TAP.

When configuring the proxy instances, the first instance terminates the encryption and adds the proxy-protocol for Guardium to collect the traffic and be able to attribute the correct analyzed client IP. The second instance removes the proxy-protocol, to not break the connection to the database. Configure the inspection engine to collect the traffic between the two proxy instances. For example, if you are using the example configurations above, then the ports to collect for Neo4j are 17473, 17687.

- If you are using K-TAP, modify the guard_tap.ini file:
 - IE parameters

```
[DB_0]
db_type=NEO4J
```

```

port_range_end=17473
port_range_start=17473
real_db_port=17473
networks=127.0.0.1/255.255.255.255,9.70.165.199/255.255.255.255

[DB_1]
db_type=NEO4J
port_range_end=17687
port_range_start=17687
real_db_port=17687
networks=127.0.0.1/255.255.255.255,9.70.165.199/255.255.255.255

• If you are using PCAP, modify the guard_tap.ini file:
  • TAP properties

  devices=ens32,lo
  ktap_installed=0

  • IE parameters

  [DB_0]
  db_type=NEO4J
  port_range_end=17473
  port_range_start=17473
  real_db_port=17473

  [DB_1]
  db_type=NEO4J
  port_range_end=17687
  port_range_start=17687
  real_db_port=17687

```

Linux-UNIX: Oracle Connection Manager configuration to monitor encrypted traffic

You can use the Oracle Connection Manager to monitor encrypted traffic, without A-TAP.

Before you begin

- S-TAP 10.x or higher is installed in the Oracle database server.
- Oracle Connection Manager v18.3 is installed and configured for SSL.

About this task

The Oracle Connection Manager is a proxy server that forwards connection requests to databases or other proxy servers. It operates on the session level. It usually resides on a computer separate from the database server and client computers. It is a custom installation option on the Clientdisk. The primary functions of Oracle Connection Manager are:

- Access control: to use rule-based configuration to filter user-specified client requests and accept others.
- Session multiplexing: to funnel multiple client sessions through a network connection to a shared server destination.
- Hardening security: can be setup as proxy server between public and trusted network.

The public (open external) network includes the web client, firewalls, and application server. The trusted (private internal) network is non-routable and exists only between the connection manager and database server. It is recommended for OCM that most actual database services, like the database listener and administrative applications like Oracle Grid Control, should be configured to run on the private network where they cannot be subjected to random port scans.

Configure the OCM in one of these models:

- [Linux-UNIX: Install and configure the Oracle Connection Manager on the database server](#)
recommended. Cant be directly to data base but all clients connected to OCM.
- [Linux-UNIX: Install and configure the Oracle Connection Manager in an Oracle RAC environment](#)
Oracle RAC cluster environments are usually set up within a private (trusted) network. Data should be only encrypted for remote clients' connections.
- [Linux-UNIX: Install and configure the Oracle Connection Manager on a remote server](#)
There are transfers of unencrypted data between the OCM and the actual database server. Install and configure the Oracle Connection Manager (OCM) on a separate server between the public network and the trusted (private) network when required for security reasons.

Linux-UNIX: Install and configure the Oracle Connection Manager on the database server

recommended. Cant be directly to data base but all clients connected to OCM.

Procedure

1. Configure the Oracle Connection Manager (OCM) environment.
 - Configure the Listener for OCM for TCPS and TCP protocols with the remote server hostname or the IP address in the file cman.ora.
 - Configure the file cman.ora with the standard parameter list for OCM and enable_ip_forwarding=yes. The rule list should include the source configured for the Oracle Database hostname or IP and destination to local host.
 - Configure sqlnet.ora in the OCM environment for SSL connections.

Example of cman.ora file:

```

cman=
(configuration=
(address=(protocol=tcps) (host=<DB_server_hostname/IP>) (port=1552))
(address=(protocol=tcp) (host=<DB_server_hostname/IP>) (port=1551))
(parameter_list =
(aso_authentication_filter=off)
(connection_statistics=yes)
(log_level=off)
(enable_ip_forwarding=yes)
(max_connections=256)
(idle_timeout=0)
(inbound_connect_timeout=0)
(
session_timeout=0)
(outbound_connect_timeout=0)
(max_gateway_processes=16)
(min_gateway_processes=2)
(remote_admin=on)
(trace_level=off)
(trace_timestamp=off)
(trace_filelen=1000)
(tr
ce_fileno=1)
(max_cmctl_sessions=4)
(event_group=init_and_term,memory_ops)
)
(rule_list=
(rule=(src=<DB_server_hostname/IP>) (dst=127.0.0.1) (srv=cmon) (act=accept))
(rule=(src=127.0.0.1) (dst=*) (srv=*) (act=reject))
(rule=(src=<DB_server_hostname/IP>) (dst=*) (srv=*) (act=reject)
(rule=(src=*) (dst=*) (srv=*) (act=accept))
)
)

WALLET_LOCATION =
(SOURCE =
(METHOD = FILE)
(METHOD_DATA =
(DIRECTORY = /home/cman/app/cman/produ
ct/18.0.0/client_1/network/admin/wallet)
)
)

```

2. Configure the Oracle server.

- Local Listeners for the database server should be listen only TCP ports for the localhost address.
- Remote listener should be set with parameters from the file cman.ora in the tnsnames.ora file.

Example of tnsnames.ora file:

```

LISTENER_CMAN =
(DESCRIPTION_LIST =
(DESCRIPTION =
(ADDRESS = (PROTOCOL = TCP) (HOST = <DB_server_hostname/IP>) (PORT = 1551))
(ADDRESS = (PROTOCOL = TCPS) (HOST = <
DB_server_hostname/IP>) (PORT = 1552))
)
)
LISTENER =
(DESCRIPTION_LIST =
(DESCRIPTION =
(ADDRESS = (PROTOCOL = TCP) (HOST = 127.0.0.1) (PORT = 1528))
)
)

```

LISTENER_CMAN is an alias for your Remote Listener and LISTENER is an alias for your Local Listener in this case.

3. Configure the Oracle clients.

- The connection string in Oracle client environments should be set for TCPS protocol with a designated port, set for that protocol in the OCM environment and hostname or IP specified for Remote Listener with the associated SERVICE_NAME.

This configuration prevents local connections from connecting via CMAN since local traffic should not be encrypted and the S-TAP should be able to capture the UID chain.

Linux-UNIX: Install and configure the Oracle Connection Manager in an Oracle RAC environment

Oracle RAC cluster environments are usually set up within a private (trusted) network. Data should be only encrypted for remote clients' connections.

Procedure

Configure the Oracle Connection Manager (OCM) environment on the main Oracle RAC node or on each node for high availability.

- Configure the Listener for OCM for TCPS and TCP protocols with the remote server hostname or Ithe P address in the file cman.ora.
- Configure the cman.ora file with standard parameter list for OCM and enable_ip_forwarding=yes. The rule list should include a source configured for server hostname or IP and destination to SCAN - LISTENER hostname or IP.
- In the cman.ora file, set the parameter REGISTRATION_INVITED_NODES with node(s) hostname(s) or IP(s). This parameter also accepts wildcards as values for group of IPs.
- Configure the file sqlnet.ora in the OCM environment for SSL connections

- Configure client's connections to connect to RAC instances using OCM and SCAN_LISTENER hostnames and corresponding ports.

Example of cman.ora file:

```
cman=
(configuration=(address=(protocol=tcps) (host=<CMAN_HOST/IP>) (port=1552))
(address=(protocol=tcp) (host=<CMAN_HOST/IP>) (port=1551))
(parameter_list =
(aso_authentication_filter=off)
(connection_statistics=yes)
(log_level=off)
(enable_ip_forwarding=yes)
(max_connections=256)
(idle_timeout=0)
(inbound_connect_timeout=0)
(session_timeout=0)
(outbound_connect_timeout=0)
(max_gateway_processes=16)
(min_gateway_processes=2)
(remote_admin=on)
(trace_level=off)
(trace_timestamp=off)
(trace_filelen=1000)
(trace_filenr=1)
(max_cmt_sessions=4)
(event_group=init_and_term,memory_ops)
(REGISTRATION_INVITED_NODES =node1_host,node2_host,node3_host/ IPs)
)

(rule_list=(rule=(src=CMAN_HOST) (dst=*) (srv=cmon) (act=accept))
(rule=(src=CMAN_HOST) (dst=*) (srv=*) (act=reject))
(rule=(src=127.0.0.1) (dst=*) (srv=cmon) (act=accept))
(rule=(src=127.0.0.1) (dst=*) (srv=*) (act=reject))
(rule=(src=:1) (dst=*) (srv=cmon) (act=accept))
(rule=(src=:1) (dst=*) (srv=*) (act=reject))
(rule=(src=*) (dst=SCAN_LISTENER_HOST/IP) (srv=DB_SERVICE_NAME) (act=accept))
)

)

WALLET_LOCATION =
(SOURCE =
(METHOD = FILE)
(METHOD_DATA =
(DIRECTORY = /home/cman/app/cman/product/18.0.0/client_1/network/admin/wallet)
)
)
```

Example of tnsnames.ora file:

```
Connection_String=
(description=
(source_route=yes)
(address_list=
(address=(protocol=tcps) (host=CMAN_HOST) (port=1552))
(address=(protocol=tcp) (host=SCAN_LISTENER_HOST) (port=SCAN_PORT) )
)
(connect_data=(service_name=DB_SERVICE_NAME))
(SECURITY=(SSL_SERVER_CERT_DN="cn=Unit,cn=Organisation,dc=us,dc=com")
)
```

Linux-UNIX: Install and configure the Oracle Connection Manager on a remote server

There are transfers of unencrypted data between the OCM and the actual database server. Install and configure the Oracle Connection Manager (OCM) on a separate server between the public network and the trusted (private) network when required for security reasons.

Procedure

1. Configure the Oracle Connection Manager (OCM) environment:

- Configure the Listener for OCM for TCPS and TCP protocols with the remote server hostname or the IP address in the file cman.ora.
- Configure the file cman.ora with the standard parameter list for OCM and enable_ip_forwarding=yes. The rule list should include the source configured for the remote server Hostname or IP and the destination to the Oracle Database hostname or IP.
- In the file cman.ora set the parameter REGISTRATION_INVITED_NODES with the Database(s) hostname(s) or IP(s). This parameter also accepts a wildcard as a value for group of IPs.
- Configure sqtnet.ora in the OCM environment for SSL connections.

Example of cman.ora file:

```
cman=
(configuration=
(address=(protocol=tcps) (host=<Remote_hostname/IP>) (port=1552))
(address=(protocol=tcp) (host=<Remote_hostname/IP>) (port=1551))
(parameter_list=(aso_authentication_filter=off)
(connection_statistics=yes)
(log_level=off)
(enable_ip_forwarding=yes)
(max_connections=256)
(idle_timeout=0)
```

```

(inbound_connect_timeout=0)
(session_timeout=0)
(outbound_connect_timeout=0)
(max_gateway_processes=16)
(min_gateway_processes=2)
(remote_admin=on)
(trace_level=off)
(trace_timestamp=off)
(trace_filelen=1000)
(trace_fileno=1)
(max_cmctl_sessions=4)
(event_group=init_and_term,memory_ops)
(REGISTRATION_INVITED_NODES = DB_server_hostname/IP)
)
(rule_list=(rule=(src=<Remote_hostname/IP>) (dst=*) (srv=cmon) (act=accept))
(rule=(src=<DB_server_hostname/IP>) (dst=*) (srv=*) (act=reject))
(rule=(src=*) (dst=*) (srv=*) (act=accept)))
)
WALLET_LOCATION =
(SOURCE =
(METHOD = FILE)
(METHOD_DATA =
(DIRECTORY = /home/cman/app/cman/product/18.0.0/client_1/network/admin/wallet))

```

2. Configure the Oracle server.

- Local Listeners for the database server should be only listen TCP ports with DB_server_hostname/IPAddress
- Remote listener should be set with parameters from cman.ora file in the tnsnames.ora file

Example of tnsnames.ora file:

```

LISTENER_CMAN =
(DESCRIBE
PTION_LIST =
(DESCRIPTION =
(ADDRESS = (PROTOCOL = TCP) (HOST = <Remote_hostname/IP>) (PORT = 1551))
(ADDRESS = (PROTOCOL = TCPS) (HOST = <Remote_hostname/IP>) (PORT = 1552))
)
)
LISTENER =
(DESCRIPTION_LIST =
(DESCRIPTION =
(ADDRESS = (PROTOCOL = TCP) (HOST = DB_server_hostname/IP) (PORT = 1528))
)
)

```

LISTENER_CMAN is alias for your Remote Listener, and LISTENER is alias for your Local Listener in this case.

3. Configure Oracle clients.

- The connection string in Oracle client environments should be set for TCPS protocol with designated port set for that protocol in OCM environment and hostname or IP specified for Remote Listener with associated SERVICE_NAME.

Ports in the Inspection Engine for Oracle should match the values set for Local Listener only.

Linux-UNIX: Oracle IE configuration

View a typical configuration for an inspection engine on an Oracle database.

If the database is up during the S-TAP installation, it should automatically set up the inspection engines for Oracle. In some complicated cases the auto-discovery process may not configure the inspection engine for a Unix S-TAP, and manual configuration is required.

Inspection engine parameters:

```

connect_to_ip=127.0.0.1,::1
db_exec_file=<FULL_PATH_TO_ORACLE_BINARY>
db_install_dir=<ORACLE_OS_USER_HOME>
db_type=oracle
db_user=<ORACLE_OS_USER>
encryption=0
db_version=<DB_VERSION>
instance_running=1
intercept_types=NULL
load_balanced=1
port_range_end=<VALUE_FOR_PORT_RANGE(END)>
port_range_start=<VALUE_FOR_PORT_RANGE(START)>
priority_count=20
real_db_port=<VALUE_FOR_PORT>
tap_identifier=<COULD_BE_CUSTOM_OR_EMPTY_DURING_SETUP>
tee_listen_port=0
unix_domain_socket_marker=NULL
networks=0.0.0.0/0.0.0.0,::/0
exclude_networks=

```

Example:

```

DB_0:
connect_to_ip=127.0.0.1,::1
db2_fix_pack_adjustment=20
db2_shmem_client_position=0
db2_shmem_size=131072
db2bp_path=NULL
db_exec_file=/${ORACLE_HOME}/bin/oracle
db_install_dir=/home/oracle18

```

```

db_type=oracle
db_user=oracle18
encryption=0
db_version=18
instance_running=1
intercept_types=NULL
load_balanced=1
port_range_end=1525
port_range_start=1520
priority_count=20
real_db_port=1521
tap_identifier=oracle_9.70.147.74(1521,1521,DB_0)
tee_listen_port=0
unix_domain_socket_marker=ORCL
networks=0.0.0.0/0.0.0.0,::/0
exclude_networks=

```

Linux-UNIX: Configuring S-TAP interception using Oracle Unified Audit

Use Oracle Unified Auditing (OUA) to capture user activities in Oracle database environments based on Oracle Unified Audit policies. All captured activities are stored in specific tables. Linux S-TAP x86_64 can dynamically load and use Oracle-provided libraries to connect to the configured Oracle services. The S-TAP can then pull data from the unified auditing tables, and send data to Guardium collectors.

Before you begin

With Oracle Unified Auditing, the S-TAP does not need to be on the same server where Oracle Unified Auditing is set up. It can be installed on any Linux x86_64-based server, either the same server (if Oracle is running on a Linux x86_64 platform) or a remote server. If the S-TAP is installed on a remote server, it captures database activities remotely.

If Oracle Instant Client is not already installed and configured, the root user must take the following steps :

1. Download Oracle Instant Client rpm from the Oracle website at <https://www.oracle.com/database/technologies/instant-client/linux-x86-64-downloads.html>.
2. Install the Oracle Instant Client Basic rpm on the Linux server where you install the S-TAP. For example:

```
rpm -ivh oracle-instantclient-basic-21.10.0.0.0-1.el8.x86_64.rpm
```

3. The installation process installs the Oracle libraries and creates the TNS_ADMIN path for Oracle Instant client. Add tnsnames.ora or ldap.ora files that contain content for Oracle Database connections that the S-TAP will monitor under the TNS_ADMIN path. The TNS_ADMIN path might be similar to the following example:

```
/usr/lib/oracle/21/client64/lib/network/admin
```

Note: The Oracle Instant Client must be installed on the same system where you install the S-TAP.

About this task

Oracle Unified Auditing with an S-TAP has the following requirements:

- Using Guardium® S-TAP with the Oracle Unified Auditing method requires Oracle database 18c and higher.
- Oracle Instant Client must be version 18 or higher.
- Unified auditing must be enabled in any Oracle database instances that you want to monitor by this method.
- The designated user for S-TAP must either be created for Oracle database access or you can use an existing user with sysdba privileges.

Procedure

1. Create a designated database user (with minimal privileges) for S-TAP as follows,
 - a. Connect to Oracle by using the `sysdba` account. For this example, the Oracle Unified Audit user is called `guardium` (`password = password`).

```

CREATE USER guardium IDENTIFIED BY password
GRANT CONNECT, RESOURCE to guardium;
GRANT SELECT ANY DICTIONARY TO guardium;
exec DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(host => 'localhost', ace  => xs$ace_type(privilege_list =>
xs$name_list('connect', 'resolve'), principal_name  => 'guardium', principal_type => xs_acl.ptype_db));

```

- b. You can verify your new user's privileges by connecting to the Oracle instance with the specified name and credentials. Run following statements:

```

select count(*) from AUDSYS.AUD$UNIFIED;
SELECT UTL_INADDR.get_host_address FROM DUAL;

```

If no errors are returned, then the user has appropriate privileges for Oracle Unified Auditing S-TAP interception.

Note: Instead of creating a new user, you can use an existing user that has `sysdba` privileges.

2. From either the Guardium GUI or the `guard_tap.ini` file, set the following parameters.

- From the Guardium GUI, browse to `Manage > Activity Monitoring > S-TAP Control`. In the Details section of S-TAP Control, make the following updates,
 - LD library paths - The path to the Oracle Instant Client libraries that are installed on the system. For example,

```
/usr/lib/oracle/19.8/client64/lib
```

- SQL configuration properties directory - The TNS_ADMIN path for Oracle Instant client. For example,

```
/usr/lib/oracle/19.8/client64/lib/network/admin
```

- From `guard_tap.ini`, set the following parameters,

```
ld_library_paths=/usr/lib/oracle/19.8/client64/lib
sqlc_properties_dir=/usr/lib/oracle/19.8/client64/lib/network/admin
```

3. Add the SQL configuration. This configuration is similar to inspection engines. Use one of the following methods:

- From the S-TAP Control page, take the following steps:
 - Click .
 - Click Add SQL Configuration.
 - Complete the details and then click Add.
 - Finally, click Apply to apply your changes.
- From the CLI, call the `create_sql_configuration` GrdAPI. For more information about parameters, see [create_sql_configuration](#).
- From `guard_tap.ini`, add one section for each database instance at the end of the file:

```
[SQLC_<0,1,2...>]
data_pull_interval=300
data_pull_num_rows=100
db_type=oracle
instance=on8pgrel
timeout=300000
username=username
```

4. Store the username and password pair for the designated user that you created (or for an existing user).

You can store the username and password pair from either the Guardium GuardAPI or from the Guardium S-TAP Control page in the GUI.

- To use the CLI, run the `store_sql_credentials` GuardAPI command from the CLI. For example,

```
grdapic store_sql_credentials staphost=STAPHOST username=guardium password=password
```
- From the S-TAP Control page in the Guardium GUI,
 - Click the Send Command , then select Store SQL credentials from the drop-down list.
 - Enter the username and password, and then click Apply.

Note: You can also update the password by entering an existing username and a new password.

Linux-UNIX: Redis configuration

Redis TCP protocol is supported by an S-TAP installed on a Redis server. If Redis is set up with SSL/TLS encryption, you need two proxies using HAProxy Load Balancer.

Capturing SSL Redis protocol activities

Capturing SSL Redis protocol activities requires two proxies using HAProxy Load Balancer. They must be set up and configured on the same database server. S-TAP can be set up with K-TAP or PCAP. K-TAP or PCAP intercepts the traffic between the two proxy ports.

Guidelines: Double-proxy set up with:

- HAProxy Load Balancer input port 18345
- Middle port 18346 where activities are captured
- Port 18347 output port, which is configured also for the Redis connection

The Redis certificate can be used, for convenience. An example for Redis connection after HAProxy Load Balancer setup:

```
redis-cli -h `hostname` -p 18345 --tls --cacert /etc/opt/redislabs/proxy_cert.pem
```

Configure the HAProxy Load Balancer in a configuration file that is typically located at `/etc/haproxy/haproxy.cfg`. For example:

```
#####
main frontend which proxys to the backends
#####
frontend main_in
bind 0.0.0.0:18345 ssl crt /etc/haproxy.pem
mode tcp
use_backend intermediate_out
backend intermediate_out
server output 127.0.0.1:18346 send-proxy
frontend intermediate_in
bind 0.0.0.0:18346 accept-proxy
mode tcp
use_backend main_out
backend main_out
server output 127.0.0.1:18347 ssl verify none crt /etc/haproxy.pem
```

Typical inspection engine configuration

```
[DB_0]
connect_to_ip=127.0.0.1,::1

You can use the S-TAP Status monitor tab of the System View to begin investigating any problems. Sometimes you might need to use other tools, particularly if you are monitoring databases for which the inspection engines cannot be verified.

Linux-UNIX: Stopping S-TAP using GIM

With GIM, you can stop the S-TAP without logging into the database server.

About this task

Use the following steps to change the STAP_ENABLED parameter and stop the S-TAP on the database server.

Procedure

1. Navigate to **Manage > Module Installation > Set up by Client**.
2. In the Choose bundle section, select your S-TAP bundle. Click Next.
After selecting a software bundle, the Selected bundle action column indicates the action that will be performed for each client. You can stop the S-TAPs that have the status Update parameters.
3. In the Choose parameters section, type **STAP_ENABLED** and type in the value 0. Click Next.

4. Click OK to stop the S-TAP now, or use the  icon to schedule the stop time, then click OK.

Linux-UNIX: Starting S-TAP using GIM

With GIM, you can start the S-TAP without logging into the database server.

About this task

Use the following steps to change the STAP_ENABLED parameter and start the S-TAP on the database server.

Procedure

1. Navigate to Manage > Module Installation > Set up by Client.
2. In the Choose clients section, select the database servers whose S-TAPs you want to start. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients. Click Next to continue.
3. In the Choose parameters section, type STAP_ENABLED and type in the value 1. Click Next.
4. Click OK to start the S-TAP now, or use the  icon to schedule the start time, then click OK.

Linux-UNIX: Start and stop S-TAP and GIM processes for various OS types/versions

Depending on the operating system type and version there are different methods used to start and stop Guardium processes. Learn how to start and stop the S-TAP and GIM processes.

First identify the method relevant for your database in [Table 1](#), then proceed to the relevant sub-section for the relevant commands.

When you stop the S-TAP or GIM from the database command line, the operating starts it again automatically.

Tip: You can also use the `guard-config-update` utility to start and stop the S-TAP, whether it was installed with GIM, RPM, or shell. When you use `guard-config-update`, you don't need to know the relevant commands. See [Linux-UNIX: Using guard-config-update to start, restart, and stop S-TAP, and view status](#).

Table 1. Startup facility based on OS and version

| OS | Version | Initialization method |
|---------|---------|-----------------------|
| AIX | all | inittab |
| Debian | all | systemd |
| HP-UX | all | inittab |
| RHEL | 5 | inittab |
| RHEL | 6 | upstart |
| RHEL | 7 | systemd |
| RHEL | 8 | systemd |
| SUSE | 11 | inittab |
| SUSE | 12 | systemd |
| SUSE | 15 | systemd |
| Ubuntu | 14.04 | upstart |
| Ubuntu | 16.04 | systemd |
| Ubuntu | 18.04 | systemd |
| Solaris | 5.10 | service |

- [Linux-UNIX: Start and stop methods for inittab](#)
To start or stop processes in inittab, you need to edit the file /etc/inittab.
- [Linux-UNIX: Start and stop methods for Solaris services](#)
Learn how to start and stop S-TAP and GIM processes for Solaris services.
- [Linux-UNIX: Start and stop methods for systemd](#)
Learn how to start and stop S-TAP and GIM processes with systemd services.
- [Linux-UNIX: Start and stop methods for upstart](#)
Learn how to start and stop S-TAP and GIM processes with upstart services.

Linux-UNIX: Start and stop methods for inittab

To start or stop processes in inittab, you need to edit the file /etc/inittab.

1. Add or erase a hash sign # to comment or comment out the service. In AIX, use a colon (:) instead.
2. Run init q to make the changes effective.

Changes to the file depend on the installation path and the version. Typical examples are:

```
gim:2345:respawn:/usr/bin/perl /usr/local/IBM/modules/GIM/11.2.0.0_r108796_1-1590008051/gim_client.pl
```

```
gsvr:2345:respawn:/usr/local/IBM/modules/perl /usr/local/IBM/modules/SUPERVISOR/11.2.0.0_r108796_1-1590008053/guard_supervisor
```

Linux-UNIX: Start and stop methods for Solaris services

Learn how to start and stop S-TAP and GIM processes for Solaris services.

Table 1. svc commands to start and stop processes

| Action | S-TAP commands |
|-------------------------------|---|
| Start S-TAP | <code>svcadm -v enable guard_utap</code> |
| Stop S-TAP | <code>svcadm -v disable guard_utap</code> |
| Verify S-TAP status | <code>svcs grep guard_utap</code> |
| Start GIM, supervisor | <code>svcadm -v enable guard_gim</code>
<code>svcadm -v enable guard_gsvr</code> |
| Stop GIM, supervisor | <code>svcadm -v disable guard_gim</code>
<code>svcadm -v disable guard_gsvr</code> |
| Verify GIM, supervisor status | <code>svcs grep guard</code> |

Linux-UNIX: Start and stop methods for systemd

Learn how to start and stop S-TAP and GIM processes with systemd services.

Table 1. systemd commands to start and stop processes

| Action | S-TAP commands |
|-------------------------------|---|
| Start S-TAP | <code>systemctl start guard_utap.service</code> |
| Stop S-TAP | <code>systemctl stop guard_utap.service</code> |
| Verify S-TAP status | <code>systemctl -t service -a grep guard_utap</code> |
| Start GIM, supervisor | <code>systemctl start guard_gim.service</code>
<code>systemctl start guard_gsvr.service</code> |
| Stop GIM, supervisor | <code>systemctl stop guard_gim.service</code>
<code>systemctl stop guard_gsvr.service</code> |
| Verify GIM, supervisor status | <code>systemctl -t service -a grep guard</code> |

Linux-UNIX: Start and stop methods for upstart

Learn how to start and stop S-TAP and GIM processes with upstart services.

- Run `initctl list` to list the upstart services.
- Run `start <service_name>` to start the service.
- Run `"stop <service_name>"` to stop the service.

Table 1. upstart commands to start and stop processes

| Action | S-TAP commands |
|--|---|
| Start S-TAP | <code>start utap</code> |
| Stop S-TAP | <code>stop utap</code> |
| Verify S-TAP status | <code>status utap</code> |
| Identify the service name of GIM and supervisor: | <code>initctl list grep gim</code>
<code>initctl list grep gsvr</code> |
| Start GIM, supervisor | <code>start gim_<revision#></code>
<code>start gsvr_<revision#></code>
For example: <code>start gim_56789</code> |
| Stop GIM, supervisor | <code>stop gim_<revision#></code>
<code>stop gsvr_<revision#></code>
For example: <code>stop gim_56789</code> |
| Verify GIM, supervisor status | <code>status gim_<revision#></code>
<code>status gsvr_<revision#></code>
For example: <code>status gim_56789</code> |

Linux-UNIX: Using guard-config-update to start, restart, and stop S-TAP, and view status

You can use the `guard-config-update` utility to update your S-TAP configuration (without using the GUI), whether S-TAP was installed with GIM, RPM, or shell.

Before you begin

For all commands, <filepath> is the path to the guard-config-update utility, where the path depends on your installation type, as follows,

- Shell installation - Default path = /usr/local/guardium/bin/guard-config-update
- GIM installation - Default path = /usr/local/modules/STAP/current/guard-config-update
- RPM installation - Default path = /opt/guardium/bin/guard-config-update

Note: If your site does not use the default filepath, make sure you know the correct location for the guard-config-update utility.

Procedure

1. Log in to the database server as root.
2. To stop S-TAP:

```
# <filepath>/guard-config-update --stop stap
Stopping STAP
utap stop/waiting
#
```

3. To start S-TAP:

```
# <filepath>/guard-config-update --start stap
Starting STAP
utap start/running, process 14969
#
```

4. To restart S-TAP:

```
# <filepath>/guard-config-update --restart stap
Restarting STAP
utap start/running, process 15331
#
```

5. To show S-TAP status:

```
# <filepath>/guard-config-update --status
Running services:
  STAP : root      15331      1 0 14:14 ?          00:00:00 /usr/local/guardium/guard_stap/guard_stap
  /usr/local/guardium/guard_stap/guard_tap.ini

Services configured:
  STAP : enabled
  TEE  : disabled
  MONITOR: disabled

DAM plaintext connections:
  tcp      0      0 9.70.147.17:24007      9.32.132.217:16016      ESTABLISHED
  tcp      0      0 9.70.147.17:51791      9.32.132.217:16016      TIME_WAIT

Linux-UNIX: Optimizing your configuration for high load

Guardium has two options for managing a high load between the data sources and the collectors, which can be implemented individually, or together.

- [Linux-UNIX: Multi-threading S-TAP to increase S-TAP throughput](#)

S-TAP multi-threading can be used in certain workloads to prevent overrunning K-TAP buffers, and increasing the throughput of data in the S-TAP and its associated K-TAP. It works by preserving multiple threads from the point of traffic interception through to the point at which traffic is sent to the collector. You can combine multi-threading with pooled connections.

- [Linux-UNIX: Increasing S-TAP and K-TAP throughput with dynamic ring buffers](#)

By default, each sqldguard data connection is associated with one S-TAP buffer. The sqldguard thread reads data from the S-TAP buffer and sends it to collector. Enable dynamic ring buffers to add S-TAP buffers to each main sqldguard data connection, and prevent an overflow in the S-TAP buffer during traffic peaks.

Linux-UNIX: Multi-threading S-TAP to increase S-TAP throughput

S-TAP multi-threading can be used in certain workloads to prevent overrunning K-TAP buffers, and increasing the throughput of data in the S-TAP and its associated K-TAP. It works by preserving multiple threads from the point of traffic interception through to the point at which traffic is sent to the collector. You can combine multi-

threading with pooled connections.

If the K-TAP is dropping a lot of traffic, or if there is evidence that intercepting the traffic is impacting the database performance, then you might consider enabling multiple K-TAP buffer support. An increased number of S-TAP threads and K-TAP buffers may mean that there is reduced lock contention in K-TAP, and the S-TAP has an improved ability to relay traffic to the collectors. But it also means that S-TAP might use more CPU and more memory, and more memory is pinned by K-TAP.

With multi-threading, the S-TAP creates extra threads, and the K-TAP creates additional buffers to store collected data. The K-TAP balances the traffic between the buffers, placing entire packets for a single session in one buffer. Each S-TAP thread reads from a different K-TAP buffer, and sends traffic data to a single Guardium® system. The higher the number of Guardium connections, the higher the throughput. This increases the CPU usage, but it should not be significant.

Pooled connections are clustered onto a main connection and are primarily intended for helping absorb the time cost of encryption by expending more CPU cycles. With pooled connections, a separate thread (the aux thread) pulls traffic from the main connection buffer queue and sends it to the collector to which the main connection thread is connected. Pooled connections are useful even when `participate_in_load_balancing=0`, whereas extra [SQLGuard_n] sections (or `num_main_thread > 1`) at that setting are for failover only.

There are no definitive rules, you first modify the configuration, then fine-tune the results. Each database has a maximum of 50 connections to its collectors. The maximum per collector is 10, which can be 10 pooled connections, or 10 main threads, or a combination.

Multi-threading does not rectify a slow or busy network.

When one or more Guardium systems can not be reached, a failover mechanism redirects the traffic from one Guardium system to another.

Multi-threading is also supported on AIX WPARs and Solaris zones.

Look at the K-TAP buffer statistics, if you see drops, you can increase the size of the buffer or you can increase the number of buffers. If throughput is your problem, you need to increase the number of buffers. If you are concerned about a measured DB impact, increase the number of buffers. If everything looks like it's usually fine but periodically you incur drops due to specific tasks, then just increase the buffer size.

Limitations

- Encrypted and unencrypted A-TAP traffic cannot be sent to the same Guardium system, for all databases, since not all database encrypted K-TAP traffic and unencrypted A-TAP traffic can share the same session.
- Policies have to be the same on all Guardium system because the policies dictate what happens to a system's traffic. If the policies are different, there's no guarantee which policy is in effect on a given session.
- `participate_in_load_balancing` values 1 and 4 are similar but they use different mechanisms to split the traffic, so the traffic from one session might get sent to multiple collectors. If you are using 1 and switch to 4, any sessions that are currently open might move to different Guardium systems, and you could lose the session information. Sessions closed before or opened after the transition are not affected.

Configuration Guidelines

The parameter `num_main_thread` in each [SQLGuard_n] section of the `guard_tap.ini` file determines the number of main connections to each collector. The maximum value of `num_main_thread` is 10 for all of the defined Guardium hosts (all of the [SQLGuard_n] sections of the `guard_tap.ini` file). The actual number of K-TAP buffers is determined automatically, depending on the total of the `num_main_thread` for all collectors of the S-TAP. The maximum number of K-TAP buffers is five. They are automatically allocated across the read threads.:

- 1-5: one S-TAP read thread for each K-TAP buffer, and one main connection to the collector.
- 6-10: one or two S-TAP read threads for each K-TAP buffer, and one or two main connections to the collector.

The maximum value of `num_main_thread` is 10 for all of the defined Guardium hosts.

Adding collectors to implement multi-threading

In the `guard_tap.ini` file:

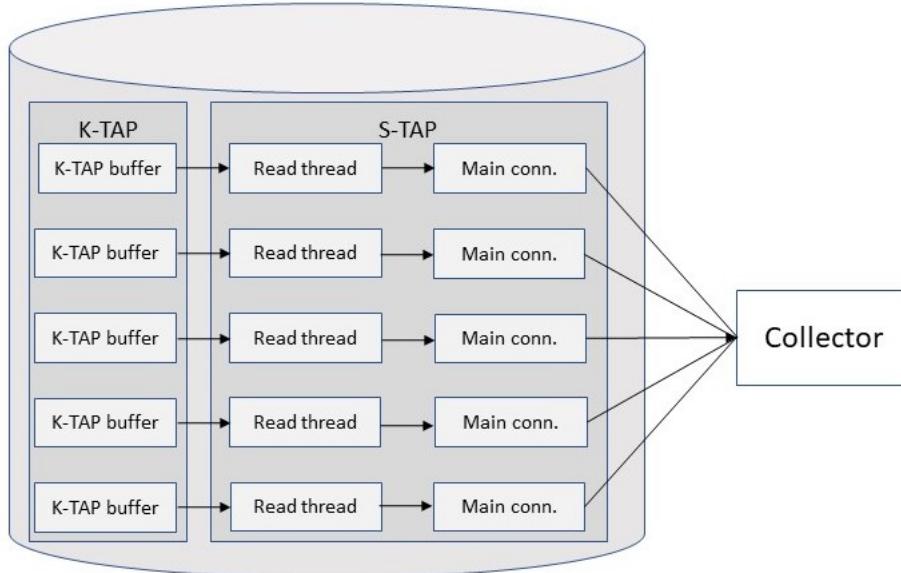

- Set `participate_in_load_balancing=4`
- Add an [SQLGuard_n] section for each added collector
- Set `num_main_thread` in all [SQLGuard_n] sections, up to a total of 10 for all collectors

Adding read threads to an under-utilized collector to implement multi-threading

If you have a relatively strong and lightly loaded collector, set or increase the `num_main_thread` parameter in the corresponding [SQLGuard_n] section.

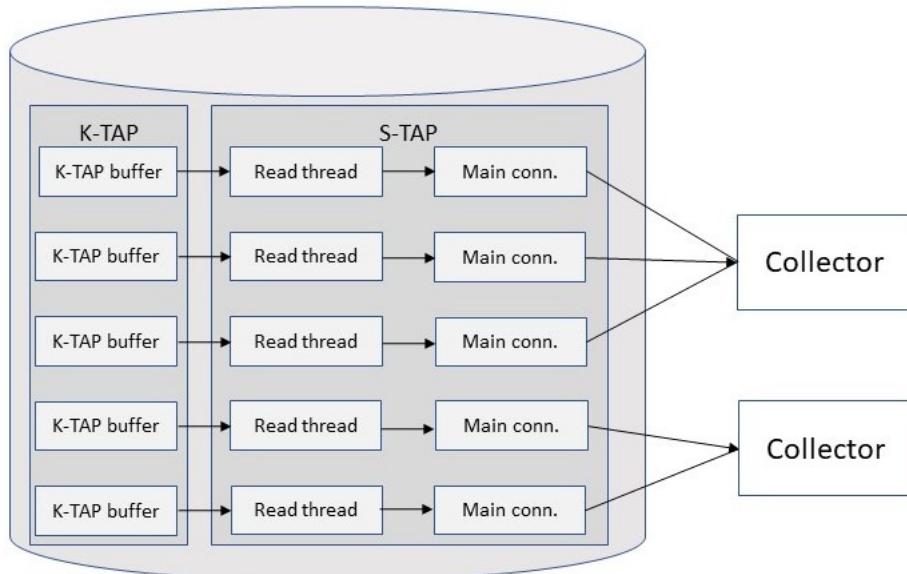

Example: One collector, five threads

```
[TAP]
...
participate_in_load_balancing=4
[SQLGuard_0]
num_main_thread=5
primary=1
```

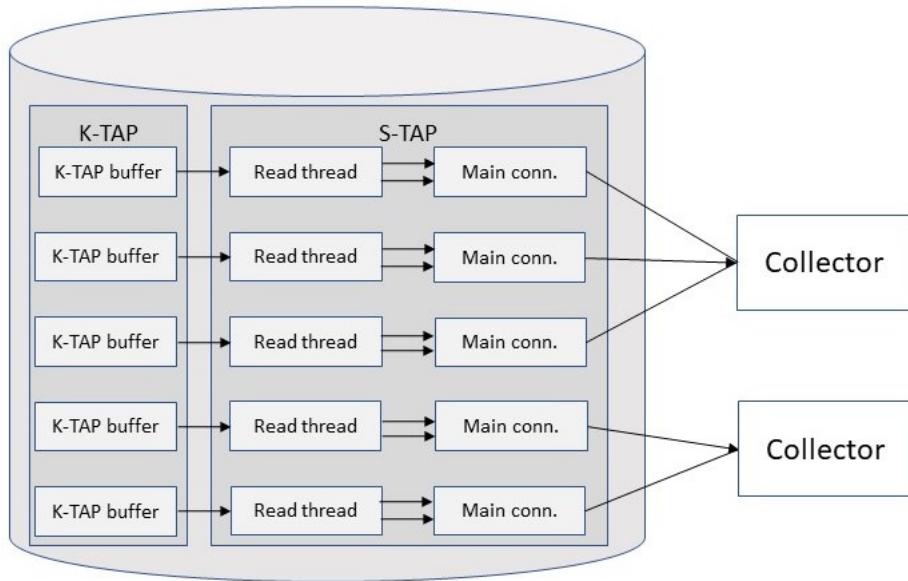

Example: Two collectors, five threads

```
[TAP]
...
participate_in_load_balancing=4
[SQLGuard_0]
num_main_thread=3
primary=1
[SQLGuard_1]
num_main_thread=2
primary=2
```

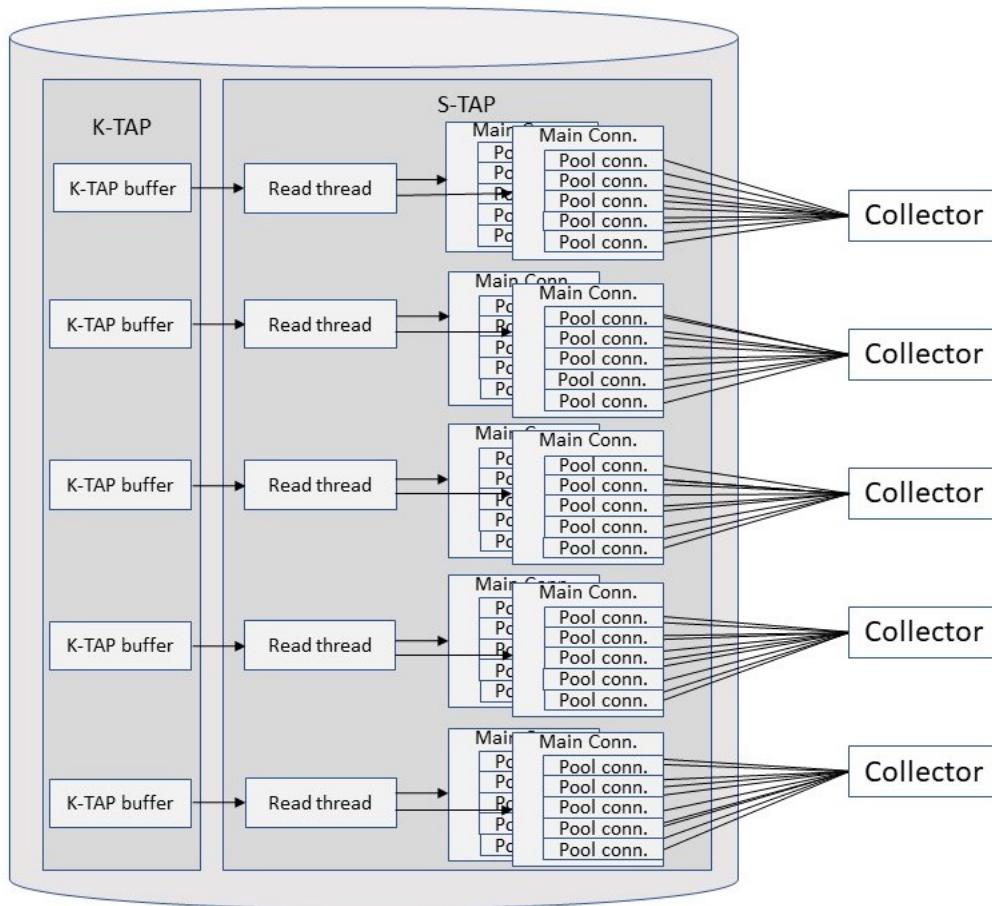

Example: Two collectors, 10 threads

```
[TAP]
...
participate_in_load_balancing=4
[SQLGuard_0]
num_main_thread=5
primary=1
[SQLGuard_1]
num_main_thread=5
primary=2
```

Example: Five collectors, 10 threads, two main connections/collector, 5 pooled threads/main connection

```
[TAP]
...
participate_in_load_balancing=4
[SQLGuard_0]
connection_pool_size=10
num_main_thread=2
primary=1
[SQLGuard_1]
connection_pool_size=10
num_main_thread=2
primary=2
...
[SQLGuard_4]
connection_pool_size=10
num_main_thread=2
primary=5
```

Linux-UNIX: Increasing S-TAP and K-TAP throughput with dynamic ring buffers

By default, each sqlguard data connection is associated with one S-TAP buffer. The sqlguard thread reads data from the S-TAP buffer and sends it to collector. Enable dynamic ring buffers to add S-TAP buffers to each main sqlguard data connection, and prevent an overflow in the S-TAP buffer during traffic peaks.

About this task

When a ring buffer becomes full, Guardium allocates a new buffer, and all data that is captured from the K-TAP is written to the newly created buffer. The sqlguard thread always reads from the first created buffer and sends data to sqlguard. When a buffer is empty and another ring buffer is already created, the empty buffer is deleted. Guardium manages the dynamic ring buffers without user intervention: when, and how many, ring buffers to allocate, or close, per main connection. The maximum number of ring buffers is 10. If the S-TAP fails over, data in all buffers is moved to the new buffers.

Procedure

- Enable Dynamic ring buffers in the UI. For more information, see [Linux-UNIX: Configuring S-TAP in the S-TAP Control page](#).
 - Change the following parameters value to 1 in the `guard_tap.ini` file.
 - `enable_dynamic_ring_buffers`
 - 12.1 and later `enable_ktap_dynamic_ring_buffers`
- For more information, see [Linux-UNIX: General parameters](#).
- Change the following parameters in GIM.
 - `gim_enable_dynamic_ring_buffers`
 - 12.1 and later `STAP_ENABLE_KTAP_DYNAMIC_RING_BUFFERS`
- For more information, see [Set up by Client](#).

Linux-UNIX: Alerts on uninstalled S-TAPs

Uninstalling an S-TAP might be evidence of harmful activity. The predefined S-TAP Uninstall Alert notifies when an S-TAP is uninstalled. You can view the S-TAP Uninstall Events report in My Dashboards.

By default the alert is scheduled hourly. View and optionally configure the Alert Receivers in the Alert Builder: Protect > Database Intrusion Detection > Alert Builder. Tip: Best practice is to leave the alert settings at their defaults. If you need to change the configuration, run the CLI command **restart gui** so that the changes take effect. The alert writes to SYSLOG in the format: Alert Name: STAP Uninstall Alert. Alert Description: STAP Uninstall Alert... ...<S-TAP host>. The S-TAP host uniquely identifies the S-TAP. It is usually the database IP.

Related concepts

- [Predefined alerts](#)

Linux-UNIX: Deleting inactive S-TAPs in a centralized environment

You can use a cron job on the central manager to delete all inactive S-TAP instances.

Procedure

1. Go to Manage > System View > Enterprise S-TAP View.
2. In the Actions menu, select Add API mapping.
3. In the Add API Mapping dialog, search for and select **delete_inactive_stap**.
4. In the Enterprise S-TAP view, right-click in any row and select Invoke > **delete_inactive_stap**.
5. Create a script to schedule running this API periodically on the central manager.

Sample shell script for running the API:

```
#!/bin/bash

echo >> ${GUARD_LOG_DIR}/delete_inactive_staps.log
echo >> ${GUARD_LOG_DIR}/delete_inactive_staps.log

echo Deleting inactive staps from all managed units $dateStr >> ${GUARD_LOG_DIR}/delete_inactive_staps.log
date >> ${GUARD_LOG_DIR}/delete_inactive_staps.log

#Run the delete inactive stap command from CM for all S-TAPs on all managed_units

echo -e "grdapi delete_inactive_stap stapHost=all api_target_host=all_managed" | su - cli >>
${GUARD_LOG_DIR}/delete_inactive_staps.log

exit 0
```

6. Create a cron job to run the script after the report is refreshed, at whatever interval you decide for both the report refresh and the cron job.

Linux-UNIX: Monitoring S-TAP in the GUI

Use these standard reports and views to monitor your S-TAP status in the GUI.

You can create alerts that are based on exceptions that are created by S-TAPs, but other domains that are used by S-TAP reports are system-private and cannot be accessed by users.

System View

S-TAP Status Monitor in the System Monitor window: For each S-TAP reporting to this Guardium® system, this report identifies the S-TAP Host, S-TAP Version, DB Server Type, Status (active or inactive), Last Response Received (date and time), Instance Name, Primary Host Name, and true/false indicators for: K-TAP, MS SQL Server Shared Memory, DB2® Shared Memory, Win TCP, Local TCP monitoring, Named Pipes Usage, Encryption, Firewall, DB install Dir, DB port Min and DB Port Max.

Click any line to view the inspection engines that are configured for this S-TAP. The bread crumbs show where you are; click ALL S-TAPs to return to the list of S-TAP. For more details, see [Linux-UNIX: Inspection engine verification](#).

S-TAP Status Monitor: For each S-TAP reporting to this Guardium system, this report identifies the S-TAP Host, DB Server Type, S-TAP Version, Status (active or inactive), Inspection Engine status, Last Response Received (date and time), Primary Host Name, and true/false indicators for: Firewall and Encrypted. Click the S-TAP Status and the Inspection Engine status to see the Verification status on all Inspection Engines.

S-TAP Events: For each S-TAP reporting to this Guardium system, this report identifies the S-TAP Host, Timestamp, Event type (Success, Error Type, and so on), and Tap Message.

If no messages display in the S-TAP Events panel, the production of event messages may have been disabled in the configuration file for that S-TAP. If this is the case, you may be able to locate S-TAP event messages on the host system in the syslog file.

Tap Monitor

S-TAP Configuration Change History: This report is displayed only when an inspection engine is added or changed. Lists S-TAP configuration changes – each inspection engine change is displayed on a separate row. Each row lists the S-TAP Host, DB Server Type, DB Port From, DB Port To, DB Client IP, DB Client Mask, and Timestamp for the change.

Primary Guardium Host Change Log: Log of primary host changes for S-TAPs. The primary host is the Guardium system to which the S-TAP sends data. Each line of the report lists the S-TAP Host, Guardium Host Name, Period Start, and Period End.

S-TAP Status: Displays status information about each inspection engine that is defined on each S-TAP Host. This report does not have From and To date parameters, since it is reporting current status. Each row of the report lists the S-TAP Host, DB Server Type, Status, Last Response, Primary Host Name, Yes/No indicators for the following attributes: K-TAP Installed, Shared Memory Driver Installed, Db2 Shared Memory Driver Installed, Named Pipes Driver Installed, and App Server Installed. In addition, it lists the Hunter DBS.

Inactive S-TAPs Since: Lists all inactive S-TAPs that are defined on the system. It has a single runtime parameter: QUERY_FROM_DATE, which is set to now -1 hour by default. Use this parameter to control how you want to define *inactive*. This report contains the same columns of data as the S-TAP Status report, with the addition of a count for each row of the report.

Linux-UNIX: S-TAP logs

The UNIX S-TAP has a few log files.

- guard_stap* logs, located in the filepath specified by the tap_log_dir parameter.
 - guard_stap.stderr.txt: contains all the output (and the extra debugging output) of S-TAP
 - guard_stap.fam.txt: Exists only if FAM is enabled; contains all the output (and extra debug) of FAM monitoring.
 - guard_stap.stdout.txt: Since v10.1.4, it is present in the system, but not used.
- UNIX system log (/var/adm/syslog, /var/log/messages, name and location as relevant on the particular system): contains K-TAP module output messages (along with output messages from all other kernel tasks).

Linux-UNIX: Viewing S-TAP debug details on the database

You can view some S-TAP debug details on the database itself, by using the .stap_state file, located in the S-TAP installation directory.

About this task

Procedure

In the S-TAP installation directory of the database, enter (by default):

```
[root@<server> ~]# /usr/local/guardium/guard_stap/stap_state_ctl /usr/local/guardium/guard_stap/.stap_state
```

Typical output:

```
Stap State:  
filename: /usr/local/guardium/guard_stap/.stap_state  
version: 1  
pid: 73347  
process_start: 1600771074  
debug_level: 0  
ticker: 619  
proxy_keys_req_sent_at: 0  
proxy_send_keys_req: 0  
proxy_send_cert_sign_req: 0  
proxy_keys_awaiting_resp: 0  
proxy_transit_key_req_sent_at: 0  
proxy_send_transit_key_req: 0  
proxy_transit_key_awaiting_resp: 0  
proxy_error_pending: 0  
pushed_keys_to_gproxyd: 0  
exit_interface_ready: 0  
[root@<server> ~]#
```

Linux-UNIX: Determine the S-TAP version

Procedure

1. From the GUI, the S-TAP version number is displayed in Manage > System View > S-TAP Status Monitor
2. Alternatively, you can display the S-TAP version number from the UNIX command line of the database server, by running the guard_stap binary with the -version or --version argument

For example, assuming the S-TAP is installed in the default installation directory, enter one of these commands:

```
-bash-3.2# <guardium_base>/modules/STAP/current/guard_stap --version
```

```
-bash-3.2# <guardium_base>/guard_stap/guard_stap --version  
STAP-doberman_r20511_1-20100728_0514
```

Linux-UNIX: S-TAP statistics

S-TAP statistics are easily viewed in the predefined S-TAP and External S-TAP Statistics report.

You can create alerts based on results.

S-TAP statistics collection is configured with the parameter `stap_statistic`. This is an advanced parameter and should be modified only by Guardium Technical Support or advanced users. It specifies the interval at which the S-TAP sends statistics to the sniffer. Valid values are:

- Positive integer: for hours
- Negative integer: minutes
- 0: do not send

Some statistics are cumulative and some are real time. Cumulative fields require reset to get the current count. Real-time fields are dynamic and do not require a reset. The values can be reset directly from the database server only, by running the following command:

```
<S-TAP Shell Install Directory>/guard_stap/ktap/current/guard_ktap_stat reset
```

or

```
<S-TAP GIM Install Directory>/modules/KTAP/current/guard_ktap_stat reset
```

Cumulative fields are indicated as such in the following lists.

- CPU statistics**
- `system_cpu_percent`
- Shows the overall CPU usage of S-TAP for the entire system. It is calculated by using the `pcpu` option from the `ps` command. These situations might indicate a problem:
- Usage is consistently at, or near, 100%. Such a condition might indicate that the `guard_stap` process is stuck in a loop and is using all of the resources on one core. Run the `guard_diag` command when you encounter such cases.
 - Overall usage is abnormally high. This number depends on the total number of cores that are running on the system. For example, consider a consistent S-TAP CPU usage of 5% on a system with 16 cores. In this case, 5% indicates that S-TAP is consistently using 80% of one core. If S-TAP is consistently running that high, it leaves little overhead to accommodate any other spikes in traffic. Worse, S-TAPs that are running close to 100% of one core might introduce performance degradation on the host server because it can make S-TAP unresponsive to K-TAP requests.
- `system_cpu_idle_percent`
- Total system CPU free.
- `stap_cpu_percent`
- Average system CPU usage of S-TAP over life of process. This statistic shows how busy the host server is overall. For example, if the system has 10 cores, and S-TAP is using 30% of one, the overall S-TAP CPU usage is about 3%. The maximum CPU an S-TAP can use depends on the threading. See [Linux-UNIX: Multi-threading S-TAP to increase S-TAP throughput](#).
- `buffer_recycled`
- Cumulative. Recycle count for this index S-TAP buffer.
- Indicates the number of times the S-TAP buffer overflowed, which is highly indicative of S-TAP performance issues on the host server. The S-TAP buffer can overflow for several reasons, including:
- Insufficient network bandwidth to accommodate the volume of data that is sent by the S-TAP to the Guardium appliance. This issue is most prevalent when the Guardium appliance and host database server are not in the same data center or LAN.
 - Guardium collector is too busy to handle the volume that is sent from S-TAP (this is a rare case).
- `timestamp`
- Time at which the record was created.
- `software_tap_host`
- The host system where data is collected. (`tap_ip` value in the S-TAP configuration.)
- The reset command resets all of the K-TAP statistics.
- K-TAP statistics**
- `timestamp`
- Time at which the record was created.
- `software_tap_host`
- The host system where data is collected. (`tap_ip` value in the S-TAP configuration.)
- `ktap_buffer_index`
- The K-TAP buffer that this cluster of parameters refers to (mostly).
- `total_bytes_so_far`
- The total number of bytes that were processed by K-TAP since the last reset of these values. Reset the counters to come to any meaningful conclusions with this data.
- This counter rolls back over to 0 after it reaches 4294967296 bytes (2^{32}). If the last reset was a while back, the counter might be a value that was rolled over several times. On its own, there is little that can be learned from looking at only the total bytes processed value. Its delta over time can be used to estimate the volume of traffic that is processed by S-TAP if K-TAP is the only driver that is used to intercept traffic. For this purpose, it is not necessary to first reset the counter. Total Bytes Processed is most helpful when it is used as baseline for some of the other statistics that are described next.
- `total_bytes_dropped_so_far`
- Cumulative. The total number of bytes that were dropped by K-TAP since the last reset of these values. Reset the counters to come to any meaningful conclusions with this data.
- By default, K-TAP uses a 4 MB buffer file, which is configurable from the `guard_tap.ini`. If the `guard_stap` process cannot read data quickly enough from this buffer, K-TAP starts dropping data and the drops are reflected in this field. The significance of any drops that are shown here should be put in the context of Total Bytes Processed so Far. An excessive number of bytes dropped can be indicative of issues, including: Insufficient resources on host server for S-TAP (`guard_stap` process) to read data from the K-TAP buffer in a timely manner.
- `total_bytes_ignored`
- Cumulative. The amount of database traffic that is ignored at the K-TAP level when IGNORE STAP SESSION rules are implemented in the Guardium policy, since the last reset of these values. It is useful for estimating how effectively the policy is ignoring traffic. Total Bytes Ignored should be considered only after a reset and in the context of Total Bytes Processed so Far.
- `total_buffer_init`
- Cumulative. The number of times the K-TAP buffer was reinitialized. S-TAP can reinitialize the K-TAP buffer if any corruption of buffered data is detected.

ioctl_requests
Cumulative. Number of K-TAP requests issued so far (not per buffer).

total_response_bytes_ignored
Cumulative. The bytes of database response traffic that is ignored at the K-TAP level as the result of any IGNORE RESPONSES PER SESSION rules that are implemented in the Guardium policy, since the last reset of these values.

total_packet_count
Number of packets seen since the last reset of these values.

time_since_last_reset_in_seconds
Time that is elapsed since last statistics reset.

CPU statistics

system_cpu_percent
Shows the overall CPU usage of S-TAP for the entire system. It is calculated by using the pcpu option from the ps command. These situations might indicate a problem:

- Usage is consistently at, or near, 100%. Such a condition might indicate that the guard_stap process is stuck in a loop and is using all of the resources on one core. Run the **guard_diag** command when you encounter such cases.
- Overall usage is abnormally high. This number depends on the total number of cores that are running on the system. For example, consider a consistent S-TAP CPU usage of 5% on a system with 16 cores. In this case, 5% indicates that S-TAP is consistently using 80% of one core. If S-TAP is consistently running that high, it leaves little overhead to accommodate any other spikes in traffic. Worse, S-TAPs that are running close to 100% of one core might introduce performance degradation on the host server because it can make S-TAP unresponsive to K-TAP requests.

system_cpu_idle_percent
Total system CPU free.

stap_cpu_percent
Average system CPU usage of S-TAP over life of process. This statistic shows how busy the host server is overall. For example, if the system has 10 cores, and S-TAP is using 30% of one, the overall S-TAP CPU usage is about 3%. The maximum CPU an S-TAP can use depends on the threading. See [Linux-UNIX: Multi-threading S-TAP to increase S-TAP throughput](#).

Buffer statistics

stap_buffer_usage_percent
Average percentage use of all S-TAP buffers.

buffer_recycled
Cumulative. Recycle count for this index S-TAP buffer.
Indicates the number of times the S-TAP buffer overflowed, which is highly indicative of S-TAP performance issues on the host server. The S-TAP buffer can overflow for several reasons, including:

- Insufficient network bandwidth to accommodate the volume of data that is sent by the S-TAP to the Guardium appliance. This issue is most prevalent when the Guardium appliance and host database server are not in the same data center or LAN.
- Guardium collector is too busy to handle the volume that is sent from S-TAP (this is a rare case).

A-TAP statistics

activated_ataps
Comma-separated list of instance names that are active.

non_activated_ataps
Comma-separated list of instance names that are inactive.

erroneous_ataps
Comma-separated list of instance names that states that appear to be improper.

dropped_priority_packets
Count of priority packets that were dropped.

Shared memory statistics

exit_number_of_shmem_segments
Total number of shmem segments.

exit_total_packets_so_far
Total packet count seen by this shm region.

exit_total_bytes_so_far
Total packet byte count seen by this shm region.

exit_total_0_16_bytes_packets
Total packet count seen where packet size > 0 && <= 16.

exit_total_16_4k_bytes_packets
Total packet count seen where packet size > 16 && <= 4000.

exit_total_4k_16k_bytes_packets
Total packet count seen where packet size > 4000 && <= 16000.

exit_total_16k_32k_bytes_packets
Total packet count seen where packet size > 16000 && <= 32000.

exit_total_32k_plus_bytes_packets
Total packet count seen where packet size > 32000.

exit_total_bytes_dropped_so_far
Total number of bytes dropped.

exit_total_packet_drops_so_far
Total number of packets dropped.

Proxy statistics

proxy_active_ssl_connections
Number of active SSL sessions through proxy.

proxy_memory_usage
Memory (in KB) that proxy is using.

proxy_cpu_usage
Amount of cpu (percentage) that proxy is using.

proxy_latency_0ms_1ms
count of packets with latency 0-1ms.

```

proxy_latency_1ms_10ms
    count of packets with latency 1ms-10ms.
proxy_latency_10ms_100ms
    Count of packets with latency 10ms-100ms.
proxy_latency_100ms_1s
    Count of packets with latency 100ms-1s.
proxy_latency_1s_plus
    Count of packets with latency greater than 1s.
proxy_last_minute_tcp_payload
    Amount of tcp data (in bytes) handled by proxy in last minute.
proxy_last_minute_tls_payload
    Amount of TLS data (in bytes) handled by proxy in last minute.
proxy_last_minute_total_connections
    Total number of connections accepted by proxy in last minute.
proxy_last_minute_ssl_accepted_connections
    Total number of SSL connections accepted by proxy in last minute.

```

S-TAP buffer statistics

```

stap_total_packets_dropped
    Total number of packets dropped due to insufficient buffer space in the S-TAP service.
stap_total_bytes_dropped
    Total number of bytes dropped due to insufficient buffer space in the S-TAP service.
stap_collector_count
    Number of collectors.
stap_collector_names
    Comma-delimited list of all the collectors that are assigned to the S-TAP.
stap_collector_packets_dropped
    Comma-delimited list of collector packet drop count, in the same order as stap_collector_names.
stap_collector_bytes_dropped
    Comma-delimited list of collector byte drop count, in the same order as stap_collector_names.

```

Linux-UNIX: S-TAP Monitor (`guard_monitor`)

The S-TAP Watchdog (`guard_monitor`) monitors S-TAP performance and responsiveness. You can configure specific actions that are triggered when the S-TAP exceeds certain thresholds.

Note: On HP-UX 11.11, the information about the process command is limited to 64-characters. This means that if the full path to the `guard_stap` binary is longer than 64-characters, the Guardium monitor cannot recognize it.

Monitoring covers:

- CPU utilization: checked with the `ps` command or using cpu time from `procfs`
- CPU responsiveness to polling: checked by sending the S-TAP process a console request and waiting for a response.

If S-TAP CPU utilization exceeds the configured threshold, or if S-TAP does not respond to the console request, the following actions can be taken:

- Automatically run `guard_diag`.
- Automatically kill the S-TAP process.
- Automatically core dump and kill the S-TAP process.
- Automatically trace S-TAP process.

Guard Monitor installs automatically at the end of the S-TAP installation. There are no user prompts and no install progress is shown. During S-TAP uninstall, Guard Monitor is automatically uninstalled. The user no longer has the option to reboot in the installer and is instead just notified that a reboot is necessary to complete the uninstall. This reboot is not critical but it is necessary if the user intends to install S-TAP again on the system. If the user uninstalls, does not reboot, and then tries to reinstall there will be an popup blocking the installation notifying the user that S-TAP is partially installed and the server needs to be rebooted.

The `guard_monitor` runs with its configuration file, `guard_monitor.ini` as its argument. The monitor is controlled by using the `guard_monitor.ini` file. For Shell installations, you can make all configuration changes directly on the configuration file. For GIM, use the interface in the GUI to make any changes.

Guard_monitor is not enabled by default. In shell installations, enable it from `initab` by uncommenting the “`umon`” line, or by using the services control facility for the particular Operating Systems (`initctl` for RedHat 6, `systemctl` for RedHat 7, `SMF` for Solaris 10 and up). For GIM installations, `guard_monitor` is enabled by setting `STAP_UTILS_START_MONITOR=y`.

Note: `guard_monitor` requires administrative privileges (root).

The default location for the S-TAP Monitor output is `/var/tmp/monitor`. This location can be configured from `guard_monitor.ini` (configuration file). See the example of the `guard_monitor.ini` file at end of this topic.

After enabling `guard_monitor`, make sure the process is running on the database server.

Examples of settings

Default thresholds are provided for each function. For example, you might want to monitor CPU usage, and set one threshold (75%) for gathering diagnostic information and a higher threshold (85%) at which the S-TAP is killed. You would set `auto_diag=1` to enable gathering of diagnostic information, and `diag_high_cpu_level=7500` to gather diagnostic information when CPU usage reaches 75%. Then set `auto_kill_on_cpu_enable=1` to enable automatic killing of the S-TAP process, and set `auto_kill_on_cpu_level=8500` to kill the process when CPU usage reaches 85%.

But you may not want to keep killing the S-TAP process repeatedly, so you can set a limit on that as well. You can limit how many times the process can be killed within one hour by setting `kill_num_in_hour=5`. Then specify what should happen when the limit is reached: code `final_action=1` to disable the S-TAP, or `final_action=2` to allow it to continue running.

Guard_monitor CPU polling parameters

| guard_monitor.ini | GIM | Description | Default |
|---------------------------|---|--|----------------|
| poll_cpu_interval | STAP-
UTILS_MONITOR_POLL_CPU_INTERVAL | Interval, in seconds, at which guard_monitor checks S-TAP CPU utilization. When checking CPU utilization, guard_monitor measures the average CPU utilization over the life of the guard_stap process using <i>ps</i> . This means that S-TAP has to run above the CPU threshold for some time before guard_monitor detects a problem. | 10 |
| cpu_measurement_timeslice | | Interval over which CPU consumption is measured, in seconds. | 0 |
| poll_stap_interval | STAP-
UTILS_MONITOR_POLL_STAP_INTERVAL | Interval at which guard_monitor sends a console S-TAP request, in seconds. | 10 |
| cpu_measurement_mode | NA | <p>Method for calculating CPU consumption:</p> <ul style="list-style-type: none"> • 0: measure single CPU consumption • 1: measure average CPU consumption across all CPU capacity of Guardium system; total CPU consumption/number of CPUs. <p>When cpu_measurement_mode=1 and cpu_measurement_timeslice=0, only one CPU usage is measured.</p> | 0 |
| nonresponsive_action | NULL | Action taken when S-TAP does not respond to polls. <ul style="list-style-type: none"> • diags • trace • NULL | |

Monitoring actions

| guard_monitor.ini | GIM | Description | Default |
|--------------------------|--|--|--|
| logs_to_rotate | STAP-
UTILS_MONITOR_LOGS_TO_ROTATE - | Logs to be rotated | /tmp/guard_stap.stderr.txt,/tmp/guard_stap.stdout.txt,/usr/local/guardium/guard_stap/ktap/ktap_install.log,/usr/local/guardium/guard_stap/guard_discovery.stderr.log |
| log_rotate_size | STAP-
UTILS_MONITOR_LOG_ROTATE_SIZE | Maximum file size of monitor log file, in KB. (Log files are rotated when they reach this size.) | 1024 |
| log_rotate_num_kept | STAP-
UTILS_MONITOR_LOG_ROTATE_NUM_KEEP | The number of rotated monitor logs on disk. | 5 |

Auto-Diag action

If S-TAP CPU utilization exceeds the configured threshold, the most basic action guard_monitor takes is an automatic guard_diag.

By default, the output from the guard_diag is placed in /var/tmp. The file name is derived from the machine name, and the time/date run; it always starts with diag.ustap.

| guard_monitor.ini | GIM | Description | Default |
|--------------------------|--|---|----------------|
| auto_diag | STAP-
UTILS_MONITOR_AUTO_DIAG | Enables automatic guard_diag. 0=no, 1=yes. | 1 |
| diag_high_cpu_level | STAP-
UTILS_MONITOR_DIAG_HIGH_CPU_LEVEL | The S-TAP CPU threshold at which guard_monitor initiates a guard_diag. Enter (%CPU threshold*100). v10.1.4 and higher: When cpu_measurement_mode=1, the % can be higher than 100. | 7500 |
| diag_num | STAP-
UTILS_MONITOR_DIAG_NUM | Enables creation of more than one guard_diag output. Integer. | 2 |

Auto-Kill action

Use these parameters to configure the S-TAP auto-kill.

| guard_monitor.ini | GIM | Description | Default |
|--------------------------|--|--|----------------|
| auto_kill_on_cpu_enable | STAP-
UTILS_MONITOR_AUTO_KILL_ON_CPU_ENABLE | Enable automatic S-TAP kill. 0=no, 1=yes. | |
| auto_kill_on_cpu_level | STAP-
UTILS_MONITOR_AUTO_KILL_ON_CPU_LEVEL | The S-TAP CPU threshold at which guard_monitor kills S-TAP. Enter (%CPU threshold*100). v10.1.4 and higher: When cpu_measurement_mode=1, the % can be higher than 100. | 8500 |
| kill_num_in_hour | STAP-
UTILS_MONITOR_KILL_NUM_IN_HOUR | The maximum number of times guard_monitor is killed in an hour. Integer value. | 5 |
| final_action | STAP-
UTILS_MONITOR_FINAL_ACTION | Action taken when max kills per hour is reached. <ul style="list-style-type: none"> • 1 = Disable S-TAP. • 2 = Stop killing S-TAP and let it continue. | |

Core dump S-TAP before kill

Some S-TAP issues, such as when S-TAP gets stuck in a loop, require more information than provided in the guard_diag output.

The guard_monitor performs automatic core dumping of the S-TAP process. The guard_monitor core dumps S-TAP before killing the process (if S-TAP auto kill is enabled).

Location of core dumps created by guard_monitor: /var/tmp/monitor/coredumps

These parameters configure auto core dumps:

| guard_monitor.ini | Description | Default |
|------------------------|---|---------|
| force_core_before_kill | The type of core dump to generate:
sigsegv: This is the most portable of the options, but requires the SA to configure ulimit to enable core dumping.
gcore: The most useful, but requires gcore to be installed on the system. Linux platforms only.
pstack: Least useful of the options, but may be the only utility available on certain systems. Linux platforms only.
NULL: disabled | |
| force_core_when | When to collect a core dump:
limitexceeded: collect core when S-TAP is killed due to exceeding a resource limit
nonresponsive: collect core when S-TAP is killed due to it being nonresponsive
always: always collect core | always |
| kill_oldcore_saved | Integer. Specifies whether generated core dumps are saved. When set to non-zero, guard_diag keeps all core dumps generated. Otherwise, it deletes the old core dumps each time a new one is generated. | |

Example of guard_monitor.ini

```
The following section header is required for GIM to recognize this .ini file.
; otherwise, it serves no purpose

[TAP]
; output dir for monitor logs, diags, traces, etc.
monitor_output_dir=/var/tmp
; location of guardium installation (need not be where monitor is installed, for example, /usr/local)
stap_dir=/usr/local
; ip to connect to for downloading configuration file and uploading diags and trace output
; this is parsed out of the guard_tap.ini, but backup value here is kept in sync
sqlguard_ip=NULL
; polling interval to verify that server end is still alive (secs)
poll_server_interval=20
; polling interval to check CPU level (secs)
poll_cpu_interval=10
; polling interval to communicate with STAP (secs)
poll_stap_interval=10
; maximum file size of monitor log file (KB)
monitor_log_rotate_size=1024
; number of rotated monitor logs to keep
monitor_log_rotate_num_kept=5
; maximum file size of log files (KB)
log_rotate_size=4096
; number of rotated logs to keep
log_rotate_num_kept=5
; logs to rotate
logs_to_rotate=/tmp/guard_stap.stderr.txt,/tmp/guard_stap.stdout.txt,/usr/local/guardium/guard_stap/ktap/ktap_install.log,
/usr/local/guardium/guard_stap/guard_discovery.stderr.log
; maximum number of STAP kills per hour (doesn't count kills resulting from auto_kill_on_intercept)
kill_num_in_hour=5
; disable STAP when kills per hour limit hit or disable kills and let STAP continue
; disable STAP: 1; disable kill: 2
final_action=2
; automatic kill STAP on CPU level on/off (1/0)
auto_kill_on_cpu_enable=0
; CPU level for kill (% * 100)
auto_kill_on_cpu_level=8500
; snif timeout for kill (secs, 0 disabled)
auto_kill_on_snif_timeout=0
; KTAP timeout for kill (secs, 0 disabled)
auto_kill_on_ktap_timeout=0
; PCAP timeout for kill (secs, 0 disabled)
auto_kill_on_pcap_timeout=0
; TEE timeout for kill (secs, 0 disabled)
auto_kill_on_tee_timeout=0
; SHMEM timeout for kill (secs, 0 disabled)
auto_kill_on_shmem_timeout=0
; automatic diags on/off (1/0)
auto_diag=1
; number of diags runs
diag_num=2
; time between diags runs (mins)
diag_interval=2
; keep old diag files or not yes/no (1/0)
diag_olddrun_saved=0
; kill STAP process after diags yes/no (1/0)
diag_auto_kill=0
; CPU level to trigger diags (% * 100)
diag_high_cpu_level=7500
; snif timeout to trigger diags (secs, 0 disabled)
diag_snif_timeout=0
```

```

; KTAP timeout to trigger diags (secs, 0 disabled)
diag_ktap_timeout=0
; PCAP timeout to trigger diags (secs, 0 disabled)
diag_pcap_timeout=0
; TEE timeout to trigger diags (secs, 0 disabled)
diag_tee_timeout=0
; SHMEM timeout to trigger diags (secs, 0 disabled)
diag_shmem_timeout=0
; automatic trace on/off (1/0)
auto_trace=0
; max time to run trace (secs)
trace_max_time=30
; max log file size for trace (MB)
trace_max_log_size=10
; keep old trace log files yes/no (1/0)
trace_oldlog_saved=0
; kill STAP when trace runs to completion yes/no (1/0)
; (e.g. is not cancelled due to low CPU)
trace_kill_on_complete=0
; CPU level to trigger trace (% * 100)
trace_high_cpu_level=6000
; low CPU level to cancel trace (% * 100)
trace_low_cpu_level=3500
; timeout for snif communication trigger (secs, 0 disabled)
trace_snif_timeout=0
; timeout for KTAP communication trigger (secs, 0 disabled)
trace_ktap_timeout=0
; PCAP timeout to trigger trace (secs, 0 disabled)
trace_pcap_timeout=0
; TEE timeout to trigger trace (secs, 0 disabled)
trace_tee_timeout=0
; SHMEM timeout to trigger trace (secs, 0 disabled)
trace_shmem_timeout=0
; auto-kill STAP when we're not intercepting databases that are configured yes/no(1/0)
; feature is also disabled when guard_tap.ini shows that STAP is running as root
auto_kill_on_intercept=0
; minimum time between STAP requested kills (mins)
intercept_min_time_interval=15
; maximum number of intercept kills per hour
intercept_max_num_in_hour=0
; number of seconds across which CPU consumption is measured (secs, 0 disabled)
; when disabled, CPU consumption is measured across the life of the process
cpu_measurement_timeslice=0
; method for calculating CPU consumption (0 or 1)
; 0: measure CPU consumption relative to one core
; 1: measure CPU consumption taking number of cores into account
cpu_measurement_mode=0
; when to collect a core dump (always, limitexceeded, nonresponsive)
; limitexceeded: collect core when STAP is killed due to exceeding a resource limit
; nonresponsive: collect core when STAP is killed due to it being nonresponsive
; always: always collect core
force_core_when=always

; STAP nonresponsive action
; run diags before killing STAP : diags
; collect trace before killing STAP: trace
; no collection, just kill STAP : NULL
nonresponsive_action=diags

```

Linux-UNIX: Troubleshooting S-TAP problems

You can use the S-TAP Status monitor tab of the System View to begin investigating any problems. Sometimes you might need to use other tools, particularly if you are monitoring databases for which the inspection engines cannot be verified.

If an S-TAP is not connected to your Guardium® system

Check whether the IBM Security Guardium S-TAP service is running on the database server:

On the database server, from the command line, run the command **ps -ef | grep stap** to verify that the S-TAP process is running. In the process list, look for /guardium/guard_stap.

Make sure that the sniffer is running on the server with the S-TAP service.

Check the communication between the sniffer and S-TAP.

For more information about possible errors, see [Table 2](#).

How to identify the S-TAP version?

- From the GUI, the S-TAP version number is displayed in Manage > System View > S-TAP Status Monitor
- Alternatively, you can display the S-TAP version number from the command line of the database server.

Run debug from the command line to quickly identify configuration issues

Use the GUI or the guard_tap.ini file to change the debug level to 4. (Other values do different things, not all of them debug). There are a few guard_stap* logs, which are located in the filepath that is specified by the tap_log_dir parameter.

- guard_stap.stderr.txt: contains all the output (and the extra debugging output) of S-TAP
- guard_stap.fam.txt: Exists only if FAM is enabled; contains all the output (and extra debug) of FAM monitoring.
- guard_stap.stdout.txt: Since v10.1.4, it is present in the system, but not used.

Verify the connection between the database server and the Guardium system

- Verify that you can ping the Guardium system at **sqlguard_ip** from the database server.

- If the ping is successful, verify that you can telnet to the following ports on the Guardium system: 16016/16018.

If there is a firewall between the database server and the Guardium system

Verify that the following ports are open for traffic between these two systems: 16016, or 16018 for encrypted connections; if you're using FAM then verify ports 16022 or 16023 for encrypted.

Note: Use the following command to check the port availability: `nmap -p port guardium hostname or IP`

Verify that the `sqlguard_ip` parameter is set to the correct guardium hostname or the IP for the Guardium system that you are connecting to.

1. Click `Manage > Activity Monitoring > S-TAP Control` to open S-TAP Control.
2. Locate the S-TAP Host for the IP address that corresponds to your database server.
3. Expand the Guardium Hosts subsection, and verify that the active Guardium Host is correctly configured.
4. If necessary, click `Modify` to update the Guardium Hosts.

Verify that the S-TAP process is not repeatedly restarting

On the database server, run the command `ps -eaf | grep stap` to verify that the process for S-TAP is not changing.

Verify that S-TAP Approval is not turned on

If S-TAP Approval is turned on, any new S-TAP that connects to the Guardium system is refused.

1. Click `Manage > Activity Monitoring > S-TAP Certification` to open S-TAP Certification.
2. Look at the S-TAP Approval Needed checkbox. If this box is checked, new S-TAPs can connect to this Guardium system only after they are added to the list of approved S-TAPs.
3. If S-TAP Approval is turned on, access the Approved Tap Clients report to view a list of approved S-TAPs. If the S-TAP that you are investigating is not on this list, return to the S-TAP Certification page, enter the IP address of the S-TAP in the Client Host field, and click `Add`.

For more information, see [Allow \(approve\) S-TAP connection to Guardium \(S-TAP certification\)](#).

If the S-TAP shows green status but no data is being processed

Check the status of the A-TAP.

Db2 shared memory traffic is not captured

Verify that the IE configuration is correct. Run the script `find_db2_shmem_parameters.sh`, located under `stap_directory/bin`. Execute it either as root or Db2 user, that uses the Db2 instance name as a parameter. It returns the shared memory parameters, including Db2 shared memory size, client position and header size. Verify that the IE parameters defined in the S-TAP match these returned values.

S-TAP verification issues

The verification process attempts to log in to your database's STAP client with an erroneous user ID and password to verify that this attempt is recognized and communicated to the Guardium system. Your S-TAP might be configured in a way that prevents the inspection engine message from reaching the Guardium system from which the request was made.

These configuration details include:

- Load balancing: if the S-TAP is configured to return responses to more than one Guardium system, the error message might be sent to a different Guardium system.
- Failover: If secondary Guardium systems are configured for the S-TAP, the error message might be sent to a secondary Guardium system if the primary Guardium system is too busy.
- `db_ignore_response`: if the S-TAP is configured to ignore all responses from the database, it does not send error messages to the Guardium system.
- Client IP/mask: if any mask is defined that is not 0.0.0.0, it might prevent the error message from being sent.
