

IBM Guardium Data Protection 12.x

Tables of Contents

Welcome	1
Product overview	1
IBM Guardium	1
What's new in this release	2
Release information	5
Product legal notices	6
Trademarks	7
Terms and conditions for product documentation	7
Privacy policy considerations	7
FIPS 140-2	7
Getting started	8
Components and topology	8
Getting started with the user interface	9
Customizing the User Interface	10
Identifying and investigating risks: getting started	10
Smart assistant for monitoring and compliance	10
System view	11
Data activity monitoring	11
Policies and rules	12
Workflows	12
Auditing	12
Classification	12
File activity monitoring on Windows and Unix-Linux file servers	12
File activity monitoring functionality	12
High level workflow for file activity monitoring	14
File activity monitoring for NAS and SharePoint	14
Key concepts and tools	15
Queries and reports	15
Access control	15
User roles	15
Groups	15
Data archive and purge	16
Guardium Installation Manager	16
Discover	16
Datasources	17
Creating a datasource definition	17
Creating a datasource group	18
Configuring your datasource	19
Amazon DynamoDB	20
Amazon Redshift	20
Apache Cassandra	21
Aster	22
Cloudera Manager	22
CockroachDB	23
Couchbase	23
DataStax Cassandra	24
Db2	25
Db2 for i	25
Db2 for z/OS	26
EDB PostgreSQL	26
GreenplumDB	27
Guardium Big Data Intelligence	27
Hive	28
Informix	28
MariaDB	29
MongoDB	30
MS SQL Server (DataDirect - Dynamic Port)	31
MS SQL Server (DataDirect)	32
MS SQL Server (Microsoft - Dynamic Port)	34
MS SQL Server (Microsoft)	35
MySQL	36
Neo4j	38
Netezza	39
Oracle (Data Direct - Service Name)	39
Oracle (Data Direct - SID)	41
Percona MySQL	42
PostgreSQL	43
SAP HANA	43
Snowflake	44
SQL DB Azure	45

Sybase	45
Sybase IQ	46
TERADATA	46
Text datasources	47
Configuring custom properties for your datasources	47
Working with existing datasources	48
Reporting on datasources	48
Defining a datasource using a service name	48
Managing KDC definitions	49
Managing datasource credentials with CyberArk	49
CyberArk deployment overview	50
Setting up the CyberArk vault system	50
Creating an application ID on CyberArk	50
Adding and removing account permissions on CyberArk	51
Deploying CyberArk on your Guardium system	51
Downloading and installing the CyberArk SDK patch	52
Installing CyberArk	52
Configuring CyberArk on your Guardium system	52
Defining Guardium datasources to access CyberArk	53
Upgrading the CyberArk SDK on a central manager or standalone system	53
Upgrading the CyberArk SDK on a managed unit	53
Uninstalling CyberArk	54
Managing datasource credentials with AWS Secrets Manager	54
Gathering required information	54
Creating a secret user	55
Creating a secret key	55
Selecting the authentication type and setting up roles	55
Authenticating by using security credentials	56
Authenticating by using IAM Role	56
Authenticating by using IAM Role for AWS Secrets Manager	56
Authenticating by using IAM Role for AWS database service	57
Authenticating by using IAM instance profile	58
Configuring the AWS Secrets Manager on your Guardium system	58
Defining Guardium datasources to access AWS Secret Manager	59
Managing datasource credentials with HashiCorp	60
Gathering required information	60
Creating a HashiCorp Policy	60
Creating and importing a client certificate	61
Configuring HashiCorp on your Guardium system	63
Defining Guardium datasources to access the HashiCorp vault	64
Database Auto-discovery	64
Cloud database service protection	65
Cloud database service protection Amazon AWS setup	66
Define AWS IAM for data streams	66
Define, modify, and delete AWS cloud DB service accounts	67
Discover and configure AWS data streams	68
Manage AWS data streams	68
Cloud database service protection Azure setup	69
Define, modify, and delete Azure cloud database service accounts	70
Monitor Azure event hubs	71
Manage Azure event hubs	72
Cloud database service protection with native audit	72
Cloud database service protection workflow	73
Define AWS IAM for native audit	74
Create, modify, delete cloud accounts	74
Discover cloud databases	75
Catalog and manage databases	76
Manage Classification and Vulnerability Assessment	76
Configure database auditing	77
Manage object auditing	79
Managing object audit in one database	79
Managing object audit in multiple databases	79
Database discovered instances rules	80
Database discovered instance rules scheduler	82
Adding reports and alerts for inspection engine changes	82
Classification	83
Classification process performance	83
Classification Rule Handling	84
Discover Sensitive Data	84
Discovery scenarios	85
Name and description	86
What to discover	86
Rule Criteria	87
Actual Member Content	88

Where to search	89
Run discovery and review report	89
Remove false-positives from discovery results	90
Audit	91
Scheduling	91
Runtime sensitive-object identification	92
Regular Expressions	92
FAM discovery and classification in Windows and UNIX-Linux file servers	93
Installing and activating the FAM discovery agent (crawler) on UNIX servers	93
Installing and activating FAM discovery agent (crawler) on Windows servers	94
File discovery and classification GIM parameters	95
Rules for GDPR File Activity	96
File discovery and classification for NAS and SharePoint	97
Supported platforms	98
Scan Permissions	98
Installing client software	100
Configure Scan Settings	100
View Scan Results	101
Creating User-Defined Criteria	102
Entitlement Optimization	102
Enable and configure entitlement optimization	103
Entitlement Optimization What's New	103
Entitlement Optimization Users and Roles	104
Entitlement Optimization Recommendations	104
Entitlement Optimization Browse entitlements	104
Entitlement Optimization What If	105
Protect	106
Active Threat Analytics	106
Threat descriptions	107
Creating threat categories from policy rules	109
Excluding items from Active Threat Analytics	109
Active Threat Analytics setup	110
Risk Spotter	111
Risk Spotter functions	112
Risk Spotter risk indicators	112
Use the Risk Spotter results	113
Create a Dynamic Auditing policy	114
Configure and enable Risk Spotter	115
Outliers detection	116
Quick start for outlier detection	117
Enabling and disabling outliers detection	117
Interpreting data outliers in the investigation dashboard	118
Interpreting file activity outliers in the investigation dashboard	119
Switching DB and OS users	120
Grouping users and objects for outliers detection	121
Outliers detection clustering	121
Real-time trust evaluator	121
Configuring the trust evaluator	122
Viewing trust evaluator status	124
Adding post-training automation	124
Configuring the connections table	124
Policies	125
Understanding policies	125
Rule types, categories, classifications	126
Minimum counts and reset intervals	126
Continue to next rule	126
Record values with policy violation	126
Values and groups of values in rules	127
Matching patterns with regular expressions	127
Special pattern tests	127
Log flat	128
Rules on flat	128
Selective audit trail	128
Analyzer rules	129
Character sets	129
Session-level policies	146
Creating session-level and advanced session-level policies	147
Creating session-level policies	147
Creating tuple parameters for session-level policies	148
Creating advanced session-level policies	148
Using session-level and advanced session-level policies	149
Wildcards	149
Tokens	150
IPv6 support	151
Groups	151
Grammar	152

Unsupported databases for session-level policies	153
Criteria	153
Tuples	156
Actions	157
Audit and ignore session actions	157
Mark session actions	158
Alert and Log actions	159
Parse actions	159
Configure actions	159
Transform actions	160
Transform parameters	162
Exception actions	162
Extrusion actions	163
Action parameters	163
Label action and criteria	163
Distinct parameter	164
Track option	165
Search parameters	165
Session-level policy examples	166
Ignoring sessions example	169
Log LOGIN_FAILED sessions only example	170
REQUEST_ERROR example	170
Add DB name on failed login example	170
Get correct service name (MS SQL Server) example	170
Ignoring exceptions examples	171
Firewall and latency issues examples	172
Sniffer overload issues examples	173
Query masking examples	174
Correct IP address (Oracle) example	175
Show SQL schema names example	175
Server and S-TAP IP addresses example	176
User authentication (Oracle) example	177
Redacting data example	177
Hostname caching example	178
Ignore specified users example (MongoDB)	178
Scheduling with SESSION_START examples	179
Logging access activity for trusted sessions example	180
Creating a custom exception message example	180
Find name in SQL query example	181
Detect local admin example	181
Strict username example (Oracle)	182
Login information dump example	182
Known limitations	183
Policy rule actions	183
Blocking rule actions	183
Alerting rule actions	184
Logging or ignoring rule actions	185
Understanding ignore actions	186
Log full details	188
Set character set	188
Rule definition fields	189
Creating and installing a policy and policy rules	192
Tagging policy rules	193
Importing rules by tag	193
Adding tags while defining policy rules	194
Managing policy rule tags	194
Using the Policy Installation tool	194
Running policy analyzer and reviewing results	195
Security incident policies	196
Security anomalies	196
Access to unaudited sensitive data	197
Administrative user accessing sensitive data	197
Administrative users and applications	197
All users	198
Credential stuffing attack	199
Repeated failed logins or possible denial of service attack	199
Suspicious user activity with sensitive data (user not privileged)	200
Quarantine users with multiple failed logins	200
Managing correlation alerts	200
Incident Management	202
How to manage the review of multiple database security incidents	203
Query rewrite	205
How query rewrite works	206

Using query rewrite	207
Enabling query rewrite	207
Creating query rewrite definitions	207
Testing query rewrite definitions	208
Defining a security policy to activate query rewrite	209
Creating a custom report to validate query rewrite results	210
File Activity policies for UNIX and Windows file servers	210
Using rules for file activity policies	210
Create a FAM policy and its rules from scratch for Windows and UNIX servers	212
Creating a FAM policy rule from the Investigative Dashboard Entitlements tab	213
File activity policies for network-attached storage (NAS) and SharePoint	213
Creating file activity policies for network-attached storage (NAS) devices	213
Creating file activity policies for SharePoint	214
Creating a DAM access policy to monitor files on NAS and SharePoint	214
Configuring consolidation of FAM MS Office events	215
Investigation Dashboard for data	216
Filtering data and saving filters in the investigation dashboard	217
Monitor and audit	218
Enabling and disabling the Investigation Dashboard	219
Basic data security monitoring policy	219
Prerequisites	220
Install the basic data security monitoring policy	220
Understand the basic data security monitoring policy rules	221
Create reports for basic data security monitoring	221
Create an Admin Users Activity report	222
Create an Administration Commands Execution report	222
Next steps for data security monitoring	222
Smart assistant for compliance monitoring	223
Databases	223
Add an individual database	224
Import multiple databases	224
Reconciling database inventory	225
Applications	226
Add an individual application	226
Import multiple applications	227
Compliance summary	227
Application summary	228
Set up compliance monitoring or application data monitoring	228
Prerequisites	228
Select compliance type	229
Select databases or applications to monitor	229
Search for sensitive data	229
Summary	230
Investigation Dashboards	230
Enabling File Activity in the investigation dashboard	231
Accessing the investigation dashboard	231
Using the Sankey chart	232
Using Data In-Sight	232
Investigation Dashboard for files	233
Filtering data and saving filters in the investigation dashboard	217
Filtering an individual chart	235
Creating, saving, and exporting investigation dashboards	235
Using the topology view	236
Local and distributed search	237
Monitoring and automatic recovery for the Investigation Dashboard	237
Viewing the Investigation Dashboard's status in deployment health views	237
Viewing Investigation Dashboard issues in reports	237
Viewing the Investigation Dashboard Issues alert for the Investigation dashboard	238
Addressing Investigation Dashboard issues	238
Running manual intervention for Investigation Dashboard issues	238
Threat Detection Analytics	239
Characteristics of an SQL injection attack	240
Characteristics of a stored procedure attack	240
Enabling and disabling threat detection analytics	240
Viewing case reports	241
Activating the audit process workflow for threat analytics	241
Working with threat diagnostic dashboards	241
Investigating SQL injection threats	242
Investigating stored procedure threats	242
Data Protection Dashboard	243
Building audit processes	244
Audit process task types	246
Audit process receivers	247
Exporting audit results	250
How to distribute workflow through Guardium groups	251

Audit Process To-Do List	259
Comparing discovery and classification results	260
Using the host references report	261
Audit and Report	261
External data correlation	261
Privacy sets	267
Custom Alerting	268
Flat Log Process	270
Running database entitlement reports	270
User Identification	271
Identify Users using the Application User Translation	272
Identify Users with API	276
Identify Users via Stored Procedures	278
Value Change Auditing	279
Creating an Audit Database	280
Monitored Table Access	282
Installing and activating the FamMonitor on Windows servers	283
Install the FamMonitor installation package with the wizard	284
Install the FamMonitor bundle with GIM	284
FamMonitor GIM installation parameters	285
Install and uninstall the FamMonitor installation package with command line	286
FamMonitor command line installation parameters	286
File Activity Monitor for NAS and SharePoint	287
Supported platforms	287
Monitoring Permissions	287
Installation	289
Configuration	289
Viewing Results	289
Uninstallation	290
How to use PCI/DSS Accelerator to implement PCI compliance	290
Workflow Builder	293
How to create Customized Workflows	294
How to use Customized Workflows	295
Opening Workflow Process Results	297
Reports	297
Predefined reports	297
Predefined admin reports	298
Predefined user reports	324
Predefined common reports	331
Creating dashboards and adding reports	333
Opening the investigation dashboard, filtered for report entities	333
Viewing reports	334
Modifying the runtime parameters	335
Refreshing reports	335
Exporting a report	335
Viewing Drill-Down Reports	336
Ad-hoc process for run once now	336
Using the Query-Report Builder	336
Optimizing queries	337
Creating a new query, modifying an existing query	338
Defining the query name and attributes	339
Managing query security roles	339
Adding a query to a datamart	340
Modifying the query drilldown control	340
Modifying the API assignment	340
Selecting the column display	340
Setting the sort order	341
Defining the Query Conditions	341
Adding a build expression on query condition	343
Having conditions	343
Modifying the report display	343
Domains, Entities, and Attributes	344
Entities and Attributes in the domains	344
Access domain	346
Access Policy domain	353
Aggregation/Archive domain	355
Alert domain	356
Analytic Threat Analytics domain	357
Analytic Outlier Details domain	358
Analytic Outliers Status domain	358
Analytic Outlier Summary domain	359
Application Data domain	359
Audit Process domain	362
Auto-discovery domain	363
BigData Intelligence Buff Usage Monitor domain	364
BigData Intelligence Classification Process Log domain	365
BigData Intelligence Classifier Results domain	365

BigData Intelligence Databases Discovered domain	366
BigData Intelligence Discovered Instances domain	366
BigData Intelligence Exception domain	367
BigData Intelligence Full SQL domain	367
BigData Intelligence Installed Patches domain	368
BigData Intelligence Instance domain	368
BigData Intelligence Outliers List Enhanced domain	369
BigData Intelligence Outliers Summary Enhanced domain	370
BigData Intelligence Policy Violations domain	370
BigData Intelligence Session domain	371
BigData Intelligence STAP Status domain	372
BigData Intelligence System Info domain	372
BigData Intelligence VA Results domain	373
CAS Changes domain	373
CAS Config domain	374
CAS Host History domain	375
CAS Templates domain	376
Catalog domain: entities and attributes	376
Classification Process Results domain	377
CM Buffer Usage Monitor domain	378
Comments domain	379
Custom DB Usage domain	379
DB Default Users Enabled domain	380
Discovered Instances domain	380
Distributed Datamart domain	380
Eagle Eye domain	381
Exceptions domain	382
FAM domain	386
FAM groups domain	387
FAM System domain	388
File Activity Monitor domain	388
Flat Log domain	389
GIM Clients domain	392
GIM Events domain	393
Group domain	393
Guard Process Log domain	393
Guardium Activity domain	394
Guardium Jobs Queue domain	394
Guardium Login domain	395
IMS Event domain	395
Installed Patches domain	401
Installed Policy domain	402
Managed units domain	404
Parser Errors domain	404
Policy Violations domain	406
Policy Violations Summary domain	412
Query Rewrite domain	415
Runtime Sensitive Object Identifier domain	418
Security Assessment Result domain	419
Sniffer Buffer Usage Monitor domain	421
S-TAP Status domain	423
S-TAP status history domain	424
S-TAP Statistics domain	424
S-TAP verification domain	425
Unit Utilization Levels domain	425
User/Role/Application domain	426
VA Summary domain	427
VA Tests domain	427
Value Change domain	428
Database Entitlement Reports	429
Custom Domains	438
Data Mart	444
Viewing your data marts	444
Extracting data mart to table	444
Extracting data mart to file	445
Manage predefined data extraction to file	446
Distributed Report Builder	448
Creating a Distributed Report	451
Working with API calls and reports	453
Mapping APIs to report results	454
How to Generate API Call from Reports	454
How to use Constants within API Calls	458
How to use API Calls from Custom Reports	462

Working with external feeds	465
Mapping an External Feed	465
Creating an external feed	466
Creating reports for z/OS	466
Working with Data Sets reports	
Built-in reports for Data Sets	467
Report entities and attributes for Data Sets	467
Working with Db2 for z/OS reports	
Built-in reports for DB2 for z/OS	470
Example reports for DB2 for z/OS	470
Report entities and attributes for DB2 for z/OS	471
Working with IMS reports	
Built-in reports for IMS	473
Example reports for IMS	474
Report entities and attributes for IMS	475
Assess and harden	477
Introducing Guardium Vulnerability Assessment	477
Database privileges for vulnerability assessments and classification	479
Deploying VA for Db2 for i	480
Using VA with Cloudera	481
Troubleshooting Cassandra	484
Set up your environment for Vulnerability Assessment	485
Types of Vulnerability Assessments	485
Defining a query-based test	486
Defining a CAS-based test	487
Assessments	488
Creating an assessment	488
Finding an assessment	489
Running an assessment	489
Viewing assessment results	489
Tuning a test	491
Determining test severity	491
Deleting an assessment	492
Creating a test exception	492
Group exceptions	492
Test detail exceptions	493
Adding custom comments to a test	493
Modifying the database version and patch level	493
VA summary	494
IBM Guardium Data Protection app in ServiceNow	494
Required schema change	495
Assessing RACF vulnerabilities	495
Configuration Auditing System (CAS)	496
CAS server authentication with SSL	498
Prerequisites, installing, and running CAS on a Windows server	498
Installing CAS from the CLI	499
Installing CAS with GIM	499
Prerequisites, installing and running CAS on a Linux, UNIX server	500
Locating the Java home directory and version	501
CAS start-up and failover	502
CAS templates	504
Working with CAS templates	508
CAS hosts	510
CAS reporting	511
CAS status	512
License information for Guardium Vulnerability Assessment	513
Example scenarios	514
Configuring your Guardium system	517
System Configuration	517
Managing data: archive, restore, aggregation, and system backup	519
Planning archiving, storage capacity, and scheduling	520
Managing stored data	523
Configure data archive	523
Archiving (audit) results	524
Restoring archived data	524
Restoring archived data on an empty appliance	525
Restoring a few days of recent data	526
Restoring and viewing audit results in the investigation center	526
Exporting (files) results	527
Viewing days whose data was not archived or exported	528
Data and Result catalogs	528
Import catalog entries	529
Export catalog entries	529
Adding, removing, and modifying catalog entries	529
Data aggregation	530
Exporting data	531

Importing data	532
Purging data	532
Configuring data purge	532
Purging data to resolve a full disk when the GUI is down	533
Configuring system backup	535
Restoring a Guardium system	535
Before you restore your Guardium system	536
Restoring a standalone collector	537
Restoring a collector with an aggregator that is not centrally managed	538
Restoring an aggregator that is not centrally managed	538
Restoring a centrally managed collector	538
Restoring a centrally managed aggregator	539
Restoring a dedicated central manager (no data aggregation)	539
Restoring default and custom certificates	540
Enabling SSH key pairs for data archive, data export, data mart	540
Transferring data to a remote host by using SSH key pairs for authentication	541
Configuring external storage	542
Configure an Amazon S3 (Amazon Simple Storage Service) target for archive or backup	542
Configuring an IBM COS (formerly Cleversafe) target for archive or backup	544
Configure an EMC Centera target for archive or backup	545
Configuring an SCP or SFTP target for archive or backup	545
Configure a Tivoli Storage Manager (TSM) archive or backup	546
Internet Protocol modes	546
Enable IPv4	547
Enable dual IP mode in an existing IPv4 deployment	548
Migrate to IPv6 in an existing IPv4 deployment	548
Enable IPv6 in a new deployment	549
Assign IPv6 addresses to your devices	550
IPv6 limitations, best practices, FAQ, and troubleshooting	550
Network mirroring methods (SPAN , N-TAP) and related inspection engines	551
Configuring inspection engines	552
Configuring the Guardium portal	555
Configuring authentication	556
Enabling smart card authentication	557
Configuring multi-factor authentication	559
Managing the TLS version	561
Global profile	562
The alert message template	564
Configuring the alerter	567
Facility and priority of syslog messages	568
Anomaly Detection	568
Session Inference	569
Allow (approve) S-TAP connection to Guardium (S-TAP certification)	569
IP to Hostname Aliasing	569
Configure Permission to Socket connection	570
Managing access to Guardium	570
Understanding Roles	571
Access for default roles and applications	573
Managing roles and permissions	578
How to create a role with minimal access	579
Managing users	580
Managing Guardium credentials with CyberArk	582
Creating a user who can run GuardAPI commands	582
Importing users from LDAP	583
Data Security - User Hierarchy and Database Associations	585
How to define User Hierarchies	586
Central Management	587
Guardium Component Services	588
Implementing Central Management	590
Implementing Central Management in a New Installation	590
Registering Units	590
Unregistering a Managed Unit	591
Synchronizing Portal User Accounts	592
Implementing Central Management in an Existing Installation	593
Using Central Management Functions	593
Managing expiring certificates	594
Deployment health views	594
Configuring a central manager for the deployment health views	595
Deployment health topology and table views	596
Deployment health dashboard	598
Scenario: Troubleshooting overloaded systems using the deployment health topology view	601
Creating a cross-CM health view	601
Viewing cross-CM health view deployment health data	602
Managing patches on a cross-CM health view system	603
S-TAP and GIM dashboard	603

Create and manage S-TAP clusters	604
Enterprise load balancing	605
Enabling enterprise load balancing and associating an S-TAP with a central manager	605
Associating S-TAP with managed units for load balancing	606
Restarting (resynchronizing) S-TAPs for enterprise load balancing	607
Viewing the enterprise load balancing load map	607
Viewing an enterprise load balancing activity report	608
Enterprise load balancing configuration parameters	608
Deployment inventory	610
Resource deployment view	610
Monitoring managed units	610
Creating managed unit groups	612
Installing security policies on managed units	612
Central patch management	613
Distributing authentication configuration	613
Distributing configurations	613
Working with configuration profiles	614
Distribute custom tables	615
Central manager redundancy	615
Managing your Guardium system	618
Guardium Administration	618
Certificates	619
Installing an appliance certificate to avoid a browser SSL certificate challenge	620
Configuring Guardium-S-TAP communication using an SSL certificate	621
Identify expired certificates and certificates that will expire within six months	622
Managing certificates by using Venafi	622
Creating a Venafi instance	622
Configuring Venafi for GUI and Sniffer certificates	622
Configuring Venafi for GIM certificates	623
Restoring the Guardium Insights certificate	624
Alerts	625
How to create a real-time alert	625
Notifications	626
Predefined alerts	626
Custom Alerting Class Administration	627
System performance and monitoring	627
Unit utilization and inspection core performance	628
Buffer usage monitor report	628
Unit utilization and Unit utilization details reports	629
Performance issue: buffer usage process not running	630
Performance issue: analyzer queue overflow	631
Performance issue: logger queue overflow	631
Configuring unit utilization data processing	632
Self Monitoring	633
Monitoring with SNMP	635
Running Query Monitor	636
Services Status panel	636
Scheduling	637
Job dependencies	637
Viewing job history	638
Aliases	639
Dates and Timestamps	640
Building Time Periods	641
Cipher suites	642
Comments	643
Customer Uploads	643
Stream Guardium data to another application	646
Big Data Intelligence	646
Big Data Intelligence with data marts	646
Configure key pair authentication for GBDI file extraction	647
Big Data Intelligence with data streaming	647
Configure GBDI data streaming	648
Exporting and importing definitions	649
Remote loggers	652
Manage Custom Classes	652
GDPR readiness: Considerations when configuring Guardium	652
Groups	653
Groups overview	653
Using the group builder	654
Creating and editing groups	654
Viewing group membership and where groups are used	655
Populating groups	655
Importing from external datasources	656
Using groups in queries and policies	657
Example: Using groups to create rules and policies	657
Predefined Groups	658

Security Roles	662
How to install patches	663
Support Maintenance	664
Product integration	664
Configure BIG-IP Application Security Manager (ASM) to communicate with Guardium system	665
Embedded integrations	665
Integrating with IBM Knowledge Catalog for federated data protection	665
Starting the IBM Knowledge Catalog and Guardium Data Protection integration	667
Setting up a transformation integration	668

Exchanging information with IBM	686
Problems and solutions	687
User interface	687
Changes are not saved when you add an inspection engine	688
HTTP error 403	688
Java.lang.IllegalStateException	688
Pages are not loading correctly	689
Policies	689
Query does not appear in the co-relation alert definition	689
Rule does not trigger	690
REDACT function causes overly masked result	690
REDACT - Working with regex on Windows DB servers	691
SSH sessions and automated CRON jobs that log in to your Oracle database are shown as failed logins	692
Reports	692
Cannot modify the receiver table for an Audit Process after it has been executed at least once	693
Cannot see multi-byte characters	693
File system is almost full	693
Guardium audit reports viewed in Microsoft Excel have rows with unexpected characters	694
Reports show IP address as 0.0.0.0	694
Request was interrupted or quota exceeded error message	694
Scheduled Job Exceptions every 5 minutes	695
Scheduled jobs exception: merge required, delay executing process	696
The database user is not shown correctly in Guardium reports when you monitor Teradata	696
Unexpected results in Guardium reports with embedded commands	696
Assess and harden	697
CAS is not working with Java 1.7 on Windows	697
Vulnerability Assessment exception group members appear in failed test	697
Configuring your Guardium system	698
Cannot configure STAP after upgrade	698
Guardium fails to recognize the network device VMXNET x	699
Guardium network interface error after system board replacement	699
SSLv3 is enabled	699
Access management	700
Cannot log in to Guardium except as admin or accessmgr	700
Guardium accessmgr password reset	700
Guardium CLI password reset	701
Aggregation	701
Cannot convert Guardium collector to aggregator	702
Data Export configuration change from a Guardium managed system's GUI fails with error	702
Difference between audit process results and report	703
HY000 errors after restoring the configuration in an aggregator	703
UI banner warning: Data not exported or archived	704
Health alerts and UI banner warning: Old partitions found	704
Internal database	705

Why is the Guardium internal database is filling up	705
Managed unit database is filling up	706
How to purge off some old audit results from the Guardium appliance	706
Resolving internal database full problems	707
Central management	708
A user is disabled in a Guardium managed unit, but shows as enabled on Central Manager	708
Central Manager does not recognize the new version of upgraded units	709
Scheduled tasks do not fire at the scheduled time	709
Torque exception in Central Management view of GUI	710
S-TAPs and other agents	710
Error opening shared memory area when you configure Guardium COMM_EXIT_LIST for DB2	710
Guardium fails to collect shared memory traffic from Informix	711
High CPU and I/O Use in Guardium S-TAP host	711
UNIX S-TAP cannot start: buffer size too large	712
S-TAP does not start automatically on Linux	712
S-TAP returns not FIPS 140-2 compliant	713
The K-TAP kernel module is still present after the uninstallation of S-TAP	713
Windows S-TAP service crashes on startup with error ID 1000	714
S-TAP is not capturing A-TAP traffic	714
Linux S-TAP is not capturing Db2 exit traffic	715
Insufficient memory when installing UNIX S-TAP	715
Collectors	716
Nanny process is killing sniffer	716
Sniffer cannot connect to UNIX S-TAP	716
Guardium Installation Manager (GIM)	716
Error installing the Guardium Installation Manager (GIM)	717
Guardium Installation Manager (GIM) service does not start in Windows	717
File activity	717
File activity is not logged in investigation dashboard or reports	717
File activity from removable disk is not logged in investigation dashboard	718
File activity appears in reports but not the investigation dashboard	718
Some files missing from classification results	718
Partial file discovery (entitlement) results in reports and investigation dashboard	718
File classification results are missing from reports and investigation dashboard	719
File activity logs	719
FAM bundle fails to install	719

This information was developed for products and services offered in the U.S.A.

IBM Guardium

IBM® Guardium® prevents leaks from databases, data warehouses and Big Data environments such as Hadoop, ensures the integrity of information and automates compliance controls across heterogeneous environments.

It protects structured and unstructured data in databases, big data environments and file systems against threats and ensures compliance.

It provides a scalable platform that enables continuous monitoring of structured and unstructured data traffic as well as enforcement of policies for sensitive data access enterprise-wide.

A secure, centralized audit repository combined with an integrated workflow automation platform streamlines compliance validation activities across a wide variety of mandates.

It leverages integration with IT management and other security management solutions to provide comprehensive data protection across the enterprise.

They are intended to enable continuous monitoring of heterogeneous database and document-sharing infrastructures, as well as enforcement of your policies for sensitive data access across the enterprise, utilizing a scalable platform. A centralized audit repository designed to maximize security, combined with an integrated compliance workflow automation application, enables the products to streamline compliance validation activities across a wide variety of mandates.

IBM Guardium is designed to help safeguard critical data. Guardium is a comprehensive data protection platform that enables security teams to automatically analyze what is happening in sensitive-data environments (databases, data warehouses, big data platforms, cloud environments, file systems, and so on) to help minimize risk, protect sensitive data from internal and external threats, and seamlessly adapt to IT changes that may impact data security. Guardium helps ensure the integrity of information in data centers and automate compliance controls.

The IBM Guardium solution is offered in two versions:

- IBM Guardium Database Activity Monitoring (DAM)
- IBM Guardium File Activity Monitoring (FAM) - Use Guardium file activity monitoring to extend monitoring capabilities to file servers.

The IBM Guardium products provide a simple, robust solution for preventing data leaks from databases and files, helping to ensure the integrity of information in the data center and automating compliance controls.

Guardium products can help you:

- Automatically locate databases and discover and classify sensitive information within them;
- Automatically assess database vulnerabilities and configuration flaws;
- Ensure that configurations are locked down after recommended changes are implemented;
- Enable high visibility at a granular level into database transactions that involve sensitive data;
- Track activities of end users who access data indirectly through enterprise applications;
- Monitor and enforce a wide range of policies, including sensitive data access, database change control, and privileged user actions;
- Create a single, secure centralized audit repository for large numbers of heterogeneous systems and databases; and
- Automate the entire compliance auditing process, including creating and distributing reports as well as capturing comments and signatures.

The Guardium solution is designed for ease of use and scalability. It can be configured for a single database or thousands of heterogeneous databases located across the enterprise.

This solution is available as preconfigured appliances shipped by IBM or as software appliances installed on your platform. Optional features can easily be added to your system after installation.

These are the key functional areas of Guardium's database security solution:

- Vulnerability assessment. This includes not just discovering known vulnerabilities in database products, but also providing complete visibility into complex database infrastructures, detecting misconfigurations, and assessing and mitigating these risks.
- Data discovery and classification. Although classification alone does not provide any protection, it serves as a crucial first step toward defining proper security policies for different data depending on its criticality and compliance requirements.
- Data protection. Guardium addresses data encryption at rest and in transit, static and dynamic data masking, and other technologies for protecting data integrity and confidentiality.
- Monitoring and analytics. This includes monitoring of database performance characteristics and complete visibility in all access and administrative actions for each instance. On top of that, advanced real-time analytics, anomaly detection and security information and event management (SIEM) integration can be provided.
- Threat prevention. This refers to methods of protection from cyberattacks such as distributed denial-of-service (DDoS) or SQL injection, mitigation of vulnerabilities that are not patched and other database-specific security measures.
- Access management. This goes beyond basic access controls to database instances. The rating process focused on more sophisticated, dynamic, policy-based access management capable of identifying and removing excessive user privileges, managing shared and service accounts, and detecting and blocking suspicious user activities.
- Audit and compliance. This includes advanced auditing mechanisms beyond native capabilities, centralized auditing and reporting across multiple database environments, enforcing separation of duties, and tools supporting forensic analysis and compliance audits.
- Performance and scalability. Although not a security feature, it is a crucial requirement for all database security solutions to be able to withstand high loads, minimize performance overhead and support deployments in high-availability configurations.

For more information on the Guardium family of products, visit <https://www.ibm.com/security/data-security/guardium>.

What's new in this release

New features, functions, and enhancements.

12.1 and later IBM Guardium V12.1

Audit process

Support is added to customize the audit process emails. For more information, see [Custom email template](#) in [Building audit processes](#).

Certificate management

- The login page now shows the certificate expiration details and provides a link to manage the certificates.
- Manage, update, and distribute all your expiring certificates from a central manager to the central manager and its managed units. For more information, see [Managing expiring certificates](#).
- View all the certificates that expire on the system within a specified threshold. For more information, see [show_expiring_certificates](#).
- Backup and restore process is enhanced for default and custom certificates. For more information, see [Restoring default and custom certificates](#).

Classifier

Support is added for new custom property, maximum length for large-text data types with PostgreSQL and Sybase.

CLI Commands

Support is added for automating the following CLI Commands:

- Restart and Start commands: `restart datastreams, restart GUI, restart insights_Kafka, restart network, restart processmgr, restart rds_monitoring, restart sniffer_buffer_usage, restart stopped_services, restart system, restart ticket-service, restart alerter, restart guardium_insights, restart icap, restart inspection-core, and start insights_Kafka`
- Store commands: `store disk_space_reserved reset, store dump_data_for_forensics, store mysql_utf8mb4, store quartz_thread_num, store remove_informix_driver_property_IFX_USE_STRENC, store system ipmode, store`

- ```
set_informix_driver_property, store system public key reset, and store system
sshd-max-connection.
• Support commands: support store rdsdiag clean, and support
dump_gdm_exception_error.
```

For more information, see [CLI Commands](#).

#### Cross-central manager(CM) health view system

- Manage patches for central managers and its managed units on cross-CM health view systems. For more information, see [Managing patches on a cross-CM health view system](#).
- Register and unregister central managers to the cross-CM health view system from the Patch Management page or by using API. For more information, see [Viewing cross-CM health view deployment health data](#).

#### Database instance discovery

Run database instance discovery from the central manager on all active S-TAP units for managed unit groups or individual managed units by using the GUI. For more information, see [Monitoring managed units](#).

#### Database discovered instances rules

- A new Manage Collectors view was added to the central manager user interface to quickly and easily find the collectors that are participating in the database discovered instances rules processing. From this dialog, the IE\_CREATION parameter for each collector can be viewed and updated.
- The new Discovered instances rules parameters report on the collector shows the timestamp of when the IE\_CREATION parameter was last changed and its current setting.
- Predefined GRDAPI mapping of modify\_guard\_param provides convenience. The IE\_creation parameter can also be viewed or updated from the command line.

For more information, see [database discovered instances rules](#).

#### Deployment health topology

Support is added for monitored processes report that provides combined information about the Investigation dashboard and Threshold alerter. For more information, see [Deployment health topology and table views](#).

#### GIM certificates

Support is added to replace the default SHA2 GIM certificate with SHA1 or SHA256 without interrupting the GIM server to GIM client communication. For more information, see [Replacing default GIM certificate with SHA1 or SHA256 certificate](#).

#### Integration

Ranger HDFS for Hortonworks and Cloudera 7 supports integration with Atlas service.

#### Policies

- Support is added to quarantine the users with multiple failed login attempts for the security incident policies. For more information, see [Quarantine users with multiple failed logins](#).
- Support is added for the following actions in the Session-level policies.
  - Log Full details with replaced values
  - Log Extrusion Counter
  - Log Masked Extrusion Counter
  - Log Only
  - Log Masked Details
  - Audit Only
  - Ignore responses per session
For more information, see [Actions](#).
- Support is added to detect the Canadian Social Insurance Number (SIN) pattern. For more information, see [Special pattern tests](#).

#### Proxy connection

Guardium supports a web proxy to connect to a remote source that requires a proxy server to connect. Use the proxy grdapi to create the proxy connections. For more information, see [proxy](#).

#### Reports

Support is added for Audit Process Task Details, Available VA Tests - CIS, and Available VA Tests - STIG predefined admin reports.

#### S-TAP

- Support is added to schedule S-TAP diagnostics from the S-TAP Diagnostic Scheduler user interface. For more information see, [Scheduling S-TAP diagnostics](#).
- Support is added for S-TAP to deliver encrypted and unencrypted login packets that contain Kerberos username to the Collector. S-TAP matches the session with the Kerberos username by using the Security Support Provider Interface (SSPI) data as the key. The following parameters are added to support this feature: SSPI\_NAME\_LIMIT, SSPI\_NAME\_TTL, SSPI\_SESSION\_TTL, and SSPI\_SESSION\_MEMORY. For more information, see [General parameters](#) and [Protocol 8 General parameters](#).
- The enhanced S-TAP load-balancing feature aims to eliminate data loss during the collector failover process. For more information, see [S-TAP load-balancing models and configuration guidelines](#) for Linux® and Unix, and [S-TAP load balancing models and configuration guidelines](#) for Windows.
- The Internal Load Balancer (ILB) helps avoid data loss caused due to collector overload. For more information, see [S-TAP load-balancing models and configuration guidelines](#) for Linux and UNIX, and [S-TAP load balancing models and configuration guidelines](#) for Windows.
- Support added to increase K-TAP throughput with dynamic ring buffers. For more information, see [Increasing S-TAP and K-TAP throughput with dynamic ring buffers](#).

#### Universal Connectors

Support is added to centrally manage the Guardium Managed Units on which the Universal Connectors are installed. For more information see, [Universal connector configuration](#).

#### Vulnerability Assessment

- Ability to exclude or specify Microsoft SQL to be scanned.

- Addition of Security Technical Implementation Guide (STIG) Oracle Database 19c benchmark.
- Available tests report filters by CIS, CVE, APAR, CAS-based, JDBC-based, and user-defined-JDBC-based.
- Addition of test severity level to the SCAP XML Export.
- CIS Microsoft SQL Server 2022 1.0 benchmark support.
- Entitlement reports for CockroachDB.
- Support is added for DynamoDB.
- Performance enhancement between central manager and managed units.
- Purge of older DPS history for older, major release versions.
- Scanning for Amazon Aurora PostgreSQL.
- Support for namespaces with HashiCorp Vault integration.
- Support of multi-tenancy for Oracle 19c pluggable databases (PDB).
- For a complete list of tests and groups that are added or updated in version 12.1, see [Vulnerability Assessment tests and groups in Guardium 12.x](#). Tests and groups that are added after the release of Guardium version 12.1 are available in the upcoming Quarterly DPS files.

#### Other enhancements

- View and manage the security settings components: sshd, ciphers, services. For more information, see [secure\\_settings](#).
- Archive and export data on target hosts for specified time intervals. For more information, see [aggregation](#).
- Configure a proxy to connect GDP and GI. For more information, see [insights\\_registration](#).
- Use an API key to run REST API authentication, which never expires, to get an access token to make REST API calls to Guardium. For more information, see [create\\_api\\_key](#), [list\\_api\\_key](#), and [revoke\\_api\\_key](#).

## 12.0 and later IBM Guardium V12.0

---

#### Access management

Guardium 12.0 adds "password last changed" and "password expired" dates to the access management page and to the list\_users API output to better support proactive password management.

#### Active threat analytics

You can now optimize resources and reduce false positives by excluding certain sources such as test data and activities that are performed by automated processes.

#### Audit process

- The audit process to-do list adds the ability to quickly change the classification result sets being compared directly from the results-comparison view itself. For more information, see [Comparing discovery and classification results](#).
- You can now modify the receivers list for active audit processes, including deleting and rearranging existing users. Changes are tracked in the "User activity audit trail" report. For more information, see [Audit process receivers](#).

#### Certificate management

- Support is added for automatic retrieval of existing certificates from Venafi using the Guardium CLI.
- The number of SAN (subject alternative name) slots have increased from nine to 99.
- The date format in the warning message under the notification icon for expiring certificates has changed from `d-m-yyyy` to `yyyy-mm-dd`.

#### Classifier

- Support is added for fire with marker option for catalog search rules.
  - Support is added for new custom properties, including maximum length for large-text data types with Microsoft SQL Server and new data-cardinality methods for Oracle.
- For more information, see [MS SQL Server \(DataDirect\)](#), and [Oracle \(Data Direct - Service Name\)](#).

#### Central management

- You can now view patch installation status of managed units from central managers.
- The cross-central-manager health view (cross-CM health view) is a new Guardium unit type that provides aggregated health views for an entire Guardium deployment. These views include health information for all available central managers, aggregators, collectors, and S-TAPs in your environment. For more information, see [Viewing deployment health data from multiple central managers](#).

#### Database discovered instances rules

- Ability to specify existing Guardium groups for filter and exclude rules.
- Ability to delete discovered instances and existing inspection engines that match specified criteria and standard operators.

For more information, see [database discovered instances rules](#).

#### Datasources

Support is added for creating new groups with username and hostname or IP address criteria.

#### Entitlement reporting

Support added for EDB PostgreSQL.

#### External ticketing

Event Management is now integrated with the ServiceNow. For more information, see [Configuring an external ticketing system](#).

#### GIM

Guardium now uses SHA256 GIM client certificates. For more information, see [GIM clients with SHA256 certificates](#).

#### IBM® Knowledge Catalog integration

- You can now use an external credential manager (AWS Secrets Manager, CyberARK, or HashiCorp) to supply credentials to the IBM Knowledge Catalog - Guardium integration.
- The Guardium-IBM Knowledge Catalog integration includes several updates to how PII is captured during an upgrade. For more information, see [Integrating with IBM Knowledge Catalog for federated data protection](#).
- To learn more information about supported datasources for IBM Knowledge Catalog, see [Integrating with IBM Knowledge Catalog for federated data protection](#) and [Adding User-Defined Functions \(UDFs\) for IBM Knowledge Catalog - Guardium integration](#).

#### Investigation dashboard

Support added for monitoring and automatic recovery to identify and recover issues in the investigation dashboard. For more information, see [Monitoring and automatic recovery for the investigation dashboard](#).

#### Network Time Protocol (NTP)

Network Time Protocol (NTP) now uses the chrony time server daemon. The **ntp** CLI commands are deprecated and replaced by **time\_server** commands. For more information, see the [store system time server](#) CLI command.

#### Runtime sensitive-object identifier

The Runtime Sensitive Object Identifier is redesigned. You can now manage runtime sensitive object identification by using the new Runtime Sensitive Object Identifier session level policy and report. For more information, see [Runtime sensitive-object identifier](#).

#### Policies

Session-level policy adds support for SQL criteria, extrusion rules through criteria server data, and the ability to use regex in groups and custom tuples.

#### S-TAP

- Define S-TAP clusters for environments with multiple S-taps that are assigned to clusters of database servers. S-TAP clusters allow Guardium to detect traffic at the cluster level, meaning that if one S-TAP in the cluster is active, all S-TAPs assigned to the cluster are also marked as active. S-TAP clusters also support automatic removal of inactive S-TAP connections for active-passive cluster configurations. For more information, see [Create and manage S-TAP clusters](#).
- Unix S-TAP and External S-TAP support OpenSSL v3.1 and FIPS140-3.
- External S-TAP supports MongoDB Atlas with MongoDB Compass.

#### TLS 1.3 support

Guardium now supports TLS 1.2 and 1.3, and support for earlier TLS versions is deprecated. For more information about moving to TLS 1.3, see [Managing the TLS version](#).

#### Universal connector

- The universal connector now offers a troubleshooting tool. For more information, see [universal connectors](#).
- Universal connector plug-ins are now preinstalled. When newer versions of the plug-ins become available, you can choose to upload them manually or wait for the next Guardium patch release to get them automatically updated.

#### Vulnerability Assessment

- Ability to display both alias and non-alias value in a report.
- Ability to find an existing vulnerability assessment by using the Security Assessment Finder screen.
- Ability to upload MS SQL opensource driver through custom uploads.
- Ability to export vulnerability assessment results through external feed.
- Support added for Oracle MySQL enterprise edition 8.0 CIS benchmark version 1.2.0, MongoDB 4.0 and MongoDB 5.0 CIS benchmark version 1.0.0, latest CIS benchmark for Db2, CIS benchmark for PostgreSQL version 15.
- Support added for Oracle MySQL enterprise edition 8.0 STIG benchmark, ver 1 rel 1, Oracle 19c benchmark.
- SSL encryption support is added for Oracle 11.x, 12.x, and 19.
- Support added for Apache Cassandra, Percona MySQL datasources.
- Support added for Apache Cassandra, PostgreSQL, and PostgreSQL EDB entitlement reports.

For a complete list of tests and groups that are added or updated in version 12.0, see <https://www.ibm.com/support/pages/node/7031317>. Tests and groups that are added after the release of Guardium version 12.0 are available in upcoming quarterly DPS reports.

#### Other enhancements

- RHEL is upgraded from RHEL 7 to RHEL 9
- The output of all CLI commands (including Guardium API commands) that modify a component of the user's system now includes the timestamp after the command finishes running.
- Ability to mark updates as "read" from the notification icon in the UI.

---

## Release information

Learn about the latest features and enhancements, system requirements, installation, upgrade, and support information.

---

### Release announcement

See the IBM Guardium release announcement for the following information:

- Detailed product description, including a description of new functionality
- Product-positioning statement
- Packaging and ordering information
- International compatibility information

---

### Release notes

For new features, enhancements, and other detailed release-related information, see the IBM Guardium detailed release notes:

12.1 [Guardium 12.1 release notes](#).

12.0 [Guardium 12.0 release notes](#).

---

## System requirements

For Guardium versions 11.0 and later, most supported platforms information is available through the [Guardium support matrix](#).

For all other supported platforms and system requirements information, including vulnerability assessment, platforms supported by external S-TAP, information about IBM i, and hardware or VM requirements, see:

- 12.1 [System Requirements for Guardium® 12.1](#)  
12.0 [System Requirements for Guardium 12.0](#)

For technical support and other resources, search the [IBM Support](#) website.

## Hardware requirements

---

For detailed hardware specifications and sizing recommendations, see:

- 12.1 [Appliance Technical Requirements for Guardium 12.1](#)  
12.0 [Appliance Technical Requirements for Guardium 12.0](#)

## Installing and upgrading Guardium

---

For installation instructions, see [Installing your Guardium system](#).

For information about upgrading to the latest version of Guardium, see [Upgrading your Guardium system](#).

If you are using an older version of Guardium software, plan ahead to allow time for upgrades. You can find information about end-of-support dates for IBM products at the [IBM Software Support Lifecycle](#) website.

For up-to-date help, access the documentation landing page for IBM Guardium: <https://www.ibm.com/docs/guardium>

Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Director of Licensing  
IBM Corporation  
North Castle Drive, MD-NC119  
Armonk, NY 10504-1785  
US.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of

non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Depending on how you are viewing this information, some images and illustrations may not appear.

## Trademarks

## Privacy policy considerations

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user, or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

This Software Offering does not use cookies or other technologies to collect personally identifiable information.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy>.

## FIPS 140-2

---

When in FIPS 140-2 mode, IBM Security Guardium uses the FIPS 140-2 approved cryptographic provider(s); IBMJCEFIPS (certificate 376) and/or IBMJSSEFIPS (certificate 409) and/or IBM Crypto for C (ICC (certificate 384) for cryptography. You can search for the certificates at the NIST web site at <https://csrc.nist.gov/>.

# Getting started

## Components and topology

Learn about Guardium appliances, agents, and other components.

### Guardium components

- Guardium systems:
  - Collectors: The collector performs real-time capture and analysis of the database activity, and logs it for further analysis and use in alerting.
  - Aggregators: Guardium aggregators collect and merge information from multiple Guardium collectors, and optionally from other aggregators. They produce holistic views of an entire environment. Collection and aggregation processes allow Guardium to easily generate enterprise-level reports. In a large enterprise environment, for example, several Guardium systems can be used for monitoring different geographic locations or business units. You can export data from multiple collectors to a single aggregator, and view database usage across all geographic areas or business units. Reports, assessments, and audit processes run from this aggregator would then reflect data collected from across the environment.
  - Central Managers: The central manager (CM) is a specialized functionality that is enabled on an aggregator. In this configuration, one Guardium system is designated as a central manager that controls and monitors an entire Guardium environment, from a single console. In this configuration, collectors and aggregators are referred to as managed units. While some applications (Audit Processes, Queries, Portlets, etc.) can be run from either a managed unit or from the central manager, application's definitions are stored on the central manager. See [Aggregation and central management](#). Central management supports hierarchical aggregation where multiple aggregators merge their data repositories to a central aggregator. This is useful for multi-level views. For example, with different Guardium aggregators assigned to different geographic locations, a central management aggregator can merge the contents of all aggregators into a single global view spanning all geographies. See [Data aggregation](#).
- To set up your central manager and managed units for Vulnerability Assessment (VA), see [Set up your environment for Vulnerability Assessment](#).
- Agents (required and most common):
  - Software TAP agent (S-TAP): [Windows: S-TAP user's guide](#) and [Linux and UNIX systems: S-TAP user's guide](#).
  - Guardium Installation Manager agent (GIM): The GIM server is installed as part of the Guardium system. It communicates with the GIM client, that is installed on servers that host databases or file systems that you want to monitor. It facilitates agent installation and updating and configuration modification of agents. See [Guardium Installation Manager](#).
  - Change Audit System agent (CAS): The CAS agent is installed on the database server. It captures change audit information of configuration files and more on the database server. See [Configuration Auditing System \(CAS\)](#).
  - Instance Discovery agent: The instance discovery agent is installed on the database server and sends database, listener, and port information to Guardium.
- Datasource: A Guardium datasource identifies a specific database instance. Access to datasources may be restricted based on the roles assigned to the datasource and to the applications that use it. For example, the Value Change Auditing application requires a high level of administrative access that would not be appropriate for other less privileged applications.
- Inspection engine: neither a component nor an agent, an inspection engine is a required configuration that specifies the database platform and the instances that the S-TAP monitors on the S-TAP host (database server). One S-TAP often has many inspection engines.

### Guardium topology

- Basic stand-alone architecture: The most basic architecture is for monitoring several databases in one data center: one stand-alone collector appliance and several Guardium S-TAP agents that are installed on the monitored database servers. The S-TAP agents capture and send the relevant database activities to the one Guardium collector for analysis, parsing, and logging.
- Mid-size architecture: The mid-size architecture monitors numerous databases across data centers. It consists of multiple collector appliances and numerous S-TAP agents that are installed on the monitored database servers in each data center. The S-TAP agents capture and send the relevant database activities to the Guardium collectors for analysis, parsing, and logging. The collectors aggregate activities that are monitored to an aggregator appliance for central reporting. In this example, the aggregator appliance is also serving as the central management appliance for the solution that enables federated management capabilities, such as Access Management, patching, and metadata repository.

- Enterprise architecture: The enterprise architecture monitors numerous databases across multiple data centers and continents. This architecture example consists of many collector appliances and numerous S-TAP agents that are installed on mainframe and distributed database servers across data centers. The S-TAP agents capture and send the relevant database activities to the Guardium collectors for analysis, parsing, and logging. The collectors aggregate activities that are monitored to the respective aggregator appliance for central reporting. A dedicated Central Manager appliance provides federated management capabilities, such as Access Management, patching, and metadata repository.

## Getting started with the user interface

Learn the basics of the Guardium user interface, including logging in for the first time, banner and navigation menus, and the user interface and data search.

### Navigation

When you first log in to the Guardium user interface, there are two main menus - the banner and the navigation menu.

You can expand and collapse the navigation menu by clicking the chevron icon  , or you can hide the navigation menu completely by clicking the show / hide icon 

The initial layout of your screen is determined by the license that is applied, the access allowed based on roles, the machine type, and a visibility factor. Examples of roles are user, admin, access manager, and CLI. Roles are assigned to users and applications to grant users specific access privileges.

### Banner Menu

The banner contains the following items:

Table 1. Banner menu

| Item                         |                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System time clock            |                                                                                   | The universal time on your Guardium system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| To-Do List                   |  | Contains the Audit Process To-Do List, which can be filtered by user, and the Processes With No Pending Results.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Help                         |                                                                                   | Open the product help by clicking Help  .Guardium Help.<br>Get information about your Guardium system, such as the version number, by clicking Help  .About Guardium.<br><br>For help content specific to a screen or feature you're working with, click  that is embedded in each page.<br>Note: However you access the Help, when you open same Information Center, where you can search and access all help content. |
| User interface / data / file |                                                                                   | Select Data or File and click  to open the Investigation Dashboard.<br>Select User Interface to search the UI. For example, if you want to find the Policy Builder, type policy builder in the User Interface Search. Click any of the results to go to that part of the user interface.                                                                                                                                                                                                                                                                                                    |
| Account type                 |                                                                                   | Indicates the account type that you logged in with. Edit your account details, such as your password or name, customize UI layout, and sign out of Guardium securely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Machine type                 |                                                                                   | Indicates what type of Guardium system you are on, such as stand-alone, managed unit, central manager, or aggregator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The banner menu also contains important startup messages such as Low RAM memory, Quick Search memory, and CPU 4-cores minimum requirement, Certificate expiration, Central Management failure, SSLv3 enabled or disabled, and No License.

Note: Guardium recommends that SSLv3 be disabled. However, in dealing with older Guardium versions that do not have the latest release installed, if SSLv3 is disabled, the Central Management functionality is impaired between the Central Manager and the managed units.

### Navigation Menu

Each icon in the navigation menu represents one phase of the Guardium security lifecycle, click any icon to expand it and see the components within the phase. The lifecycle-centric navigation menu is one way to navigate the user interface and is consistent across roles. Menu items can be customized and do or don't appear based on your role.

| Phase       |                                                                                     | Description                                                                                                                                                                                      |
|-------------|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Setup       |  | Configure your network settings, check the status of your services, and setup datasource definitions, groups, aliases, and alerts.                                                               |
| Manage      |  | Manage your environment's overall health, S-TAPs, data, modules, maintenance, and reports.                                                                                                       |
| Discover    |  | Automatically discover new databases that are introduced to your environment, and find and classify sensitive data.                                                                              |
| Harden      |  | Assess your environment's current weaknesses with Vulnerability Assessment and monitor changes that are made to your environment with Configuration Auditing System (CAS).                       |
| Investigate |  | Monitor database activities and investigate suspicious activity in any part of your environment.                                                                                                 |
| Protect     |  | Protect your environment with data security policies that block suspicious activity and prevent unauthorized access to data. For more information about policies, see <a href="#">Policies</a> . |
| Comply      |  | Reach compliance initiatives with audit processes and granular reporting.                                                                                                                        |
| Reports     |  | Create your own report or use one of many predefined reports to report on any part of your environment. For more information about reports, see <a href="#">Reports</a> .                        |

| Phase         |  | Description                                                                                                                                                                                  |
|---------------|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| My Dashboards |  | Create your own dashboards to easily review reports that are of primary interest to you. For more information about dashboards, see <a href="#">Creating dashboards and adding reports</a> . |

## Commonly Found Icons

Many of the finder and builder applications in Guardium share this set of icons.

| Icon   | Description                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------|
| New    | Create an item, such as a group or datasource definition.                                                          |
| Modify | Modify an item.<br>Note: When you modify items, the best practice is to clone the item, and then modify the clone. |
| Clone  | Clone an item to create a copy of the item.                                                                        |
| Delete | Delete an item.                                                                                                    |

## Customizing the user interface

Guardium® supports customizing the navigation menu for specific users and roles.

The Customize Navigation Menu and Customize User/Role tools allow you to conveniently change the content and organization of the navigation menu. You can access these tools in several locations:

- All users can customize their own navigation menu by opening the User menu in the Guardium banner and selecting Customize.
- Administrative users can customize the navigation menu for other users and roles by opening the User menu and selecting Customize User/Role or by navigating to Setup > Tools and Views > Customize User/Role.
- Users logged in as `accessmgr` can customize the navigation menu for other users and roles by navigating to Access > Access Management, selecting Role Browser, and clicking the Customize Navigation Menu link.

The tool provides a consistent customization experience for all users.

The Navigation Menu list reflects the organization and contents of the Guardium navigation system. Select tools and reports from the Available Tools and Reports list and use the icon to add items to the Navigation Menu list. Remove items from the Navigation Menu list by clicking the icon next to an item. Use drag and drop or the icon controls to rearrange items within Navigation Menu list.

It is possible to define a new Guardium home page (that is, the first page seen after logging into the system) by selecting an item from the Navigation Menu list and clicking the icon.

After clicking the OK button, the Guardium navigation menu is updated to reflect any changes you made in the Navigation Menu list.

The following limitations apply when using these tools:

- You cannot delete the My Dashboards group, but you can delete individual dashboards within the group.
- New groups that are empty will not be saved.
- Empty groups shown in the Navigation Menu list will not appear in the Guardium navigation menu.

## Identifying and investigating risks: getting started

Guardium®'s Active Threat Analytics, Risk Spotter, and Investigation Dashboard give you both a bird's eye view of potential risks in your system, risk trends over time, and tools to investigate the potential risks. Incorporate these tools into your daily Guardium routine to increase your abilities to identify and manage risks.

### [Active Threat Analytics](#)

Active Threat Analytics shows potential security breach cases, based on the outlier mining process and identified attack symptoms. Use its dashboard to view and investigate cases, and take actions on individual cases.

### [Risk Spotter](#)

Risk Spotter is a First of its Kind technology, changing the security paradigm to an Artificial Intelligence Data Protection Policy. It uses a smart algorithm to search within and outside your policy radar (your installed policies), and it uses a holistic algorithm to dynamically assess risk factors. Its dynamic risk assessment considers many risk factors, including: outliers, vulnerability, volume of activities, access to sensitive data, type of commands (privileges). Risk Spotter presents the risky users and risk trends across your entire system, in easy to read graphs. The Risk Spotter page contains all the configuration and results, and actions you can take.

### [Investigation Dashboard](#)

The Investigation Dashboard provides powerful tools for identifying and assessing problems that might exist in your Guardium environment. It uses either local or system-wide unfiltered data, and provides numerous filter options to query data across an entire Guardium environment, potentially from any Guardium collector within that environment.

## Smart assistant for monitoring and compliance

Learn how to deploy monitoring agents to your database servers and configure database monitoring for compliance with security standards and regulations.

## About this task

---

Smart assistant for monitoring and compliance is comprised of the following two tools:

### Deploy monitoring agents

Use the Deploy Monitoring Agents tool to automatically activate GIM clients, install S-TAPs, and begin monitoring database traffic.

The Deploy Monitoring Agents tool simplifies the process of establishing a Guardium deployment. Building on existing Guardium Installation Manager (GIM) infrastructure, the Deploy Monitoring Agents tool helps you quickly find database servers, install monitoring agents (S-TAPs), and configure inspection engines for your databases. In addition, the tool provides a centralized view for tracking and reviewing deployment status.

### Compliance monitoring

After deploying monitoring agents (S-TAPs), use the Compliance Monitoring tool to establish monitoring for specific security standards and regulations.

Guardium provides several compliance monitoring templates--groups, security policies, and reports corresponding to specific standards and regulations--including the following:

- Basel Committee on Banking Supervision (BASEL II)
- General Data Protection Regulation (GDPR)
- General Data Protection Regulation for Db2 for z/OS (GDPR for Db2 for z/OS)
- Health Insurance Portability and Accountability Act (HIPAA)
- Payment Card Industry Security Standard (PCI)
- Personally Identifiable Information (PII)
- Sarbanes-Oxley Compliance (SOX)

These compliance monitoring templates are especially useful for organizations that must comply with one of the associated standards or regulations in a short period of time. After installing security policies, the compliance monitoring tool guides administrators or compliance officers through the initial setup and population of groups with organization-specific information such as client IP addresses and specific privileged user IDs. In addition, the compliance monitoring tool periodically checks your Guardium environment for new databases that can be monitored using the compliance monitoring templates.

## Procedure

---

1. Review the following information to begin familiarizing yourself with the tools.
  - [Smart assistant for deploying monitoring agents](#)
  - [Smart assistant for compliance monitoring](#)
2. Deploy monitoring agents for your database servers.
  - a. Verify that you have met the prerequisites for using the Deploy Monitoring Agents tool: [Prerequisites for deploying monitoring agents](#).
  - b. Deploy monitoring agents to your database servers: [Deploy monitoring agents](#).
3. Configure compliance monitoring for your database servers.

## Results

---

After successfully deploying monitoring agents and configuring compliance monitoring for your database servers, Guardium begins monitoring your database traffic.

For more information about interpreting what you see on the compliance monitoring dashboard, see [Compliance summary](#).

## System view

---

The System View is the default initial view for many users. It enables you to see key elements of system status.

Three tabs under the System View display different types of status information:

- The S-TAP Status Monitor displays summary data about S-TAPs that are deployed in your environment. Icons represent the high-level status, and you can drill down to view information about inspection engines.
- The Unit Utilization tab displays information about the usage of each Guardium® system.
- The System Monitor tab displays up-to-date details about incoming data, CPU usage, and other information.

## Data activity monitoring

---

Information about key security concepts used in Guardium data activity monitoring.

- [Policies and rules](#)

A security policy contains an ordered set of rules to be applied to the observed traffic between database clients and servers. Each rule can apply to a request from a client, or to a response from a server. Multiple policies can be defined and multiple policies can be installed on a Guardium system at the same time.

- [Workflows](#)

Workflows consolidate several database activity monitoring tasks, including asset discovery, vulnerability assessment and hardening, database activity monitoring and audit reporting, report distribution, sign-off by key stakeholders, and escalations.

- [Auditing](#)

Guardium provides value change auditing features for tracking changes to values in database tables.

- [Classification](#)

Guardium supports the discovery and classification of sensitive data to allow the creation and enforcement of effective access policies.

## Policies and rules

A security policy contains an ordered set of rules to be applied to the observed traffic between database clients and servers. Each rule can apply to a request from a client, or to a response from a server. Multiple policies can be defined and multiple policies can be installed on a Guardium system at the same time.

Each rule in a policy defines a conditional action. The condition can be a simple test, for example a check for any access from a client IP address not found in an Authorized Client IPs group, or the condition can be a complex test that evaluates multiple message and session attributes such as database user, source program, command type, time of day, etc. Rules can also be sensitive to the number of times a condition is met within a specified timeframe.

The action triggered by the rule can be a notification action (e-mail to one or more recipients, for example), a blocking action (the client session might be disconnected), or the event might simply be logged as a policy violation. Custom actions can be developed to perform any tasks necessary for conditions that may be unique to a given environment or application.

## Workflows

Workflows consolidate several database activity monitoring tasks, including asset discovery, vulnerability assessment and hardening, database activity monitoring and audit reporting, report distribution, sign-off by key stakeholders, and escalations.

Workflows are intended to transform database security management from a time-consuming manual activity performed periodically to a continuously automated process that supports company privacy and governance requirements, such as PCI-DSS, SOX, Data Privacy and HIPAA. In addition, workflows support the exporting of audit results to external repositories for additional forensic analysis via Syslog, CSV/CEF files, and external feeds.

For example, a compliance workflow automation process might address the following questions: what type of report, assessment, audit trail, or classification is needed, who should receive this information and how sign-offs are handled, and what is the schedule for delivery?

## Auditing

Guardium provides value change auditing features for tracking changes to values in database tables.

For each table in which changes are to be tracked, you can select which SQL value-change commands to monitor (insert, update, delete). Before and after values are captured each time a value-change command is executed against a monitored table. This change activity is uploaded to Guardium on a scheduled basis, after which all of Guardium's reporting and alerting functions can be used.

You can view value-change data from the default Values Changed report, or you can create custom reports using the Value Change Tracking domain.

## Classification

Guardium supports the discovery and classification of sensitive data to allow the creation and enforcement of effective access policies.

A classification policy is a set of rules designed to discover and tag sensitive data elements. Actions can be defined for each rule in a classification policy, for example to generate an email alert or to add a member to a Guardium group, and classification policies can be scheduled to run against specified datasources or as tasks in a workflow.

Discovery and classification routines become important as the size of an organization grows and sensitive information like credit card numbers or personal financial data become present in multiple locations, often without the knowledge of the current administrators responsible for that data. This frequently happens in the context of mergers and acquisitions, or when legacy systems have outlasted their original owners. Guardium classification discovers and tags this sensitive data so appropriate access policies can be applied.

## File activity monitoring on Windows and Unix-Linux file servers

File Activity Monitoring discovers the sensitive data on your servers; classifies content using pre-defined or user defined definitions; configures rules and policies about data access, and actions to be taken when rules are met.

File activity monitoring consists of the following capabilities:

- Discovery includes collecting metadata and entitlements for files and folders.
- Classification uses *decision plans* to identify potentially sensitive data in the files, such as credit card information or personally identifiable information.
- Monitoring and collection of audit information and policy rules, and real time alerts or blocking of suspicious users or connections.
- [\*\*File activity monitoring functionality\*\*](#)  
FAM functionality on Windows and UNIX file servers is similar to data monitoring. Understand the similarities and differences.
- [\*\*High level workflow for file activity monitoring\*\*](#)  
Use this general workflow to plan and execute file activity monitoring on file servers in the Linux, Unix and Windows environments.

## File activity monitoring functionality

FAM functionality on Windows and UNIX file servers is similar to data monitoring. Understand the similarities and differences.

[FAM Support](#) lists the supported platforms for FAM discovery, classification, and monitoring.

Figure 1. FAM functionality in UNIX file servers

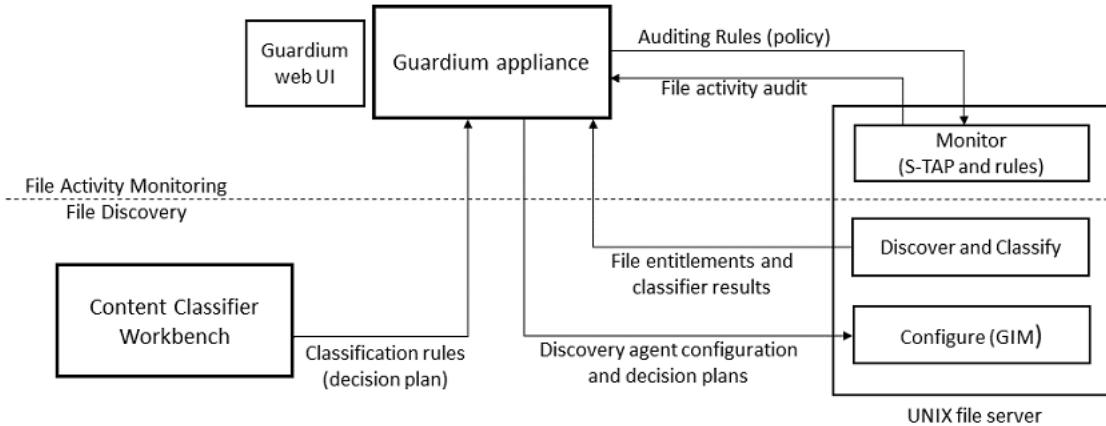

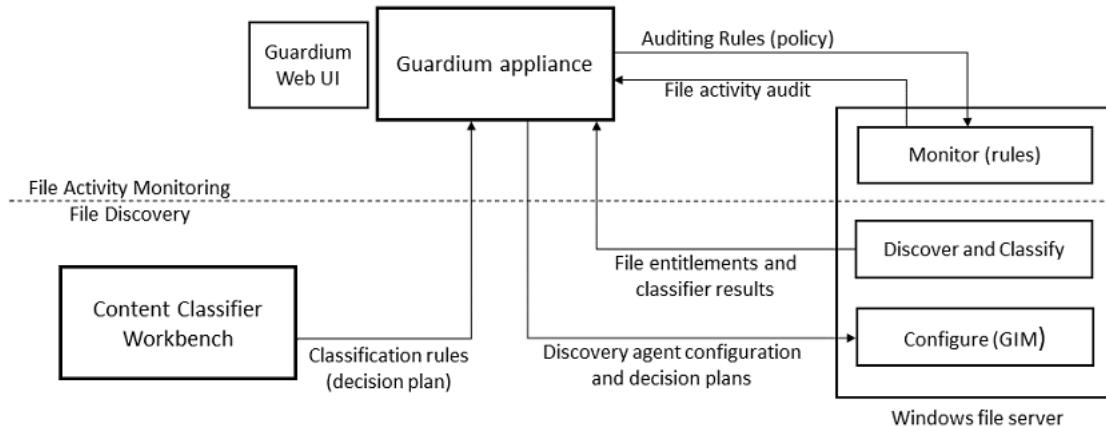

Figure 2. FAM functionality in Windows file servers

#### Discovery and classification

FAM discovery and classification (Windows file system, AIX file system, Red Hat, and Ubuntu) give entitlement and content classification details of given file server folders. Based on its results, you can create smart policies, define groups, and audit their files, focusing on the important assets (by using FAM monitoring).

The basic discovery scan identifies the list of folders and files, their owner, access permissions, size, and the date and time of the last update. It also identifies user permissions and group permissions. Discovery supports all file types. Classification is defined by decision plans. Each decision plan contains rules for recognizing a certain type of data. (Decision plans for File Activity Monitoring are analogous to classification policies for Data Activity Monitoring.) FAM classification for Linux® and Windows is based on [IBM Content Classification](#). Classification supports many types of files, including: Plain text, HTML, Office, PDF, PST (Microsoft Outlook folder; Microsoft Outlook must be installed), and NSF (Lotus Notes® database) format. Lotus Notes is not required but NSF is supported by running a script that is installed with IBM® Content Classification. For complete lists of supported text types, see [What data types are supported](#) and Oracle Text Supported Document Formats in Oracle documentation. Default decision plans exist for HIPAA, PCI, SOX, and Source Code. You can change the classification entities from the resulting reports or investigation dashboard, by using the default decision plans. In addition, you can create new plans, or modify existing plans, by using the Content Classifier workbench, a Windows application you upload to your collector appliance. See the requirements for IBM Content Classification Version 8.8, in the <http://www-01.ibm.com/support/docview.wss?uid=swg27020838> IBM technote. Plans are activated and configured through the Guardium® Installation Manager (GIM).

Discovery and classification are handled by a discovery agent, called the file crawler. The file crawler sends the file metadata, and data from its discovery and classification processes, to the Guardium system. The scan schedule is configurable. Subsequent (incremental) scans, after initial discovery and classification, identify incremental changes of new and changed files only. Install and configure the file crawler with the Guardium Installation Manager (GIM) just as you would any other bundle.

#### Monitor, Audit, and Block

FAM monitors, alerts, and blocks file access according to the Guardium policy rules. The rules specify which file servers and files to monitor and what actions to take if policy rules are violated, for example, log the violation, alert, or block access. Monitored Operations are Read, Write, Execute, Delete, Change Owner, Permissions, Properties. Any activity that matches the security policy rules criteria is sent to the Guardium collector where it is stored in the Guardium repository. (FAM is different from database activity monitoring, where the S-TAP sends all data activity to Guardium for monitoring.) All events that are recorded in the Guardium repository are audited events.

In UNIX servers, file activity monitoring is implemented by the S-TAP, running on the file server. For NFS volumes, it is important that an S-TAP installed and configured on all servers that access those volumes. One S-TAP agent can manage both file server and database activity monitoring. If you have licenses for both capabilities, you can use the same S-TAP agent for both file and database activity monitoring. Install and configure S-TAP with the Guardium Installation Manager (GIM) just as you would any other bundle.

In Windows servers, file activity monitoring is implemented by the FamMonitor bundle. It is installed independently from S-TAP.

UID chain for FAM: FAM identifies the process and the user that performed the access (and not external programs). For instance if Process 1 (`user janedoe`) creates Process 2 (`user johndoe`), then for file events that are related to process 2, FAM reports the UID chain of `{janedoe, johndoe}`. For example,

```
(1,root,systemd)>(10077,root,sshd)>(50136,root,sshd)>(50169,donald,sshd)>(50170,donald,bash)->(50217,donald,ls)
```

UID chain is always enabled in Windows databases. For Linux-Unix, enable the UID chain with the `hunter_trace` parameter. For more information, see [Linux-Unix: General Parameters](#).

Monitoring activities are presented in the following predefined reports: **Users privileges**, **File privileges**, **Count of activity per user**, **Count of activity per client**, **Files open to “public”**, **Dormant users**, **Dormant Files**, and others. In addition, monitoring activities are also shown in the **FAM – Access report** (log of all monitored activity), and in the Investigation Dashboard.

Access to files can also be blocked, even if the operating system permissions allow access. The rules are preinstalled into the S-TAP, which then loads them into the file system filter driver. The driver blocks access to the file so that the data in the file is never delivered to the user.

Important: Windows Administrator and Linux ROOT user activities are not monitored or blocked by File Activity Monitoring.

## High level workflow for file activity monitoring

Use this general workflow to plan and execute file activity monitoring on file servers in the Linux, Unix and Windows environments.

Prerequisites:

- FAM license keys must be installed.
- For UNIX file servers: S-TAP for FAM is installed.
- For Windows file servers: FamMonitor bundle is accessible
- CentOS v7.9 requires that the following libraries are installed: **32-bit libstdc+5 and libstdc+6**
- FAM discovery agent (also known as the FAM bundle or FAM agent) must be accessible. Required for file discovery and classification. Download from [Fix Central](#) or obtain from your Guardium representative.
- Disk space requirements for FAM bundle: 2GB. AIX platforms require an additional 2GB during installation.
- To install the FAM discovery agent successfully on AIX, it is recommended to set the process data size to unlimited. Access the file `/etc/security/limits` and change this line to **default: data = -1**.
- Supported servers and platforms are listed in <https://supportcontent.ibm.com/support/pages/node/6245402>.
- For complete lists of supported data types, see [What data types are supported](#) and Oracle Text Supported Document Formats in Oracle documentation.

**Windows servers only:** From V11.0, the FAM monitor package is a standalone package, and is installed independently. (It is not installed with S-TAP, as it was in previous releases.) When upgrading to v11.0, whether or not you use the GDPR accelerator:

- If you're using FAM and S-TAP: Upgrade the STAP to 11.0. This uninstalls the previous FAM (FsMonitor driver and StapAT service). Then install the 11.0 FAM crawler and FamMonitor.
- If you're using FAM only: Uninstall the S-TAP. This uninstalls the previous FAM (FsMonitor driver and StapAT service). Then install the 11.0 FAM crawler and FamMonitor.

## FAM GDPR Accelerator

Use the FAM GDPR Accelerator to guide you through the entire process of enabling and configuring FAM, including for GDPR compliance. The Accelerator supports Windows, Linux, and UNIX platforms.

1. Access the Module upload page: Accelerators > GDPR > Assess > Prepare > Upload FAM Module for GDPR, and upload the FAM module.
2. Follow the instructions in the GDPR Accelerator GUI page to complete the FAM GDPR configuration. See the overview in Accelerators > GDPR > GDPR Compliance.
3. See the rules that can be used to create decision plans for FAM GDPR in [Rules for GDPR File Activity](#).

## FAM without GDPR Accelerator

If you are not using the FAM GDPR Accelerator, use this workflow for file activity monitoring:

1. Install the FAM crawler for discovery and classification.
  - a. For UNIX file servers. This also installs the monitoring capabilities: [Installing and activating the FAM discovery agent \(crawler\) on UNIX servers](#).
  - b. For Windows file servers: [Installing and activating FAM discovery agent \(crawler\) on Windows servers](#).
  - c. Configure [File discovery and classification GIM parameters](#).
2. Windows servers only: Install the FamMonitor installation package, see [Installing and activating the FamMonitor on Windows servers](#).
3. Monitor and investigate results:
  - Review File activity in reports, including the following predefined reports: File Activities, File Entitlement, Files Count of Activity Per Client, Files Count of Activity Per Server, Files Count of Activity Per User, Files Privileges.
  - For ongoing investigation and analysis, use Investigation Dashboards, which include text search and outliers capability as well as enhanced visualizations. See:
    - [Investigation Dashboard for files](#)
    - [Interpreting file activity outliers in the investigation dashboard](#)
4. Protect: create and apply policies for ongoing monitoring and protection for file servers. See [File Activity policies for UNIX and Windows file servers](#).  
Note: FAM rules might not be applied to certain operations on file descriptors, such as changing the owner or permissions for a file, on these platforms:
  - AIX
  - 12.1 and later Solaris

## File activity monitoring for NAS and SharePoint

Guardium monitors file activity, and perform discovery and classification on NAS devices and SharePoint servers in a Windows environment.

- For monitoring of activity across files and directories residing on NAS devices and SharePoint in the Windows environment, see [File Activity Monitor for NAS and SharePoint](#).

- For discovery, entitlement and classification of files and directories residing on NAS devices and SharePoint in the Windows environment, see [Discovery and Classification for NAS and SharePoint](#).

## Key concepts and tools

Information about key concepts pertaining to Guardium administration.

- [Queries and reports](#)

Guardium queries describe a set of information obtained from the collected data. Each query has a corresponding report with the same name.

- [Access control](#)

Guardium provides access maps as a way to conveniently show data access between database clients and database servers.

- [User roles](#)

A role defines a group of Guardium users who share the same access privileges.

- [Groups](#)

Guardium supports the grouping of elements to simplify creating and managing policies and to clarify the presentation of reports.

- [Data archive and purge](#)

Data Archive backs up data that has been captured by a Guardium system. When configuring Data Archive, data purge criteria may also be specified.

- [Guardium Installation Manager](#)

The Guardium Installation Manager (GIM) is used to install and maintain Guardium components on managed systems.

## Queries and reports

Guardium queries describe a set of information obtained from the collected data. Each query has a corresponding report with the same name.

Guardium queries describe a set of information obtained from the collected data. Queries are based on three elements: entities, fields, and conditions. Entities define the scope of a query, fields list the columns of data to be returned by the query, and conditions define tests to match against the data (greater than, less than, contains, etc.)

The default report is a tabular report, with each attribute displayed in a separate column. All runtime parameters and presentation components of a tabular report can be customized.

## Access control

Guardium provides access maps as a way to conveniently show data access between database clients and database servers.

Data access by applications and tools can be categorized according to many dimensions, including what data is being accessed, how it is being accessed, or how many SQL calls are being made. In an enterprise environment, it is very important to get a good handle on database access. This requirement can stem from the need to understand and secure access to the database due to compliance initiatives and even due to the need to tune and optimize your database environment. Because there can be many databases and a very large number of database clients in enterprise environments, getting a handle on the data access paths can be difficult.

The deployment health topology and table views show the data flow relationships between systems in your environment. These views make it easy to identify problematic systems and investigate the underlying issues. Access the topology view by navigating to [Manage > System View > Deployment Health Topology](#). Access the table view by navigating to [Manage > System View > Deployment Health Table](#).

## User roles

A role defines a group of Guardium users who share the same access privileges.

When a role is assigned to an application or the definition of an item (a specific query, for example), only those Guardium users who are also assigned that role can access that component. If no security roles are assigned to a component (a report, for example), only the user who defined that component and the admin user can access it.

At installation time, Guardium is configured with a default set of roles and a default set of user accounts. The Guardium access manager can create new roles and modify existing roles as needed.

## Groups

Guardium supports the grouping of elements to simplify creating and managing policies and to clarify the presentation of reports.

Grouping can simplify the process of creating policy and query definitions. It is often useful to group elements of the same type, and grouping can make the presentation of information on reports more straightforward. Groups are used by all subsystems, and all users share a single set of groups.

For an example of grouping, assume that your company has 25 separate data objects containing sensitive employee information, and you need to report on all access to these items. You could formulate a very long query testing for each of the 25 items. Alternatively, you could define a single group called sensitive employee info containing those 25 objects. That way, in queries or policy rule definitions, you only need to test if an object is a member of that group.

An additional benefit of groups is that they can ease maintenance requirements when the group's composition changes. To continue the example, if your company decides that two more objects need to be added to the sensitive employee info group, you only need to update the group definition and not all of the queries, reports, and policies that reference the group.

## Data archive and purge

Data Archive backs up data that has been captured by a Guardium system. When configuring Data Archive, data purge criteria may also be specified.

There are two archive operations: Data Archive and Results Archive. The path to these archive operations is Manage > Data Management > Data Archive or Results Archive (Audit).

### Data Archive

With Data Archive, data is typically archived at the end of the day on which it is captured, which ensures that in the event of a catastrophe, only the data of that day is lost. The purging of data depends on the application and depends on business and auditing requirements, but in most cases data can be kept on the machines for more than six months.

### Results Archive

Results Archive backs up audit task results (e.g. reports, assessment tests, entity audit trail, privacy sets, and classification processes) as well as the view and sign-off trails and the accommodated comments from workflow processes. Results sets are purged from the system according to the workflow process definition.

In an aggregation environment, data can be archived from the collector, from the aggregator, or from both locations. Most commonly, the data is archived only once, and the location from where it is archived varies depending on the customer's requirements.

Purge is enabled by default, at a 60 day interval.

## Related tasks

- [Managing stored data](#)
- [Purging data](#)

## Guardium Installation Manager

The Guardium Installation Manager (GIM) is used to install and maintain Guardium components on managed systems.

The GIM component includes a GIM server, which is installed as part of the Guardium system, and a GIM client, which must be installed on servers that host databases and file servers you want to monitor. After installing the GIM client, it works with the GIM server to perform the following tasks:

- Check for updates to installed software
- Transfer and install new software
- Uninstall software
- Update software parameters

If your environment includes a Guardium system configured as a Central Manager, you must decide which Guardium systems you want to use as GIM servers. You can either manage all of your GIM clients from a single Guardium system, such as the central manager, or you can manage them in groups from the different Guardium systems. If you manage all of your GIM clients from a single Guardium system, then you can view the status of all the GIM clients and perform related tasks from a single interface. If you choose to manage your GIM clients in groups from separate Guardium systems, then you can use each system to work with the GIM clients that it manages, but no overall or environment-wide view is available.

## Discover

Discovery refers to processes of locating and identifying objects in your environment that must be tracked for security and compliance purposes.

Discovery is the process of finding important objects such as privileged users, sensitive data, and datasources. Classification is the process of appropriately identifying what is discovered for security and compliance purposes. These processes of discovery and classification are important in large organizations where mergers, acquisitions, and legacy systems introduce new objects to your environment in unstructured or unpredictable ways. GuardiumGuardium® helps you incorporate these objects into your environment so you can enforce effective security policies and ensure compliance.

A common scenario involves the discovery of sensitive data. Sensitive data refers to regulated information like credit card numbers, personal financial data, social security numbers, and other information that requires special handling. Guardium supports two different approaches for discovering sensitive data: by using the Discover Sensitive Data workflow builder, or by using the Policy Builder with other Guardium tools. The Discover Sensitive Data workflow builder is intended as an all-inclusive tool for establishing discovery and classification processes for sensitive data. Use it to specify rules for discovery, define actions to take on discovered data, specify which data sources to scan, distribute reports, and run the workflow on an automated schedule. For more advanced users, the Policy Builder supports more granular discovery and classification rules that can be easily incorporated into existing processes and Guardium applications.

- [Datasources](#)

Datasources store information about your database or repository such as the type of database, the location of the repository, or credentials that might be associated with it. You must define a datasource in order to use it with Guardium applications.

- [Database Auto-discovery](#)

The Auto-Discovery application scans and probes your servers for open ports to prevent unknown or unwanted connections to your network. You can run auto-discovery processes on demand, or schedule the processes on a periodic basis.

- [Cloud database service protection](#)

Protect your cloud databases by using data activity stream monitoring or by using native audit.

- [Database discovered instances rules](#)

Use the Database Discovered Instances Rules UI from a central manager to determine how to manage inspection engines for discovered databases.

- [Classification](#)

Classification policies and processes define how Guardium discovers and treats sensitive data such as credit card numbers, social security numbers, and personal financial data.

- [Discover Sensitive Data](#)  
Create an end-to-end scenario for discovering and classifying sensitive data.
  - [Runtime sensitive-object identification](#)  
Runtime sensitive-object identification processes response data looking for predefined patterns that match personally-identifiable and other sensitive information.
  - [Regular Expressions](#)  
Regular expressions can be used to search traffic for complex patterns in the data.
  - [FAM discovery and classification in Windows and UNIX-Linux file servers](#)  
File activity discovery and classification ensures integrity and protection of sensitive data on UNIX-Linux and Windows file servers.
  - [File discovery and classification for NAS and SharePoint](#)  
File Discovery, Entitlement and Classification (FDEC) for NAS and SharePoint servers enables scanning for file entitlement and classification of sensitive data which may be related to regulatory laws (e.g., GDPR, HIPAA).
  - [Entitlement Optimization](#)  
Entitlement Optimization mediates between the role of the DBA in providing users the entitlements that are required to perform their jobs efficiently, and the role of Security in keeping entitlements as accurate and as minimal as possible to prevent system vulnerabilities.
- 

## Datasources

Datasources store information about your database or repository such as the type of database, the location of the repository, or credentials that might be associated with it. You must define a datasource in order to use it with Guardium® applications.

- [Creating a datasource definition](#)  
A datasource is a database connection that is created and configured for use with Guardium applications such as Vulnerability Assessment and classifier. A datasource can be created by using the Datasource Definitions tool or by creating and uploading a CSV file by using the Customer Uploads tool in the Guardium user interface. You can also create a datasource by using Guardium APIs.
  - [Creating a datasource group](#)  
A datasource group is a collection of datasources that you can act on as a single unit. You can specify a datasource group in most Guardium applications where you can specify a single datasource, such as security assessments, classification, and discovery scenarios. Create datasource groups from the Datasource Definitions page in the Guardium UI or by using Guardium APIs.
  - [Configuring your datasource](#)  
The configuration varies depending on the type of database you are using.
  - [Configuring custom properties for your datasources](#)  
Enrich your datasources by defining and assigning custom properties.
  - [Working with existing datasources](#)  
After you create a datasource definition, you can clone, modify, or delete the datasource.
  - [Reporting on datasources](#)  
Guardium provides reports on the datasources that are in your environment and any changes made to them.
  - [Defining a datasource using a service name](#)  
You can define a datasource that enables your users to connect to an Oracle database by using the service name by using a custom URL.
  - [Managing KDC definitions](#)  
If your datasource requires authentication using Kerberos, you can specify the information needed for Guardium to obtain a Kerberos ticket before making the connection.
  - [Managing datasource credentials with CyberArk](#)  
Guardium supports the CyberArk Application Password Provider, a robust solution to the numerous maintenance and security challenges that arise in managing passwords. Use CyberArk to securely store, provision, audit, and manage your Guardium datasource credentials.
  - [Managing datasource credentials with AWS Secrets Manager](#)  
Integrate your Guardium system with the Amazon Web Services (AWS) Secrets Manager to securely store, manage, rotate, and retrieve credentials for your datasources that use the Amazon Relational Database Service (RDS).
  - [Managing datasource credentials with HashiCorp](#)  
Integrate your Guardium system with HashiCorp to securely store, manage, rotate, and retrieve credentials for all supported datasources. You can configure your Guardium system to authenticate to the HashiCorp vault by using a username and password with no Transport Layer Security (TLS), server-side authentication with TLS, or client-side authentication with TLS. If you use client-side authentication with TLS, you must create and import a client signed certificate on all your systems such as the central manager and managed units, if any.
- 

## Creating a datasource definition

A datasource is a database connection that is created and configured for use with Guardium® applications such as Vulnerability Assessment and classifier. A datasource can be created by using the Datasource Definitions tool or by creating and uploading a CSV file by using the Customer Uploads tool in the Guardium user interface. You can also create a datasource by using Guardium APIs.

### Before you begin

Ensure that the Guardium user has the privileges that are necessary to access the database. To assign database access privileges to a user, the database administrator must download and run a set of scripts on the database server. For more information, see [Database privileges for vulnerability assessments and classification](#).

You can also create a datasource group for any applications that use datasources. A datasource group can be static (based on available datasources), or dynamic (based on criteria).

### About this task

Use the following procedure to define a datasource by using the Datasource Definitions tool.

### Procedure

1. Open the Datasource Definitions tool by clicking **Setup > Tools and Views > Datasource Definitions**.
2. Click the **Datasources** tab.
3. Click  to open the Create datasource window. The inputs vary depending on your choice of application, database type, and datasource.
4. Select an Application type.
5. Enter a unique name for the datasource.
6. From the Database type menu, select the database or type of file.
7. Select Share datasource to share the datasource definition across all Guardium applications. If the datasource is not shared, you can use the definition only with the selected application type.
8. The authentication protocol depends on your choice of Database type.
  - Select Use SSL and Import server SSL certificate. The Add certificate option is available to datasources that support mutual SSL authentication. The certificate for mutual SSL authentication is added after the datasource configuration is saved.
  - To use LDAP authentication, select LDAP and proceed with assigning datasource credentials.
  - For Kerberos, pick a predefined Kerberos configuration from the Kerberos config menu and enter the Realm and KDC server.  
Tip: To check whether a Kerberos configuration exists on the Guardium GUI, go to **Setup > Tools and Views > Kerberos Configuration**. To create a new Kerberos configuration that defines your KDC and Realm, click .

The login credentials must be a valid Kerberos user ID and password that is also used for certificate authority (CA). Test your Kerberos credentials to ensure that it can be used to log in to the Hive beeline command line.
9. Select the appropriate Credential type.
  - Choose Assign credentials to manually enter the User name and password for the datasource.
  - Choose External password to obtain your password from an external credential management system. Select your credential management application from the External password type menu.
  - If credentials are not assigned, choose None.
10. Configure the Host name/IP address, Port number, Database, Connection property, and Custom URL. If you use Configuration Auditing System (CAS), click the Advanced tab and configure the CAS database instance.  
Tip: The inputs vary depending on the type of database you are using. For more information, see [Configuring your datasource](#).
11. Optional: Click the Custom tab and select a property from a list of customized values to assign to the datasource. If the custom properties are not configured, you can temporarily save the datasource and assign the properties later. For more information, see [Configuring custom properties for your datasources](#).
12. Save the datasource and test the connection. If applicable, add the mutual SSL authentication certificate by using the Add certificate button.  
The certificate is a PEM file that contains both the private key and the certificate. You must include both the BEGIN and END lines for the private key and certificate. You can also install the certificate by using the CLI. For more information, see [Installing an appliance certificate](#).  
Note: When you test the connection to an SSL datasource for the first time, you might encounter the following error:

```
Could not connect to: 'jdbc:db2://hostname:port_number/db_name' for user: 'Your_datasource_name_DB2(Security Assessment)'. DataSourceConnectException: Could not connect to: 'Your_datasource_name_123.123.123.123:port_number' for user: 'db2inst1'. Exception: com.ibm.db2.jcc.am.DisconnectNonTransientConnectionException: [jcc][t4][2030][11211] [4.15.134] A communication error occurred during operations on the connection's underlying socket, socket input stream.
```

The error occurs when the GUI does not have the correct keystore file for the certificate that is loaded into memory. To fix the error, restart the GUI and test the connection again.

## What to do next

You can use the options in the menu to test the connection for one or more datasources, add the datasources to a group, and update the credentials or custom properties, if necessary.

## Creating a datasource group

A datasource group is a collection of datasources that you can act on as a single unit. You can specify a datasource group in most Guardium® applications where you can specify a single datasource, such as security assessments, classification, and discovery scenarios. Create datasource groups from the Datasource Definitions page in the Guardium UI or by using Guardium APIs.

## Before you begin

Make sure that you have the necessary privileges to access the database.

## About this task

Use the following procedure to define a datasource group from the Datasource Definitions page.

## Procedure

---

1. From the Guardium UI, browse to Setup > Tools and Views > Datasource Definitions.

2. Click the Datasource groups tab.

When you open the tab, the table is always populated with the All datasources group.

To view the datasources in any group, click the  icon in the Group name column.

3. Click  to open the Create group window.

Note: From Datasource groups, you can select an existing datasource group and click  to clone the datasource group. The copy of the selected group opens in the Create group window.

4. Enter a name for the new group.

5. Select the Group type

- Datasources based on criteria - Specify criteria to find existing datasources to include in the group. Use the dropdown lists to select the datasources for your group based on Datasource type, Application type, and Severity. You can also specify a User name or Host name/IP to narrow the datasources to include in this group.
- Selected datasources - Select existing datasources from the Available Datasources table.

- From the Available Datasources table, you can take the following actions:

- Click  to create a new datasource.
- Select a datasource and click  to update that datasource.
- Use the Filter box to filter on the datasource name, type, hostname or IP address, or username.
- Select the datasources that you want to include in the group. You can select the checkbox in the table heading to select all available datasources. If you created a filter, only the filtered datasources are selected.

- After you create the list of datasources for your group, click  to move the selected list to the Selected Datasources table.

6. Optionally, click Roles to assign one or more roles to this group.

7. When you are done, click Save to save your group.

## What to do next

---

You can specify a datasource group in most Guardium applications that accept datasources, including classification and Vulnerability Assessments (VA). You can edit or copy any existing datasource group, including the All datasources group.

You can also create and manage datasource groups by using GrdAPIs or REST APIs. The datasource group APIs all contain the words **datasource\_groupRef** in their name.

Parameters to configure a text datasource.

## Amazon DynamoDB

12.1 and later Configure an Amazon DynamoDB datasource on your Guardium® system.

### Supported Authentication Methods

| AWS Authentication   | Supported |
|----------------------|-----------|
| Security Credentials | Yes       |
| IAM role             | Yes       |
| IAM instance profile | Yes       |

Note: To set up and configure the AWS authentication type for your Guardium datasource, see [Selecting the authentication type and setting up roles](#).

### Parameters

| Field                            | Description                                                                                           |
|----------------------------------|-------------------------------------------------------------------------------------------------------|
| AWS authentication configuration | Required. The name of the AWS authentication configuration.                                           |
| Region                           | Required. The location of your data center region that is configured on your AWS management console.. |

## Amazon Redshift

Configure an Amazon Redshift datasource on your Guardium® system.

### Supported Authentication Methods

| <b>Authentication</b> | <b>Supported</b> |
|-----------------------|------------------|
| Local user            | Yes              |
| LDAP                  | No               |
| Kerberos              | No               |
| SSL                   | Yes              |
| Mutual SSL            | No               |

Note:

SSL certificates are included with the JDBC driver that Guardium uses to connect to Amazon Redshift. The default authentication method is SSL.

## Parameters

| <b>Field</b>        | <b>Description</b>                                                                                                                                                                                                                                                                               |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname of the datasource.                                                                                                                                                                                                                                                        |
| Port number         | Required. Default value: 5439                                                                                                                                                                                                                                                                    |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |

## Apache Cassandra

Configure an Apache Cassandra datasource on your Guardium® system.

Note: To use this feature, you must install the latest Guardium Vulnerability Assessment patch for version 11.5.

## Supported Authentication Methods

| <b>Authentication</b> | <b>Supported</b> |
|-----------------------|------------------|
| Local user            | Yes              |
| LDAP                  | No               |
| Kerberos              | No               |
| SSL                   | Yes              |
| Mutual SSL            | Yes              |

## Parameters

| <b>Field</b>        | <b>Description</b>                                                                                                                                                                                                                                                                               |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 9042.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| <b>Field</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account      | The name of the account owner.<br>Example: cassandra                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Directory    | The name of the installation directory.<br>Define pipe separated variables for all Apache Cassandra datasources that run CAS scripts or templates.<br><br>Example:<br><code>/home/cassandra   installpath=/home/cassandra/apache-cassandra-4.x   logpath=/home/cassandra/apache-cassandra-4.x/log   CASSANDRA_CONF_PATH=/home/cassandra/apache-cassandra-4.x/conf</code><br><br>Where: <ul style="list-style-type: none"><li>• home/cassandra : is the home directory path for the Cassandra user. This entry is required.</li><li>• installpath=/home/cassandra/apache-cassandra-4.x : is the Red Hat Package Manager (RPM) default installation location. For .tar files, use the path to the folder where Apache Cassandra was extracted.</li><li>• logpath=/home/cassandra/apache-cassandra-4.x/log : is the default path to the log file. This path can be modified.</li><li>• CASSANDRA_CONF_PATH=/home/cassandra/apache-cassandra-4.x/conf : is the default RPM location of the configuration file. The default .tar file path is \$installpath/conf.</li></ul> |

### Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

### Parameters

---

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 2406.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.<br>Example: beehive                                                                                                                                                                                                                                                    |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

---

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                       |
|-----------|-------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: beehive                |
| Directory | The name of the installation directory.<br>Example: /home/beehive |

## Cloudera Manager

---

Configure a Cloudera Manager datasource on your Guardium® system.

### Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

### Parameters

---

| Field               | Description                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                        |
| Port number         | Required. Default value: 7184.                                                                                                                                                                 |
| Cluster name        | Required. The display name of the Cluster in the Cloudera Manager GUI.                                                                                                                         |
| Connection property | Properties that must be included to establish a connection with the datasource.<br>The Cloudera Manager datasource uses the Cloudera Manager Java™ API for a connection. It does not use JDBC. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                      |

## CAS (Configuration Auditing System) database instance

---

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                   |
|-----------|-------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: root                               |
| Directory | The name of the installation directory.<br>Example: installpath=/opt/cloudera |

---

## CockroachDB

12.1 and later Configure a CockroachDB datasource on your Guardium® system.

### Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

---

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 26257.                                                                                                                                                                                                                                                                  |
| Database            | Required. The name of the database.<br>For example, defaultdb.<br>For Vulnerability Assessment (VA) tests that require scanning other databases, the VA assessment scan will get a list of all required databases from the CockroachDB instance and run the test.                                |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

---

## Couchbase

Configure a Couchbase datasource on your Guardium® system.

You must configure one datasource per Couchbase instance.

### Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | Yes       |

## Steps to create, configure, and import the SSL client certificate into your Guardium system

---

1. Use the Couchbase online documentation to setup Couchbase Server's support of X.509 certificates.
2. When you configure the server certificates, create a customized certificate extensions file, which adds the node constraints to the generic constraints that are already specified. Add both IP and DNS with hostname to the `subjectAltName` to avoid getting an error. For example: `echo "subjectAltName = IP:9.42.32.60,DNS:dba-informix02.rtp.raleigh.ibm.com" \>> ./server.ext.tmp.`
3. Use the Couchbase online documentation to create an SSL client certificate to import into your Guardium system. The SSL client certificate must contain the client certificate and its private key.
4. Create an SSL Datasource on your Guardium system.

## Parameters

---

| Field        | Description                                             |
|--------------|---------------------------------------------------------|
| Host Name/IP | Required. The hostname or IP address of the datasource. |

| Field               | Description                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port number         | Required. Default value: 8091<br>When you connect using custom ports, use the externally visible ports on the client side.<br><br>For cluster manager ports, enter the custom port number.<br><br>For custom query service port (kv port) enter the custom value in the Connection property field by using the format in this example:<br>customKvPort=11214 |
| Database            | The name of the database.<br><br>If LDAP authentication is used, specify a valid bucket name for the database.<br>Note: All the Couchbase vulnerability assessment tests are configuration tests and privilege tests. The tests do not scan or access any data that's stored in a bucket.                                                                    |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.                                                             |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | For the default installation of Couchbase, enter the "root" user. For a non-root or non-sudo installation, enter the OS user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Directory | The name of the installation directory.<br>You can specify multiple paths for the database instance directory. Indicate a separate path by using a pipe " " with spaces.<br><br>For example:<br>/root installpath=opt/couchbase.<br><br>Where:<br>/root is the instance account directory.<br>installpath=opt/couchbase is the installation directory.<br><br>When you install Couchbase with an RPM package, you must have root or sudo privileges. It is likely that the home directory of root user /root is the instance account directory. For a non-root or non-sudo installation, the instance account directory is the home directory of the OS user account under which Couchbase is installed.<br><br>When you install Couchbase with an RPM package, the installation directory is /opt/couchbase by default. For a non-root or non-sudo installation, enter the path to the installation location. For example: /home/cb651/cb/opt/couchbase. |

## DataStax Cassandra

Configure a DataStax Cassandra datasource with DataDirect connection on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 9042.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field | Description |
|-------|-------------|
|       |             |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: <code>cassandra</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Directory | The name of the installation directory.<br>Define pipe separated variables for all DSE Cassandra datasources that run CAS scripts or templates.<br><br>Example:<br><br><code>/var/lib/cassandra   installpath=/var/lib/cassandra   logpath=/var/log/cassandra   compath=/usr/share/dse   CASSANDRA_CONF_PATH=/etc/dse/cassandra   DSE_CONF_PATH=/etc/dse</code><br><br>Where: <ul style="list-style-type: none"> <li>• <code>/var/lib/cassandra</code> Is the home directory path for the Cassandra user. This entry is required.</li> <li>• <code>installpath=/var/lib/cassandra</code> Is the Red Hat Package Manager (RPM) default installation location. For .tar files, use the path to the folder where DataStax Enterprise was extracted.</li> <li>• <code>logpath=/var/log/cassandra</code> Is the default path to the log file. This path can be modified.</li> <li>• <code>compath=/usr/share/dse</code> Is the default RPM path to the location of the components. The components are DSE Analytics, DSEFS, DSE Search, DSE Graph, DSE Advanced Replication, DSE In-Memory, DSE Multi-Instance, DSE Tiered Storage and DSE Performance services. The default .tar file path is <code>\$installpath/resources</code>.</li> <li>• <code>CASSANDRA_CONF_PATH=/etc/dse/cassandra</code> Is the default RPM location of the configuration file. The default .tar file path is <code>\$installpath/resources/cassandra/conf</code>.</li> <li>• <code>DSE_CONF_PATH=/etc/dse</code> Is the default RPM location. The default .tar file path is <code>\$installpath/resources/dse/conf</code>.</li> </ul> |

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                        |
| Database name       | The name of the database.                                                                                                                                                                                                                                                                                      |
| Port number         | Required. Default value: <code>50000</code> .                                                                                                                                                                                                                                                                  |
| Schema              | The name of the database schema.                                                                                                                                                                                                                                                                               |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is <code>property1=value;property2=value</code> , where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.<br>Example: For an encrypted connection, enter <code>securityMechanism=13</code>                                                     |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: <code>db2inst1</code>                                                                                                                                                                                     |
| Directory | The name of the installation directory.<br>Usually the home directory of db2inst1 or C:\Program Files\IBM\SQLLIB on Windows<br><br>The program db2cmd.exe must be on the system path, or in the bin subdirectory of the Database Instance Directory. |

## Db2 for i

Configure a Db2® for i datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 446.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Service name        | The service name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Schema              | The name of the database schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br><br>When a password is due to expire, a warning prompt appears 7 days before the expiration date. This expiration message might cause the login to fail. To avoid this scenario, add <code>prompt=false</code> to the connection properties. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.<br>Example: <code>property1=com.ibm.as400.access.AS400JDBCDriver;translate binary=true</code>                                                                                                                                                                                                                                                                          |

## Db2 for z/OS

Configure a Db2® for z/OS® datasource on your Guardium® system.

## Prerequisite

Download and install the Db2 for z/OS JDBC license file from Passport Advantage. For more information, see [Uploading a JDBC license file for mainframe hosts to the Guardium system](#).

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                        |
| Location name       | Required. The location of the database.                                                                                                                                                                                                                                                                                                                                        |
| Port number         | Required. Default value: 446.                                                                                                                                                                                                                                                                                                                                                  |
| Schema              | The name of the database schema.                                                                                                                                                                                                                                                                                                                                               |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>To enhance database performance, enter <code>resultSetHoldability=2</code> |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                      |

## EDB PostgreSQL

Configure an EnterpriseDB PostgreSQL datasource on your Guardium® system.

## Supported Authentication Methods

| <b>Authentication</b> | <b>Supported</b> |
|-----------------------|------------------|
| Local user            | Yes              |
| LDAP                  | No               |
| Kerberos              | No               |
| SSL                   | Yes              |
| Mutual SSL            | Yes              |

## Parameters

| <b>Field</b>        | <b>Description</b>                                                                                                                                                                                                                                                                               |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 5432.                                                                                                                                                                                                                                                                   |
| Database            | Required. The name of the database.<br>For example, postgres.<br>For Vulnerability Assessment (VA) tests that require scanning other databases, the VA assessment scan will get a list of all required databases from the EDB PostgreSQL instance and run the test.                              |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| <b>Field</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account      | The name of the account owner.<br>Example: enterpriseedb                                                                                                                                                                                                                                                                                                                                                                                                          |
| Directory    | The name of the installation directory.<br>You can specify multiple paths for the database instance directory. Indicate a separate path by using a pipe " " with a space before and after the delimiter.<br><br>For example: /var/lib/edb   PostgreSQL_DATA=/var/lib/edb/as14/data<br><br>Note: PostgreSQL_DATA should be the same path as the PGDATA environment variable. It is the data directory from where the EDB PostgreSQL cluster (instance) is running. |

## GreenplumDB

Configure a GreenplumDB datasource on your Guardium® system.

## Supported Authentication Methods

| <b>Authentication</b> | <b>Supported</b> |
|-----------------------|------------------|
| Local user            | Yes              |
| LDAP                  | No               |
| Kerberos              | No               |
| SSL                   | No               |
| Mutual SSL            | No               |

## Parameters

| <b>Field</b>        | <b>Description</b>                                                                                                                                                                                                                                                                               |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 5432.                                                                                                                                                                                                                                                                   |
| Database            | Required. The name of the database.                                                                                                                                                                                                                                                              |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## Guardium Big Data Intelligence

Configure a Guardium® Big Data Intelligence (GBDI) datasource on your Guardium system.

## Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | Yes       |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

---

| Field               | Description                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                   |
| Port number         | Required. Default value: 27117.                                                                                                                                           |
| Database            | The name of the database.                                                                                                                                                 |
| Connection property | Properties that must be included to establish a connection with the datasource.                                                                                           |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number. |

## Hive

---

Configure a Hive datasource on your Guardium® system.

To set up a Hive datasource, use the Apache Hive JDBC driver 1.1.1.

## Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | Yes       |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

---

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 10000.                                                                                                                                                                                                                                                                  |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

---

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                   |
|-----------|-------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: root                               |
| Directory | The name of the installation directory.<br>Example: installpath=/opt/cloudera |

## Informix

---

Configure an Informix® datasource on your Guardium® system.

## Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |

| Authentication | Supported |
|----------------|-----------|
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Port number         | Required. Default value: 1526                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Informix server     | The name of the Informix server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Database            | The name of the database.<br>The default is sysmaster.<br><br>When the database name is sysmaster, the db_locale that is specified in the connection property field is used to connect to the sysmaster database.<br>For other databases, the db_locale in the sysdbslocale table is used.                                                                                                                                                                                                                                                                          |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br><br>For Informix Unicode databases, the connection property <code>IFX_USE_STRENC=true</code> might be required.<br><br>Use the CLI command <code>store set_informix_driver_property</code> to set <code>IFX_USE_STRENC=true</code> on all Informix datasources. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                                                                                                                           |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>Example: informix                                                                                                                                                                                                                                                                                                                                                         |
| Directory | The name of the installation directory.<br>On UNIX, the default is /opt/IBM/informix<br><br>On Windows, the default is C:\Program Files\IBM\Informix<br><br>An environment variable INFORMIXDIR can be defined.<br>The program <code>servicename.cmd</code> must be on the system path, where <code>servicename</code> is the name of the Informix server that is defined in the Datasource Definition GUI. |

## MariaDB

Configure a MariaDB datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Database name       | The name of the database.                                                                                                                                                                                                                                                                        |
| Port number         | Required. Default value: 3306.                                                                                                                                                                                                                                                                   |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field   | Description                    |
|---------|--------------------------------|
| Account | The name of the account owner. |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Directory | <p>The name of the installation directory.<br/>An environment variable <i>MYSQL_HOME</i> may be defined.</p> <p>Example for rpm and yum installation: <i>MARIADB_HOME=/var/lib/mysql/</i></p> <p><i>MARIADB_HOME</i> (from MariaDB 10.6) is the environment variable that shows the path to the directory that contains the server-specific <i>my.cnf</i> file. If there is a <i>my.cnf</i> file in the MariaDB data directory but not in the MariaDB base directory, then <i>MARIADB_HOME</i> is set to the MariaDB data directory. Otherwise, <i>MARIADB_HOME</i> is set to the MariaDB base directory.</p> |

## MongoDB

Configure a MongoDB datasource on your Guardium® system.

### Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | Yes       |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Port number         | Required. Default value: 27017.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Database            | The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Connection property | <p>Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is <i>property1=value;property2=value</i>, where each property and value pair is separated by a semicolon.</p> <p>For examples, refer to the database vendor's JDBC documentation.</p> <p>Example:</p> <ul style="list-style-type: none"> <li>• <i>streamTypenio2 netty</i>: The stream type to use for connections. If unspecified, nio2 is used.</li> <li>• <i>sslInvalidHostNameAllowed=true false</i>: Specify whether invalid hostnames for SSL are allowed or not.</li> <li>• <i>connections.connectTimeoutMS=ms</i>: How long a connection takes to be open before it times out.</li> <li>• <i>socketTimeoutMS=ms</i>: How long a send or receive on a socket takes before it times out.</li> <li>• <i>maxIdleTimeMS=ms</i>: Maximum idle time of a pooled connection. A connection that exceeds this limit is closed.</li> <li>• <i>maxLifeTimeMS=ms</i>: Maximum life time of a pooled connection. A connection that exceeds this limit is closed.</li> </ul> |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

Important: To allow CAS scripts to run successfully as the *MONGOD* user, you must change the entry in */etc/passwd* from */bin/false* to */bin/bash*. By updating this file path, you can see data in the predefined CAS Saved Data report and avoid a potential No CAS Data result in your vulnerability assessment.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Account   | <p>The name of the account owner.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>• <i>mongodb</i></li> <li>• <i>mongos</i></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Directory | <p>The name of the installation directory.</p> <p>You can specify multiple paths for the database instance directory. Indicate a separate path by using a pipe "!" with spaces.</p> <p>For example, <i>/var/lib/mongo ! MongoBinary=/usr/bin ! dbpath=/var/lib/mongo ! logpath=/var/log/mongodb ! keytab=/home/keytab ! dbdumppath=/opt/backup ! sslpath=/etc/ssl ! keyfile=/home/mongod/mongo_server.keyfile</i>.</p> <p>Where:</p> <ul style="list-style-type: none"> <li>• <i>/var/lib/mongo</i> path is the home directory path for the MongoDB user. This entry is required.</li> <li>• <i>MongoBinary=/usr/bin</i> is the path to the MongoDB binary. The variable <i>MongoBinary</i> is case-sensitive.</li> <li>• <i>dbpath=/var/lib/mongo</i> is the path to the data files. In this example, it is the same as the MongoDB home directory.</li> <li>• <i>logpath=/var/log/mongodb</i> is the path to the MongoDB log.</li> <li>• <i>keytab=/home/keytab</i> is the directory to the MongoDB keytab file.</li> <li>• <i>dbdumppath=/opt/backup</i> is the directory to the MongoDB backup dump.</li> <li>• <i>sslpath=/etc/ssl</i> is the path to MongoDB SSL files.</li> <li>• <i>keyfile=/home/mongod/mongo_server.keyfile</i> points to the MongoDB keyfile.</li> </ul> <p>It is not required to define all the paths that are listed in this example. The paths that are not defined are not analyzed.</p> |

## MS SQL Server (DataDirect - Dynamic Port)

Configure an MS SQL Server DataDirect - dynamic port datasource on your Guardium® system.

The MS SQL Server DataDirect - dynamic port datasource can be used to connect dynamically to an MS SQL Server database when the dynamic function is enabled in the MS SQL Server database server. It can also be used to connect dynamically when a client does not have a defined port value.

### Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

### Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Instance name       | The name of the instance to which you want to connect on the server.                                                                                                                                                                                                                                                                                                                                                                                       |
| Database            | The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>Example: domain=domain_name;AuthenticationMethod=authentication_method;<br>encryptionMethod=encryption_method;validateServerCertificate=true_or_false. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                  |

### Adding custom properties for classification

To improve the performance of Guardium classification scans, you can add the following custom properties for Microsoft SQL Server.

- LARGE-TEXT-DATA-TYPE-MAX-LENGTH - By default, when scanning large data types like XML or VARCHAR(MAX), the classifier only samples the first 3000 characters. Use the LARGE-TEXT-DATA-TYPE-MAX-LENGTH property to define a custom length in the range of 0 - 2147483647 characters.
- MAXDOP - The MAXDOP property defines how many processors MS SQL Server uses for parallel plan execution. The default setting of 0 allows MS SQL Server to use all available processors (up to a maximum of 64). Setting MAXDOP to 1 prevents parallel plan generation. Allowed values are 0 - 32,767. For more information, see *Set the Max Degree of Parallelism Option* in the Microsoft SQL Docs.
- TRANSACTION-ISOLATION-LEVEL - When you add this property with *READ-UNCOMMITTED*, the classifier reads all rows (including uncommitted rows). *READ-UNCOMMITTED* is the only value currently supported for the TRANSACTION-ISOLATION-LEVEL property, and the value must be uppercase and include the hyphen. For more information, see *SET TRANSACTION ISOLATION LEVEL* in the Microsoft SQL Docs.

You can add or change custom properties from either the Guardium UI or by using GRDAPi commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can use GRDAPi to manage custom properties. For example, use the following to create MAXDOP and TRANSACTION-ISOLATION-LEVEL custom properties:

```
grdapicreate_datasource_custom_property name=MAXDOP values=1
grdapicreate_datasource_custom_property name="TRANSACTION-ISOLATION-LEVEL" values="READ-UNCOMMITTED"
```

Use the following to add the MAXDOP and TRANSACTION-ISOLATION-LEVEL properties to a MS SQL Server datasource:

```
grdapicreate_datasource_by_name customProps="TRANSACTION-ISOLATION-LEVEL=READ-UNCOMMITTED"
name="yourmssqlserverdatabasename"
grdapicreate_datasource_by_name customProps=MAXDOP=1 name="yourmssqlserverdatabasename"
```

Use the following to add additional MAXDOP values (where 2,4 indicates the list of values added):

```
grdapicreate_datasource_custom_property name=MAXDOP addValues=2,4
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

For more information about classification, see [Discover Sensitive Data](#).

### CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field   | Description                                                                |
|---------|----------------------------------------------------------------------------|
| Account | The name of the account owner. Required if Windows Authentication is used. |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Directory | <p>The name of the installation directory.<br/>To use the datasource for Vulnerability Assessments, enter the path to your database instance home directory, for example,</p> <ul style="list-style-type: none"> <li>• MSSQL2014, default instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL12.MSSQLSERVER\MSSQL</li> <li>• MSSQL2016, Name instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL13.SQL2016\MSSQL</li> <li>• Oracle 2019<br/>C:\Program Files\Microsoft SQL Server\MSSQL15.MSSQLSERVER\MSSQL</li> <li>• Oracle 2022<br/>C:\Program Files\Microsoft SQL Server\MSSQL16.MSSQLSERVER\MSSQL</li> </ul> <p>To use the datasource for other tests such as CAS file monitoring, enter the path to the MS SQL Server directory, for example,</p> <ul style="list-style-type: none"> <li>• C:\Program Files (x86)\Microsoft SQL Server</li> <li>• C:\Program Files\Microsoft SQL Server</li> </ul> |

## MS SQL Server (DataDirect)

Configure an MS SQL Server DataDirect datasource on your Guardium® system.

Tip: To set a dynamic IP, go to the DB server and set the dynamic port type to 0. Remove TCP/IP and restart the services.

### Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

### Parameters

| Field         | Description                                                          |
|---------------|----------------------------------------------------------------------|
| Host Name/IP  | Required. The hostname or IP address of the datasource.              |
| Port number   | Required. Default value: 1433.                                       |
| Instance name | The name of the instance to which you want to connect on the server. |
| Database      | The name of the database. The default value is <i>Master</i> .       |

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Connection property | <p>Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is <code>property1=value;property2=value</code>, where each property and value pair is separated by a semicolon.</p> <p>For examples, refer to the database vendor's JDBC documentation.</p> <p>For example,</p> <pre><code>domain=domain_name;AuthenticationMethod=authentication_method; encryptionMethod=encryption_method;validateServerCertificate=true_or_false;</code></pre> <p>Where:</p> <ul style="list-style-type: none"> <li>• <code>domain_name</code> is the name of the domain server. If the driver cannot determine the domain name, the connection fails and produces an error.</li> <li>• <code>AuthenticationMethod</code> determines the authentication method that the driver uses when a connection is established. If the authentication method is not supported by the database server, the connection fails and produces an error.</li> </ul> <p>The following values for <code>AuthenticationMethod</code> are valid:</p> <ul style="list-style-type: none"> <li>◦ <code>ntlm</code></li> <li>◦ <code>ntlmjava</code></li> <li>◦ <code>ntlm2java</code></li> </ul> <p>For Windows authentication, use the following property:</p> <pre><code>domain=domain_name;AuthenticationMethod=ntlmjava</code></pre> <p>To use NTLMv2 for Windows authentication, use the following property:</p> <pre><code>domain=domain_name;AuthenticationMethod=ntlm2java</code></pre> <p>Attention:</p> <ul style="list-style-type: none"> <li>◦ If you specify <code>AuthenticationMethod=ntlmjava</code> when the <code>LMCompatabilityLevel</code> is restricted to NTLMv2, an error is returned. When the <code>LMCompatabilityLevel</code> is restricted to NTLMv2, <code>AuthenticationMethod</code> must be set to <code>ntlm2java</code>.</li> <li>◦ If you specify <code>AuthenticationMethod=ntlmjava</code> or <code>AuthenticationMethod=ntlm2java</code>, you must also specify the name of the domain server that administers the database. You can specify the domain server by using the <code>domain</code> property. If the <code>domain</code> property is not specified, the driver tries to determine the domain server from the <code>user</code> property. If the driver cannot determine the domain server name, it returns an exception.</li> </ul> <ul style="list-style-type: none"> <li>• For nonstandard databases:</li> </ul> <p>If you are using a nonstandard database Unicode such as <code>Azeri_Cyrillic_100_CI_AS</code> or <code>Chinese_Hong_Kong_Stroke_90_CI_AS</code>, then add the following parameter to the connection property:</p> <pre><code>CodePageOverride=UTF-8</code></pre> <ul style="list-style-type: none"> <li>• For SSL authentication:</li> </ul> <p>To use SSL, add the following property,</p> <pre><code>encryptionMethod=SSL;validateServerCertificate=false</code></pre> <ul style="list-style-type: none"> <li>• Connecting to named instances:</li> </ul> <ul style="list-style-type: none"> <li>◦ Microsoft SQL Server 2000 and higher support multiple instances of a Microsoft SQL Server database that is running concurrently on the same server.</li> <li>◦ An instance is identified by an instance name. To connect to a named instance by using a connection URL, use the following URL format,</li> </ul> <pre><code>jdb:datadirect:sqlserver://server_name\\instance_name</code></pre> <p>Where:</p> <ul style="list-style-type: none"> <li>▪ <code>server_name</code> is the IP address or hostname of the server.</li> <li>▪ <code>instance_name</code> is the name of the instance to which you want to connect on the server.</li> </ul> <p>For example, the following connection URL connects to an instance named <code>instance1</code> on <code>server1</code>:</p> <pre><code>jdb:datadirect:sqlserver://server1\\instance1;User=test;Password=secret</code></pre> <p>Where the first backslash character (\) in <code>\\instance_name</code> is an escape character.</p> |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Adding custom properties for classification

To improve the performance of Guardium classification scans, you can add the following custom properties for Microsoft SQL Server.

- `LARGE-TEXT-DATA-TYPE-MAX-LENGTH` - By default, when scanning large data types like XML or `VARCHAR(MAX)`, the classifier only samples the first 3000 characters. Use the `LARGE-TEXT-DATA-TYPE-MAX-LENGTH` property to define a custom length in the range of 0 - 2147483647 characters.
- `MAXDOP` - The `MAXDOP` property defines how many processors MS SQL Server uses for parallel plan execution. The default setting of 0 allows MS SQL Server to use all available processors (up to a maximum of 64). Setting `MAXDOP` to 1 prevents parallel plan generation. Allowed values are 0 - 32,767. For more information, see *Set the Max Degree of Parallelism Option* in the Microsoft SQL Docs.
- `TRANSACTION-ISOLATION-LEVEL` - When you add this property with `READ-UNCOMMITTED`, the classifier reads all rows (including uncommitted rows). `READ-UNCOMMITTED` is the only value currently supported for the `TRANSACTION-ISOLATION-LEVEL` property, and the value must be uppercase and include the hyphen. For more information, see `SET TRANSACTION ISOLATION LEVEL` in the Microsoft SQL Docs.

You can add or change custom properties from either the Guardium UI or by using GRDAPi commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can use GRDAPi to manage custom properties. For example, use the following to create MAXDOP and TRANSACTION-ISOLATION-LEVEL custom properties:

```
grdapicreate_datasource_custom_property name=MAXDOP values=
grdapicreate_datasource_custom_property name="TRANSACTION-ISOLATION-LEVEL" values="READ-UNCOMMITTED"
```

Use the following to add the MAXDOP and TRANSACTION-ISOLATION-LEVEL properties to a MS SQL Server datasource:

```
grdapi add_custom_property_to_datasource_by_name customProps="TRANSACTION-ISOLATION-LEVEL=READ-UNCOMMITTED"
name="yourmssqlserverdatabasename"
grdapi add_custom_property_to_datasource_by_name customProps=MAXDOP=1 name="yourmssqlserverdatabasename"
```

Use the following to add additional MAXDOP values (where **2,4** indicates the list of values added):

```
grdapi update_datasource_custom_property name=MAXDOP addValues=2,4
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

For more information about classification, see [Discover Sensitive Data](#).

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## MS SQL Server (Microsoft - Dynamic Port)

Configure an MS SQL Server Microsoft - dynamic port datasource on your Guardium® system.

The MS SQL Server Microsoft - dynamic port datasource can be used to connect dynamically to an MS SQL Server database when the dynamic function is enabled in the MS SQL Server database server. It can also be used to connect dynamically when a client does not have a defined port value.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Instance name       | The name of the instance to which you want to connect on the server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Database            | The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>Example:<br><br>trustServerCertificate=true<br><br>If you are not using trustServerCertificate=true in your connection property, you must configure the server certificates with the CN and SAN so <b>hostNameInCertificate</b> or the <b>serverName</b> can be used in the connection property for TLS verification.<br>The value passed to <b>serverName</b> must match the Common Name (CN) or DNS name in the Subject Alternate Name (SAN) in the server certificate for a TLS connection to succeed. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Adding custom properties for classification

---

To improve the performance of Guardium classification scans, you can add the following custom properties for Microsoft SQL Server.

- **LARGE-TEXT-DATA-TYPE-MAX-LENGTH** - By default, when scanning large data types like XML or VARCHAR(MAX), the classifier only samples the first 3000 characters. Use the LARGE-TEXT-DATA-TYPE-MAX-LENGTH property to define a custom length in the range of 0 - 2147483647 characters.
- **MAXDOP** - The MAXDOP property defines how many processors MS SQL Server uses for parallel plan execution. The default setting of 0 allows MS SQL Server to use all available processors (up to a maximum of 64). Setting MAXDOP to 1 prevents parallel plan generation. Allowed values are 0 - 32,767. For more information, see *Set the Max Degree of Parallelism Option* in the Microsoft SQL Docs.
- **TRANSACTION-ISOLATION-LEVEL** - When you add this property with *READ-UNCOMMITTED*, the classifier reads all rows (including uncommitted rows). *READ-UNCOMMITTED* is the only value currently supported for the TRANSACTION-ISOLATION-LEVEL property, and the value must be uppercase and include the hyphen. For more information, see *SET TRANSACTION ISOLATION LEVEL* in the Microsoft SQL Docs.

You can add or change custom properties from either the Guardium UI or by using GRDAPI commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can use GRDAPIs to manage custom properties. For example, use the following to create MAXDOP and TRANSACTION-ISOLATION-LEVEL custom properties:

```
grdapi create_datasource_custom_property name=MAXDOP values=1
grdapi create_datasource_custom_property name="TRANSACTION-ISOLATION-LEVEL" values="READ-UNCOMMITTED"
```

Use the following to add the MAXDOP and TRANSACTION-ISOLATION-LEVEL properties to a MS SQL Server datasource:

```
grdapi add_custom_property_to_datasource_by_name customProps="TRANSACTION-ISOLATION-LEVEL=READ-UNCOMMITTED"
name="yourmssqlserverdatabasename"
grdapi add_custom_property_to_datasource_by_name customProps=MAXDOP=1 name="yourmssqlserverdatabasename"
```

Use the following to add additional MAXDOP values (where 2, 4 indicates the list of values added):

```
grdapi update_datasource_custom_property name=MAXDOP addValues=2,4
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

For more information about classification, see [Discover Sensitive Data](#).

## CAS (Configuration Auditing System) database instance

---

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Account   | The name of the account owner. Required if Windows Authentication is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Directory | <p>The name of the installation directory.<br/>To use the datasource for Vulnerability Assessments, enter the path to your database instance home directory, for example,</p> <ul style="list-style-type: none"><li>• MSSQL2014, default instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL12.MSSQLSERVER\MSSQL</li><li>• MSSQL2016, Name instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL13.SQL2016\MSSQL</li><li>• Oracle 2019<br/>C:\Program Files\Microsoft SQL Server\MSSQL15.MSSQLSERVER\MSSQL</li><li>• Oracle 2022<br/>C:\Program Files\Microsoft SQL Server\MSSQL16.MSSQLSERVER\MSSQL</li></ul> <p>To use the datasource for other tests such as CAS file monitoring, enter the path to the MS SQL Server directory, for example,</p> <ul style="list-style-type: none"><li>• C:\Program Files (x86)\Microsoft SQL Server</li><li>• C:\Program Files\Microsoft SQL Server</li></ul> |

## MS SQL Server (Microsoft)

---

Configure an MS SQL Server Microsoft datasource on your Guardium® system.

Tip: To set a dynamic IP, go to the DB server and set the dynamic port type to 0. Remove TCP/IP and restart the services.

## Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

---

| Field               | Description                                                                                                                                                                                                                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                       |
| Port number         | Required. Default value: 1433.                                                                                                                                                                                                                                                                |
| Instance name       | The name of the instance to which you want to connect on the server.                                                                                                                                                                                                                          |
| Database            | The name of the database. The default value is <i>Master</i> .                                                                                                                                                                                                                                |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon. For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                     |

## Adding custom properties for classification

To improve the performance of Guardium classification scans, you can add the following custom properties for Microsoft SQL Server.

- LARGE-TEXT-DATA-TYPE-MAX-LENGTH - By default, when scanning large data types like XML or VARCHAR(MAX), the classifier only samples the first 3000 characters. Use the LARGE-TEXT-DATA-TYPE-MAX-LENGTH property to define a custom length in the range of 0 - 2147483647 characters.
- MAXDOP - The MAXDOP property defines how many processors MS SQL Server uses for parallel plan execution. The default setting of 0 allows MS SQL Server to use all available processors (up to a maximum of 64). Setting MAXDOP to 1 prevents parallel plan generation. Allowed values are 0 - 32,767. For more information, see *Set the Max Degree of Parallelism Option* in the Microsoft SQL Docs.
- TRANSACTION-ISOLATION-LEVEL - When you add this property with *READ-UNCOMMITTED*, the classifier reads all rows (including uncommitted rows). *READ-UNCOMMITTED* is the only value currently supported for the TRANSACTION-ISOLATION-LEVEL property, and the value must be uppercase and include the hyphen. For more information, see *SET TRANSACTION ISOLATION LEVEL* in the Microsoft SQL Docs.

You can add or change custom properties from either the Guardium UI or by using GRDAPi commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can use GRDAPi to manage custom properties. For example, use the following to create MAXDOP and TRANSACTION-ISOLATION-LEVEL custom properties:

```
grdapapi create_datasource_custom_property name=MAXDOP values=1
grdapapi create_datasource_custom_property name="TRANSACTION-ISOLATION-LEVEL" values="READ-UNCOMMITTED"
```

Use the following to add the MAXDOP and TRANSACTION-ISOLATION-LEVEL properties to a MS SQL Server datasource:

```
grdapapi add_custom_property_to_datasource_by_name customProps="TRANSACTION-ISOLATION-LEVEL=READ-UNCOMMITTED"
name="yourmssqlserverdatabasename"
grdapapi add_custom_property_to_datasource_by_name customProps=MAXDOP=1 name="yourmssqlserverdatabasename"
```

Use the following to add additional MAXDOP values (where 2, 4 indicates the list of values added):

```
grdapapi update_datasource_custom_property name=MAXDOP addValues=2,4
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

For more information about classification, see [Discover Sensitive Data](#).

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner. Required if Windows Authentication is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Directory | <p>The name of the installation directory. To use the datasource for Vulnerability Assessments, enter the path to your database instance home directory, for example,</p> <ul style="list-style-type: none"> <li>MSSQL2014, default instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL12.MSSQLSERVER\MSSQL</li> <li>MSSQL2016, Name instance<br/>C:\Program Files\Microsoft SQL Server\MSSQL13.SQL2016\MSSQL</li> <li>Oracle 2019<br/>C:\Program Files\Microsoft SQL Server\MSSQL15.MSSQLSERVER\MSSQL</li> <li>Oracle 2022<br/>C:\Program Files\Microsoft SQL Server\MSSQL16.MSSQLSERVER\MSSQL</li> </ul> <p>To use the datasource for other tests such as CAS file monitoring, enter the path to the MS SQL Server directory, for example,</p> <ul style="list-style-type: none"> <li>C:\Program Files (x86)\Microsoft SQL Server</li> <li>C:\Program Files\Microsoft SQL Server</li> </ul> |

## MySQL

Configure a MySQL datasource on your Guardium® system.

## Supported Authentication Methods

Note: For SQL statements, the Guardium appliance supports UTF8 characters of up to 3 bytes in length. UTF8 characters 4 bytes or longer are not supported and do not display correctly. This is a limitation of the Guardium appliance.

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Port number         | Required. Default value: 3306.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Database            | The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>If the database server is in the UTC time zone and you are unable to establish a connection, use the following connection properties:<br><code>useUnicode=true;useJDBCCompliantTimezoneShift=true;useLegacyDatetimeCode=false;serverTimezone=UTC</code> |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                                                                                                                   |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field   | Description                    |
|---------|--------------------------------|
| Account | The name of the account owner. |

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Directory | <p>The name of the installation directory.<br/>An environment variable <code>MYSQL_HOME</code> may be defined.</p> <p>Note: A MySQL datasource with a Unicode database name is not supported. The datasource name in MySQL must be ASCII.<br/>To use the following feature, you must install the latest Guardium Vulnerability Assessment patch for version 11.5:</p> <p>Required environment variable:</p> <p><code>datadir</code> - The path to the MySQL server data directory. For MySQL Binary installation, the default path is <code>datadir=/usr/local/mysql/data</code>. For MySQL rpm or yum installation, the default path is <code>datadir=/var/lib/mysql</code></p> <p><code>MYSQL_HOME</code> is an environment variable containing the path to the directory in which the server-specific <code>my.cnf</code> file resides.</p> <p>If <code>MYSQL_HOME</code> is not set and you start the server using the <code>mysqld_safe</code> program, <code>mysqld_safe</code> sets it to <code>BASEDIR</code>, the MySQL base installation directory.</p> <p>If directories are not set to default, Optional variables can be set on the datasource CAS database instance Directory:</p> <p><code>\$log_bin_basename</code> - basename for the log bin files with full path (for example: <code>/var/lib/mysql/binlog</code>, will check for all log files starting with <code>binlog</code> under the <code>/var/lib/mysql</code> directory)</p> <p><code>\$slow_query_log_file</code> - slow query log file name with full path</p> <p><code>\$log_error</code> - Error log file name with full path</p> <p><code>\$general_log_file</code> - General log file name with full path</p> <p><code>\$relay_log_basename</code> - Basename for the relay logs files with full path (for example: <code>/var/lib/mysql/&lt;hostname&gt;-relay-bin.nnnnnn</code>)</p> <p><code>\$plugin_dir</code> - plugin dir with full path</p> <p><code>\$ssl_dir</code> - folder path where ssl key files are in with full path</p> <p><code>\$audit_log_file</code> - audit log file name with full path</p> <ul style="list-style-type: none"> <li>Example 1 - MySQL default installation with CAS instance OS account is <code>root</code>:<br/>Account: <code>root</code><br/>Directory: <code>/root / datadir=/var/lib/mysql</code></li> <li>Example 2 - MySQL binaries installation with CAS instance OS account is <code>mysql8c</code>:<br/>Account: <code>mysql8c</code><br/>Directory: <code>/home/mysql8c / datadir=/home/mysql8c/mysql/data/</code></li> <li>For example3 - MySQL installation with CAS instance OS account is <code>root</code> and non-default directories:<br/>Account: <code>root</code><br/>Directory: <code>/root / datadir=/opt/IBM/data/mysql/   slow_query_log_file=/opt/IBM/data/mysql/mysql-slow.log / log_error=/opt/IBM/data/mysql/mysql-error.log   general_log_file=/opt/IBM/data/mysql/localhost.log / relay_log_basename=/opt/IBM/data/mysql/localhost-relay-bin / ssl_dir=/opt/IBM/etc/keys</code></li> </ul> |

## Neo4j

Configure a Neo4j datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                        |
| Port number         | Required. Default value: 7687.                                                                                                                                                                                                                                                                                 |
| Database            | The name of the database.<br>Example: <code>system</code> .                                                                                                                                                                                                                                                    |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is <code>property1=value;property2=value</code> , where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |

| Field      | Description                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Custom URL | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number. |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.<br>For an RPM installation, the default account owner is <i>neo4j</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Directory | The name of the installation directory.<br>You can specify multiple paths for the database instance directory. Indicate a separate path by using a pipe " " with spaces.<br><br>For example:<br><code>/var/lib/neo4j   NEO4J_HOME=/var/lib/neo4j</code><br><br>Where: <ul style="list-style-type: none"> <li>• /var/lib/neo4j is the instance account directory.<br/>In an RPM (Red Hat Package Manager) installation, an OS user <i>neo4j</i> and an account directory path /var/lib/neo4j, is created by default. For .tar files, use the path to the home directory of the OS user account, under which Neo4j is installed.</li> <li>• NEO4J_HOME=/var/lib/neo4j is the Neo4j installation directory.<br/>In an RPM installation, the NEO4J_HOME directory is /var/lib/neo4j, by default. For .tar files, use the path to the folder where Neo4j is extracted.</li> </ul> |

## Netezza

Configure a Netezza® datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 5480.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.                                                                                                    |
| Directory | The name of the installation directory. This is not required as the Netezza installation is in the same location on all machines. |

## Oracle (Data Direct - Service Name)

Configure an Oracle datasource with DataDirect connection on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
|                |           |

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Service name        | The service name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Schema              | The name of the database schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Connection property | <p>Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon. For examples, refer to the database vendor's JDBC documentation.</p> <p>The Oracle JDBC driver does not require a connection property. But the latest Oracle JDBC driver must be downloaded from Oracle. The filename is ojdbc7.jar. Search and download the open source JDBC drivers. For example: use the search query <a href="#">open source JDBC driver for Oracle</a>. Then upload the driver to the appliance using the Guardium Customer Uploads function.</p> <p>If you continue to use the Oracle DataDirect driver, then you must specify a connection property to the datasource.</p> <ul style="list-style-type: none"> <li>Use the following definitions for the Oracle DataDirect driver connection property:<br/><i>DataIntegrityLevel=required;EncryptionLevel=required;DataIntegrityTypes=(MD5,SHA1)</i></li> <li>If you use CRYPTO_CHECKSUM_TYPES in your sqlnet.ora, use the following examples: <ul style="list-style-type: none"> <li>oracle.net.encryption_client=rc4_256;oracle.net.crypto_checksum_types_client=MD5</li> <li>oracle.net.encryption_client=aes256;oracle.net.crypto_checksum_types_client=MD5</li> <li>oracle.net.encryption_client=rc4_256;oracle.net.crypto_checksum_types_client=SHA1</li> </ul> </li> <li>To authenticate to Oracle LDAP, which is also known as OID, use the LDAP server host or IP, the LDAP server port, the Oracle instance name and the realm. Enter the custom URL <i>jdbc:guardium:oracle:@ldap://w13ku2x32t4:389/on0maver;cn=OracleContext;dc=vguardium;dc=com</i></li> <li>The Oracle default user sys, is the owner of the database instance and has super user privileges, similar to root on Unix. The SYSDBA role has administrative privileges that are required to perform many high-level administrative operations such as starting and stopping the database, as well as performing operations such as backup and recovery. This SYSDBA role can also be granted to other users. The phrase sys as SYSDBA refers to the connection method required to connect as the sys user.</li> <li>To monitor values for Oracle 10 open source driver, enter the connection property: <i>internal_logon=sysdba</i></li> <li>To use the SYSDBA role, enter the connection property <i>SysLoginRole=sysdba</i></li> <li>To initiate an SSL datasource connection with server signed or mutual authentication, enter the connection property: <i>EncryptionMethod=SSL</i>.</li> </ul> <p>For an Oracle encrypted connection, define the connection property as:<br/><i>oracle.net.encryption_client=REQUIRED;oracle.net.encryption_types_client=RC4_40</i>. Note: A datasource that is defined to use 3DES168 encryption, throws an ORA-17401 protocol error or ORA-17002 checksum error when it encounters any SQL error. To fix this error, close and reopen the connection.</p> <p>If the connection is unsuccessful because the HostNameInCertificate does not match, enter this string as the connection property using the certificate name provided in the error message: <i>EncryptionMethod=SSL;HostNameInCertificate=certificate name</i>.</p> |
| Custom URL          | <p>The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.</p> <ul style="list-style-type: none"> <li>When you specify a Custom URL field with the Oracle Open Source format, specify <i>jdbc:guardium:oracle://:SID=&lt;SID&gt;</i>.</li> <li>When you create a datasource for an Oracle database with Oracle Advanced Security enabled, specify <i>EncryptionLevel=required</i> in the Custom URL field of the datasource definition.</li> </ul> <p>To initiate an SSL datasource connection using the Oracle JDBC driver, setup the connection URL using one of the examples below. Refer to the Oracle JDBC connection syntax.</p> <p>Example:</p> <pre>jdbc:oracle:thin:@(description= (address=(protocol=tcp)(port=1522)(host=adwc.uscom-west-1.oraclecloud.com))(connect_data=(service_name=VOVO0MKSEWWJ3PSJ_ISVDRIVERSDB_medium.dwcs.oracle.com))(security=(ssl_server_cert_dn="CN=adwc-dev.uscom-east-1.oraclecloud.com,OU=Testing Domain,O=End Point,L=Redwood Shores,ST=California,C=US"))</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Adding custom properties for classification

By default, the classifier uses `count *` to determine cardinality for random sampling. For Oracle datasources, Guardium supports alternative methods for determining cardinality: the DATA-CARDINALITY-FOR-SAMPLING-TABLES custom property for tables, and the DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE custom property for views.

### DATA-CARDINALITY-FOR-SAMPLING-TABLES

When sampling tables, this custom property uses database statistics to determine cardinality. To enable the database statistics method, add DATA-CARDINALITY-FOR-SAMPLING-TABLES = STATISTICS as a custom property for the datasource. When using this property, the classifier retrieves the number of rows from the `all_tables` data dictionary view.

Notes:

- The property name must be entered as DATA-CARDINALITY-FOR-SAMPLING-TABLES (all capital letters, with hyphens), and the only valid value is STATISTICS.
- The value of num\_rows in all\_tables might not be up-to-date. When using this property, work with your Oracle administrator to ensure the database statistics are current.

- After you run the discovery scenario with DATA-CARDINALITY-FOR-SAMPLING-TABLES = STATISTICS, click the  for the data source in the Process Run Log. You can see that the datasource is using the custom property.

#### DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE

When sampling views, this custom property provides a percentage value that the classifier uses to determine the sample. To enable this method, add DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE = [0.000001 to <100] as a custom property for the datasource. This method uses `sample_percent` where the specified value is the probability that each row is selected for the sample.

Note:

- The property name must be entered as DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE (all capital letters, with hyphens), and the allowed values are 0.000001 to <100.

You can add or change custom properties from either the Guardium UI or by using GRDAPi commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can also use GRDAPi to manage custom properties. For example, assuming a datasource created with the following command:

```
grdapicreate_datasource type="Oracle (DataDirect - Service Name)" user="dbusername" password="yourdbpassword"
host="dbhostname" name="nameofthisdbconnection" shared=true application="Classifier" port=1521 serviceName="on9stuff"
dbName="nameofschema"
```

Use the following commands to create the DATA-CARDINALITY-FOR-SAMPLING-TABLES and DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE custom properties:

```
grdapicreate_datasource_custom_property name=DATA-CARDINALITY-FOR-SAMPLING-TABLES values=STATISTICS
grdapicreate_datasource_custom_property name=DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE values=10
```

Then use the following commands to add the properties to the Oracle datasource:

```
grdapicustom_property_to_datasource_by_name customProps="DATA-CARDINALITY-FOR-SAMPLING-TABLES=STATISTICS"
name="nameofthisdbconnection"
grdapicustom_property_to_datasource_by_name customProps="DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE=10"
name="nameofthisdbconnection"
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                     |
|-----------|---------------------------------|
| Account   | The Oracle installation user.   |
| Directory | The directory of \$ORACLE_HOME. |

## Oracle (Data Direct - SID)

Configure an Oracle datasource with DataDirect connection on your Guardium® system.

### Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | Yes       |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                         |
| Port number         | Required. Default value: 1521.                                                                                                                                                                                                                                                                                                                                                  |
| SID name            | The Oracle system ID.                                                                                                                                                                                                                                                                                                                                                           |
| Schema              | The name of the database schema.                                                                                                                                                                                                                                                                                                                                                |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon. For examples, refer to the database vendor's JDBC documentation.                                                                                   |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.<br>Example:<br><code>jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCPS)(HOST=hostname.domain.com ip address )(PORT=1525)))(CONNECT_DATA=(SERVER=DEDICATED)(SID=Oracle_SID))</code> |

## Adding custom properties for classification

By default, the classifier uses `count *` to determine cardinality for random sampling. For Oracle datasources, Guardium supports alternative methods for determining cardinality: the DATA-CARDINALITY-FOR-SAMPLING-TABLES custom property for tables, and the DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE custom property for views.

#### DATA-CARDINALITY-FOR-SAMPLING-TABLES

When sampling tables, this custom property uses database statistics to determine cardinality. To enable the database statistics method, add DATA-CARDINALITY-FOR-SAMPLING-TABLES = STATISTICS as a custom property for the datasource. When using this property, the classifier retrieves the number of rows from the `all_tables` data dictionary view.

Notes:

- The property name must be entered as DATA-CARDINALITY-FOR-SAMPLING-TABLES (all capital letters, with hyphens), and the only valid value is STATISTICS.
- The value of num\_rows in all\_tables might not be up-to-date. When using this property, work with your Oracle administrator to ensure the database statistics are current.
- After you run the discovery scenario with DATA-CARDINALITY-FOR-SAMPLING-TABLES = STATISTICS, click the  for the data source in the Process Run Log. You can see that the datasource is using the custom property.

#### DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE

When sampling views, this custom property provides a percentage value that the classifier uses to determine the sample. To enable this method, add DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE = [0.000001 to <100] as a custom property for the datasource. This method uses `sample_percent` where the specified value is the probability that each row is selected for the sample.

Note:

- The property name must be entered as DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE (all capital letters, with hyphens), and the allowed values are 0.000001 to <100.

You can add or change custom properties from either the Guardium UI or by using GRDAPIS commands. After you add the custom properties, the information displays in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

You can also use GRDAPIS to manage custom properties. For example, assuming a datasource created with the following command:

```
grdapi create_datasource type="Oracle (DataDirect - SID)" user="dbusername" password="yourdbpassword" host="dbhostname" name="nameofthisdbconnection" shared=true application="Classifier" port=1521 serviceName="on9stuff" dbName="nameofschema"
```

Use the following commands to create the DATA-CARDINALITY-FOR-SAMPLING-TABLES and DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE custom properties:

```
grdapi create_datasource_custom_property name=DATA-CARDINALITY-FOR-SAMPLING-TABLES values=STATISTICS
grdapi create_datasource_custom_property name=DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE values=10
```

Then use the following commands to add the properties to the Oracle datasource:

```
grdapi add_custom_property_to_datasource_by_name customProps="DATA-CARDINALITY-FOR-SAMPLING-TABLES=STATISTICS" name="nameofthisdbconnection"
grdapi add_custom_property_to_datasource_by_name customProps="DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE=10" name="nameofthisdbconnection"
```

You can also use GRDAPIS to update the custom properties:

```
grdapi update_datasource_custom_property name=DATA-CARDINALITY-FOR-SAMPLING-VIEWS-PERCENTAGE addValues=1,2,5
```

For more information about the custom property APIs, see [Datasource custom property APIs](#).

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                     |
|-----------|---------------------------------|
| Account   | The Oracle installation user.   |
| Directory | The directory of \$ORACLE_HOME. |

## Percona MySQL

Configure a Percona MySQLdatasource on your Guardium® system.

Note: To use this feature, you must install the latest Guardium Vulnerability Assessment patch for version 11.5.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 3306.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Directory | The name of the installation directory.<br>Example for rpm and yum installation:<br><br><i>MYSQL_HOME=/var/lib/mysql/</i><br><br>Note:<br><i>MYSQL_HOME</i> is the environment variable containing the path to the directory holding the server-specific my.cnf file.<br><br>If <i>MYSQL_HOME</i> is not set, and the server is started with mysqld_safe, <i>MYSQL_HOME</i> is set as follows: If there is a <i>my.cnf</i> file in the MySQL data directory, but not in the MySQL base directory, <i>MYSQL_HOME</i> is set to the MySQL data directory. Else, <i>MYSQL_HOME</i> is set to the MySQL base directory. |

## PostgreSQL

Configure a PostgreSQL datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | Yes       |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 5432.                                                                                                                                                                                                                                                                   |
| Database            | Required. The name of the database.<br>For example, <i>postgres</i> .<br>For Vulnerability Assessment (VA) tests that require scanning other databases, the VA assessment scan will get a list of all required databases from the PostgreSQL instance and run the test.                          |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## Adding custom property for classification

12.1 and later To improve the performance of Guardium classification scans, you can add the following custom property for PostgreSQL.

- LARGE-TEXT-DATA-TYPE-MAX-LENGTH - By default, when scanning large data types like XML, VARCHAR(MAX), or TEXT, the classifier samples only the first 3000 characters. Use the LARGE-TEXT-DATA-TYPE-MAX-LENGTH property to define a custom length in the range of 0 - 2147483647 characters.

You can add or change custom properties from either the Guardium UI or by using GRD API commands. After you add the custom properties, the information is displayed in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

For more information about classification, see [Discover Sensitive Data](#).

## SAP HANA

Configure a SAP HANA datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Port number         | Required. Default value: 30015.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Database            | Required. The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>Configuring SSL:<br><br>When you create your server's public and private key pair or public key certificate, the Common Name (CN) must match the server's hostname and use the Fully Qualified Domain Name (FQDN). The Subject Alternative Name (SAN) must use the server's hostname with FQDN and the server's IP.<br><br>If SSL is incorrectly configured, the connection fails because the hostname cannot be verified. To bypass a hostname verification error, use the following workaround:<br><br>Set the connection property <i>hostNameInCertificate=ServerHostname</i> . Where <i>ServerHostname</i> is the CN that was used in the certificate and not the hostname with which the connection was established. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## CAS (Configuration Auditing System) database instance

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | Required. The name of the account owner.<br>The syntax is <SID>adm<br><br>Example: <i>hxeadm</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Directory | Required. The name of the installation directory.<br>You can specify multiple paths for the database instance directory. Indicate a separate path by using a pipe " " with spaces.<br><br>For example:<br><br><i>/usr/sap/HXE/home   SID=HXE   logpath=/hana/shared/log   datapath=/hana/shared/data   installpath=/usr/sap .</i><br><br>Where: <ul style="list-style-type: none"><li>• /usr/sap/HXE/home is the home directory for the instance account.</li><li>• SID=HXE is the system ID. The SAP system ID (SID) is the identifier for the SAP HANA system.</li><li>• logpath=/hana/shared/log is the path to the log directory of the SAP HANA system. The default log location is /hana/log/&lt;SID&gt;.</li><li>• datapath=/hana/shared/data is the path to the data directory of the SAP HANA system. The default data location is /hana/data/&lt;SID&gt;.</li><li>• installpath=/usr/sap is the installation path that is specific to the operating system on which the SAP HANA studio is installed. As an example, for Linux, the installation path is /usr/sap for Linux.</li></ul><br>All the paths that are listed in this example are required entries. |

## Snowflake

Configure a Snowflake datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

Note:

The default authentication method is SSL.

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname of the datasource.                                                                                                                                                                                                                                                        |
| Port number         | Required. Default value: 443                                                                                                                                                                                                                                                                     |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |

## SQL DB Azure

Configure an SQL DB Azure datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                     |
| Port number         | Required. Default value: 1433                                                                                                                                                                                                                                                                                                                                               |
| Database            | The name of the database.<br>For security assessments, the required value is master.                                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the Microsoft SQL Server JDBC driver documentation.<br>Note: Azure Active Directory authentication is not supported. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                   |

## Sybase

Configure a Sybase datasource on your Guardium® system.

## Supported Authentication Methods

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | Yes       |
| Mutual SSL     | No        |

## Parameters

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                      |
| Port number         | Required. Default value: 4100.                                                                                                                                                                                                                                                                                                                                               |
| Database            | The name of the database. For Vulnerability Assessment, use the database instance name.                                                                                                                                                                                                                                                                                      |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>For a default character set of Roman 8, enter the property charSet=utf8. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                    |

## CAS (Configuration Auditing System) database instance

---

If you are a CAS user, configure the CAS database instance.

| Field     | Description                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Account   | The name of the account owner. Often <code>sybase</code> .                                                                                                                                               |
| Directory | The name of the installation directory.<br>For UNIX, enter <code>/home/sybase</code><br><br>For Windows, enter <code>C:\sybase</code><br><br>An environment variable <code>SYBASE</code> may be defined. |

## Adding custom property for classification

---

12.1 and later To improve the performance of Guardium classification scans, you can add the following custom property for Sybase.

- `LARGE-TEXT-DATA-TYPE-MAX-LENGTH` - By default, when scanning large data types like XML, `VARCHAR(MAX)`, or `TEXT`, the classifier samples only the first 3000 characters. Use the `LARGE-TEXT-DATA-TYPE-MAX-LENGTH` property to define a custom length in the range of 0 - 2147483647 characters.

You can add or change custom properties from either the Guardium UI or by using GRD API commands. After you add the custom properties, the information is displayed in the Details for datasource output. For more information about adding custom properties from the UI, see [Configuring custom properties for your datasources](#).

For more information about classification, see [Discover Sensitive Data](#).

## Sybase IQ

---

Configure a Sybase IQ datasource on your Guardium® system.

## Supported Authentication Methods

---

| Authentication | Supported                                                                                                                                         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Local user     | Yes                                                                                                                                               |
| LDAP           | No                                                                                                                                                |
| Kerberos       | No                                                                                                                                                |
| SSL            | Yes. Limited support for encrypted TDS connections over TLS in some versions only. For more information, see the database vendor's documentation. |
| Mutual SSL     | No                                                                                                                                                |

## Parameters

---

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Port number         | Required. Default value: 2638.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Database            | The name of the database.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is <code>property1=value;property2=value</code> , where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation.<br>To use SSL, set <code>ENCRYPT_PASSWORD=true</code> .<br>Note: You must start the Sybase IQ server with the parameter <code>TDS=ENCRYPTED</code> . |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                                                                                                                                                                                           |

## TERADATA

---

Configure a TERADATA datasource on your Guardium® system.

## Supported Authentication Methods

---

| Authentication | Supported |
|----------------|-----------|
| Local user     | Yes       |
| LDAP           | No        |
| Kerberos       | No        |
| SSL            | No        |
| Mutual SSL     | No        |

## Parameters

---

| Field | Description |
|-------|-------------|
|       |             |

| Field               | Description                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host Name/IP        | Required. The hostname or IP address of the datasource.                                                                                                                                                                                                                                          |
| Port number         | Required. Default value: 1025.                                                                                                                                                                                                                                                                   |
| Database            | The name of the database.                                                                                                                                                                                                                                                                        |
| Connection property | Properties that must be included in the JDBC URL to establish a JDBC connection with the datasource. The required format is property1=value;property2=value, where each property and value pair is separated by a semicolon.<br>For examples, refer to the database vendor's JDBC documentation. |
| Custom URL          | The connection string to the datasource. When the custom URL is not provided, the datasource connection is made by using properties such as the hostname and port number.                                                                                                                        |

## Text datasources

Parameters to configure a text datasource.

### Parameters

| Text datasource | Port number |
|-----------------|-------------|
| Text            | 0           |
| Text:HTTP       | 8000        |
| Text:FTP        | 22          |
| Text:SAMBA      | 445         |
| Text:HTTPS      | 8443        |
| N_A             | 0           |

## Configuring custom properties for your datasources

Enrich your datasources by defining and assigning custom properties.

### About this task

By configuring custom properties, you can better manage your datasources, organize your workflow, and efficiently accomplish complex processes.

Consider a scenario where you'd like to assess the vulnerability of the datasources that are residing in a specific geographical location. You can define the name of the location as a custom property, assign the property to all the datasources that reside in that location, and group the datasources by the custom property. The custom property can also be added to an existing datasource group. You can now configure a security assessment to scan only the active datasources that are in the group.

Custom properties are flexible and can be reconfigured or deleted, as needed. You can create any number of customized properties based on your business needs and assign multiple properties to one datasource. You can also import existing values from the Guardium® compliance monitoring application. Manually import selected properties or dynamically import updated values when new properties are added to compliance monitoring. When you export your datasource, the assigned properties are also exported.

You can enrich your datasource in two simple steps:

1. Define a custom property with one or more associated values.
2. Assign the customized property to your datasource.

The following procedure describes the configuration process in detail.

### Procedure

1. Open the Datasource Definitions tool by clicking [Setup > Tools and Views > Datasource Definitions](#).
2. To add a new custom property, click [Custom properties > Manage](#)
  - a. From the Manage custom properties window, click  to create a custom property. In the Property name field, enter the name of the custom property. Example: Data center.
  - b. Under Valid values, click  to add one or more custom values to the custom property. Example: New York, San Francisco, Chicago.
  - c. Click Save.
  - d. Repeat steps [2.a](#) to [2.c](#) to add more custom properties based on your business needs. Examples: Country, Continent, Business unit. You can create any number of custom properties with any number of associated values.
3. To assign the custom property, select your datasource or datasource group from the Datasource Definitions page. Then click [Custom properties > Add to datasources](#).
  - a. Select the appropriate Property name from drop-down menu.
  - b. Select the appropriate Value from the drop-down menu.
  - c. Click  another to add another custom defined property to the datasource. You can add multiple properties to one datasource or datasource group.
  - d. Click Save to assign the properties to the selected datasource or group.
4. Optional: Assign additional properties by repeating step [3](#). You can also edit the datasource by selecting the datasource, then clicking , accessing the Custom tab, and selecting a different value for the datasource.
5. Optional: If applicable, import custom properties from industry and application groups that you have defined in your Guardium compliance monitoring application. You can import all or selected properties. Check Update custom datasource properties with industries and application updates to dynamically import properties and as when they are updated.

6. Optional: Edit or delete custom properties, as needed. When a custom property is deleted, it's also removed from all associated datasources and datasource groups.
7. View all the assigned properties for a datasource in the Datasource Definitions page under the Custom column.

---

## Working with existing datasources

After you create a datasource definition, you can clone, modify, or delete the datasource.

### Procedure

---

- To open the Datasource Definitions page, browse to Setup > Tools and Views > Datasource Definitions.
- From Datasource Definitions, you can use the horizontal scroll bar to see the application type for each datasource. Select a datasource of the application type that you want to modify.

## Cloning a datasource

---

### Procedure

- Select the datasource that you want to clone from the Select datasource window, and click .
- The cloned datasource displays Datasource Definition as **Copy of <original datasource>**. All of the information from the original datasource definition appears in the dialog. Change any of the fields as needed.
- Click Save to save the cloned datasource.

## Modifying a datasource

---

### Procedure

- Select the datasource that you want to modify from the Select datasource window, and click .
- The information that you entered when the datasource definition was created appears in the Datasource Definition dialog. Change any of the fields as needed.
- Click Save to save the changes that you made to the datasource.

## Deleting a datasource

---

### Procedure

From the Datasource Definitions page, select the datasource that you want to remove, and click . The datasource and all its references are deleted.

---

## Reporting on datasources

Guardium® provides reports on the datasources that are in your environment and any changes made to them.

### Procedure

---

- Open the Datasources report by navigating to Reports > Report Configuration Tools > Datasources. The table that appears lists all datasources, and the information that is stored in each datasource definition.
- Right-click any cell in the table and you are given two options: Datasource Version History, and Invoke.
  - Click Datasource Version History to view changes made to the datasource definition.
  - Click Invoke to select and run one of the available APIs for the datasource.

Note: You can customize the run time and presentation parameters of the Datasources report by clicking the pencil icon.

## Defining a datasource using a service name

You can define a datasource that enables your users to connect to an Oracle database by using the service name by using a custom URL.

## About this task

---

You must enter the hostname, port, service name, and the custom URL.

## Procedure

---

1. Determine the Oracle service name.

You can use commands like these:

```
SQL> set line size 5000;
SQL> select host_name, instance_name from v$instance;
SQL> select name from v$database;
SQL> show parameter service
```

Use the name that appears in the VALUE column.

2. Load the appropriate Oracle JDBC thin driver to the Guardium® system.

- a. Download the driver for your Oracle database from the Oracle website.
  - b. Open the Customer Uploads window by browsing to Harden > Vulnerability Assessment > Customer Uploads.
  - c. Locate the section titled Upload Oracle JDBC driver. Click Browse and browse to the location to which you downloaded the file. Click Use open-source driver for all.
  - d. Restart the Guardium user interface after the upload is complete.
3. Define the datasource for this database.
- a. Browse to Setup > Tools and Views > Datasource Definitions.
  - b. Select  to add an Oracle datasource.
  - c. Define the datasource as described in [Creating a datasource definition](#).
  - d. Enter the service name in the Service Name field. In the custom URL field, enter `jdbc:oracle:thin@//hostname:port/svcname` where `hostname` and `port` are the standard values for the database and `svcname` is same value that you entered in the Service Name field.
  - e. Click Save to save your changes.

## Managing KDC definitions

---

If your datasource requires authentication using Kerberos, you can specify the information needed for Guardium to obtain a Kerberos ticket before making the connection.

## About this task

---

You can assign a KDC to a specific datasource or managed unit group, to provide Guardium authentication for Mongo and Hive databases. The appliance gets a ticket via the JDBC connection, so the users do not need to get tickets themselves. Note that this is independent from what the appliance itself is set up to use.

You can define up to 5 Kerberos Key Distribution Centers (KDC) on a Central Manager, and one on a standalone Guardium. To add a Key Distribution Center to Guardium you specify:

- realm: domain name in uppercase letters
- KDC: hostname of the Kerberos server
- encryption type for Kerberos tickets
  - des-cbc-md5
  - des-cbc-crc
  - rc4-hmac
  - des3-cbc-sha1
  - aes128-cts-hmac-sha1-96
  - aes256-cts-hmac-sha1-96

The default is aes256-cts-hmac-sha1-96, which is the most secure encryption type.

## Procedure

---

1. Click Setup > Tools and Views > Kerberos configuration
2. Click  to create a new configuration.
3. Specify Name, KDC, and Realm.
4. Specify Encryption Type. The default is aes256-cts-hmac-sha1-96.
5. Click Save.

## What to do next

---

After you have created a Kerberos KDC, you can select it when configuring your datasource setup.

## Managing datasource credentials with CyberArk

---

Guardium supports the CyberArk Application Password Provider, a robust solution to the numerous maintenance and security challenges that arise in managing passwords. Use CyberArk to securely store, provision, audit, and manage your Guardium datasource credentials.

## Existing Challenges

---

- Datasource credentials are updated by database administrators, and manually passed on to users. Easy access to this highly sensitive information creates significant security risks and vulnerability.
- Periodical updates to passwords require manual synchronization across all datasources.
- The challenge is compounded in a large-scale environment where hundreds or thousands of datasource credentials require systematic maintenance.

## Benefits of using CyberArk with Guardium

---

- Credentials are defined, secured, and managed in a digital vault, eliminating the need to embed them locally in the Guardium system.
- Depending on business needs, any number of vaults can be configured by using the CyberArk web console.
- Passwords are automatically generated and replaced for all supported database types, meeting audit and regulatory requirements.
- The CyberArk Application Password Provider that is integrated with Guardium, allows retrieved credentials to be securely cached locally. This reduces the frequency in communication between the Guardium system and the CyberArk vault, improving speed and performance. If there is a network outage, the datasources remain intact and functional.
- **[CyberArk deployment overview](#)**  
The datasource credentials, along with access control, dependencies, and work flows are defined in the vault. Each Guardium system is then configured to access the vault, and retrieve the stored credentials. After the systems are set up, the passwords can be provisioned and maintained with no manual intervention.
- **[Setting up the CyberArk vault system](#)**  
The CyberArk administrator must set up and configure the CyberArk vault server. For detailed information, see the CyberArk documentation.
- **[Deploying CyberArk on your Guardium system](#)**  
The Guardium system administrator must use the following workflow to deploy CyberArk in the Guardium environment.
- **[Upgrading the CyberArk SDK on a central manager or standalone system](#)**  
When an upgrade patch is available, use this procedure to upgrade the CyberArk SDK on your central manager or standalone system .
- **[Upgrading the CyberArk SDK on a managed unit](#)**  
Use the GUI on the central manager to distribute the CyberArk upgrade credentials and upgrade patch to the managed units.
- **[Uninstalling CyberArk](#)**  
Uninstall CyberArk from your Guardium system using the Command line Interface.

## CyberArk deployment overview

---

The datasource credentials, along with access control, dependencies, and work flows are defined in the vault. Each Guardium® system is then configured to access the vault, and retrieve the stored credentials. After the systems are set up, the passwords can be provisioned and maintained with no manual intervention.

Here is an overview of the work flow that is used to deploy CyberArk:

1. Set up the vault system on CyberArk. For more information, see [Setting up the CyberArk vault system](#).
2. Download and install the CyberArk SDK patch. For more information, see [Downloading and installing the CyberArk SDK patch](#).
3. Install CyberArk on your Guardium system. For more information, see [Installing CyberArk](#).
4. Configure CyberArk. For more information, see [Configuring CyberArk on your Guardium system](#).
5. Define datasources by using CyberArk credentials. For more information, see [Defining Guardium datasources to access CyberArk](#).

## Setting up the CyberArk vault system

---

The CyberArk administrator must set up and configure the CyberArk vault server. For detailed information, see the CyberArk documentation.

Use this workflow to set up the CyberArk vault system.

1. Verify that your databases are supported by CyberArk for automatic password provisioning. If your database is not supported, you can continue to store your credentials on CyberArk. However, the passwords are not automatically provisioned.
  2. Set up a vault in the CyberArk vault server.
  3. Set up one or multiple safes within the CyberArk vault.
  4. Populate the safe with the CyberArk objectnames (Guardium® datasource names) and their respective passwords.
  5. Create a group and make it the owner of the safe. All safes inherit the group's permissions automatically.
  6. Create a CyberArk application ID by using the CyberArk web console and grant the necessary permissions. For more information, see [Creating an application ID on CyberArk](#). This application ID is used to configure CyberArk on your Guardium system.
  7. Provide the following information to the Guardium system administrator:
    - Vault host name or IP address
    - Vault user name
    - Vault password
    - Standby vault server IP address list, if any
    - Group name, Application IDs, corresponding safe names, and folder names
    - CyberArk objectnames
- **[Creating an application ID on CyberArk](#)**  
The CyberArk administrator must create an application ID, assign it to a safe, and grant the required permissions. This application ID is used to configure the Guardium system.
  - **[Adding and removing account permissions on CyberArk](#)**  
The CyberArk administrator can grant or revoke permissions to the Guardium system on the CyberArk vault server.

## Creating an application ID on CyberArk

---

The CyberArk administrator must create an application ID, assign it to a safe, and grant the required permissions. This application ID is used to configure the Guardium system.

## Before you begin

---

The safe that you use to store your CyberArk objectnames (Guardium datasources) must be set up in the CyberArk vault.

## Procedure

---

1. Log in to the CyberArk web console.
2. Select Applications from the menu bar and click Add Application.
3. In the name field, enter an arbitrary Application ID name. All the other fields can remain empty. Click Add to add the application.
4. In the menu bar, select Policies > Access Control (Safes) and click the safe that you use to store your CyberArk objectnames.
5. Click Members to view the safe details.
6. On the Members tab, click Add Member to access the Add Safe Member screen.
7. In the Search field, enter your Application ID name, and click Search.
8. Select your application ID name from the search results. Mark the check box for Retrieve Accounts, and clear the check boxes for all other enabled permissions.
9. Click Add to add the application ID to the safe.

## What to do next

---

If you are using multiple safes to store CyberArk objectnames, repeat steps 2 - 9 to create and assign application IDs for each safe.

Provide the application ID, corresponding safe name, and folder name to your Guardium system administrator. Each Guardium datasource is configured to access the safe that is assigned to this application ID.

## Adding and removing account permissions on CyberArk

---

The CyberArk administrator can grant or revoke permissions to the Guardium system on the CyberArk vault server.

The Guardium system's account inherits all permissions from the group that it is added to. The minimum group permissions that are required are: List, Retrieve, and View Accounts.

Use the following procedures to add or remove the Guardium system's account from the CyberArk group.

## Providing permission to the Guardium system

---

Use the following procedure to provide permission to the Guardium system on CyberArk.

Note: The CyberArk administrator must grant permission to complete installation of CyberArk on the Guardium system.

1. Use the CyberArk client to log in to vault server.
2. From the menu, go to Tools > Administrative Tools > Users and Groups.
3. On the Users and Groups on Server Vault page, select the group that owns your safe. Click Update.
4. On the Update group page, click Add and select User from the drop-down menu.
5. On the Add Members to Group page click the Applications folder, select the member (Guardium system's account name) *Prov\_Guardium system's address*, and click the right arrow button to move the member to the group.
6. Click ok to add the account to the group.

## Revoking the Guardium system's permissions on CyberArk

---

When CyberArk is uninstalled from the Guardium system, use the following procedure to revoke permissions on CyberArk.

Note: To reinstall CyberArk on your Guardium system, you must remove the CyberArk account from the group.

1. Use the CyberArk client to log in to vault server.
2. From the menu, go to Tools > Administrative Tools > Users and Groups.
3. On the Users and Groups on Server Vault page, click the Applications folder, and select the member (Guardium system's account name) *Prov\_Guardium system's address*.
4. Click Delete to remove the account from the group.

## Deploying CyberArk on your Guardium system

---

The Guardium system administrator must use the following workflow to deploy CyberArk in the Guardium environment.

1. [Downloading and installing the CyberArk SDK patch](#)  
Download and install the CyberArk SDK patch on your Guardium® system.
2. [Installing CyberArk](#)  
Install CyberArk on your Guardium system by using the Command Line Interface.
3. [Configuring CyberArk on your Guardium system](#)  
Create a CyberArk application ID configuration on your Guardium system to access the assigned CyberArk safe.
4. [Defining Guardium datasources to access CyberArk](#)  
Configure the datasources on your Guardium system for automatic password provisioning. You can create a new datasource definition or edit an existing definition.

# Downloading and installing the CyberArk SDK patch

Download and install the CyberArk SDK patch on your Guardium® system.

## Before you begin

The CyberArk SDK/module/installer that is used by IBM Guardium is under restriction by CyberArk from export to certain areas of the world. To obtain this software, you must contact IBM support by [opening an IBM support case](#) to ensure compliance with these restrictions before downloading. In the case description, mention the geographic location, specifically the Country and State, of your Guardium deployment where the CyberArk patch will be deployed.

## Procedure

1. Download the CyberArk SDK patch to your central manager or standalone system.
2. Install the patch by using the command **store system patch install sys** and entering the patch number to install. To install the patch on a managed unit, use the GUI of the central manager to distribute the patch to one or more managed units. For more information, see [Central Patch Management](#).

Next topic: [Installing CyberArk](#)

# Installing CyberArk

Install CyberArk on your Guardium system by using the Command Line Interface.

## Before you begin

- The CyberArk administrator must set up the vault system with the required permissions.
- Obtain the CyberArk vault hostname or IP address, vault username, and vault password from the CyberArk administrator.
- If you installed CyberArk before, your Guardium system's account, *Prov\_Guardium system's address*, can exist in the CyberArk vault server. Delete the account from the vault server before you begin installation. For more information, see [Revoking the Guardium system's permissions on CyberArk](#).

## Procedure

1. Using the Guardium CLI, run the command **store cyberark install**.
2. If you meet the prerequisites, type **yes**.
3. When prompted, enter the vault hostname or IP address, the vault username, and vault password.
4. If you have standby vault servers available, you can optionally configure them now.  
A standby vault server IP list is a group of vault IP addresses that are set up by the CyberArk administrator. These vaults are used as a backup when a connection cannot be made to the primary vault server.
  - a. To add the standby vault server IP address list to your Guardium system, run the CLI command **store cyberark config\_failover**.
  - b. Enter a comma-separated list of CyberArk vault server IP addresses beginning with your primary vault server's IP address. The CyberArk Application Password Provider connects to the first available IP address on the list. If a connection cannot be made, the agent tries to access the next available IP address until it can successfully connect to a CyberArk vault server.
  - c. Confirm the new IP address list.

## What to do next

Provide the Guardium system's account name that is generated during the installation, to the CyberArk administrator. This account must be granted the appropriate permissions on the CyberArk vault server. For more information, see [Providing permission to the Guardium system](#).

After the account is granted permission, configure the CyberArk application ID on your Guardium system. For more information, see [Configuring CyberArk on your Guardium system](#).

Previous topic: [Downloading and installing the CyberArk SDK patch](#)

Next topic: [Configuring CyberArk on your Guardium system](#)

# Configuring CyberArk on your Guardium system

Create a CyberArk application ID configuration on your Guardium system to access the assigned CyberArk safe.

## Before you begin

Obtain the application IDs, corresponding safe names, and folder names from your CyberArk administrator.

## About this task

Each CyberArk application ID must be configured on your Guardium system to access the assigned CyberArk safe.

## Procedure

1. Log in to your Guardium system as the `admin` user.
2. Go to `Setup > Tools and Views > CyberArk Configurations`.
3. Click  to open the Create New CyberArk Configuration dialog.
4. In the `Name` box, enter an arbitrary name for the configuration. This name is used to configure your Guardium datasources to access the CyberArk vault.
5. In the `Application ID` box, enter the name of your application ID provided by your CyberArk administrator.
6. In the `Safe Name` box, enter the name of the CyberArk safe that is assigned to the Application ID.
7. In the `Folder Name` box, enter the name of the folder where the CyberArk safe is located.
8. Click `Save` to save the configuration.
9. If you have multiple application IDs, you can optionally create multiple configurations on your Guardium system by repeating steps 3 to 8. Alternatively, use the Guardium API command `create_cyberark_config`. For more information, see [create\\_cyberark\\_config](#).

## What to do next

Set up your Guardium datasources to access the credentials stored on CyberArk. For more information, see [Defining Guardium datasources to access CyberArk](#).

Previous topic: [Installing CyberArk](#)

Next topic: [Defining Guardium datasources to access CyberArk](#)

## Defining Guardium datasources to access CyberArk

Configure the datasources on your Guardium® system for automatic password provisioning. You can create a new datasource definition or edit an existing definition.

### Before you begin

Obtain the CyberArk objectname from your CyberArk administrator for each corresponding Guardium datasource.

### Procedure

1. To access an existing datasource definition, go to `Setup > Tools and Views > Datasource Definitions`, and click . To create a new datasource definition, see [Creating a datasource definition](#).
2. Configure the Credential type by selecting the External password radio button.
3. In the External password type Location drop-down, select CYBERARK.
4. In the CyberArk config drop-down, select the name of the CyberArk configuration that contains the Guardium datasource credential. For more information, see [Configuring CyberArk on your Guardium system](#).
5. In the CyberArk object name Location box, enter CyberArk objectname that corresponds with the Guardium datasource credential.
6. Click `Save`.
7. Click `Test connection` to ensure that the Guardium system can connect to the CyberArk vault and fetch the datasource credential.

## What to do next

Repeat steps 2 to 7 to configure all your Guardium datasources to access CyberArk.

Note: To provision passwords with no manual intervention, ensure that the CyberArk administrator enabled automatic management for your Guardium system's account. If your database is not supported, you can continue to store your credentials on CyberArk. However, the passwords are not automatically provisioned.

Previous topic: [Configuring CyberArk on your Guardium system](#)

## Upgrading the CyberArk SDK on a central manager or standalone system

When an upgrade patch is available, use this procedure to upgrade the CyberArk SDK on your central manager or standalone system .

### Before you begin

- Download the CyberArk upgrade patch.
- Obtain the CyberArk credentials that are required to connect to the CyberArk vault from the CyberArk administrator. The credentials that are required are the CyberArk vault web server hostname or IP address, the vault username, and the vault password.

### Procedure

1. Using the Guardium® CLI, enter the CyberArk credentials by using the command `store cyberark upgrade_parameter`.
2. Run the command `show system patch available` to list the patches that are available.
3. Run the CLI command `store system patch install sys` and enter the patch number to install.
4. Run the CLI command `show system patch installed` to display the status of the upgrade patch. If required, rerun the command to view the updated status of the installation.

## Upgrading the CyberArk SDK on a managed unit

Use the GUI on the central manager to distribute the CyberArk upgrade credentials and upgrade patch to the managed units.

## Before you begin

---

- Download the CyberArk upgrade patch.
- Obtain the CyberArk upgrade credentials that are required to connect to the CyberArk vault from the CyberArk administrator. The credentials that are required are the CyberArk vault web server hostname or IP address, the vault username, and the vault password.

## Procedure

---

1. On the central manager's GUI, access Manage > Central Management > Distribute Configuration Profiles.
  2. Create a CyberArk configuration profile, enter the CyberArk upgrade credentials, and distribute the profile to the managed units. For more information, see [Working with configuration profiles](#).
  3. Distribute the upgrade patch to the managed units. For more information on patch distribution, see [Central Patch Management](#).
- 

## Uninstalling CyberArk

Uninstall CyberArk from your Guardium system using the Command line Interface.

## Before you begin

---

To uninstall the CyberArk Application Password Provider, you must remove the corresponding entry for your Guardium system from the CyberArk vault server first. For more information, see [Revoking the Guardium system's permissions on CyberArk](#).

## Procedure

---

1. Using the Guardium CLI, run the command **store cyberark uninstall**.
  2. Type **yes** in the Guardium CLI to uninstall CyberArk.
- 

## Managing datasource credentials with AWS Secrets Manager

Integrate your Guardium® system with the Amazon Web Services (AWS) Secrets Manager to securely store, manage, rotate, and retrieve credentials for your datasources that use the Amazon Relational Database Service (RDS).

1. [Gathering required information from AWS Secrets Manager](#)  
Obtain the AWS Secrets Manager configuration information from the AWS management console.
  2. [Creating a secret user](#)  
Create a database user and assign credentials.
  3. [Creating a secret key](#)  
Create and configure a secret name and secret access key for the secret user on the AWS management console.
  4. [Selecting the authentication type and setting up roles](#)  
Guardium supports three authentication types to connect to the AWS Secrets Manager and AWS database services - Security Credentials, IAM Role, and IAM Instance Profile. Set up and configure the authentication type for your Guardium datasource.
  5. [Configuring the AWS Secrets Manager on your Guardium system](#)  
Configure the AWS Secrets Manager on your Guardium system. Each secret user must be configured on your Guardium system to access the AWS Secrets Manager.
  6. [Defining Guardium datasources to access AWS Secret Manager](#)  
Configure the datasources on your Guardium system for automatic password provisioning using the AWS Secrets Manager. You can create a new datasource definition or edit an existing definition.
- 

## Gathering required information from AWS Secrets Manager

Obtain the AWS Secrets Manager configuration information from the AWS management console.

## Before you begin

---

Ensure that the RDS service for your datasources is created.

## Procedure

---

Login to the AWS management console as an administrator and gather the following information:

- DB identifier (Guardium® instance name)
- DB name (Guardium service name)
- Endpoint (Guardium host name)
- Port number
- The location of your AWS data center.

Next topic: [Creating a secret user](#)

## Creating a secret user

Create a database user and assign credentials.

### Procedure

Your database administrator must create a database user (secret user) for your Guardium® datasource. The username and password that are assigned to this user are managed by the AWS Secrets Manager.

### What to do next

Note the username and password. This information is used when you create a secret key.

Previous topic: [Gathering required information from AWS Secrets Manager](#)

Next topic: [Creating a secret key](#)

## Creating a secret key

Create and configure a secret name and secret access key for the secret user on the AWS management console.

### Before you begin

Ensure that you have the secret username and password that you used to create a secret user. For more information, see [Creating a secret user](#).

### Procedure

1. Log in to the Amazon AWS management console and ensure that you are connected to the relevant data center.
2. Access Services > Security, Identity, & Compliance > Secrets Manager to view, edit, or create a secret.
3. Edit a secret by clicking the Secret name. To create a secret, click Store a new secret.
4. Select the secret type by clicking Credentials for RDS database.
5. Enter the secret username and password.
6. Use the DefaultEncryptionKey to encrypt your secret information.
7. Choose your RDS database and click Next.
8. Enter a Secret name and description. This secret name is used in the Guardium® datasource definition to reference your datasource and retrieve the datasource credentials.
9. Select Enable automatic rotation and select the required rotation interval from the drop-down.
10. Select Create a new Lambda function to perform rotation.
11. In the SecretsManager field, enter your secret name.
12. Under Select which secret will be used to perform the rotation select Use this secret. Then, click Next.
13. Review your entries, then click Store.

## Results

You can now click the Secret name to do the following:

- View the username and password by clicking Retrieve secret value.
- Change the password for the secret user, if required, by clicking Rotate secret immediately.

### What to do next

Note the name of the secret. This information is used when you define your datasources to retrieve credentials from the AWS Secrets Manager.

Previous topic: [Creating a secret user](#)

Next topic: [Selecting the authentication type and setting up roles](#)

## Selecting the authentication type and setting up roles

Guardium® supports three authentication types to connect to the AWS Secrets Manager and AWS database services - Security Credentials, IAM Role, and IAM Instance Profile. Set up and configure the authentication type for your Guardium datasource.

- [Authenticating by using security credentials](#)  
Create an access key ID and a secret access key to use this legacy authentication type.
- [Authenticating by using IAM Role](#)  
The IAM role authentication type allows for an IAM Instance Profile to be assumed by specifying a Role Amazon Resource Name (ARN) in addition to an access key ID and secret access key. In this authentication scenario, temporary security credentials are used to connect to AWS Secrets Manager/AWS Secret Manager or AWS database services.
- [Authenticating by using IAM instance profile](#)  
You can authenticate by using the IAM instance profile only when you use a Guardium instance that is deployed on AWS EC2.

Previous topic: [Creating a secret key](#)

Next topic: [Configuring the AWS Secrets Manager on your Guardium system](#)

# Authenticating by using security credentials

Create an access key ID and a secret access key to use this legacy authentication type.

## Procedure

1. In the Amazon AWS management console, click your user name. From the menu, select My Security Credentials.
2. Under Access keys for CLI, SDK, & API access, select Create access key to generate an access key ID and secret access key.  
Note: If an access key ID and a secret access key already exist, you can delete them or make them inactive. However, you might lose connectivity to an application that is using the keys.

# Authenticating by using IAM Role

The IAM role authentication type allows for an IAM Instance Profile to be assumed by specifying a Role Amazon Resource Name (ARN) in addition to an access key ID and secret access key. In this authentication scenario, temporary security credentials are used to connect to AWS Secrets ManagerAWS Secret Manager or AWS database services.

- [Authenticating by using IAM Role for AWS Secrets Manager](#)
- [Authenticating by using IAM Role for AWS database service](#)

# Authenticating by using IAM Role for AWS Secrets Manager

## About this task

Learn how to connect to AWS Secrets Manager using IAM role.

## Procedure

1. Log in to the Amazon AWS management console and ensure that you are connected to the relevant data center.
2. Click Services. Then, from the Security, Identity, & Compliance menu, select IAM.
3. From the menu, select Roles and then click Create role.
4. Under Common use cases, select EC2. Click Next: Permissions, then click Next: Tags, and then click Next: Review.
5. In the Role name field, enter the role name that you want to create. Example: to create role for *Guardium\_AWS\_Secret\_Manager\_Role*
6. Click Create role to create the Role ARN. Your Role ARN appears in the following format: *arn:aws:iam:<AWS Account ID>:instance-profile/<Role name>*.
7. Click Attach policies and then click Create policy to create three policies to integrate your Guardium® system with the AWS Secrets Manager. You can use the visual editor or JSON to add your code.

- a. Create a policy to assume role.

Example code:

```
Secret-mgr-assume-role-policy
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": "sts:AssumeRole",
 "Resource": "arn:aws:iam::role/*"
 }
]
}
```

Click Review policy and save the policy. The policy appears in the following format: *arn:aws:iam:<AWS Account ID>:policy/<policy-name>*

- b. Create a second policy to list the secret manager service to read secrets for all resources.

Example code:

```
Secret-mgr-read-all-secret-policy
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": "secretsmanager:GetSecretValue",
 "Resource": "arn:aws:secretsmanager:*:01234567901:secret:*
```

In the example, 01234567901 indicates the AWS account number. The wildcard *secret:\** indicates that all secrets are read.

Click Review policy and save the policy. The policy appears in the following format: *arn:aws:iam:<AWS Account ID>:policy/<policy-name>*

8. Define the trust relationship for the secret user by accessing Services->Identity and Access Management (IAM)->Roles. Select the role, click Trust relationships, then click Edit trust relationship and enter the code to create a trust relationship. Example:

```
Trust relationship
{
 "Version": "2012-10-17",
```

```

 "Statement": [
 {
 "Effect": "Allow",
 "Principal": {
 "AWS": [
 "arn:aws:iam::01234567901:role/Test1_Guardium_AWS_Secret_Manager_Role",
 "arn:aws:iam::01234567901:role/Test2_Guardium_AWS_Secret_Manager_Role",
 "arn:aws:iam::01234567901:user/nameofuser",
],
 "Service": "ec2.amazonaws.com"
 },
 "Action": "sts:AssumeRole"
 }
]
}

```

In the example, `01234567901` indicates the AWS account number and `nameofuser` is the username that is used to login to the AWS account.

Include the lines `arn:aws:iam::01234567901:role/Test1_Guardium_AWS_Secret_Manager_Role` or `arn:aws:iam::01234567901:role/Test2_Guardium_AWS_Secret_Manager_Role` in your code only when you use IAM instance profile and you want the roles to assume an alternate role.

In the example, `Test1_Guardium_AWS_Secret_Manager_Role` and `Test2_Guardium_AWS_Secret_Manager_Role` are the rolenames that are allowed to assume an alternate role `Guardium_AWS_Secret_Manager_Role`.

Review the code and click Update trust policy.

## What to do next

Note the following information:

- The access key ID and the secret access key for the secret user.
- The role ARN that is created in step [6](#).

This information is used to configure the AWS Secrets Manager on your Guardium system.

## Authenticating by using IAM Role for AWS database service

### About this task

12.1 and later Learn how to connect to AWS database services by using IAM role.

### Procedure

- Log in to the Amazon AWS management console and make sure that you are connected to the relevant data center.
- Click Services. Then, from the Security, Identity, & Compliance menu, select IAM.
- From the menu, select Roles and then click Create role.
- Under Common use cases, select EC2. Click Next: Permissions, then click Next: Tags, and then click Next: Review.
- In the Role name field, enter the role name that you want to create. Example: to create role for `Guardium_AWS_<databaseName>_Role`
- Click Create role to create the Role ARN. Your Role ARN appears in the following format: `arn:aws:iam:<AWS Account ID>:instance-profile/<Role name>`.
- Click Attach policies and then click Create policy to create three policies to integrate your Guardium® system with AWS database services. You can use the visual editor or JSON to add your code.

- Create a policy to assume role.

Example code:

```

Database-assume-role-policy
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": "sts:AssumeRole",
 "Resource": "arn:aws:iam::*:role/*"
 }
]
}

```

Click Review policy and save the policy. The policy appears in the following format: `arn:aws:iam:<AWS Account ID>:policy/<policy-name>`

- Create a second policy with the minimum access permissions required to run VA tests for your AWS database services.

Example code for DynamoDB:

```

DynamoDB-VA-policy
{
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": [
 "dynamodb:DescribeTable",
 "dynamodb:GetResourcePolicy",
 "dynamodb>ListTables",
 "dynamodb>ListStreams",
 "dynamodb>CreateTable",
 "dynamodb>DeleteTable",
 "dynamodb:DescribeContinuousBackups",
]
}

```

```

 "cloudtrail>ListTrails",
 "cloudtrail>GetEventSelectors",
 "iam>ListEntitiesForPolicy"
],
 "Resource": "arn:aws:secretsmanager:*:01234567901:secret:*
```

Click Review policy and save the policy. The policy appears in the following format: `arn:aws:iam:<AWS Account ID>;policy/<policy-name>`

8. Define the trust relationship for the secret user by accessing Services > Identity and Access Management (IAM) > Roles. Select the role, click Trust relationships, then click Edit trust relationship and enter the code to create a trust relationship. Example:

```

Trust relationship
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
 "Principal": {
 "AWS": [
 "arn:aws:iam::01234567901:role/Test1_Guardium_AWS_Database",
 "arn:aws:iam::01234567901:user/nameofuser",
],
 "Service": "ec2.amazonaws.com"
 },
 "Action": "sts:AssumeRole"
 }
]
}
```

In the example, `01234567901` indicates the AWS count number and `nameofuser` is the username that is used to login to the AWS account.

Include the lines `arn:aws:iam::01234567901:role/Test1_Guardium_AWS_Database_Role` in your code only when you use IAM instance profile and you want the roles to assume an alternate role.

In the example, `Test1_Guardium_AWS_Database` is the rolename that is allowed to assume an alternate role `Guardium_AWS_<databaseName>_Role`.

Review the code and click Update trust policy.

## What to do next

---

Note the following information:

- The access key ID and the secret access key for the secret user.
- The role ARN that is created in step [6](#).

This information is used to configure the AWS Secrets Manager on your Guardium system.

## Authenticating by using IAM instance profile

---

You can authenticate by using the IAM instance profile only when you use a Guardium instance that is deployed on AWS EC2.

### Before you begin

---

Create the IAM role, the related policies, and obtain the Role ARN. For more information, see [Authenticating by using IAM Role](#).  
Note:

- When you configure the IAM instance profile for the AWS Secrets Manager on your Guardium system, you can use the Role ARN that is assigned on the AWS Secrets Manager or optionally use an alternate Role ARN.
- To monitor streams by using different IAM roles, create an account for each IAM role.

### Procedure

---

1. Log in to the Amazon AWS management console and ensure that you are connected to the relevant data center.
2. Access Services > Compute > EC2.
3. Under Resources, click Running instances.
4. Select the Guardium® EC2 image.
5. Access Action > Instance settings > Attach/Replace IAM Role.
6. From the IAM Role drop down, select the Role ARN that you created for the IAM Role configuration.

## What to do next

---

Configure the AWS Secrets Manager on your Guardium system.

## Configuring the AWS Secrets Manager on your Guardium system

---

Configure the AWS Secrets Manager on your Guardium® system. Each secret user must be configured on your Guardium system to access the AWS Secrets Manager.

## Before you begin

---

Make sure that you have the access key ID, the secret access key, and the Role ARN, if applicable, for your secret user. For more information, see [Selecting the authentication type and setting up roles](#).

## Procedure

---

1. Access Setup> Tools and Views> AWS Secret Manager Configurations.  
12.1 and later Access Setup> Tools and Views > AWS Authentication Configuration.
2. Click  to open the Create New AWS Secret Manager Configuration dialog.  
12.1 and later Click  to open the Create New AWS Authentication Configuration dialog.
3. In the Name field, enter an arbitrary name for the configuration. This name is used to configure your Guardium datasources to access the AWS Secrets Manager.
4. 12.1 and later Select the Secrets Manager checkbox.
5. In the Secret key for username field, enter the exact value of the Secret Key label for the *username* field that is specified in your AWS Secrets Manager Secret value vault. If the label for *username* is defined by the user, enter the user-defined value. The default value is *username*.
6. In the Secret key for password field, enter the exact value of the Secret Key label for the *password* field that is specified in your AWS Secrets Manager Secret value vault. If the label for *password* is defined by the user, enter the user-defined value. The default value is *password*.  
12.1 and later  
Note: If you do not select the Secrets Manager check box, ignore step 5 and step 6.
7. Select the Authentication type for your secret user. For more information on authentication types, see [Selecting the authentication type and setting up roles](#).
8. Depending on the type of authentication that you select, enter the AWS access key ID, the AWS secret access key ID, and the Role ARN.  
Note:
  - When you configure the IAM instance profile for the AWS Secrets Manager on your Guardium system, you can use the Role ARN that is assigned on the AWS Secrets Manager or optionally use an alternate Role ARN.
  - To monitor streams by using different IAM roles, create an account for each IAM role.
9. Click Save to save the configuration.

## What to do next

---

Note the name of your configuration. This information is used when you define your datasources to retrieve credentials from the AWS Secrets Manager.

Previous topic: [Selecting the authentication type and setting up roles](#)

Next topic: [Defining Guardium datasources to access AWS Secret Manager](#)

## Related reference

---

- [API to list AWS Secrets Manager configurations](#).
- [API to update an AWS Secrets Manager configuration](#).
- [API to delete an AWS Secrets Manager configuration](#).

## Defining Guardium datasources to access AWS Secret Manager

---

Configure the datasources on your Guardium® system for automatic password provisioning using the AWS Secrets Manager. You can create a new datasource definition or edit an existing definition.

## Before you begin

---

Ensure that you gathered the following information:

- The name of the AWS Secrets Manager configuration. For more information, see [Configuring the AWS Secrets Manager on your Guardium system](#).
- The secret name. For more information, see [Creating a secret key](#).
- The location of your AWS data center, hostname, port number, and service name. For more information, see [Gathering required information from AWS Secrets Manager](#).

## Procedure

---

1. To access an existing datasource definition, go to Setup> Tools and Views> Datasource Definitions, and click . To create a new datasource definition, see [Creating a datasource definition](#).
2. Configure the Credential type by selecting the External password radio button.
3. In the External password type Location drop-down, select AWS Secrets Manager.
4. In the AWS Secrets Manager config drop-down, select the name of the AWS Secrets Manager configuration.
5. In the Secret name field, enter the secret name that you created on your AWS management console.
6. Enter the Region location of your data center that is configured on your AWS management console.
7. Enter the Host name/IP, Port number, and Service name that you gathered from your AWS management console.
8. Click Save and Test connection to ensure that the Guardium system can connect to the AWS Secrets Manager and fetch the datasource credential.

## What to do next

---

Repeat steps [2](#) to [8](#) to configure all your Guardium datasources to access the AWS Secrets Manager.

## Managing datasource credentials with HashiCorp

Integrate your Guardium® system with HashiCorp to securely store, manage, rotate, and retrieve credentials for all supported datasources.

You can configure your Guardium system to authenticate to the HashiCorp vault by using a username and password with no Transport Layer Security (TLS), server-side authentication with TLS, or client-side authentication with TLS. If you use client-side authentication with TLS, you must create and import a client signed certificate on all your systems such as the central manager and managed units, if any.

### 1. Gathering required information from HashiCorp

Obtain the HashiCorp configuration information from your HashiCorp administrator.

### 2. Creating a HashiCorp Policy

The HashiCorp administrator must create a policy that contains the permissions that are required to read and list the credentials and roles from the HashiCorp vault.

### 3. Creating and importing a client certificate

If you are using client-side authentication with TLS to access the HashiCorp vault, you must create and import a client certificate on all your systems such as the central manager and managed units.

### 4. Configuring HashiCorp on your Guardium system

Configure your Guardium system to access the HashiCorp vault and retrieve datasource credentials.

### 5. Defining Guardium datasources to access the HashiCorp vault

Configure the datasources on your Guardium system for automatic password provisioning by using HashiCorp. You can create a new datasource definition or edit an existing definition.

---

## Gathering required information from HashiCorp

Obtain the HashiCorp configuration information from your HashiCorp administrator.

## Before you begin

Ensure that the HashiCorp administrator has set up and configured the following items for your HashiCorp vault.

- Secrets: the default path or the custom path to the datasource credentials.
- Access: the authentication method and policy information
- Policies: the permissions that include static or dynamic credentials, roles, and configuration information for client web certificates. For more information on creating a policy, see [Creating a HashiCorp Policy](#).

## Procedure

Gather the following information from your HashiCorp administrator.

- The role name that is unique to your datasource.
- The custom path to your datasource credentials, if any.
- The hostname and IP address for your database, if applicable.
- The port number for your database.
- The database name.

Next topic: [Creating a HashiCorp Policy](#)

---

## Creating a HashiCorp Policy

The HashiCorp administrator must create a policy that contains the permissions that are required to read and list the credentials and roles from the HashiCorp vault.

## Procedure

The following is an example of a policy with the minimum amount of privilege that is required to access the vault.

```
Permissions to dynamic roles and creds for different paths
path "database/creds/*" {
 capabilities = ["read", "list"]
}

Permissions to dynamic roles and creds for different paths
path "database/roles/*" {
 capabilities = ["read", "list"]
}

Permissions to static roles and creds for different paths
path "database/static-creds/*" {
 capabilities = ["read", "list"]
}

Permissions to static roles and creds for different paths
```

```

path "database/static-roles/*" {
 capabilities = ["read", "list"]
}

Permissions to dynamic roles and creds for different paths
path "custom/123/abc123/databases/mongo/mongo123/creds/*" {
 capabilities = ["read", "list"]
}

Permissions to dynamic roles and creds for different paths
path "custom/123/abc123/databases/mongo/mongo123/roles/*" {
 capabilities = ["read", "list"]
}

Permissions to static roles and creds for different paths
path "custom/123/abc123/databases/mongo/mongo123/static-creds/*" {
 capabilities = ["read", "list"]
}

Permissions to static roles and creds for different paths
path "custom/123/abc123/databases/mongo/mongo123/static-roles/*" {
 capabilities = ["read", "list"]
}

Configure for client web certificates
path "auth/*" {
 capabilities = ["read"]
}

```

Previous topic: [Gathering required information from HashiCorp](#)  
 Next topic: [Creating and importing a client certificate](#)

---

## Creating and importing a client certificate

If you are using client-side authentication with TLS to access the HashiCorp vault, you must create and import a client certificate on all your systems such as the central manager and managed units.

### Procedure

1. On your Guardium® system, create a certificate signing request (CSR) file by using the CLI command **create csr alias**.

Copy the CSR starting at the '----BEGIN NEW CERTIFICATE REQUEST----' tag and ending at the '----END NEW CERTIFICATE REQUEST' tag.

Provide the CSR file to a Certificate Authority (CA) of your choice to obtain a valid certificate. The certificate must be in PEM format to import into your Guardium system. After you receive the PEM certificate from your CA, import the certificate by using the CLI command **store certificate keystore alias**.

Example:

```

create csr alias

Please enter a one-word alias to uniquely identify this certificate:
vault

If the Common Name (CN=) field is used as an Identifier, prefix the identifier with ID: (example ID:1234).

What is the Common Name (CN=) for this certificate (default: gmachine.com) ?

What is the name of your organizational unit (OU=) ? YourTeam

What is the name of your organization (O=) ? YourCompany

What is the name of your city or locality (L=) ? YourCity

What is the name of your state or province (ST=) ? YourState

What is the two-letter country code for this unit (C=) ? US

What encryption algorithm should be used?
1=dsa
2=rsa
3=ecdsa
Default: RSA

Invalid input or no input. Using default 'RSA'

What is the keysize to use (1=1024 or 2=2048. Default '2048') ?
Invalid input or no input. Using default '2048'

Add up to 99 optional SANs (Subjective Alternative Name) in fully qualified domain name format. To continue without adding
a SAN, press Enter.

What is the name of SAN #1 ?

Generating CSR...

Certificate Request:
Data:
Version: 0 (0x0)

```

```
Subject: C=US, ST=YourState, L=YourCity, O=YourCompany, OU=YourTeam, CN=gmachine.com
```

```
-----BEGIN NEW CERTIFICATE REQUEST-----
```

```
#####
#####
```

```
-----END NEW CERTIFICATE REQUEST-----
```

```

```

```
store certificate keystore alias
```

```
ok
```

- On the Guardium system that contains the CA certificate, copy the CSR file to the database server to have it sign with a CA root certificate.  
Example:

```
openssl x509 -req -in gmachine_signing_request.csr -CA ca_root_certificate.crt -CAkey ca_private_key.key -CAcreateserial -out gmachine_signed_certificate.crt -days 10000 -sha256
```

- Configure the HashiCorp vault with the new trusted client certificate that is allowed to authenticate.

Example:

```
[root@Hashicorp ssl]# vault write auth/cert/certs/gmachine \
 display_name=gmachine \
 policies=guardium_policy \
 certificate=@gmachine_signed_certificate.crt \
 ttl=3600
Success! Data written to: auth/cert/certs/gmachine
```

- Store the signed client certificate that is sent back from the database server into the tomcat.keystore of your Guardium system.

If the client certificate is signed by a self-sign CA certificate, then you must also upload the CA certificate along with the signed client certificate.  
Example to import both the CA certificate and the signed client certificate together:

```
store certificate keystore alias console
```

```
Please enter a one-word alias to uniquely identify this certificate:
vault
```

```
Found the following Certificate Signing Request (CSR):
```

```

```

```
Certificate Request:
```

```
Data:
```

```
Version: 0 (0x0)
```

```
Subject: Subject: C=US, ST=YourState, L=YourCity, O=YourCompany, OU=YourTeam, CN=gmachine.com
```

```
-----BEGIN NEW CERTIFICATE REQUEST-----
```

```
#####
#####
```

```
-----END NEW CERTIFICATE REQUEST-----
```

```

```

```
Are you importing a certificate that corresponds to this CSR? [y/N]
```

```
y
```

```
Please paste your End-Entity certificate below in PEM encoded format. A certificate in
PEM encoded format should include the '-----BEGIN CERTIFICATE-----' and '-----END
CERTIFICATE-----' tags. The Certificate Authority (CA) Root and Intermediate
certificate(s) (if applicable) will also need to be pasted at this time for
validation purposes. Please ensure that all certificates are in PEM format and
include the aforementioned tags. When pasting multiple certificates, please make
sure that each certificate is pasted on a new line in the following order:
```

```
-----BEGIN CERTIFICATE-----
(End-Entity certificate)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Intermediate certificate(s) - if applicable)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Root certificate)
-----END CERTIFICATE-----
```

```
Once done pasting your certificate(s), press ENTER followed by CTRL-D to continue.
```

```
-----BEGIN CERTIFICATE-----
```

```
#####
#####
```

## Configuring HashiCorp on your Guardium system

Configure your Guardium® system to access the HashiCorp vault and retrieve datasource credentials.

## Before you begin

If you are using client-side authentication with TLS, create and import a client certificate on all your systems including the central manager and managed units. For more information, see [Creating and importing a client certificate](#).

## About this task

Use the following procedure to configure your Guardium system to access the HashiCorp vault by using the Guardium UI.  
Note: Create this configuration only on your central manager or stand-alone system.

## Procedure

1. Access Setup > Tools and Views > HashiCorp Configurations.
  2. Click  to open the Create New HashiCorp Vault Access Configuration dialog.
  3. In the Name field, enter a name for the HashiCorp configuration.
  4. Select the Authentication type for the configuration. You can authenticate to the HashiCorp vault by using a username and password with no TLS, server-side authentication with TLS, or client-side authentication with TLS.
  5. Enter the HashiCorp vault hostname.
  6. Enter the HashiCorp vault port number.
  7. Depending on the type of authentication, enter the username, password, and select the Use TLS option, if applicable:
    - If the authentication type is Username & Password without TLS, enter the username and password. Do not check Use TLS.
    - If the authentication type is Username & Password with server-side authentication, enter the username and password. Then, check Use TLS.
    - If the authentication type is TLS Certificates with client-side authentication, check Use TLS and import the client signed certificate if you haven't already.
  8. Save and Test connection.

## What to do next

Note the name of your configuration. This information is used when you define your datasources to retrieve credentials from the HashiCorp vault.  
Important: If you rebuild your Guardium system, you must delete any related TLS certificates from the HashiCorp vault. Then, create and import the client certificates again.

**Previous topic:** [Creating and importing a client certificate](#)  
**Next topic:** [Defining Guardium datasources to access the HashiCorp vault](#)

## Related reference

- [API to create a HashiCorp configuration.](#)

## Defining Guardium datasources to access the HashiCorp vault

Configure the datasources on your Guardium® system for automatic password provisioning by using HashiCorp. You can create a new datasource definition or edit an existing definition.

### Procedure

1. To access an existing datasource definition, go to **Setup > Tools and Views > Datasource Definitions**, and click . To create a new datasource definition, see [Creating a datasource definition](#).
2. Configure the Credential type by selecting the External password radio button.
3. In the External password type drop-down, select HashiCorp.
4. In the HashiCorp configuration drop-down, select the name of the HashiCorp configuration.
5. In the Role field, enter role name for the datasource that is created by the HashiCorp administrator .
6. Enter the Path if the HashiCorp administrator created a custom path to access the datasource credentials.
7. Enter the Host name/IP, Port number and Database information for the datasource if it has not been configured already.
8. Click Save and Test connection to ensure that the Guardium system can connect to the HashiCorp vault and fetch the datasource credential.

### What to do next

Repeat steps [2](#) to [8](#) to configure all your Guardium datasources to access the HashiCorp vault.

**Previous topic:** [Configuring HashiCorp on your Guardium system](#)

## Database Auto-discovery

The Auto-Discovery application scans and probes your servers for open ports to prevent unknown or unwanted connections to your network. You can run auto-discovery processes on demand, or schedule the processes on a periodic basis.

### Database Auto-discovery Overview

There are many scenarios where databases can exist undetected on your network and expose your network to potential risk. Old databases might be forgotten and unmonitored, or a new database might be added as part of an application package. A rogue DBA might also create a new instance of a database to conduct malicious activity outside of the monitored databases.

Auto-discovery uses scan and probe jobs to ensure that no database goes undetected in your environment.

- A *scan* job scans each specified host (or hosts in a specified subnet), and compiles a list of open ports that are specified for that host.
- A *probe* job uses the results of the scan to determine whether there are database services that are running on the open ports. A probe job cannot be completed without first running a scan. View the results of this job in the Databases Discovered predefined report.

Follow these steps to use the Auto-discovery application:

1. Create an Auto-discovery process to search specific IP addresses or subnets for open ports.
2. Run the Auto-discovery process on demand or on a scheduled basis.
3. View the results of the process with Auto-discovery reports, or create custom reports.

Auto discovery has its own processes that are independent of audit processes, but they work exactly the same way as audit processes.

You can only enter IPs when doing a scan, you cannot enter host names. However, Guardium does detect host names as part of the report. Guardium does not truncate host names in the Guardium product. However, it may be necessary to configure the report to have wider columns.

Guardium auto-discovery does not guess about databases that appears during a probe. If Guardium auto-discovery says it has found a database, then it is 100% certain what the database is.

Attention: Database auto-discovery works with the following databases:

- Db2
- Informix
- MongoDB
- Microsoft SQL Server
- MySQL
- Netezza
- Oracle
- PostgreSQL
- SAP HANA
- Sybase
- Teradata

Auto-discovery only finds running databases. Databases need to be started if discovery is to be used during the installation. Due to how the AIX KTAP interception works, the databases need to be restarted after the first time S-TAP runs. If the databases are not restarted, some interception does not work.

## Create an Auto-discovery Process

Specify which host and ports the Auto-discovery process scans.

1. Configure Auto-discovery by clicking Discover > Database Discovery > Auto-discovery Configuration.
2. Click New to create a new process and open the Auto-discovery Process Builder.
3. Enter a Process name that is unique on your Guardium® system.
4. To run a probe job immediately after the scan job completes, check the Run probe after scan check box.
5. To scan for open ports on hosts where discovery is blocked, check the Skip host discovery check box.  
Note: Host discovery requires ports 80 and 443. If those ports are blocked, using Skip host discovery forces scanning for open ports on those hosts. This is equivalent to `nmap -Pn`.
6. For each host or subnet to be scanned, enter the host and port, and click Add scan. Each time that you add a scan, it is added to the task list.  
Note:
  - Wildcard characters are enabled. For example: to select all addresses beginning with 192.168.2, use 192.168.2.\*.
  - Specify a range of ports by putting a dash between the first and last port numbers in the range. For example: 4100-4102.
  - After you add a scan, modify the host or port by typing over it. Click Apply to save the modification.
  - If you have a dual stack configuration, you will need to set up a scan for both the IPv4 and the IPv6 addresses.
  - To remove a scan, click the Delete this task icon for the scan. If a task has scan results dependent upon it, the scan cannot be deleted.
7. When finished adding scans, click Apply, and run the job or schedule the job in the future.

See [Scheduling](#) if you need help defining a schedule.

## Run or Schedule an Auto-discovery Process

---

Run or schedule scan and probe jobs as part of the Auto-discovery process.

1. Click Discover > Database Discovery > Auto-discovery Configuration.
2. Select the process to-be run from the Auto-discovery Process Selector list and do one of the following:
3.
  - To run a job immediately, click Run Once Now.
  - To schedule a job in the future, click Modify Schedule (see [Scheduling](#) if you need help defining a schedule).  
Note: A probe job cannot run without the results of the scan job. You can schedule the two jobs to run individually, or you configure the probe job to run after the scan job by modifying a process, and checking the Run probe after scan check box.
4. After you start or schedule a job, you can click Progress Summary to display the status of this process.

## Auto-discovery Reports

---

Open the Auto-discovery reports by clicking Discover > Reports and selecting from the available reports.

You can create custom reports with the Auto-discovery Query Builder. Open the Auto-discovery Query Builder by clicking Discover > Database Discovery > Auto-discovery Query Builder.

## Databases Discovered Report

---

Open the Databases Discovered report by clicking Discover > Reports > Databases Discovered.

The main entity for this report is the Discovered Port. Each individual port that is discovered has its own row in the report. The columns that are listed are: Time Probed, Server IP address, Server Host Name, DB Type, Port, Port Type (usually TCP), and a count of occurrences.

There are no special runtime parameters for this report, but it excludes any discovered ports with a database type of Unknown.

When an auto-discovery process definition changes, the statistics for that process are reset.

## Auto-discovery Tracking Domain

---

The Auto-discovery Tracking domain contains all of the data reported by Auto-discovery processes. Click any entity name to display its attributes.

Auto-discovery Tracking Domain Entities

- Auto-discovery Scan provides a time stamp for each scan operation.
- Discovered Host provides the IP address and host name for each discovered host.
- Discovered Port provides a time stamp, identifies the port, and provides the database type for each port discovered open.

## Cloud database service protection

---

Protect your cloud databases by using data activity stream monitoring or by using native audit.

### Cloud database service protection for Amazon AWS with data streams

---

After you define a cloud DB service account with an audit type of Data Streams, you can use cloud database service protection with data streaming to monitor AWS data streams from selected Guardium collectors. For more information, see [Cloud database service protection Amazon AWS setup](#).

### Cloud database service protection for Azure event hubs

---

After you define a cloud DB service account with an audit type of Data Streams, you can use cloud database service protection with data streaming to monitor Azure event hubs from selected Guardium collectors. For more information, see [Cloud database service protection Azure setup](#).

## Cloud database service protection with native audit

---

Cloud database protection provides classification, vulnerability assessment, and object auditing on cloud databases, using the native audit. For more information, see [Cloud database service protection workflow](#)

- [Cloud database service protection Amazon AWS setup](#)

You can use AWS database activity monitoring to provide cloud database service protection with Guardium. Before you can define a Guardium cloud DB service account, you need to perform a few setup steps.

- [Cloud database service protection Azure setup](#)

Use database activity monitoring to provide cloud database service protection for Azure event hubs.

- [Cloud database service protection with native audit](#)

Cloud database protection provides classification, vulnerability assessment, and object auditing on cloud databases, using the native audit.

---

## Cloud database service protection Amazon AWS setup

You can use AWS database activity monitoring to provide cloud database service protection with Guardium®. Before you can define a Guardium cloud DB service account, you need to perform a few setup steps.

Note: AWS supports data activity monitoring only for new clusters.

### Create an Amazon RDS cluster

---

To use database activity monitoring, create an Amazon RDS cluster that uses Aurora PostgreSQL-compatible with PostgreSQL 10.7 database engine.

Take the following steps to create the Amazon RDS cluster:

1. From your AWS account, create a new KMS key (do not use the default KMS key).
2. Create an Amazon RDS cluster in a region that supports data activity monitoring (DAS).
3. Wait until the cluster and instances are created before you enable the database activity monitoring.

Note: Note the following limitations on database activity monitoring traffic:

- The following rules and policies are not supported:
  - Returned data and extrusion rules
  - Policies that interact with S-TAP (such as S-GATE, Ignore, Terminate)
  - SQL errors (AWS limitation)
- Audit data is processed in the order that it was received
- If more than one Guardium collector consumes from a stream, traffic is randomly distributed (because each collector has a different session ID)

## Define the AWS Identity and Access Management policy

---

Define the Identity and Access Management (IAM) policy for your AWS account as described in [Define AWS IAM for data streams](#).

After you create the Amazon RDS cluster and define the AWS IAM policy, you can define a Guardium cloud DB service account, as described in [Define, modify, and delete AWS cloud DB service accounts](#).

- [Define AWS IAM for data streams](#)

Define the Identity and Access Management (IAM) policy for your Amazon Web Services (AWS) account, depending on the required permissions.

- [Define, modify, and delete AWS cloud DB service accounts](#)

Define a Guardium cloud DB service account for Amazon AWS with your database credentials, and modify or delete the cloud DB service account.

- [Discover and configure AWS data streams](#)

Discover data streams in the AWS cloud account, and assign data streams to Guardium collectors.

- [Manage AWS data streams](#)

Manage and troubleshoot AWS data streams.

---

## Define AWS IAM for data streams

Define the Identity and Access Management (IAM) policy for your Amazon Web Services (AWS) account, depending on the required permissions.

The minimum IAM permissions for data streams include viewing the configuration and changing tags. The following JSON example defines the minimum permissions that you need to run cloud database service protection. You can use the sample JSON (or create your own) with the following changes:

- For the values in the Resource parameter, change the account portion of the Amazon Resource Name (ARN) to your account.
- For the KMS resource, change to the key that you used to create the database activity stream. If your site has multiple keys, you can set the key to the \* (asterisk) wildcard.

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
 "Action": [
 "kinesis>ListStreams",
 "cloudwatch:PutMetricData",
 "cloudwatch:GetMetricStatistics"
],
 "Resource": "*"
 }
]
}
```

```

},
{
 "Effect": "Allow",
 "Action": [
 "kinesis:RegisterStreamConsumer",
 "kinesis:DescribeStreamConsumer",
 "kinesis>ListStreamConsumers",
 "kinesis:DescribeStreamSummary",
 "kinesis:DescribeStream",
 "kinesis:GetShardIterator",
 "kinesis:GetRecords",
 "kinesis>ListShards",
 "kinesis:SubscribeToShard"
],
 "Resource": "arn:aws:kinesis::stream/*"
},
{
 "Effect": "Allow",
 "Action": [
 "kms:Decrypt"
],
 "Resource": "*"
},
{
 "Effect": "Allow",
 "Action": [
 "dynamodb>CreateTable",
 "dynamodb:DescribeTable",
 "dynamodb:GetItem",
 "dynamodb:PutItem",
 "dynamodb:Scan",
 "dynamodb:UpdateItem",
 "dynamodb>DeleteItem"

}

```

## Define, modify, and delete AWS cloud DB service accounts

Define a Guardium cloud DB service account for Amazon AWS with your database credentials, and modify or delete the cloud DB service account.

### Define a Guardium cloud DB service account

#### About this task

Create cloud accounts to manage the connection between your AWS cloud databases and Guardium.

#### Procedure

1. Browse to Discover > Database Discovery > Cloud DB Service Protection.
2. Click  to open the Create Cloud DB Service Account Definition window.
3. Define the account:
  - Name: An account name that is unique to your site.
  - Provider: Select Amazon as the provider name from the menu.
  - Audit type: Select Data Streams to use AWS database activity monitoring. If Audit type does not display, then you must enable access to data streams. For more information, see [enable\\_datastream](#).
  - Authentication type: Depending on the authentication type that you select, provide the requested information. The authentication types are:
    - Security Credentials: Select to specify user-based credentials to manage AWS access.
    - IAM Role: Select to use IAM roles to manage to your AWS access.
    - To monitor streams using different IAM roles, create an account for each IAM role.
  - IAM Instance Profile: Select when your Guardium instance is on EC2 and the EC2 instance has an attached IAM role with configured policies.  
Note: To use an IAM instance profile, the central manager and all collectors must be on EC2 and configured with an instance profile.

Depending on the configuration, the Authentication type can include the following options:

  - AWS access key ID and AWS secret access key ID: Supplied by Amazon.
  - Role ARN: The Amazon resource name (ARN) for the permissions that are assigned when you define the AWS IAM (as described in [Define AWS IAM for data streams](#)).
4. Click Create.

The account is created and the Cloud DB Service Accounts list updates with the new Cloud account.

#### What to do next

Discover and start monitoring the data streams. For more information, see [Discover and configure AWS data streams](#).

### Modify a cloud DB service account

You can modify all parameters except the provider.

#### Procedure

1. Select the cloud account under Cloud DB Service Accounts, and click in the right pane.
2. Modify the configuration.
3. Click Save.

## Delete a cloud DB service account

---

When you delete a cloud DB service account, Guardium no longer monitors database activity.

### Procedure

1. Select the account in the Cloud DB Service Accounts pane and click
2. From the Confirmation window, click Yes to delete the account or No to cancel the deletion.

## Discover and configure AWS data streams

---

Discover data streams in the AWS cloud account, and assign data streams to Guardium collectors.

### About this task

---

After you define your Guardium cloud DB service account for Amazon AWS, you can discover available data streams and assign them to Guardium collectors.

### Procedure

---

1. Browse to Discover > Database Discovery > Cloud DB Service Protection, and click the name of a Cloud DB service account. The Cloud DB Service Account page opens, and displays the Discover Streams table.  
Note: The next time that you access the Cloud DB Service Account page, the table is closed. Click Discover Streams to reopen the table.
2. Select the row of each region whose streams you want to discover and click Discover.  
Optionally, use the filter to limit your search. For example, type us into the filter window to show only data streams that contain the letters "us." Guardium searches the regions, and adds any new streams from the selected regions to the Streams table.
3. Scroll down to the Streams table (or click Hide Discover Streams).
4. Select a stream and then click Assign Collector to open the Assign Collector to Selected Stream window. Enter the following information:
  - Collector: Select one or more collectors from the Select collector list.  
Note: You can assign collectors only to the central manager (in a managed environment).
  - DB Type: The database type.
  - DB DNS endpoint: Your DB DNS endpoint.
  - Port: The DB DNS endpoint port.
  - Cluster resource ID: Required. The cluster resource ID for the AWS RDS cluster associated with the stream. If you enter an invalid or unknown cluster resource ID, an error is reported in the status for the stream.
  - Consumer group name: Determines whether multiple consumers have a shared or separate view of this data stream. The consumer group name can be any unique name. To share the data stream view, use the same consumer group name.
5. Optionally, select Start monitoring stream. If you do not start monitoring now, you can enable monitoring from the Streams table later.

### What to do next

---

Select the stream and use Enable monitoring and Disable monitoring to turn monitoring of the selected stream on and off.  
Manage your data streams. For more information, see [Manage AWS data streams](#).

## Manage AWS data streams

---

Manage and troubleshoot AWS data streams.

After your data streams are enabled and running, you can use the Streams table to track and manage the data streams.

### The Status column

---

The Stream table Status column provides a quick view of the health of the data stream. The meaning of the status colors is as follows,

- Green - Good. The Comments column reads All Good.
- Blue - Not yet configured.
- Gray - Unavailable.
- Yellow - Warning. Usually, yellow status includes the message `consumerNoInboundRecords`, which indicates that the consumer received no records in the last 10 minutes. This status is usually okay. However, if you see a yellow status when your database is processing queries, then something might be configured incorrectly, most likely on the network or cloud side.
- Red - An error condition. The Comments column might contain useful information about why the error occurred.

Tip: Hover your mouse over a status spot to see a status description.

## Enable and disable monitoring

---

From the Streams header, you can enable or disable monitoring for individual streams.

- To start monitoring a stream, select a disabled stream and click Enable Monitoring.
- To stop monitoring a stream, select a running stream and click Disable Monitoring.

## View information about individual collectors

---

For central manager configurations, when a stream is enabled, the Stream column displays a small  icon. Click the  to show details about each collector. In the Monitor enabled column, you can turn individual collectors on and off.

## View status history

---

Select a stream and then click Status History to view the status history for this stream. The following information displays for each collector in the stream:

- Status from and Status to - The start and end times for this status history period. When the state changes, the status history period ends.
- Collector (for central manager configurations) - The collector for this status history period.
- Status - The state of the collector during this period.
- Comments - Notes about the status. When a collector fails, the Comments section often contains useful information about why the failure occurred.

## Filter stream data

---

From the Streams header, enter text into the Filter dialog. The Streams table displays any stream with text that matches the filter text; the remaining streams are hidden.

## Create a stream manually

---

While it is recommended that you discover streams, you can, if needed, add a stream manually, as follows:

1. In the Streams table, click  to open the Add a new stream dialog.
2. In the Add a new stream dialog, specify the required parameters from the AWS console:
  - Stream name - The name of the stream from the RDS cluster configuration.
  - Region - One of the regions from the Select region list.
  - Collector - Collectors that are assigned to the stream.
  - DB type - The database type for the stream.
  - DB DNS endpoint - Your DNS endpoint.
  - Port - The DB DNS endpoint port.
  - Cluster resource ID - The cluster resource ID from your AWS account.
  - Consumer group name - Determines whether multiple consumers have a shared or separate view of this data stream. The consumer group name can be any unique name. To share the data stream view, use the same consumer group name.

## Cloud database service protection Azure setup

---

Use database activity monitoring to provide cloud database service protection for Azure event hubs.

You can use database activity monitoring to provide cloud database service protection for Azure event hubs with Guardium®. Before you can define a Guardium cloud database service account for Azure, you need to set up your Azure account or gather information about your existing account.

Note:

- Cloud database service protection for Azure event hubs works with Microsoft Azure SQL Database, Azure SQL Managed Instance, and Microsoft Azure Cosmos DB.
- To use cloud database service protection with Azure, you need to be able to create Consumer Groups, which requires the Azure Standard Pricing Tier. You cannot use the \$Default Consumer Group.
- 12.1 and later For 12.1 and later versions of Guardium, you can configure a single Azure event hub for different Azure cloud databases of the same type.

Important: If you are using Azure SQL Managed Instance, you must enable logging at both the server and database levels before you define the cloud database service account.

1. Make sure that the ssh, 5671, and 5672 ports are open.
2. Use SQL Server Management Studio (SSMS) to set up and enable a Server Audit Specification that sends SQL Security Audit Events to the Event Hub.
3. From your managed database, set up and enable the Database Audit Specification.
4. On the Azure Managed Instance page, browse to Monitoring > Diagnostic Settings > Logs > Categories, and then select SQL Security Audit Event.

## Gathering Microsoft Azure information

---

To use database activity monitoring, you need the following information about each Microsoft Azure event hub that you want to monitor. These parameters are created when you configure an Azure event hub. For detailed information about configuring Azure, see the Microsoft Azure documentation. Find or create the following Azure parameters:

- Namespace: The Event Hubs namespace.
- Event Hub Name: Created from within the Event Hubs namespace.
- Shared access policy name and key: From the Event Hubs Namespace. To create a shared access policy, select *Event Hubs Name* > Shared Access Policy > *your policy name* to generate a shared access key.  
Note: Do not use the shared access policy in the Event Hub.  
Select Manage, Send, and Listen options for the Policy Name.
- Consumer Group Name: From the Event Hubs Instance page for the selected Event Hub. From Entities, select or create a Consumer Group.  
Notes:

If you use the same Consumer Group for multiple collectors, traffic is split between the collectors. If you create a Consumer Group for each collector, each collector gets its own copy of the traffic.

You cannot use the \$Default Consumer Group.

- Storage Connection String: Create a storage account (from the Azure dashboard) and then from Storage accounts, select Shared access signature to generate a shared access signature and connection string. The Storage account contains checkpoints for consumer progress in the Event Hubs partition. For example:

```
BlobEndpoint=https://mystoragename.blob.core.windows.net/;QueueEndpoint=https://mystoragename.queue.core.windows.net/;File
Endpoint=https://mystoragename.file.core.windows.net/;TableEndpoint=https://mystoragename.table.core.windows.net/;SharedAccessSignature=sv=2019-12-12&ss=bfqt&srt=scs&sp=rw&ldacupx&se=2025-09-16T00:54:06Z&st=2020-09-
15T16:54:06Z&spr=https&sig=q%2FTuyiJqkNgfdfgdfgzaNj3V7Y0cr2EbLqo16Hg%3D
```

Note: On the Shared access signature window, change the expiry end date to meet your requirements.

- Cluster resource Id: To find the cluster (or database) resource string:
  - For AzureSQL - From the Azure dashboard, browse to Properties > Resource ID.
  - For any Cosmos data source - The resource ID is the part of the URL that starts with /subscriptions and ends with the *data source name*. You can copy the resource ID from the URL, for example, if the URL for Microsoft Azure is:

```
https://portal.azure.com/#@company.onmicrosoft.com/resource/subscriptions/8333367e-1234-467d-b3fc-
5b78c5721df0/resourceGroups/rg1/providers/Microsoft.DocumentDb/databaseAccounts/ibmcosmostable1/overview
```

Then the Cosmos resource ID is:

```
/subscriptions/8333367e-1234-467d-b3fc-
5b78c5721df0/resourceGroups/rg1/providers/Microsoft.DocumentDb/databaseAccounts/ibmcosmostable1
```

12.1 and later For 12.1 and later versions of Guardium, you don't need to create the Azure parameter, Cluster resource Id.

After you create your account and have the necessary information, you can define the cloud DB service accounts that you need.

## Tips and tricks

- Before you start, create standard naming conventions to prevent later confusion. Consider including the name of the Event Hub and the name of the database that you are monitoring for each related element. For example, if the database name is **use1-db5**, use the following naming conventions:
  - Namespace: **use1-ehn1**
  - Shared Access: **use1-ehn1-sa1**
  - Event Hub: **use1-db5-ehn1-eh3**
  - Consumer Group: **use1-db5-ehn1-eh3-cg**
- From the Guardium collector, make sure that outbound ports 443 and 5671 are available for the connections between the collector and Azure Event Hub.
- When you create a namespace, consider selecting Enable Auto-Inflate.
- Cosmos databases do not use usernames. Therefore, usernames are never returned from Cosmos.
- To help debug database activity monitoring issues, use the **support store datastreams\_diag** and **support must\_gather datastreams\_issues** CLI commands. In general, use Support CLI commands only under the guidance of IBM Technical Support. For more information, see [Support CLI Commands](#).
- Safeguarding your storage connection string always is important because it contains sensitive data about your storage account. So, regularly regenerate your storage connection string to ensure the highest level of security for your storage. For more information about configuring storage connection strings, see the Azure Blob Storage documentation.
- Define, modify, and delete Azure cloud database service accounts**  
Define a Guardium cloud database service account for Azure with your database credentials, and modify or delete the cloud database service account.
- Monitor Azure event hubs**  
After you define your Guardium cloud DB service account for Azure, you can assign the Azure event hub to a Guardium collector for monitoring.
- Manage Azure event hubs**  
Manage and troubleshoot event hub monitoring from Guardium.

## Define, modify, and delete Azure cloud database service accounts

Define a Guardium cloud database service account for Azure with your database credentials, and modify or delete the cloud database service account.

### Define a Guardium cloud database service account

#### About this task

Create cloud accounts to manage the connection between your Azure event hubs and Guardium®.

#### Procedure

- Browse to Discover > Database Discovery > Cloud DB Service Protection.
- Click  to open the Cloud DB Service Account pane.
- To use database activity monitoring with data streams, select Data Streams as the Audit type. If Audit type does not display, then you must enable access to data streams. For more information, see [enable\\_datastream](#).
- Define the account:
  - Name: A name for this account.
  - Provider: Select Azure from the Provider menu.
- Configure the Azure account. From Azure Configuration, enter the following information:
  - Shared access policy name
  - Shared access policy key

For more information about the shared access policy name and key, see [Gathering Microsoft Azure information](#)

6. Click Create.  
The account is created and the Cloud DB Service Accounts list updates with the new cloud account.

## What to do next

Monitor event hubs. For more information, see [Monitor Azure event hubs](#).

## Modify a cloud DB service account

You can modify any parameters except the provider and audit type.

### Procedure

1. Select the cloud account under Cloud DB Service Accounts, and click in the right pane.
2. Modify the configuration.
3. Click Save.

## Delete a cloud DB service account

When you delete a cloud DB service account, Guardium no longer monitors database activity.

### Procedure

1. Select the account in the Cloud DB Service Accounts pane and click .
2. From the Confirmation window, click Yes to delete the account or No to cancel the deletion.

## Monitor Azure event hubs

After you define your Guardium cloud DB service account for Azure, you can assign the Azure event hub to a Guardium collector for monitoring.

## About this task

For Azure, Guardium monitors event hubs. To start monitoring event hubs, you need to take the following steps:

- In Azure, associate the event hub to the database you want to monitor.
- In Guardium, use the Event Hubs window to associate an Azure event hub with a Guardium collector.

## Procedure

From Azure, associate the event hub to your database.

1. From the Azure home page, take the following steps, depending on whether your site uses an Azure SQL Database or a Cosmos database.
  - For an Azure SQL Database:
    - Select SQL databases, and then select the database that you want to associate with Guardium.
    - Under Security, select Auditing.
    - Turn Auditing to ON.  
Note: Do not enable auditing on both the database and the server. Note that if you enable auditing on the server you will receive records for all databases on that server.
    - Under Audit log destination, select Event Hub (preview).
    - Select Event hub Configure and then configure the Event hub details by selecting the Event hub namespace, the Event hub policy name, and the Event hub name .
    - Click OK to save your changes.
  - For any supported Cosmos database:
    - Select Azure Cosmos DB, and then select the database that you want to associate with Guardium.
    - From Monitoring, open Diagnostic Settings
    - Click Add Diagnostic setting.
    - Select Event hub Configure and then configure the Event hub details by selecting the Event hub namespace, the Event hub policy name, and the Event hub name .
    - Under Logs, select DataPlaneRequests.
    - From Add Diagnostic setting, enter a name for this datastream and select Stream to event hub.
    - Click Save to save your changes.

Then, from Guardium, you can associate the Azure event hub with a Guardium collector:

2. In Guardium, browse to Discover > Database Discovery > Cloud DB Service Protection, and select a Cloud DB service account.  
The Cloud DB Service Account window opens, and displays the Event Hubs table.
3. From the Event Hubs window, click to open the Add a new event hub pane.
4. Enter the following information, which is described in [Gathering Microsoft Azure information](#):
  - Event Hub Name: The name of your Azure event hub.
  - Collector: The name or IP address of the Guardium collector.
  - Namespace: Your Azure event hub namespace.
  - DB Type: Select the database type for your data.
  - DB DNS endpoint: The DNS name of the database. For example, `mycosmostable1.table.cosmos.azure.com`.
  - Port: The DB DNS port.

- Consumer Group Name: The Azure consumer group name.
  - Storage Connection String: The Azure storage connection string.
  - Cluster resource id: The database resource ID for the data source.
- 12.1 and later For 12.1 and later versions of Guardium, you don't need DB DNS endpoint, Port, and Cluster resource Id for a new event hub pane.
5. Optionally, select Start monitoring event hub. If you do not start monitoring now, you can enable monitoring from the Event Hubs table later.

## What to do next

---

Select the event hub and use Enable monitoring and Disable monitoring to turn monitoring of the selected event hub monitoring on and off. Manage your event hubs. For more information, see [Manage Azure event hubs](#).

---

## Manage Azure event hubs

Manage and troubleshoot event hub monitoring from Guardium.

After you enable event hub monitoring, you can track and manage the event hubs and event hub streams from the Event Hubs table.

## The Status column

---

The Event Hub table Status column provides a quick view of the health of the event hub. The meaning of the status colors is as follows:

- Green: Good. The Comments column reads All Good.
- Blue: Not yet configured.
- Gray: Unavailable.
- Orange: Warning.
- Red: An error condition. The Comments column might contain useful information about why the error occurred.

Tip: Hover your mouse over a status spot to see a status description.

## Enable and disable monitoring

---

From the Event Hubs header, you can enable or disable monitoring for individual event hubs.

- To start monitoring an event hub, select a disabled event hub and click Enable Monitoring.
- To stop monitoring an event hub, select a running event hub and click Disable Monitoring.

## View information about individual collectors

---

For central manager configurations: When an event hub is enabled, the Event Hub column displays a small  icon. Click the  to show details about each collector. In the Monitor enabled column, you can turn individual collectors on and off.

## View status history

---

Select an event hub and then click Status History to view the status history for this event hub. The following information displays for each collector in the event hub:

- Status from and Status to: The start and end times for this status history period. When the state changes, the status history period ends.
- Collector (for central manager configurations): The collector for this status history period.
- Status: The state of the collector during this period.
- Comments: Notes about the status. When a collector fails, the Comments section often contains useful information about why the failure occurred.

## Filter event hub data

---

From the Event Hubs header, enter text into the Filter dialog. The Event hubs table displays any stream with text that matches the filter text; the remaining event hubs are hidden.

---

## Cloud database service protection with native audit

Cloud database protection provides classification, vulnerability assessment, and object auditing on cloud databases, using the native audit.

After you set up the Guardium® connection with the cloud, you can:

- Discover database instances, and catalog them in Guardium.
- Assign catalogued data sources to a Classification process or create a new process: Classification runs on the cloud databases and identifies objects according to the defined rules.
- Assign catalogued data sources to a Vulnerability Assessment (VA) process or create a new process (requires a valid VA license): VA runs on the cloud databases and uses the data in Guardium reports.
- Enable DB auditing: Oracle Standard Auditing data is pulled from the cloud for Guardium reports, depending on installed policies. For more information, see the Oracle documentation about Database Auditing.
- Enable object auditing (Oracle's audit trail):

- Review the Classification results and select objects for object auditing. (DB auditing must be enabled.) Object auditing tracks all activities that are performed on the objects. Guardium uses this data in reports, the investigation dashboard, and other areas.
- Configure Guardium to add objects automatically, per data source.
- Set a default per account, inherited by all of its data sources. Setting a default is especially useful for databases whose objects need auditing without any further evaluation. Set a high but reasonable limit of what you expect the classification process to find. You also want to prevent an overflow of objects if there is a mistake in your classification, so don't set it too high. (An overflow can affect the database performance.)

Note: AWS permissions are required to perform Guardium functions on the cloud DB. See [Define AWS IAM for native audit](#).

In on-premises databases, the S-TAP installed in the database sends all database traffic to the Guardium system. In the cloud environment, Guardium pulls log files from the cloud DB, and processes the data similar to S-TAP data. The difference is that the S-TAP records all database activity, whereas in the cloud environment, only the tables that you select are audited. Another difference is that there can be a slight delay in data retrieval from the cloud.

Activity on audited databases and objects is written to the database logs. The volume of log activity increases with the number of monitored items. High volume log activity can impact the database performance. You need to ensure that you are capturing all relevant data, while not overloading the system.

You can run cloud database service protection in a central manager environment and on a stand-alone Guardium collector.

In the context of cloud DB service protection, database refers to the database on the cloud, and data source refers to the Guardium cataloged database.

Only one Guardium system can own the DB audit and object audit of any one DB. Other Guardium systems can access the same cloud account and see the DB details, but cannot disable the DB audit or access the object audit data. You can move ownership from one Guardium system to another, for example if one goes down without expectation of recovery.

Discovery, Classification, and VA are supported for all Amazon RDS database engines.

**Limitations:**

- You must keep the RDS definition updated, for example, DB instance deletions, or changes in credentials.
- Guardium supports Oracle V.11, V.12, V.18, V.19 databases on an AWS cloud. (Since Oracle 12 audit does not contain login records, the client IP is not available.)
- Extrusion rules are not supported, including redaction and testing for patterns in the returned data.
- Return data is not supported, including records affected and logging of bind variable values.
- Rule actions that interact with S-TAP are not supported; for example, S-GATE Terminate, Ignore, and query rewrite.
- Failed logins are not captured by the Oracle audit, and therefore are not forwarded to Guardium.
- Statements not captured by the Oracle audit, for example Statements with syntax errors, cannot be monitored.
- Audit data has bind variable values but not type, for example, 123, so when it is replaced in SQL, surrounding quotation marks are always added.
- When variable values contain ASCII control character, for example, '\001' or multiple byte characters, the audit file is not downloadable.
- Blob bind variable values are not supported.
- [Cloud database service protection workflow](#)  
Provide protection for your cloud database services by using native audit.
- [Define AWS IAM for native audit](#)  
Define the Identity and Access Management (IAM) policy for your Amazon Web Services (AWS) account, depending on the required permissions.
- [Create, modify, delete cloud accounts](#)  
Create a Guardium cloud DB service account with your database credentials, and modify or delete the cloud account.
- [Discover cloud databases](#)  
Discover databases in the cloud account by selecting the regions you want to search.
- [Catalog and manage databases](#)  
Catalog databases to create the datasources in Guardium, modify users and passwords, and update the database configuration.
- [Manage Classification and Vulnerability Assessment](#)  
Assign datasources to an existing classification or vulnerability assessment process, or create new processes.
- [Configure database auditing](#)  
Enable auditing on the database so that object auditing data can get pulled by Guardium. Modify the limit of objects added automatically to classification, and modify the collector.
- [Manage object auditing](#)  
View the potentially sensitive objects identified by the classification processes in the databases that you manage, and enable object auditing on selected objects to monitor all activities performed on these objects.

## Cloud database service protection workflow

Provide protection for your cloud database services by using native audit.

### About this task

This is a general workflow for providing cloud database service protection with native audit. Your specific workflow depends on what you want to achieve with the cloud database audit.

### Procedure

1. Define the AWS Identity and Access Management policy as described in [Define AWS IAM for native audit](#).
2. Create a cloud account as described in [Create, modify, delete cloud accounts](#).
3. Discover its database instances as described in [Discover cloud databases](#).
4. Catalog the databases that you want to work with as described in [Catalog and manage databases](#). Cataloging creates a data source within Guardium so that you can manage the cloud database Guardium functions on the specific database.
5. Optionally add the data source to a new or existing VA process (requires Vulnerability Assessment license) or to a new or existing Classification process. For more information, [Manage Classification and Vulnerability Assessment](#).
6. Optionally enable DB Audit on relevant databases, as described in [Configure database auditing](#). Restart the databases either now from the Guardium UI, or later from the DB console. After DB auditing is enabled, it performs standard Oracle auditing. When you enable DB Auditing, your Guardium system becomes the unique

- owner of the DB Audit on this DB. No other Guardium system can modify the DB Audit or the object audit. To see Classification results, run Classification once (Run once now) after you enable the DB Audit, or wait for the next scheduled run. (The data source must be assigned to a Classification process.)
7. Review the Classification results of your data sources (requires a classification process and DB Audit):
    - View the objects, grouped either by the object or the classification process that identified the objects, and use filters to further refine the results
    - Enable or disable object audit: individually, by table
    - Drill down from the objects grouping to open a list of all databases that contain the selected object in their classification results. In this view, you can also enable and disable object auditing.
  8. Periodically repeat steps [3](#) through [7](#).
  9. Review the data sources periodically, checking for New objects, and optionally adding or removing objects from the object audit. For example, you might remove objects that do not need auditing but were automatically added, or if a database is having performance issues. Or you might identify a suspicious object that is not audited, and add it to the object audit.

## Define AWS IAM for native audit

Define the Identity and Access Management (IAM) policy for your Amazon Web Services (AWS) account, depending on the required permissions.

### Minimum permissions

The minimum IAM permissions include viewing configuration and changing tags. They do not include enabling the DB audit, or restarting a DB. The following JSON example defines the minimum permissions, without which you cannot run cloud database service protection.

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Action": [
 "rds:DescribeDBParameters",
 "rds:DescribeDBInstances",
 "rds:DescribeDBParameterGroups",
 "rds:DownloadDBLogFilePortion",
 "rds:DescribeDBLogFiles",
 "rds>ListTagsForResource",
 "rds:RemoveTagsFromResource",
 "rds:AddTagsToResource",
 "ec2:DescribeSecurityGroups",
 "ec2:DescribeVpcs"
],
 "Effect": "Allow",
 "Resource": "*"
 }
]
}
```

### Additional permissions

Full permission is enabled with these parameters.

Enable, disable DB audit on instance

When not configured, the Enable DB Auditing and Disable DB Auditing buttons are disabled. You need to ask your DBA to enable or disable the DB instance on the AWS console.

```
"rds:CopyDBParameterGroup",
"rds>CreateDBParameterGroup",
"rds:ModifyDBInstance",
"rds:ModifyDBParameterGroup",
```

Restart DB instance

When not configured, Restart is disabled, and you need to request the DBA to restart the DB instance on the AWS console.

```
"rds:RebootDBInstance",
```

Handle security group when the supported platform is EC2

When not configured, the DBA needs to add the Guardium® IP to the security group. When configured, Guardium adds its IP to the security group of the DB instance. If the Guardium system cannot identify its own IP due to the network configuration, then the DBA needs to add the IP on the AWS console.

```
"rds:ModifyDBInstance",
"rds:AuthorizeDBSecurityGroupIngress",
"rds>CreateDBSecurityGroup",
```

Handle security group when the supported platform is VPC

When not configured, the DBA needs to add the Guardium IP to the security group. When configured, Guardium adds its IP to the security group of the DB instance. If the Guardium system cannot identify its own IP due to the network configuration, then the DBA needs to add the IP on the AWS console.

```
"rds:ModifyDBInstance",
"ec2:AuthorizeSecurityGroupIngress",
"ec2>CreateSecurityGroup",
```

When configuring these parameters, Guardium creates an inbound rule in the RDS instance security group, with collector public IP CIDR mask = 24.

## Create, modify, delete cloud accounts

Create a Guardium cloud DB service account with your database credentials, and modify or delete the cloud account.

## Create cloud account

---

### About this task

Create cloud accounts to manage the connection between your cloud databases and Guardium®.

Tip: If you are managing multiple databases in this account, consider defining a default classification process so that you do not need to define the properties for each discovered database.

### Procedure

1. Browse to Discover > Database Discovery > Cloud DB Service Protection.
2. Click  to open the Create Cloud DB Service Account Definition pane.
3. Define the account:
  - Name: An account name that is unique to your site.
  - Provider: Select the provider name from the menu. Currently Amazon is the only available provider.
  - Audit type: Select Native.
  - AWS access key ID and AWS secret access key ID: Supplied by your cloud services provider. The account secret key functions as a password. Make sure that the access key and title are both unique so that you do not have multiple account names with the same access\_id.
4. Configure Database Auditing and Classification:
  - Default classification Process. Optional. All cataloged databases in this account are assigned to the specified classification process. You can modify the classification process, per database, after they are cataloged.
  - Limit objects added automatically: When the DB Auditing is enabled, you can specify the maximum number of objects that are found by classification to automatically enable for object auditing. You can modify the number of objects to find, per database, after they are discovered. Objects that are enabled automatically appear as Enabled in the managed objects window. To add objects automatically, set a high but reasonable limit of what you expect the classification process to find. To prevent an overflow of objects if there is an error in your classification, don't set the limit too high (which can affect the database performance). Let's say that you set the limit to 15, and classification identifies five objects on the first run. Those five objects are enabled for DB Audit. The next classification run identifies five more objects, and those objects are also enabled. However, no new objects are enabled if the number of audited objects plus the number of newly classified objects exceeds the specified limit. Therefore, if the next Classification run identifies seven objects, then those objects are not enabled, because that will exceed the specified limit (15). If set to zero, objects are not automatically enabled for object auditing.
5. Test access to the cloud. Click Test Access to make sure that your account has access to the cloud.  
If the test fails to access the cloud, check the following items:
  - Your Guardium system has access to Amazon.
  - You supplied the correct keys.
6. Click Create.  
The account is created and the Cloud DB Service Accounts list updates with the new Cloud account.

### What to do next

Discover databases and catalog them, set up classification and vulnerability assessment, and object auditing. For more information, see [Discover cloud databases](#).

## Modify a cloud account

---

You can modify all parameters except the provider.

### Procedure

1. Select the cloud account under Cloud DB Service Accounts, and click  in the right pane.
2. Modify the configuration.
3. If you modify any credentials, click Test Access to test the access to the cloud.
4. Click Save.

## Delete a cloud account

---

For data streams, deleting an account disconnects the database from the Guardium managed units. For native audit, deleting an account disables the object audit and the DB audit on all the databases owned by the current environment.

### Procedure

1. Select the account in the Cloud DB Service Accounts pane, click , and confirm.
2. Restart the DB from the DB console. If you do not have Amazon access to the DB, ask your DBA to disable DB auditing and to restart the DB. It's important to stop auditing and restart the DB so that the DB stops writing to the Guardium log files.

## Discover cloud databases

---

Discover databases in the cloud account by selecting the regions you want to search.

### About this task

---

The databases table is populated and updated when you run Discover. Once a database has been discovered, it stays in the table, regardless of whether the database is still in the cloud..

Every time you navigate to Discovery > Database Discovery > Cloud DB Service Protection, Guardium informs you if the DB auditing status in the cloud is different from the status reported in the UI, with a message above the Database table: DB auditing status has changed for some databases. Click Refresh to update the table. When you see this message, click Refresh to refresh the display.

You can also perform this check on demand by clicking Retrieve status. The retrieve can take a few minutes. When it's complete, a message appears only if any of the DB audit statuses have changed. If there are changes, click Refresh.

You can also upload cloud database definitions by CSV file. The required parameters are listed in [Cloud Datasource APIs](#); the API parameter **cloudTitle** must be replaced with the parameter **environmentTitle** (they have the same function, but different names). See the upload procedure in Create Datasource for CSV uploaded via the Upload CSV menu in [Customer Uploads](#), using the path Harden > Vulnerability Assessment > Customer Uploads to upload your file.

## Procedure

---

1. Navigate to Discovery > Database Discovery > Cloud DB Service Protection, and click the service account name.  
When you create a cloud account, the Discover Databases table is open, showing a list of all of the regions, with their RDS endpoints.
2. When you access this page subsequently, the table is closed. Click Discover Databases.  
The table opens showing the regions.
3. Select the row of each region whose databases you want to discover. Use the filter if relevant.
4. Click Discover.  
Guardium searches the regions, and adds any databases that were not previously discovered to the databases table.

## Catalog and manage databases

---

Catalog databases to create the datasources in Guardium, modify users and passwords, and update the database configuration.

### About this task

---

Cataloging creates the datasources within Guardium® that are used for classification, vulnerability assessment, auditing, and reports. Databases that are not cataloged have a red icon in the GuardiumDatasource column of the DB table.

## Procedure

---

1. Catalog the databases you want to audit.
  - a. In the Databases table, select one or more databases.
  - b. Click Datasource > Catalog Datasource.
  - c. Enter the case-sensitive DB user and password that you received from your DBA. If you selected more than one database, be sure you want them to use the same user and password pair.
  - d. Optionally select, modify or clear the default Classification process.
  - e. Click Catalog.The Guardium datasource name appears in the Databases table.
2. Update the user or password:
  - a. In the Databases table, select one or more datasources.
  - b. Click Datasource > Update User and Password and modify the details. Both fields must be specified.
  - c. Click Catalog.
3. Modify one datasource definition.
  - a. Select the datasource and click Datasource > Open Datasource Definition
  - b. Modify as relevant. See parameter details in [Creating a datasource definition](#).
  - c. Optionally test connectivity to the database by clicking Test Connection.
  - d. Click Save.

## Manage Classification and Vulnerability Assessment

---

Assign datasources to an existing classification or vulnerability assessment process, or create new processes.

### About this task

---

The Vulnerability Assessment menu is available only if you have a valid VA license.

Once you assign a classification process to a datasource, classification data is collected and handled the same as an on-premises database. You can assign classification when you are not the owner, but you must take ownership in order to enable object audit and view the results.

A green icon indicates the process is running. A yellow icon means there is no schedule defined for the process. A red icon in the Classification Process or VA column indicates no classification or VA assigned, or an error. View VA errors in Harden > Vulnerability Assessment > Assessment Builder > View Results. View classification errors in Discover > Classification > Discover Sensitive Data > Review Report ribbon > Process Log.

If you get a classification error `file bdump-file-listing in BDUMP not found Unable to retrieve results for: 'RDSADMIN.TRACEFILE'` add RDSADMIN to the pre-defined schema group Excluded Classification schemas - Oracle in the Group Builder.

## Procedure

---

1. Assign one or more datasources to an existing Classification process.

- a. Select one or more datasources.
  - b. Click Classification > Add to Classification.
  - c. Select the Classification Process and click Save.
  - d. Optionally click Edit/View to modify or run the classification process.
  - e. If you want to enable object auditing automatically for the objects found by classification process, click **Edit/View** to open the classification process; in the Where to search ribbon, select the checkbox Enable object auditing for Cloud DBs.
  - f. Alternatively, run the classification: click Run Now in the Run Discovery ribbon in the Discover > Classification > Discover Sensitive Data.
2. Create a new Classification process, and assign one or more datasources to it.
    - a. Select one or more datasources.
    - b. Click Classification > Create Classification.
    - c. Follow procedure in [Discover Sensitive Data](#). Enable object auditing for Cloud DBs is selected by default. Leave it selected.
    - d. Run the classification: after you define Where to Search, click Run Now, or after you save the process click Run Now in the Run Discovery ribbon.
  3. Assign one or more datasources to an existing Vulnerability Assessment.
    - a. Select one or more datasources.
    - b. Click Vulnerability Assessment > Add to Vulnerability Assessment.
    - c. Select the Vulnerability Assessment process and click Save.
    - d. Run the process: navigate to Harden > Vulnerability Assessment > Assessment Builder, select the process and click Run once now.
  4. Create a new Vulnerability Assessment, and assign one or more datasources to it.
    - a. Select one or more datasources.
    - b. Click Vulnerability Assessment > Create Vulnerability Assessment.
    - c. Enter a description of the vulnerability assessment; enter one or more email addresses, separated by commas, to receive the results as part of an audit process that you define.
    - d. Click Save.

The VA process is created with all tests, the selected datasources, and the receivers you defined.

    - e. Run the process: navigate to Harden > Vulnerability Assessment > Assessment Builder, select the process and click Run once now.

## Configure database auditing

Enable auditing on the database so that object auditing data can get pulled by Guardium®. Modify the limit of objects added automatically to classification, and modify the collector.

### About this task

The databases table presents various details of the discovered databases. You can use the colored indicators in the table to see the status of any datasource at a quick glance. Red indicates no configuration, for example the database is not cataloged, or the datasource was not assigned to a classification or VA process. There are hover tips on the color-coded status indicators to give you more information when the color is red or yellow. Use the predefined filter list to filter any of the columns that have the color-coded status indicators, or the free text filter for other values.

If there is a collector defined for the datasource, it appears in the Active Collector column if you are the owner. Otherwise the column is blank.

The DB Audit Owner is the CM host name in a CM environment. In a standalone system the value is the collector's host name.

The DB Auditing column has one of the following values.

- Enabled. When followed by pending restart, indicates that the status will take effect upon instance restart.
- Disabled. When followed by pending restart, indicates that the status will take effect upon instance restart.
- configuration does not match requirement. (The AWS parameter audit trail is not configured according to Guardium's requirement XML, EXTENDED. Ask your DBA to modify this value.) When followed by pending restart, indicates that the status will take effect upon instance restart.
- Not supported for this db engine. Activity monitoring is not currently supported by Guardium.

If you own the instance, a classification process is assigned, and DB audit is enabled, you should see results in the Objects column. The total is the number of objects identified by the classification processes assigned to this instance; Audited is the number of those objects that are enabled for Object Audit; New is the number of objects that have been found by a classification process but have not been enabled automatically. These objects require review. See [Manage object auditing](#).

You should see results in the Objects column if the datasource is assigned to a classification process, the process has run since enabling the DB audit, and you are the owner. If you don't see objects, verify the classification process and run it again.

## Modify limit of objects added automatically and collector

You can modify the limit of objects added automatically and the collector on one or more databases simultaneously. Fields that are left blank are not modified.

### Procedure

1. Select one or more databases.
2. Click DB Auditing > DB Auditing Configuration .
3. Modify the number of Limit objects added automatically. When the DB Auditing is enabled, you can specify the maximum number of objects that are found by classification to automatically enable for object auditing. You can modify the number of objects to find, per database, after they are discovered. Objects that are enabled automatically appear as Enabled in the managed objects window. To add objects automatically, set a high but reasonable limit of what you expect the classification process to find. To prevent an overflow of objects if there is an error in your classification, don't set the limit too high (which can affect the database performance). Let's say that you set the limit to 15, and classification identifies five objects on the first run. Those five objects are enabled for DB Audit. The next classification run identifies five more objects, and those objects are also enabled. However, no new objects are enabled if the number of audited objects plus the number of newly classified objects exceeds the specified limit. Therefore, if the next Classification run identifies seven objects, then those objects are not enabled, because that will exceed the specified limit (15). If set to zero, objects are not automatically enabled for object auditing.
4. Collector appears in, and is mandatory for, a Central Manager environment. Select a collector from the drop-down list of all collectors in the CM environment. This is the collector that pulls the audit data (activities) from the DB.
5. Click Apply.

## Enable auditing on one database

---

You can enable DB auditing on one database at a time.

### About this task

You can configure the parameter Limit objects added automatically or the collector with any permission level. Other changes require DB permissions. Your access keys may or may not include these permissions. The instructions below cover all levels of permission.

When you enable DB Auditing, your Guardium system becomes the unique owner of the DB Audit on this DB. No other Guardium system modify the DB Audit or the object audit. Another system can forcefully take ownership by clicking Start owning DB Audit.

Run classification at least once after enabling DB audit to see and manage objects for auditing. If no objects are found, check your policies.

#### CAUTION:

When you start managing the database, the Amazon RDS tag IBM Guardium IP is created with the value of your Guardium hostname. This tag should not be modified or removed.

### Procedure

1. Select the row of the database.
2. Click DB Auditing > DB Auditing Configuration.
3. Optionally modify the value of objects added automatically to the Object Audit.
4. In CM environment, if there is no collector defined, select one from the drop-down list and click Apply. The dialog refreshes, and the buttons are enabled.
5. If Enable DB Auditing is enabled, click it. The dialog and the table refreshes showing You are now owner of the DB audit. The dialog box refreshes. Either click Restart to restart the database now (a confirmation message appears), or click Wait for next manual restart for example, to wait for a maintenance window. If you choose Wait for next manual restart, you need to access the cloud console directly at a later time. If you click Restart and you do not have sufficient access rights, an error appears. Request your DBA to configure **audit trail** as XML, EXTENDED and restart the instance.
6. If Enable DB Auditing is not enabled, click Own DB Audit. The dialog box refreshes. Click Wait for next manual restart and request your DBA to configure **audit trail** as XML, EXTENDED and restart the instance.
7. If you made changes to the DB audit status, click Retrieve Status and wait for the message saying the status has changed, then click Refresh. The DB Audit Owner column shows the host name of the CM or the collector's hostname in a standalone Guardium, and the icon in the DB Auditing turns green.

## Disable auditing on one database

---

You can disable DB auditing on one database at a time. When you disable the DB audit, you also relinquish ownership of the DB auditing.

### About this task

When you stop owning or disable the DB Audit, the entire object audit is disabled as well and the list of objects that can be audited (the come from the classification results) are deleted.

### Procedure

1. Select the row of the database.
2. Click DB Auditing > DB Auditing Configuration.
3. Click Disable DB Auditing, then click Wait for next manual restart, for example to wait for a maintenance window, or click Restart to restart the database now. If you choose Wait for next manual restart, you need to access the cloud console directly at a later time. If don't have permission to change the configuration, click Stop Owning DB Audit and request your DBA to disable the DB audit on this instance.
4. Click Retrieve Status to refresh the display with the latest status from the cloud.

### Results

If there were changes, a message appears: DB auditing status has changed for some databases. Click Refresh to update the table. Click Refresh. The status changes to disabled or disabled pending restart, the icon in the DB Auditing turns red, and the DB Audit Owner column is blank.

## Starting and stopping DB audit ownership

---

### About this task

You can modify the DB ownership status of one database at a time.

Owning the DB Audit gives you exclusive rights to the DB Audit and Object Audit definitions, and access to the object audit data (see [Manage object auditing](#)). Other Guardium systems can access the same cloud account but can only see the DB details.

With full access rights, when you enable the DB audit, you also take ownership of the DB. If your access keys do not provide full access rights, then you take ownership without enabling the DB audit. When DB audit is enabled (by the DBA) you will have access to the audit data. Conversely, when you disable the DB Audit, you relinquish ownership. If your access keys do not provide full rights, you would stop owning DB audit, and request the DBA to disable the DB audit.

You can move ownership from one Guardium system to another.

If you are transferring ownership between two live systems, first stop owning the DB Audit on the current owner, then take ownership on the second Guardium system. All auditing is stopped when one Guardium system relinquishes ownership. You'll need to define the auditing process on the new Guardium system: assign the DB to a classification, run the process, and add objects to the Object Audit.

#### CAUTION:

Stop owning the DB Audit on one before starting to own it on the second. Otherwise the data will go to the previous collector, as well as the new collector. Two collectors with different policies (different CMs) receiving the same activities, produce different, or incomplete, results on each collector.

If you are transferring ownership from a Guardium system that has gone down without expectation of recovery, you can start owning the DB Audit from another Guardium system, while maintaining the audit definitions, only the ownership changes. In this scenario, stop the original Guardium from owning the DB Audit in the DB console.

### Procedure

1. In the databases table, select the row of the database.
2. To stop owning DB audit: Click DB Auditing > DB Auditing Configuration > Stop owning DB audit.
3. To start owning DB audit: Click DB Auditing > DB Auditing Configuration > Start owning DB audit.

## Manage object auditing

View the potentially sensitive objects identified by the classification processes in the databases that you manage, and enable object auditing on selected objects to monitor all activities performed on these objects.

### About this task

**Prerequisite:** DB auditing must be enabled and owned by you, and classification must run at least once on this the datasource.

New objects are objects that have been found by classification processes that have not been enabled for auditing. You can filter for all new objects, and then either enable them for object auditing, or clear the **New** flag. When there are no New objects, then you are up to date with evaluating the new objects. Remember, Guardium® could receive new data every time the classification process runs. When new objects are found that were not added automatically to the object audit, there is a notice **New objects were found**.

The **Found by Classification** column lists all the classification processes that identified this object.

The status Mixed in the Object Audit Status column means the object audit is enabled in some datasources and disabled in other datasources.

Enabling and disabling object auditing is a heavy process, and can take a few minutes. There is a waiting icon while the cloud processes the auditing changes.

You can review objects found in one datasource or multiple datasources by selecting the rows of the datasources you want to review from the Databases table. The object audit windows shows all objects found by all classification processes on the selected database or databases.

- [Managing object audit in one database](#)
- [Managing object audit in multiple databases](#)

## Managing object audit in one database

### About this task

The Objects in Datasource <name> window lists all objects found by the classification processes run on this datasource. Objects can be found by more than one classification process.

When objects have been identified by the classification process but were not enabled automatically for object audit, **New objects found** appears above the objects table. Click New Only to filter for all new found objects that require handling. New objects could be found every time the classification runs. When there are no New objects, you are up to date with the new objects evaluation.

Review the data sources periodically, checking for New objects, and optionally adding or removing objects from the object audit. For example, you might remove objects that do not need auditing but were automatically added, or if a database is having performance issues. Or you might identify a suspicious object that is not audited, and add it to the object audit.

Use the classification filter for objects that you know must be audited. Select all objects in the filtered view, and enable object auditing.

### Procedure

1. If you assigned the Classification process **before** you enabled DB Audit, run the Classification once now and wait a few minutes (or wait for the next scheduled run) for Guardium® to identify objects.
2. Select one datasource. Consider using the filter New objects found to identify datasources with new objects.
3. Select DB Auditing > Manage Object Auditing.  
The Manage Object Auditing window opens listing all objects found by the classification processes to which this datasource is assigned.
4. Consider using the filter New only to identify all objects classified as New.
5. Select one or more objects (rows) in the table.
6. To enable audit trail, select Actions > Enable Audit.  
The system responds with the success or failure of the operation.
7. To clear the New flag, click Actions > Clear New flag.
8. To disable audit trail, select Actions > Disable audit.  
The system responds with the success or failure of the operation.

## Managing object audit in multiple databases

### About this task

This view lists all objects found by the classification processes run on the selected datasources. Objects can be found by more than one classification process. View the objects grouped by object (default), or classification. The Found by Classification column lists all the classification processes that identified the object.

When objects are identified by the classification process but were not enabled automatically for object audit, **New objects found** appears above the objects table. Click New Only to filter for all new found objects that require handling. Review the New objects and either enable object auditing, or clear the New flag.

New objects could be found every time the classification runs. When there are no New objects, you are up to date with the new objects evaluation.

Review the data sources periodically, checking for New objects, and optionally adding or removing objects from the object audit. For example, you might remove objects that do not need auditing but were automatically added, or if a database is having performance issues. Or you might identify a suspicious object that is not audited, and add it to the object audit.

**Group by Object:** To view all new found objects, type New in the text filter.

To enable or disable the object audit on one object in all the selected datasources, select the row(s) and click Action > Enable / Disable

To take action per datasource, click Present in # datasources to view all datasources whose classification processes have identified the selected object

**Group by Classification** is especially useful when you have almost identical datasources, or classification policies, whose objects need auditing without any further evaluation, for example GDPR.

## Procedure

1. If you assigned the Classification process **before** you enabled DB Audit, run the Classification once now (or wait for next scheduled run) and wait a few minutes for Guardium® to identify objects.
2. When grouped by object:
  - a. Select multiple datasources that have New objects in the Objects column of the Databases Table. Use the filter New objects found to identify these datasources.
  - b. Click DB Auditing > Manage Object Auditing. The Manage Object Auditing window opens.
  - c. If the object must always be audited in all the datasources, select the row(s) and click Actions > Enable Audit.  
The system responds with the success or failure of the operation.
  - d. If you want to enable the object audit on individual databases, click the number in the Present in # Datasources column, in the row of the object to open the Datasources containing <object> window. This window shows all datasources whose classification processes have identified the selected object. Select one or more datasource rows and click Actions > Enable Audit.
3. For a classification process whose identified objects always need auditing without further evaluation: Click the Classification radio button (above the table); select one or more rows of classification processes, and click Actions > Enable Audit.

## Database discovered instances rules

Use the Database Discovered Instances Rules UI from a central manager to determine how to manage inspection engines for discovered databases.

### Before you begin

Before you configure the Database Discovered Instances Rules in the GUI, you need to enable inspection engine creation by using the `modify_guard_param` API command from the CLI. To enable creating inspection engines, call the following API:

```
grdap! modify_guard_param paramName=IE_CREATION paramValue=1
```

For more information, see the [modify\\_guard\\_param](#) API command.

### Configuring the database discovered instance rules

Guardium® can be configured to discover databases that are created on both Windows and UNIX systems. In many cases, you might want Guardium to create and run inspection engines on all newly discovered databases. However, there are scenarios in which you want control when and how Guardium creates new inspection engines. In these cases, Database Discovered Instances Rules provides a way to manage inspection engine creation. You can configure discovered instances rules from a central manager in a managed environment or on a stand-alone system.

From a central manager, select Database Discovered Instances Rules from Discover > Database Discovery .

From the GUI, you can take the following actions:

- Click Enable to start automatically creating inspection engines.
- 12.1 and later Click Manage Collectors to view a list of collectors that are managed by the central manager. You can filter the collectors by status and use the check box to quickly and easily enable or disable multiple collectors.
- To generate a report of the discovered instances rules without creating inspection engines, select the Report results of discovered instances rules (don't create inspection engines) checkbox. You can use this report to:
  - Determine the impact of your changes before you create new inspection engines.
  - Report on changes to your existing database configurations (such as unexpected changes to port ranges or [for UNIX] DB installation directory).
- Select whether you want to manage inspection engines for a Windows or UNIX environment.
- Choose whether to create inspection engines for all discovered databases, or to specify rules that determine when an inspection engine is created.

If you select Specify rules to create inspection engines, then you can specify rules for your site.

Note: By default, if parameters for an existing inspection engine are a 100% match with an inspection engine that matches a newly discovered database, Guardium does not create a new inspection engine.

## Creating inspection engines use cases

Table 1. Inspection engine use cases

| Rule | Existing inspection engine | Newly discovered instance |  | Use case |
|------|----------------------------|---------------------------|--|----------|
|      |                            |                           |  |          |

| Rule    | Existing inspection engine              | Newly discovered instance                    | Use case                                                                                                                                                                                                                                                 |
|---------|-----------------------------------------|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filter  | Ignore                                  | Add or ignore, depending on filter criteria. | You want to detect only inspection engines that meet certain criteria, such as specified ports, protocols, or servers. Create a filter to prevent creating inspection engines that do not meet the criteria.                                             |
| Exclude | Remove                                  | Don't add inspection engine.                 | You have database instances that no longer need monitoring. Delete existing inspection engines that meet the rules, and do not add an inspection engine if it meets the specified rules. Use an advanced rule to specify a rule that requires operators. |
| Ignore  | Keep                                    | Don't add inspection engine.                 | You have inspection engines that you want to keep, regardless of whether they are discoverable (such as a late mount configurations or a passive cluster). Preserve existing configurations that meet all of specified rules.                            |
| Replace | Remove                                  | Add                                          | Update existing inspection engines to meet new criteria, such as upgrading to a new database version or changing the installation directory path.                                                                                                        |
| Merge   | Update or remove, depending on settings | Ignore, depending on settings                | Consolidate existing inspection engines and discovered instances to avoid creating new and unnecessary inspection engines.                                                                                                                               |
| Add     | Keep                                    | Add                                          | Create an inspection engine whenever a new database is found in your environment and the newly discovered instance does not match any of the Filter, Exclude, Ignore, or Replace rules.                                                                  |

## Specifying inspection engine rules

The rules to create inspection engines fall into the following categories: Filter, Exclude, Ignore, Replace, and Add. The rules are hierarchical. That is, Guardium checks the Filter rule first; if it does not apply, then it checks the Exclude rule, and so on. If none of the rules applies, Guardium creates (adds) a new inspection engine.

Note: For all rules, click the Add rule  to add an OR statement. Click the  after the parameter to add an AND statement.

To define rules:

1. Click Filter to open the Filter pane. Use Filter to specify ports, protocols, or servers to ignore (that is, to filter out those inspection engines from discovery).
  - a. Click Add rule to add a filtering rule.
  - b. Select a parameter from the parameter list and specify a value for that parameter.

Note: For the Port range start and Port range end parameters, if you select the in or not in operators, separate multiple values with commas, and use a hyphen to specify an inclusive range of ports. For example: 1520-1530, 1621, 1622.

2. Click Exclude to open the Exclude pane. Use Exclude to delete outdated inspection engines.
  - a. Click Add rule to add an exclude rule.
  - b. Select a parameter from the parameter list and specify a value for that parameter.

Important: If any of the specified parameters match inspection engine parameters, Guardium deletes that inspection engine. Therefore, you need to be precise about which parameters you select.

For example, if you specify only the Exclude rule DB version = 12, Guardium deletes the inspection engines on any database type with version 12 (such as Oracle 12c, Informix® v12.10, or Db2® v12).

3. Click Ignore to open the Ignore pane. Use Ignore to determine whether an inspection engine exists that meets all of the match criteria. If an exact match is found, Guardium does not create a new inspection engine (that is, Guardium ignores the new database instance).

Note: A built-in implicit Ignore rule checks new discovered database instances against all of the available criteria. When all criteria match, the Ignore rule is triggered. Therefore, in general, you do not need to configure this rule.

4. Click Replace to open the Replace pane. Use Replace to update individual parameters in one or more inspection engines. Guardium provides suggested match criteria for Replace, but these are not required.

For example, say that your site updates the database version and installation directory for a database. In this case, you want to update only the DB version and DB install dir parameters for the existing inspection engines. To do so, specify all of the parameters for the inspection engines to match against; that is, everything except DB version and DB install dir. Guardium compares all of the newly discovered databases (with the new database version and installation directory) against all of the inspection engines and updates the inspection engines that match the selected criteria. Since you did not specify the DB version and DB install dir, the corresponding inspection engines are updated with the new version and install directory parameters.

5. Click Merge to open the Merge pane. The following merge options provide ways of associating discovered instances with existing inspection engines to avoid creating new and unnecessary inspection engines:

Do not create inspection engine for discovered instances where port range is within matching inspection engine port range

Enabling this setting reuses inspection engines when the port range of a discovered instance is within the port range of an existing inspection engine. This setting causes Guardium to ignore discovered instances when they meet the following criteria:

- The existing inspection engine port range contains the discovered instance port range
- All of the following criteria match between the existing inspection engine and the discovered instance: db\_type, db\_install\_dir, db\_exec\_file, db\_user, unix\_domain\_socket\_marker

Update inspection engines where port range is within matching discovered instance port range

Enabling this setting expands the port range of an existing inspection engine when its port range is within the port range of a discovered instance. This setting causes Guardium to update the existing inspection engine when the following criteria are met:

- The discovered instance port range contains the existing inspection engine port range
- All of the following criteria match between the existing inspection engine and the discovered instance: db\_type, db\_install\_dir, db\_exec\_file, db\_user, unix\_domain\_socket\_marker

Note: For Oracle databases, if discovery\_ora\_use\_port\_ranges is enabled, this setting allows Guardium to remove redundant inspection engines after the port range of an existing inspection engine is expanded. For more information, see [Discovery parameters](#).

You can further restrict the scope of this setting by defining additional criteria using the  Add update rule (optional) control. The available criteria and operators are the same as what is available for the Filter and advanced Exclude rules.

6. Click Add to open the Add pane. If a newly discovered instance does not meet any of the previous criteria (for Exclude, Replace, or Ignore), Guardium creates a new inspection engine based on the discovered instance.

Note: The Create inspection engines checkbox is selected by default. If you clear Create inspection engines, Guardium does not create inspection engines. In general, make sure that Create inspection engines is selected.

7. When you are done, click Save to save your changes or Cancel to clear all of your changes and start over.

At the Save configuration and overwrite previous settings message, click Save again to save your changes or Cancel to return to your current settings without saving.

The next time Guardium looks for new database instances, the selected rules apply.

## What to do next

---

After you configure the Database Discovered Instances Rules, you can discover database instances from [Manage > Activity Monitoring > S-TAP Control > Send command](#)  to open the S-TAP Commands window.

To run database instance discovery, select Run Database Instance Discovery from the list and then make sure that Replace Inspection Engines is not selected. When you click Apply, database instance discovery runs. For more information, see [Linux-UNIX: Discover database instances](#) or [Windows: Discover database instances](#).

The results of filter rule application details are available in the [Discovered Instances Rules Results](#) report.

You can also add or configure reports and alerts that trigger when an inspection engine changes. For more information, see [Adding reports and alerts for inspection engine changes](#).

Tip: If you encounter an exception when you run the `grdapi apply_rules_on_discoveredinstances` API, make sure that the managed unit is the primary host for the S-TAP. Exceptions can occur when the S-TAP points to multiple appliances and the current managed unit is not set as the primary host.

## Creating inspection engines from the API

---

Use the following APIs to manage inspection engine creation:

- [apply\\_rules\\_on\\_discoveredinstances](#)
- IE\_CREATION, as described under [Inspection engine parameter](#) in [modify\\_guard\\_param](#).
- [Database discovered instance rules scheduler](#)  
Schedule times to search for discovered instances, based on specified rules.
- [Adding reports and alerts for inspection engine changes](#)  
After you configure and enable database discovered instances rules, you can add a report and an alert that triggers whenever an inspection engine is replaced or added.

## Database discovered instance rules scheduler

---

Schedule times to search for discovered instances, based on specified rules.

For managed units and stand-alone systems, use the database discovered instance rules scheduler to specify when you want your system to search for discovered instances, based on the rules you specify for [Database discovered instances rules](#). To open the scheduler, browse to [Discover > Database Discovery > Database Discovered Instance Rules Scheduler](#). For more information, see [Scheduling](#).

Notes:

- From a central manager configuration profile, you can define a schedule for some or all managed units. For more information, see [Working with configuration profiles](#).
- The input for database discovered instances rules comes from S-TAP discovery, which runs on its own schedule. S-TAP discovery typically runs every 24 hours (but you can change it to run more often from S-TAP control). You can see the output of the S-TAP discovery process from the Discovered Instances report on the collector.

## Adding reports and alerts for inspection engine changes

---

After you configure and enable database discovered instances rules, you can add a report and an alert that triggers whenever an inspection engine is replaced or added.

## Procedure

---

1. You can access reports in several ways. One method is to browse to My Dashboards and then select either Create New Dashboard or an existing dashboard from your My Custom Dashboards list.
2. From the dashboard, click Add Report and then select Discovered Instances Rules Add or Replace Log.
3. From the Discovered Instances Rules Add or Replace Log report, select  to manage runtime parameters. In addition to the parameters described in [Modifying the runtime parameters](#), you can set the value of Enter Value for Report Only. This option filters data based on the setting (on the Database Discovered Instances Rules page) for Report results of discovered instances rules (don't create inspection engines), as follows,
  - Enter Yes to display only rows where Report results... is selected.

- Enter No to display only rows where Report results... is cleared.
  - Leave the entry as % (the default) to display all rows.
4. By default, alerts generated by Discovered Instances Rules Alert - Discovered Instance Add or Replace are captured in SYSLOG if the alert is active. Use the Alert Builder, as described in [Predefined alerts](#), to modify the alert and select Active to turn on this alert.

## Results

---

When an inspection engine is replaced or added, an alert message is now generated, based on the parameters in the Discovered Instances Rules Add or Replace Log report.

## Classification

Classification policies and processes define how Guardium® discovers and treats sensitive data such as credit card numbers, social security numbers, and personal financial data.

Discovery and classification processes become important as the size of an organization grows and sensitive information like credit card numbers and personal financial data become present in multiple locations, often without the knowledge of the current administrators responsible for that data. This frequently happens in the context of mergers and acquisitions, or when legacy systems have outlasted their original owners. Creating workflows for discovering sensitive data allows you to identify sensitive data in your environment and take appropriate actions, such as applying access policies.

*Classification processes* consist of classification policies that have been associated with one or more datasources. Classification processes can be submitted to be run once or, if login credentials have been stored for all the datasources used in the process, scheduled to run on a periodic basis in a compliance workflow automation process.

*Classification policies* consist of classification rules and classification rule actions designed to find and tag sensitive data in specified datasources.

*Classification rules* use regular expressions, Luhn algorithms, and other criteria to define rules for matching content when applying a classification policy.

*Classification rule actions* specify a set of actions to be taken for each rule in a classification policy. For example, an action might generate an email alert or add an object to a Guardium group. Each time a rule is satisfied, that event is logged, and thus can be reported upon (unless ignore is specified as the action to be taken, in which case there is no logging for that rule).

- [Classification process performance](#)

Classification processes are handled with sampling routines and timeout parameters that ensure minimal performance impact on database servers.

- [Classification Rule Handling](#)

Classification rules are handled according to flexible matching and grouping criteria.

---

## Classification process performance

Classification processes are handled with sampling routines and timeout parameters that ensure minimal performance impact on database servers.

When the classifier runs, you have the option of specifying how it samples records. The default behavior takes a random sampling of rows by using an appropriate statement for the database platform in question. For example, the classifier samples using a `rand()` statement for SQL databases. The alternative behavior is sequential sampling, which reads rows, in order, up to the specified sample size. Random sampling is the default behavior and is recommended because it provides more representative results. However, random sampling may incur a slight performance penalty when compared to sequential sampling.

Attention:

- Random sampling is not supported for Sybase or PostgreSQL: sequential sampling is always used, even in random sampling is selected.
- If random sampling fails on Oracle datasources, sequential sampling is used instead. Random sampling may fail if the classifier encounters certain error conditions, for example selecting ROWID from a join view without a key-preserved table (ORA-1445).
- In some instances, classification rules are applied only to the first 3000 characters, no matter how large or long the sample data is. This 3000 character limitation applies to the following datatypes and datasources,
  - Text data for Sybase and PostgreSQL
  - XML data for MS SQL

For both random and sequential sampling, the default sample size is 2000 rows or the total number of available rows, whichever is fewer. Larger or smaller sample sizes may be specified. If you check the random sampling box, it selects 2000 rows randomly from that table/view and then scans. If the table contains less than 2000 rows, it scans all the rows. If you clear the random sampling box, it selects the first 2000 rows from that table/view and then scans. The default query timeout value is 3 minutes (180 seconds). If the process is running but stuck for 30 minutes, the entire process will be halted.

To further minimize the impact of classification processes on the database server, long-running queries will be canceled, logged, and the remainder of the table skipped. Any rows acquired up to that point will be used while evaluating rules for the table. Similarly, if a classification process runs for an extensive time period without completing, the entire process is halted, logged with the process statistics, and the next classification process is started. This behavior is uncommon and usually only happens on servers that are already experiencing performance problems.

The classifier periodically throttles itself to idle so it does not overwhelm the database server with requests. If many classification rules are sampling data, the load on the database server should remain constant but the process may take additional time to run.

The classifier handles false positives by using excluded groups for schema, table and table columns. Previously, it could be a complex process to set up Guardium to ignore false positive results for future classification scans. Now, when you review classifier results, you can easily add false positive results to an exclusion group, and add that group to the classification policy to ensure those results are ignored in future scans.

---

## Multi-thread classifier

Guardium can run multiple classification threads in parallel to optimize the performance and utilization of the CPU. The number of threads that can run in parallel can be identified by multiplying the number of CPU cores in the machine by 2.

As an example, if there are 4 CPU cores, then 8 would be the maximum number of classifier processes that can be defined and run concurrently. The cap limit, irrespective of the number of CPU cores, is 100.

To retrieve or define the concurrency limit, use [set\\_job\\_process\\_concurrency\\_limit](#).

## Classification Rule Handling

Classification rules are handled according to flexible matching and grouping criteria.

### Fire only with Marker

The Fire only with Marker rule allows for the grouping of Classifier rule types by the same exact name. Additionally, all returned rules using a marker must return data based on the same table name. If two, or more, rules are defined with the same marker then those rules will fire together and together such that if both rules fire on the same table then they both will be logged and their actions invoked. If on the other hand only one of them fires on a table then neither of the rules will be logged or have their actions invoked. Being able to have multiple rules fire together becomes important when you care about sensitive data appearing together within the same table. For example, you may want to know when a table has both a social security number and a Massachusetts drivers license.

Fire only with Marker is a constant value, can be named any value, and must have the exact same value across rules you want to group. This means that if one rule has a marker of ABC then the other rule that you want to group it with must also have a marker named ABC. Any other marker value and the rules are no longer grouped.

You must use at least two rules of any values based on looking for data within the same table name.

### Continue on Match

Fire only with Marker is also based on the Continue on Match rule. As an example, if the following rules are defined such that Rule 3 does not match Continue on Match then no results are returned regardless if all three marker rules were positive. This is because you didn't get to run Rule 4 and the grouping does not fire because all Fire only with Markers must run and return positive results.

Rule 1. Firemarker rule ABC (continue on match)

Rule 2. Firemarker rule ABC (continue on match)

Rule 3. Firemarker rule ABC (continue on match)

Rule 4. Firemarker rule ABC (continue on match)

### Unmatched Columns Only

Use this option for reducing the granularity of data results. Some organizations may want to do a survey of their data to discover which tables and columns have sensitive data without necessarily needing to find every type of sensitive data in that column. A new option for Continue on match, With Unmatched Columns only, means that as soon as the classifier finds a match for that column, it will ignore that column as it continues its processing.

Table 1. Summary of available classifier processing options

| Continue on match | With Unmatched Columns only | Granularity of Result                                                                                                      |
|-------------------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------|
| No                | N/A                         | Table. Classifier will stop processing rules after the first hit in the table.                                             |
| Yes               | Yes                         | Table and column. Classifier will record the first hit for any given column and ignore it thereafter for subsequent rules. |
| Yes               | No                          | Detailed. Classifier will record hits for all columns for all rules.                                                       |

### Classification with Luhn algorithm

When a rule name begins with guardium://CREDIT\_CARD, and there is a valid credit card number pattern in the Search Expression box, the classification policy will use the Luhn algorithm (a widely-used algorithm for validating identification numbers such as credit card numbers), in addition to standard pattern matching. The Luhn algorithm is an additional check and does not replace the pattern check. A valid credit card number is a string of 16 digits or four sets of four digits, with each set separated by a blank. There is a requirement to have both the guardium://CREDIT\_CARD rule name and a valid [0-9]{16} number in the Search Expression box in order to have the Luhn algorithm involved in this pattern matching.

### Discover Sensitive Data

Create an end-to-end scenario for discovering and classifying sensitive data.

### About this task

Discovery and classification processes become important as the size of an organization grows and sensitive information like credit card numbers and personal financial data propagate to multiple locations. This often happens in the context of mergers and acquisitions or when legacy systems have outlasted their original owners. As a result, sensitive data may exist beyond the knowledge of the person who currently owns that data. This is a common yet extremely vulnerable scenario, since you cannot protect sensitive data unless you know it exists.

Sensitive data discovery scenarios span three critical aspects of enterprise security:

- Discovery: locating the sensitive data that exists anywhere in your environment
- Protection: monitoring and alerting when sensitive data is accessed
- Compliance: creating audit trails for reviewing the results of sensitive data discovery processes

The Discover Sensitive Data end-to-end scenario builder streamlines the processes of discovery, protection, and compliance by integrating several Guardium® tools into a single user-friendly interface.

Table 1. Discover sensitive data tools map

| Value                                                                                      | Scenario Task        | Description                                                                             | Result                                                      |
|--------------------------------------------------------------------------------------------|----------------------|-----------------------------------------------------------------------------------------|-------------------------------------------------------------|
|  Discover | Name and Description | Provide a name and description for the scenario and its related processes and policies. | Creates a classification process and classification policy. |
|                                                                                            | What to discover     | Create rules and rule actions for discovering and classifying data.                     | Optionally creates new datasource definitions.              |
|                                                                                            | Where to search      | Identify datasources to scan.                                                           |                                                             |
|                                                                                            | Run discovery        | Run the scenario.                                                                       |                                                             |
|  Protect  | Review report        | Review the results and define ad hoc grouping and alerting actions.                     | Creates an access policy.                                   |
|  Comply   | Audit                | Define recipients, a distribution sequence, and review options.                         | Creates an audit process.                                   |
|                                                                                            | Schedule             | Create a schedule to run at defined intervals.                                          |                                                             |

This sequence of tasks guides you through the processes of creating a new discovery scenario. This includes creating *classification policies* consisting of rules and rule actions for discovering sensitive data, creating *classification processes* by identifying datasources to scan for sensitive data, defining ad hoc policies (for grouping and alerting, for example), and creating *audit processes* that distribute results to different stakeholders at scheduled intervals.

## What to do next

Continue to the next section and begin creating a discovery and classification scenario.

### 1. [Discovery scenarios](#)

Create a new discovery scenario or select an existing discovery scenario to copy or edit.

### 2. [Name and description](#)

Provide a name and description for your discovery scenario.

### 3. [What to discover](#)

Create policies consisting of rules and rule actions for discovering and classifying sensitive data.

### 4. [Where to search](#)

Identify datasources to scan for sensitive data.

### 5. [Run discovery and review report](#)

Optionally run your discovery scenario and review the results.

### 6. [Audit](#)

Optionally create an audit process by defining receivers, a distribution sequence, and review options for the discovery and classification report.

### 7. [Scheduling](#)

Optionally activate the audit process by scheduling it to run at defined intervals.

---

## Discovery scenarios

Create a new discovery scenario or select an existing discovery scenario to copy or edit.

## Procedure

---

### 1. Navigate to Discover > Classification > Discover Sensitive Data.

### 2. Create, copy, or edit a discovery scenario.

- Click the  icon to create a new scenario.

- Click the  icon to copy an existing scenario or template. When copying a discovery scenario, click the Reuse button to reuse the classification policy associated with the scenario or click the Create copy button to create and use a copy of the classification policy.
- Click an existing scenario name from the Discovery Scenarios list to begin editing that scenario.

Discovery scenarios are displayed in the following format: `scenario`

`name (classification policy name) (datasource type)`. For example, a discovery scenario named `discover_cad1` using the classification policy `policy_cad1` and used with Relational type datasources is displayed as `discover_cad1 (policy_cad1) (Relational)`.

Some discovery scenarios or templates are provided by default, including the following:

### GDPR [template]

The GDPR [template] scenario provides the latest set of discovery rules and language support for your GDPR compliance strategy. Templates can be copied or edited and saved under a different name, and the GDPR [template] will always receive the latest GDPR discovery rules and language support.

### GDPR

The GDPR scenario provides a basic set of discovery rules that can be used as part of a GDPR readiness strategy. You can edit and save changes to the GDPR scenario, but the scenario will not receive updated rules or language support over time.

Important: If the GDPR [template] is available, using the older GDPR scenario is not recommended because the GDPR scenario does not receive updates.

When editing a pre-defined discovery template and saving the changes, Guardium automatically saves the scenario under a unique name in the format `Copy [timestamp] of [discovery template name]`. For example, editing and saving the GDPR [template] scenario results in a discovery scenario named `Copy [2018-01-01 12:00:00] of GDPR [template]`.

Next topic: [Name and description](#)

## Name and description

Provide a name and description for your discovery scenario.

### About this task

During this step, you may also specify *security roles* that can access the discovery scenario.

### Procedure

1. Open the Name and Description section and provide or edit the name and optional description of the scenario.
2. Create or select a classification policy to use with the discovery scenario.
  - Click the  icon to name a new classification policy. The classification policy is created when saving the discovery scenario.
  - Use the drop-down menu to select an existing classification policy. Rules for the classification policy are automatically loaded into the What to discover section of discover sensitive data tool. When selecting and editing a pre-defined classification policy, Guardium automatically saves the policy under a unique name in the format `Copy [timestamp] of [policy template name]`. For example, editing and saving the GDPR [template] policy results in a classification policy named `Copy [2018-01-01 12:00:00] of GDPR [template]`.
3. Provide category and the classification labels for tagging violations.  
"Sensitive" is the default value for category and classification labels.
4. Use the Datasource type menu to identify the type of datasources used with the scenario.  
For example, select Relational (SQL) for relational databases like MySQL or Document for document-type databases like MongoDB. It is not possible to use multiple datasource types in the same discovery scenario.
5. Optionally, click the Roles button to specify *security roles* that can access the discovery scenario.

### What to do next

Continue to the next section of the discovery scenario, What to discover.

**Previous topic:** [Discovery scenarios](#)

**Next topic:** [What to discover](#)

## What to discover

Create policies consisting of rules and rule actions for discovering and classifying sensitive data.

### About this task

*Classification policies* contain ordered sets of rules and rule actions that identify and take actions on sensitive data. Each rule in a policy defines a conditional action that is taken when the rule matches. The conditional test can be simple, for example a wildcard string found anywhere in a table or collection, or a complex test that considers multiple conditions. For discover sensitive data scenarios, the action triggered by a rule can be a grouping action that adds the matches to a specified group or an alerting action that triggers a notification. Multiple grouping and alerting actions can be combined and ordered to create sophisticated responses to matched rules.

This task guides you through the processes of creating and editing classification rules and rule actions for use in your discovery scenario.

### Procedure

1. Open the What to discover section to define rules for discovering data.
2. Use the Language menu to filter rule templates by the selected language and countries where the selected language is a national language.  
Templates for universal patterns like credit card numbers and email addresses are displayed for all Languge menu selections.
3. Add rules to your discovery scenario or edit existing rules by doing one of the following:
  - Click the  icon to create a new rule.
  - Select rules from the Classification Rule Templates table and click the  icon to add predefined rules.
  - Click the  icon to edit an existing rule.
4. When adding or editing classification rules, use the following procedure.
  - a. Select a Rule type based on the type of search being performed.
    - Search for data matches specific patterns or values in the data.The following data types are supported when searching for data:

|             |           |
|-------------|-----------|
| BIGINT      | NUMERIC   |
| CHAR        | NVARCHAR  |
| DATE        | NVARCHAR2 |
| DECIMAL     | REF       |
| DOUBLE      | SMALLINT  |
| FLOAT       | TIME      |
| INTEGER     | TIMESTAMP |
| LONGVARCHAR | TINYINT   |
| NCHAR       | VARCHAR   |
| NUMBER      | VARCHAR2  |
  - For relational-type datasources, Catalog search matches table or column names in the database. For document-type datasources, Catalog search matches collection or field names in the database.

- Search for unstructured data matches specific values or patterns in an unstructured data file, for example CSV, TXT, or CEF files. Search for unstructured data rules only work with datasources using the database type TEXT.
- b. Provide a name and description while optionally specifying a *special pattern test* at the beginning of the Name field. The rule name will also be used to name the rule associated with the classification policy in the Classification Policy Builder. If you require a special pattern test, it is recommended that you work with its corresponding template (for example, use Bank Card - Credit Card Number for credit card numbers).
- c. Open the Rule Criteria section to define a *regular expression* and other search criteria for the rule. If you are working with a rule template, an appropriate *regular expression* is provided by default.
- Attention: For rules created in the discover sensitive data scenario, the default Data type includes both Number and Text.
- d. Open the Actions section and define any *rule actions* that should be taken when rule criteria match.
- e. When defining multiple *rule actions*, you can optionally click the  icon and use the  and  icons to change the order in which the actions are executed.
- Note: The Ignore and Log result *rule actions* cannot be combined with other *rule actions* and must be used as the only action in a rule. The Log policy violation *rule action* can only be used once in a rule.
- f. Click Save when you are finished adding or editing rule definitions to return to the What to discover section of the discovery scenario.
5. Optionally click the  icon and use the  and  icons to change the order in which rules are applied. Rule order is important as the default behavior stops rule execution after the first match unless Continue on match is selected under Rule criteria.

## What to do next

Continue to the next section of the discovery scenario, Where to search.

**Previous topic:** [Name and description](#)

**Next topic:** [Where to search](#)

## Rule Criteria

This topic describes classification rule criteria.

The rule criteria displayed in the Discover Sensitive Data interface reflect the datasource-type defined for the scenario. Not all classification rule criteria are available for all datasource types. For example, the Relational (SQL) datasource type includes rule criteria for Compare to values in SQL while the Document datasource type does not.

Table 1.

| Attribute                  | Description                                                                                                                                                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Table type                 | Select one or more table types to search: Synonym, Table, or View. Table is selected by default.                                                                                                                                                             |
| Collection type            | Select one or more collection types to search: Collection or View. Collection is selected by default.                                                                                                                                                        |
| Data type                  | Select one or more data types to search: Number, Text, or Date. Number and Text are selected by default.                                                                                                                                                     |
| Search expression          | Optionally enter a regular expression to define a search pattern to match. To test a regular expression, click the RE button to open the regular expression editor.                                                                                          |
| Table name like            | Optionally enter a specific name or wildcard pattern. If omitted, all table names are selected.                                                                                                                                                              |
| Collection name like       | Optionally enter a specific name or wildcard pattern. If omitted, all collection names are selected.                                                                                                                                                         |
| Column name like           | Optionally enter a specific name or wildcard pattern. If omitted, all column names are selected.                                                                                                                                                             |
| Field name like            | Optionally enter a specific name or wildcard pattern. If omitted, all field names are selected.                                                                                                                                                              |
| Continue on match          | If the next rule in the classification policy should be evaluated after this rule is matched, mark the Continue on Match checkbox. The default is to stop evaluating rules once a rule is matched.                                                           |
| One match per column       | When continuing after a match, evaluate subsequent rules only on columns not matched by a previous rule.                                                                                                                                                     |
| One match per field        | When continuing after a match, evaluate subsequent rules only on fields not matched by a previous rule.                                                                                                                                                      |
| Calculate confidence score | Calculate confidence score during scanning. It is calculated as hits/sample size. Calculating a confidence score impacts the performance of the scan.                                                                                                        |
| Search wildcard            | Optionally enter a specific value or a wildcard pattern. If omitted, all values are selected.                                                                                                                                                                |
| Minimum length             | Optionally enter a minimum length. If omitted, there is no limit.                                                                                                                                                                                            |
| Maximum length             | Optionally enter a maximum length. If omitted, there is no limit.                                                                                                                                                                                            |
| Evaluation name            | Optionally enter a fully qualified Java™ class name that has been created and uploaded. The Java class will then be used to fire and evaluate the string. Note: There is no validation that the class name entered was loaded and conforms to the interface. |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fire only with marker      | <p>The Fire only with marker allows for the grouping of classifier rules: rules with the same marker fire at the same time. Additionally, all returned rules using a marker must return data based on the same table or collection name. If two or more rules are defined with the same marker, those rules will fire together such that if both rules fire on the same table or collection they will both be logged and their actions invoked. On the other hand, if only one rule fires on a table or collection then neither of the rules will be logged or have their actions invoked. Being able to have multiple rules fire together becomes important when you care about sensitive data appearing together within the same table or collection. For example, you may want to know when a table or collection has both a social security number and a Massachusetts drivers license.</p> <p>The fire only withMarker is a constant value, can be named to any value, and must have the exact same value across the rules you want grouped. This means that if one rule has a marker of ABC then the other rule that you want to group it with must also have a marker named ABC.</p> <p>The Fire only with Marker also interacts with the Continue on Match flag. For example, if the following rules were defined such that Rule 3 does not match the Continue on match then no results will be returned regardless if all three marker rules were positive. This is because you didn't get to run Rule 4 and the grouping will not fire because all Fire only with markers must execute with positive results.</p> <p>Rule 1. Firemarker rule "ABC" (continue on match)</p> <p>Rule 2. Firemarker rule "ABC" (continue on match)</p> <p>Rule 3. Firemarker rule "ABC" (continue on match)</p> <p>Rule 4. Firemarker rule "ABC" (continue on match)</p> |
| Hit percentage             | Optionally enter a percentage of matching data that should be achieved for this rule to fire. Data is returned if the percentage of matching data examined is greater than or equal (>=) then the percentage value entered, noting that an empty entry means it is not a condition and will not affect whether the rule fires or not and return data to the view screen. A 0 percentage will cause the rule to fire for this condition and return data to the view screen, and a percentage of 100 requires that all must match.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Compare to values in SQL   | <p>Optionally enter a SQL statement. The SQL entered, which must be based on returning information from one and only one column, will then be used as a group of values to search against the tables and columns selected.</p> <p>Note: If used, the Compare to values in SQL should observe the following rules:</p> <ul style="list-style-type: none"> <li>The SQL statement MUST begin with <b>SELECT</b>.</li> <li>The SQL statement SHOULD NOT utilize the ; (semi-colon).</li> <li>The SQL entered MUST specify a schema value name in order to be accurate in returning results.</li> <li>Good examples:</li> </ul> <pre>SELECT ename FROM scott.emp select EMPNUMBER from SYSTEM.EMP where EMPNUMBER in(5555,4444) select DNAME from SCOTT.DEPT where DNAME like 'A%G' SELECT ZIP from SCOTT.FOO where ZIP in (SELECT ZIP FROM SCOTT.FOO)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Compare to values in group | Optionally select a group. The group selected will then be used as a group of values to search against the tables and columns selected. As long as one of the values within a group, that is either a public or a classifier group, matches, then the value rule will return data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Show unique values         | Mark the Show Unique Values checkbox to add details on what values matched the classification policy rules to the comments field of the resulting report. The row count for each match is indicated in parenthesis following the value. For example, 3 <b>matched distinct values [1662 (1), 436 (3), 629 (27)]</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Unique values mask         | Use regular expressions in the Unique values mask field to redact the unique values. For example, mark the Show unique values checkbox and use <b>([0-9] {2} - [0-9] {3}) - [0-9] {4}</b> in the Unique values mask field to log the last four digits and redact the prefix digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Exclude schema             | Optionally select a group of schema to exclude.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Exclude table              | Optionally select a group of tables to exclude.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Exclude table column       | Optionally select a group of table columns to exclude. The following wildcard character is supported: %                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Actual Member Content

Use the Actual Member Content field to define how objects are labeled by the Add to Group of Objects rule action.

Table 1.

| Actual Member Content Selection | Value in Group              |
|---------------------------------|-----------------------------|
| Object Name Only                | tableName                   |
| Like Name%                      | tableName%                  |
| Like %Name                      | %tableName                  |
| Like %Name%                     | %tableName%                 |
| %/%.Name                        | %/.tableName                |
| Fully Qualified Name            | schemaName.tableName        |
| Like Full%                      | schemaName.tableName%       |
| Like %Full                      | %schemaName.tableName       |
| Like %full%                     | %schemaName.tableName%      |
| %/Full                          | %/.schemaName.tableName     |
| Read/%.Name                     | Read/%.tableName            |
| Change/%.Name                   | Change/%.tableName          |
| Read/Full                       | Read/schemaName.tableName   |
| Change/Full                     | Change/schemaName.tableName |

If your rules return the table name **JJ\_CREDIT\_CARD** from the schema **DB2INST1**, and you have specified an Add to Group of Objects action, the Actual Member Content selections behaves as follows:

- Selecting Fully Qualified Name adds `DB2INST1.JJ_CREDIT_CARD` to the selected group.
- Selecting Object Name Only adds `JJ_CREDIT_CARD` to the selected group.
- Selecting Change/Full adds `Change/DB2INST1.JJ_CREDIT_CARD` to the selected group.

## Where to search

Identify datasources to scan for sensitive data.

## About this task

Datasources store information about your database or repository such as the type of database, the location of the repository, or authentication credentials that may be associated with it. Adding datasources to a discovery scenario creates a *classification process* where *classification policies* are applied to the selected datasources.

In this task, identify the datasources you would like to search for sensitive data.

## Procedure

1. Open the Where to search section to identify the datasources you would like to search for sensitive data.
2. Add datasources to your discovery scenario by doing one of the following:
  - Click the  icon to open the Create Datasource dialog and add a new datasource definition.
  - Select datasources from the Available Datasources table and click the  icon to add existing datasources. Note that the list of datasource is filtered by the datasource type defined for the scenario. For example, scenarios using the `Relational (SQL)` datasource type only list relational-type datasources.
  - Select a group from the Available datasource groups table and click the  icon to add a group of datasources. For groups containing multiple types of datasources, only datasources matching the datasource type defined for the scenario are used. For example, scenarios using the `Document` type datasource only use `Document` type datasources and ignore any `Relational` type datasources that exist in the group.
3. Define a new datasource, or edit an existing datasource by selecting the datasource and clicking the  icon.  
New datasources defined through the discovery scenario can also be viewed or edited through the Datasource Definitions tool.
  - a. Provide or edit the name of the datasource.
  - b. Select the appropriate database type from the Database type menu and provide the requested information to complete the datasource definition.  
The available fields differ depending on the selected database type. Note that the list of database types is filtered by the datasource type defined for the scenario. For example, scenarios using the `Relational (SQL)` datasource type only list relational-type databases.
  - c. When you are finished editing the datasource definition, click Save to save your work and optionally click Test Connection to verify the datasource connection.
  - d. When you are finished working with the datasource definition, click Close to close the dialog.
4. If you are using this classification process for cloud databases also, select Enable object auditing for Cloud DBs.

## Results

A *classification process* is created after adding datasources to your discovery scenario and saving the scenario. To view or edit this process directly, use the Classification Process Builder.

## What to do next

Continue to the next section of the discovery workflow, Run discovery.

**Previous topic:** [What to discover](#)

**Next topic:** [Run discovery and review report](#)

## Related concepts

- [Datasources](#)

## Related tasks

- [Creating a datasource definition](#)
- [Configuring custom properties for your datasources](#)

## Run discovery and review report

Optionally run your discovery scenario and review the results.

## About this task

After defining policies for discovering sensitive data and identifying datasources to search, you can run the *classification process* and review the results. Running the process and reviewing the results allows you to refine your policies, for example specifying additional search criteria if you find the results too broad. It may be necessary to go through several iterations of refining policies, running the process, and assessing the results before achieving the desired results.

## Procedure

1. Open the Run discovery section to test your discovery scenario.
2. Click Run Now to begin.

Attention:

- Depending on the policies you have specified and the number of datasources you have selected to search, it may take several minutes or more to complete the process of identifying sensitive data. The process status is indicated next to the Run Now button, or you can monitor the process using the Guardium Job Queue.

If progress indication does not begin and the Run Now button becomes enabled without indicating that results are available, save the scenario and try running the job again.

- By default, the classifier uses `count *` to determine cardinality for random sampling. For Oracle datasources, Guardium also supports using database statistics to determine cardinality. For more information, see the DATA-CARDINALITY-FOR-SAMPLING-TABLES = STATISTICS custom property in the [Oracle \(Data Direct - SID\)](#) or [Oracle \(Data Direct - Service Name\)](#) documentation.

3. When the discovery scenario has finished running, open the Review report section to see the results.

- Use the Generation time menu to select the report instance to view.

- The  icon lists the datasources included in the report.
- Click the  icon to adjust report settings such as aliases and hierarchical groups.
- Open the Process log to review detailed log information.
- Use the Filter box to refine results (filtering is not supported with more than 10,000 results).

4. While reviewing the results, you can define additional rules and actions based on the results.

- a. Select the row(s) containing data you want to define actions against.
- b. Click Add to Group to define a grouping action, or click Advanced Actions to define other actions such as alerting, logging, or ignoring.
- c. After completing the dialog to define an action, click OK to return to the results report.

Attention:

- Actions added from the results table are considered ad hoc actions that run only as invoked from the results table. These actions will not appear in the [What to discover](#), [Edit rule](#), [Actions](#) section of your discovery scenario, and they will not run automatically as part of the discovery scenario or related *classification processes*.
- Use the Policy Builder to review, edit, and install alerting actions and access rules.
- Use the Group Builder to review and edit grouping actions.
- Use the Privacy Set Builder for to review privacy set actions.
- Use the Incident Management tool to review policy logging actions.

## Results

---

After running the search for sensitive data, monitor its status next to the Run Now button or using the Guardium Job Queue. You can use the Group Builder to review any grouping actions or the Policy Builder to review and install any alerting actions that were added from the results table.

## What to do next

---

Optionally, continue to the next section of the discovery scenario, Audit.

- [Remove false-positives from discovery results](#)

Learn how to mark false-positives in your discovery results and prevent them from appearing in future scans.

Previous topic: [Where to search](#)

Next topic: [Audit](#)

---

## Remove false-positives from discovery results

Learn how to mark false-positives in your discovery results and prevent them from appearing in future scans.

### About this task

---

After defining policies for discovering sensitive data and identifying datasources to scan, you can run the discovery scan and review the results. While reviewing results of a discovery scan, you may find some false-positive matches in the results. You can add these false positives to an exclusion group so they are ignored in subsequent scans. If automatically populating a sensitive objects group based on discovery scan results, removing false positives from that sensitive objects group ensures that actions or policies defined for that group function correctly.

This example uses a discovery scenario with relational-type datasources, but the procedure applies to all datasource types with minor differences. For example, relational-type scenarios use the Add to group of tables to exclude action while document-type scenarios use the Add to group of collections to exclude action.

### Procedure

---

1. Navigate to Discover > Classification > Discover Sensitive Data and select the discovery scenario to review.
2. Review discovery scan results and add false-positives to exclusion groups.
  - a. Click to open the Review report section and see the results of the discovery scan.  
If there are no results, this may mean that the discovery process has not yet run. Click to open the Run discovery section to see the last-run timestamp.
  - b. In the results table, select one or more rows containing false-positive data and click the Add to group button to define a grouping action.  
Group for exclusion based on the granularity of the selected data:
    - Add to Group of Schemas to Exclude
    - Add to Group of Tables to Exclude
    - Add to Group of Tables/Columns to Exclude  
It is possible to add one false-positive to an exclusion group of schemas and another false-positive to an exclusion group of tables or columns.
  - c. Use the Select Exclude Group dialog to select or create an exclusion group.
  - d. Click OK to close the dialog and return to the discovery results table.

#### Attention:

- The original results remain in the table after adding false-positive data to exclusion groups. This is because the result viewer shows the results of the most recent discovery scan. To ensure that the objects have been added, review the exclusion group members using the Group Builder.
- Actions performed from the results table are considered ad hoc actions that run only as invoked from the table. These actions will not appear in the What to discover > Edit rule > Actions section of the discovery scenario, and they will not run automatically as part of the discovery scenario or related classification processes.

### 3. Add exclusion groups to the rule that triggered the false-positive match.

- a. In the Review report section, use the Rule description column in the results table to identify which rule matched the false-positive data.
- b. Click to open the What to discover section and select the rule from the Selected classification rules table. Click the icon to begin editing the rule.
- c. From the Edit rule page, click to open the Rule criteria section, and click the Show advanced options link.
- d. Add the exclusion group to either the Exclude schema, Exclude table, or Exclude table column parameter. Choose the granularity that matches your selection for the false-positives in the discovery results.
- e. Click the Save button to save the rule.
- f. Click the Save button to save the discovery scenario.

### 4. Remove false-positive data from the sensitive objects group.

Discovery template rules automatically add matches to a sensitive objects group, and your own rules may define a similar behavior. To prevent the false-positives from appearing in future discovery scans, remove the false-positive data from the sensitive object group.

- a. Navigate to Setup > Tools and Views > Group Builder.
- b. Select the appropriate sensitive objects group and click the icon.
- c. On the Members tab of the Edit group dialog, select the false-positives and click the icon.
- d. Click the Save button to update the group.

## Results

The next time you run the discovery scenario, the false-positives identified using this procedure will not appear as matches.

## Audit

Optionally create an audit process by defining receivers, a distribution sequence, and review options for the discovery and classification report.

## About this task

You can define any number of receivers for the results of a discovery workflow, and you can control the order in which they receive results. In addition, you can specify process control options, such as whether a receiver needs to sign off on the results before they are sent to the next receiver.

## Procedure

1. Open the Audit section to define receivers for discovery reports.
2. Use the Audit process menu to select an audit process to use with the discovery scenario.  
When creating a new discovery scenario, a new audit process name is suggested in the format of [scenario name] Audit process [timestamp]. For example, creating a scenario named discover\_cadl results in an audit process named disover\_cadl Audit process [2018-01-01 12:00:00].
3. Add receivers to your discovery scenario by clicking the icon and defining options for how the reports are delivered.
  - If sending the report to Guardium users, roles, or groups, you will need to define process control options.
  - If sending the report to email recipients, provide their email address and filter the report by a Guardium username that is appropriate for the email recipient.
4. Click OK to add the receiver to the discovery workflow.  
Continue adding additional receivers to the scenario if needed.
5. Optionally click the icon and use the and icons to change the order in which reports are distributed to recipients. This is important when using sequential distribution as it determines which receivers must review or sign the report before it is sent to subsequent receivers.

## Results

An *audit process* is created after defining receivers and saving the discovery scenario. To view, edit, or run this process directly, use the Audit Process Builder.

The *audit process* remains inactive until it is scheduled using the Schedule section of the discovery scenario or using the Audit Process Builder. You can also run the *audit process* by visiting the Audit Process Builder, selecting the *audit process*, and clicking Run Once Now.

## What to do next

Optionally, continue to the next section of the discovery workflow, Schedule.

**Previous topic:** [Run discovery and review report](#)

**Next topic:** [Scheduling](#)

## Related concepts

- [Building audit processes](#)

## Scheduling

Optionally activate the audit process by scheduling it to run at defined intervals.

## About this task

A schedule becomes part of an *audit process* along with any receivers specified in the Audit section of the discovery scenario. Defining a schedule runs the *audit process* at specified intervals and ensures that results from the associated *classification process* are regularly distributed and reviewed.

## Procedure

1. Open the Schedule section to define a schedule for discovering data.
2. Use the Schedule by menu to set daily or monthly intervals for the *audit process*.
3. Use the Start schedule every and Repeat every check boxes to define how many times per day and how many times within each hour to run the *audit process*.
4. Use the Start date and time controls to define an explicit date and time for the schedule to begin.
5. Clear the Activate schedule check box to deactivate the *audit process* while retaining scheduling information for later use. The Activate schedule box is checked by default, meaning that the audit process becomes active after saving the schedule.
6. When you have defined a schedule, click Save to finish editing and close the workflow editor.

## Results

An *audit process* is created after defining a schedule and saving the discovery scenario. To view or edit this audit process directly, use the Audit Process Builder. Review the Scheduled Jobs report to see the status, start time, and next fire time for scheduled audit tasks.

Previous topic: [Audit](#)

- [Building audit processes](#)

## Runtime sensitive-object identification

Runtime sensitive-object identification processes response data looking for predefined patterns that match personally-identifiable and other sensitive information.

## About this task

Runtime sensitive-object identification matches user-selectable patterns for data such as credit card numbers, international bank numbers, email addresses, and personal identification numbers for various countries. Use the **Runtime Sensitive Object Identifier** session-level policy to enable runtime sensitive object identification, select patterns to match, and view the results.

Note: If runtime sensitive-object identification is active when you upgrade to Guardium 12.0, the installed rules from your previous version are changed to a migrated **Runtime Sensitive Object Identifier** policy. Use the methods described in [Creating session-level and advanced session-level policies](#) to add or remove patterns, change predefined rules, or copy and create new rules. Pattern names from earlier releases migrate as rule names to Guardium 12.0.

The *IPV6 address and Belgium: National Number* patterns are deprecated and will not migrate to Guardium 12.0.

## Procedure

1. From the Guardium® UI, browse to Security>Security Policies>Policy Builder for Data to open the Security Policies page.
2. From the Security Policies page, select the **Runtime Sensitive Object Identifier [template]**.  
You can either run the policy as is, or make a copy () and customize the policy for your specific needs. For more information about using session-level policies, see [Creating session-level and advanced session-level policies](#).
3. View results using the Runtime Sensitive Object Identifier report.  
You can modify the report to display the information that you need. For more information, see the [Runtime Sensitive Object Identifier](#) report.

## What to do next

You can copy, and then modify the Runtime Sensitive Object Identifier policy as required for your needs. For information about making changes to a policy, see [Creating session-level and advanced session-level policies](#).

## Related information

- [Runtime Sensitive Object Identifier](#)

## Regular Expressions

Regular expressions can be used to search traffic for complex patterns in the data.

The IBM® Guardium® implementation of regular expressions conforms with PCRE. This information does not provide a comprehensive description of how regular expressions are constructed or used. The important point to keep in mind about pattern matching or XML matching using regular expressions is that the search for a match starts at the beginning of a string and stops when the first sequence matching the expression is found. Different or the same regular expressions can be used for pattern matching and XML matching at the same time. For more detailed information, see the PCRE web site: <https://www.pcre.org/>

# FAM discovery and classification in Windows and UNIX-Linux file servers

File activity discovery and classification ensures integrity and protection of sensitive data on UNIX-Linux and Windows file servers.

Restriction: FAM discovery agent (crawler) is only applicable to Guardium® Data Protection versions 11.4, 11.5 and 12.0.

- [Installing and activating the FAM discovery agent \(crawler\) on UNIX servers](#)

Install the GIM client on a UNIX file server, then use it to install the file activity monitoring discovery agent (crawler).

- [Installing and activating FAM discovery agent \(crawler\) on Windows servers](#)

Install the GIM client on the file server, then use it to install the FAM discovery agent.

- [File discovery and classification GIM parameters](#)

These GIM parameters configure file discovery and classification for each collector.

- [Rules for GDPR File Activity](#)

Use the rules listed here to create decision plans for FAM GDPR.

## Installing and activating the FAM discovery agent (crawler) on UNIX servers

Install the GIM client on a UNIX file server, then use it to install the file activity monitoring discovery agent (crawler).

### Before you begin

- Restriction: FAM discovery agent (crawler) is only applicable to Guardium® Data Protection versions 11.4, 11.5 and 12.0.
- License keys must be installed. See [Install license keys](#).
- S-TAP for FAM must be installed. Required for file monitoring and policy enforcement. See [Linux-UNIX: Installing, upgrading and uninstalling S-TAP agents](#).
- Verify that a bash shell is installed.
- Verify that the Compatibility standard C++ libraries i686 package libraries are installed. When running ICC with the incorrect libstdc version, the client will receive a bnsRun error. If the FAM discovery agent is already installed, uninstall and re-install the agent after you install the libraries.
- FAM discovery agent (also known as the FAM bundle or FAM agent) must be accessible. Required for file discovery and classification. Download from [Fix Central](#) or obtain from your Guardium representative.
- Disk space requirements for FAM bundle: 2GB. AIX platforms require an additional 2GB during installation.
- The FAM discovery agent (crawler) does not support TLS encryption.

Tip: To install the FAM discovery agent successfully on AIX, it is recommended to set the process data size to unlimited. Access the file /etc/security/limits and change this line to **default: data = -1**.

### Procedure

1. Install the GIM client on the file server. See [Guardium installation manager](#).
2. Download the FAM bundle and save it in an accessible drive.  
The UNIX bundle has a name like: guard-bundle-FAM\_r\*\*\*\*\*\_trunk\_\*\*\*\*.gim.
3. On the central manager (if there is one), upload and import the FAM bundle. If there is no central manager, upload and import the FAM bundle to the appliance.
  - a. Navigate to [Manage > Module Installation > Upload Modules](#).
  - b. Under [Upload Module](#), click [Browse](#) and navigate to the FAM bundle. Click [Upload](#).
  - c. Under [Import uploaded modules](#), select the FAM bundle and click [Install/Update](#).
4. Install and configure the FAM bundle using [Manage > Module Installation > Set up by Client](#).  
For more information on GIM, see [Set up by Client](#).
  - a. To enable the FAM monitor, set [STAP\\_FAM\\_ENABLED](#) to 1 (enabled). This is required even if you are only using the FAM discovery agent.
  - b. FAM discovery is enabled by default ([FAM\\_ENABLED](#)).  
Configure additional parameters as relevant.
    - Configure [SOURCE\\_DIRECTORIES](#) for the directories you want to scan.
    - By default, the agent performs basic scanning for entitlement information. To enable scanning based on decision plans, such as for SOX or HIPAA, set [FAM\\_IS\\_DEEP\\_ANALYSIS](#) to true. By default, it uses all of the default decision plans. You can specify which decision plans you want it to use.
    - The default schedule for the scanning is every 12 hours, and starts immediately upon configuration. You can change these using GIM parameters [FAM\\_SCHEDULER\\_HOUR\\_INTERVAL](#), [FAM\\_SCHEDULER\\_START](#), [FAM\\_SCHEDULER\\_REPEAT](#).See full parameter list in [File discovery and classification GIM parameters](#).
5. Verify that the FAM discovery agent installed successfully by viewing the Guardium S-TAP Status Monitor report (add the report from My Dashboards). Look for the [FAM\\_Agent](#) suffix in the IP address of the S-TAP host.
6. To trigger file rediscovery later without uninstalling and reinstalling the FAM bundle:
  - a. Remove the files under the work directory. If Guardium is installed in the default directory, the files to be removed are in this directory on the file server: [/usr/local/IBM/modules/FAM/current/files/work](#)
  - b. Change any FAM parameters in GIM, for example, changing the time interval from 5 to 10 minutes.
  - c. Click [Apply to Selected](#) then click [Install/Update](#).

### Results

Discovery and Classification results: After you install the FAM discovery agent (file crawler), a basic run of the file crawler begins, using the initial path that you specified during the installation. Each time the crawler completes its run, it sends a status message that is included in the Files Crawler Configuration report. This process gathers the list of folders and files, their owner, access permissions, size, and the time and date of the last update.

# Installing and activating FAM discovery agent (crawler) on Windows servers

Install the GIM client on the file server, then use it to install the FAM discovery agent.

## Before you begin

- Restriction: FAM discovery agent (crawler) is only applicable to Guardium® Data Protection versions 11.4, 11.5 and 12.0.
- License keys must be installed. See [Install license keys](#).
- FAM discovery agent (also known as the FAM crawler or FAM agent) must be accessible. Required for file discovery and classification. Download from [Fix Central](#) or obtain from your Guardium representative.
- Either a Windows S-TAP or the Windows FAM Monitor must be available.
- Verify that the Compatibility standard C++ libraries i686 package libraries are installed.
- .NET 4.5 or above is installed. If not yet installed, .NET 4.5 requires 5 GB.
- Disk space requirements: 2GB.
- The FAM discovery agent (crawler) does not support TLS encryption.

The FAM monitor package is a standalone package, and is installed independently. When upgrading from 11.0 and higher:

- If you're using FAM and S-TAP:
  1. Upgrade the S-TAP to your current version. This uninstalls the previous FAM (FsMonitor driver and StapAT service).
  2. Install the FAM crawler and FamMonitor.
- If you're using FAM only:
  1. Uninstall the S-TAP. This uninstalls the previous FAM (FsMonitor driver and StapAT service).
  2. Install the FAM crawler and FamMonitor.

## Procedure

1. Make sure that the following Guardium features are installed:
    - The GIM client on the file server. For more information, see [Installing the GIM client on a Windows server](#)
    - An S-TAP, the FAM Monitor, or both. For more information about installing the FAM Monitor, see [Installing and activating the FamMonitor on Windows servers](#)
  2. Download the FAM bundle and save in an accessible drive.  
The monitoring and discovery agent bundle name has the format: guard-FAM-guardium\_r\*\*\*\*\*Windows-Server-x86\_x64\_ia64.gim.
  3. On the central manager if there is one, otherwise on an appliance, upload and import the FAM discovery agent bundle.
    - a. Browse to Manage > Module Installation > Upload Modules.
    - b. Under Upload Module, click Browse and navigate to the FAM bundles. Click Upload.
    - c. Under Import uploaded modules, select the FAM bundles and click Install/Update.
- Configure additional parameters as relevant:
- Note: You can also configure GIM parameters using the grdapi command: **gim\_update\_client\_params**.
- Configure SOURCE\_DIRECTORIES for the directories you want to scan.
  - By default, the agent performs basic scanning for entitlement information. To enable scanning based on decision plans, such as for SOX or HIPAA, set FAM\_IS\_DEEP\_ANALYSIS to true. By default, it uses all of the default decision plans. You can specify which decision plans you want it to use.
  - The default schedule for the scanning is every 12 hours, and starts immediately upon configuration. You can change these using GIM parameters FAM\_SCHEDULER\_HOUR\_TIME\_INTERVAL, FAM\_SCHEDULER\_START, FAM\_SCHEDULER\_REPEAT.
- See full parameter list in [File discovery and classification GIM parameters](#).
4. Verify that the FAM discovery agent installed successfully by viewing the Guardium S-TAP Status Monitor report (add the report from My Dashboards). Look for the FAM\_Agent suffix in the IP address of the S-TAP host.
  5. To trigger file rediscovery later without uninstalling and reinstalling the FAM bundle:
    - a. Remove the files under the work directory. If Guardium is installed in the default directory, the files to be removed are in this directory on the file server: /usr/local/IBM/modules/FAM/current/files/work
    - b. Change any FAM parameter in GIM, for example, changing the time interval from 5 to 10 minutes.
    - c. Click Apply to Selected then click Install/Update.

## Results

When the installation of the FAM discovery agent (file crawler) is complete, a basic run of the file crawler begins, using the initial path that you specified during the installation. Each time the crawler completes its run, it sends a status message that is included in the Files Crawler Configuration report. This process gathers the list of folders and files, their owner, access permissions, size, and the time and date of the last update.

## File discovery and classification GIM parameters

These GIM parameters configure file discovery and classification for each collector.

Configure file discovery and classification per collector. These parameters can be configured during installation, or later using GIM (Manage > Module Installation > Set up by Client) or using the GuardAPI command **gim\_update\_client\_params**. You can only update one collector at a time when using the GuardAPI.

| GIM Parameter                       | client.ini                     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | GUI |

## File discovery and classification for NAS and SharePoint

File Discovery, Entitlement and Classification (FDEC) for NAS and SharePoint servers enables scanning for file entitlement and classification of sensitive data which may be related to regulatory laws (e.g., GDPR, HIPAA).

NAS or network-attached storage is a file-level storage system based on networked appliances containing multiple storage devices. SharePoint is a web-based collaborating platform and a document management and storage system.

This Guardium product includes a Windows-based service performing scheduled scans of either NAS or SharePoint, and a configuration application for configuring the scan's targets, schedule, and classification criteria. This client software can be seen in S-TAP Control and the scan results are in the File Entitlement report.

- [\*\*Supported platforms for file discovery\*\*](#)
- [\*\*Scan Permissions\*\*](#)  
NAS and SharePoint permissions for File Discovery, Entitlement and Classification (FDEC)
- [\*\*Installing client software\*\*](#)  
Install File Discovery, Entitlement and Classification (FDEC) for your NAS or SharePoint environment.
- [\*\*Configure Scan Settings\*\*](#)  
Launch the Scan Configuration Utility using **ConfigurationFDEC.exe** in the installation directory under Bin\|. The configuration utility executable is the same for both NAS and SharePoint environments.
- [\*\*View Scan Results\*\*](#)  
View File Discovery, Entitlement and Classification (FDEC) scan results.
- [\*\*Creating User-Defined Criteria\*\*](#)  
The Criteria Editor is a utility that allows users to create criteria from scratch or by copying and editing a pre-defined criteria item.

---

## Supported platforms for file discovery

For the list of supported platforms for files, see [Guardium Supported Platforms for Files](#).

---

## Scan Permissions

NAS and SharePoint permissions for File Discovery, Entitlement and Classification (FDEC)

---

### SharePoint Scan Permissions

The SharePoint Agent is capable of auditing permissions and content, or Access Auditing (SPAA) and Sensitive Data Discovery Auditing, on SharePoint servers. It is installed on the application server which hosts the *Central Administration* component.

If limited provisioning of the service account is not required by the organization, then the following permissions are sufficient for successful SharePoint Agent-based scans:

- Local Administrator group membership on the on server where the SharePoint Agent is installed
- Site Collection Administrator on all Site Collections to be scanned
- DB\_Owner or SPDataAccess should be applied on the desired Configuration database and all Content databases depending on the SharePoint version:
  - For SharePoint 2013 and 2016: SPDataAccess on the SharePoint Content database and all Configuration databases
  - For SharePoint 2010: DB\_Owner on the SharePoint Content database and all Configuration databases

#### SharePoint Scan Permissions: Less Privileged Model

If restricted permissions are desired by the organization, the following permissions are needed for the service account to successfully run SharePoint Agent-based scans.

Prior to installation of the SharePoint Agent, the service account to be supplied during installation and later used to run the Access Auditing (SPAA) and/or Sensitive Data Discovery Auditing scans against the targeted SharePoint environment needs the following permissions:

- Log on as a Service in the Local Security Policy
- Local group membership to IIS\_IUSRS
- Performance Log Users (For Sensitive Data Discovery Only)

After the SharePoint Agent installation, this service account needs the following additional permissions to run the Access Auditing (SPAA) and/or Sensitive Data Discovery Auditing scans:

- Site Collection Administrator on all Site Collections to be scanned
- Local 'Users' group membership on server where the SharePoint Agent is installed

If the scans will include Web Application scoping, then the following permissions are also needed (this can be skipped if running full farm scans):

- Local group membership to Backup Operators
- Local group membership to WSS\_WPG
- WSS\_CONTENT\_APPLICATION\_POOLS on the SharePoint Configuration database

After the FDEC SharePoint Agent is installed, ensure that the service account has the following permissions:

- Full Control on the agent install directory, for example C:\Program Files\IBM\FDECforSP

The FDEC SharePoint Agent utilizes Microsoft APIs. The Microsoft APIs require an account with the following permissions in order to collect all of the data:

- WSS\_CONTENT\_APPLICATION\_POOLS on the SharePoint Content database(s)
- WSS\_CONTENT\_APPLICATION\_POOLS on the SharePoint Configuration database

If scans will include Web Application scoping, this last permission will already have been met.

## NAS Scan Permissions

### NetApp Data ONTAP Cluster-Mode Permissions

The credential used to collect file system data from a NetApp Data ONTAP Cluster-Mode device must have the ability to:

- Enumerate shares by executing specific API calls
- Bypass NTFS security to read the entire folder structure to be scanned and collect file/folder permissions

#### Share Enumeration – API Calls (Cluster-Mode)

To enumerate the shares on a NetApp Data ONTAP Cluster-Mode device, File System scans require a credential provisioned with the following CLI commands at minimum.

| CLI Command                     | Access   |
|---------------------------------|----------|
| version                         | Readonly |
| volume                          | Readonly |
| vserver                         | Readonly |
| server fpolicy                  | Readonly |
| security login role show-ontapi | Readonly |

Important: In order to enumerate shares on NetApp Data ONTAP Cluster-Mode device v8.3+, the credential needs to have at least the following permission on the target host: Group membership in the Power Users group.

#### Bypass NTFS Security (Cluster-Mode)

It is possible to enable a credential to bypass NTFS security on NetApp Data ONTAP Cluster-Mode devices by provisioning access to a special share: ONTAP\_Admin\$. In order to access the ONTAP\_Admin\$ share, the credential must be associated with an FPolicy on the target device.

The FPolicy can be an “empty” FPolicy and should have minimal impact on an organization’s system. The policy name must be “StealthAUDIT”.

### NetApp Data ONTAP 7-Mode Permissions

The credential used to collect file system data from a NetApp Data ONTAP 7-Mode device must have the ability to:

- Enumerate shares by executing specific API calls
- Bypass NTFS security to read the entire folder structure to be scanned and collect file/folder permissions

The following sections outline the required permissions granted to the credential used within the assigned Connection Profile for these target hosts.

#### Share Enumeration – API Calls (7-Mode)

To enumerate the shares on a NetApp Data ONTAP 7-Mode device, File System scans require a credential provisioned with access to (at minimum) the following API calls:

- login-http-admin
- api-system-api-list
- api-system-get-version
- api-cifs-share-list-iter-\*

#### Bypass NTFS Security (7-Mode)

In order to bypass NTFS, the credential needs to at least have the following permissions on the target host:

- Group membership in both of the following groups:
  - Power Users
  - Backup Operators

Note: All NetApp groups are assigned an RID. Built-in NetApp groups such as Power Users and Backup Operators are assigned specific RID values. On 7-Mode NetApp devices, system access checks for a group are identified by the RID assigned to the group and not by the role it has. Therefore, the ability to bypass access checks with the Power Users and Backup Operators group has nothing to do with the power role or the backup role. Neither role is required. For example, the built-in Power User group, even when stripped off all roles, still has more file system access capabilities than any other non-built-in group.

### EMC Celerra, VNX, VNxe, VMAX3, or Unity Permissions

The credential used to collect file system data from an EMC Celerra, VNX, VNxe,VMAX3, or Unity device needs to at least have the following permissions on the target host:

- Group membership in both of the following groups:
  - Power Users
  - Backup Operators

These permissions grant the credential the ability to enumerate shares, access the remote registry, and bypass NTFS security on folders.

If there are folders to which the credential is denied access, it is likely that the Backup Operators group does not have the “Back up files and directories” right. In that case, it is necessary to assign additional “Back up files and directories” right to those groups or to create a new local group, using Computer Management from a Windows server. Then assign rights to it using the CelerraManagementTool.msc plugin which is available to EMC customers.

Note: In order to successfully scan EMC devices from a Windows Server 2012 or newer, the “Require Secure Negotiate” policy must be turned off on that server. This is due to a problem that is caused by the “Secure Negotiate” feature which was added to SMB 3.0 for Windows Server 2012 and Windows 8. This feature depends upon the correct signing of error responses by all SMBv2 servers, including servers that support only protocol versions 2.0 and 2.1. Some third-party file servers do not return a signed error response; therefore, the connection fails.

### EMC Isilon Permissions

The credential used to collect file system data from an EMC Isilon device must have the following permissions on the target host:

- Group membership in the local Administrators group – LOCAL:System Provider
- Rights on the actual file tree or to the IFS root share
  - Share Permissions
    - Read access
  - Folder Permissions
    - List Folder / Read Data

- Traverse Folder / Execute File
- Read Permissions

These permissions grant the credential the ability to audit folders and shares. In order to execute scoped Classification scans, the credential must also have the LOCAL\System provider selected in each access zone in which the shares to be scanned reside.

#### Hitachi Permissions

The credential used to collect file system data from a Hitachi device must have the following permission on the target host:

- Group membership in both of the following local groups:
  - Local Administrators
  - Backup Administrators

This permission grants the credential read access to all target folders and files.

## Installing client software

Install File Discovery, Entitlement and Classification (FDEC) for your NAS or SharePoint environment.

### Before you begin

- Users must have matching administrative privileges on both the server side as well as NAS and SharePoint environments. For more information, see [Scan Permissions](#).
- For detailed platform prerequisites and support for NAS devices, see [Supported platforms for file discovery](#).

### Procedure

1. Determine what environment to use. If you want to install the client to scan a NAS device, install the client on a Windows server that can access the NAS device through the network. But if a user wants to install the client to scan SharePoint, install it directly on the SharePoint server or SharePoint server farm.  
Note: Do not install any other Guardium products on this server.
2. Download the FDEC for NAS and SharePoint package to the server from [Fix Central](#) and extract the file.  
Note: Before you extract the file, it is recommended that you can unblock the compressed file that is downloaded to the server. To unblock the compressed file:
  - a. Browse the file in your server, right-click on the file, and select Properties.
  - b. Select Unblock, and save your changes
 If the file is already unblocked, then the Unblock option is not available.
3. Go to the FDEC package installer directory and run the executable file **setup.exe** in the installer directory.  
The default installation directory for FDEC for NAS is C:\Program Files\IBM\FDECforNAS.  
The default installation directory for FDEC for SharePoint is C:\Program Files\IBM\FDECforSP.
4. Follow the prompts in the wizard to complete the installation.
  - a. Specify the service user who has admin privileges for the share they want to scan.
  - b. In the Network Addresses page, enter a list of Guardium hostnames or IP addresses. If there is a failover, the FDEC agent connects to the next appliance on the list.

## Configure Scan Settings

Launch the Scan Configuration Utility using **ConfigurationFDEC.exe** in the installation directory under Bin\|. The configuration utility executable is the same for both NAS and SharePoint environments.

Use the following options to configure the scan settings:

| Scan configuration | Description                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan Name          | An arbitrary name for your scan.                                                                                                                                                                                                                                                                                                                                                   |
| Guardium Appliance | The hostname or IP address of your Guardium Appliance.<br>In a NAS environment, scans can run concurrently, and each scan can be configured with a different appliance address.<br>Click Manage to enter a list of Guardium® appliances. You can test the connection on each appliance individually. In the event of a failover, the agent connects to the next appliance on list. |
| Local Host Address | The IP address of the local host.                                                                                                                                                                                                                                                                                                                                                  |
| Scan Host          | For NAS, this is the IP or hostname of NAS environment.<br>For SharePoint, Scan Host is auto-filled with localhost.                                                                                                                                                                                                                                                                |

| Scan configuration                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan Paths                           | <p>Here are some examples of scan paths:</p> <ul style="list-style-type: none"> <li>For NAS: NameOfShareDrive</li> </ul> <p>Notes:</p> <ul style="list-style-type: none"> <li>The NameOfShareDrive supports the share, zone, or drive name. However, you cannot specify the path.</li> <li>To make scanning time of the whole NAS device more manageable, you can split it into smaller shares, and create a scan for each share.</li> </ul> <ul style="list-style-type: none"> <li>For SharePoint: http://SharePointServer/my/test</li> </ul> <p>Click  to select, add, or remove site collections to the scan. To create a farm-wide scan, do not specify a path.</p> <ul style="list-style-type: none"> <li></li> </ul> |
| Scan Every                           | <p>The scan schedule can be configured in hours or days. By default, the frequency of the scan is every 12 hours.</p> <p>Scans can also be scheduled to run at a specific time.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Run Now                              | <p>Use this option to run a scheduled scan immediately.</p> <p>To activate the Run Now button, click </p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Directory Level                      | The number of levels that will be scanned in the directory structure. The default is 100                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Scan Options                         | <ul style="list-style-type: none"> <li>Containers Only: scans only directories, and will not trigger classification on the objects themselves.</li> <li>All Objects: scans everything including files, directory tree, and will match criteria.</li> <li>Matches Only: this scan only returns records that trigger criteria.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                    |
| Scan Criteria                        | <p>This allows for upload of various criteria sets. You may select the specific criteria you wish to use for classifying files. As an example: GDPR sensitive data patterns can be selected from the GDPR.update file. For criteria that align with other compliance guidelines such as HIPAA, select patterndefs.update.</p> <p>To create user-defined criteria, see <a href="#">Creating User-Defined Criteria</a>.</p>                                                                                                                                                                                                                                                                                                  |
| Scan Service Account                 | <p>The service account for each scan can be configured independently to reflect the environment being scanned.</p> <p>After you save a scan, click  to activate the scan.</p> <p>Click  to stop a scan.</p> <p>Click  to restart a scan.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| New Scan, Save Scan, and Delete Scan | <p>Use these buttons to create, save, or delete a scan.</p> <p>You must click the  button to activate a scan after it is saved.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Purge scan DB                        | Purge your local database periodically for fresh scan results. You must also purge the local database in the event that a scan is interrupted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Scan Status                          | This displays the scan status including Started Last Scan, Finished Last Scan, Scanned Objects, New and Updated Objects, Deleted or Renamed Objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Note:

- After you configure and save the scan, click to activate the scan.
- Scans can be scheduled to run concurrently. But if two scans target the same host, they will run consecutively.
- The default maximum size for file classification is 2MB.

#### Notes on Upgrading:

It is not recommended to upgrade the scan configuration utility until the scan is finished. Upgrading or stopping the service may corrupt the scan results.

When you upgrade your scan utility, you must reenter the service account credentials. During the upgrade, all active scans will have new services created for them, and they will begin running according to their schedule. You must click the play button to enable all new, and inactive scans.

---

## View Scan Results

View File Discovery, Entitlement and Classification (FDEC) scan results.

### About this task

Before you run the scan, check to see if the agent is connected to the appliance. The scan results can be viewed through the File Entitlement and Directory Entitlement reports on My Dashboard.

### Procedure

- Click My Dashboards > Create New Dashboard to open a new dashboard.
- Click Add Report to display a list of available reports. The Add a Report dialog shows a list of all reports that meet your criteria. You can browse the list of reports or type a string in the Filter field. The list of reports is updated as you type.
- The scan results can be viewed through the File Entitlement and Directory Entitlement reports. Click on the report to add it to your dashboard.

## Results

---

You now have a dashboard that gives you easy access to the File Entitlement and Directory Entitlement reports.

## Creating User-Defined Criteria

The Criteria Editor is a utility that allows users to create criteria from scratch or by copying and editing a pre-defined criteria item.

The criteria editor can be launched from **DLPCriteriaEditor.exe** in the installation directory under Bin\SensitiveData.

To create a new criterion from scratch, click the "+" button and select the criteria type. Provide the needed information for the selected criteria.

To change a pre-defined criterion, right-click the desired System Criteria list and select Copy. A copy of the selected criteria list will appear under My Criteria with *copy* added to the name. The copy can then be edited as desired.

There are three types of criteria to choose from:

- Regular Expression Criteria
- Keywords Criteria
- Summary Criteria

Two items are included as part of all three criteria types:

1. The Title appearing under My Criteria should be unique and descriptive.
2. The Only for use in Summaries checkbox causes the criteria to be used only as part of the summary criteria.

### Regular Expression Criteria

Regular Expression criteria are a set of pattern-matching rules that provide a concise and flexible means for matching strings of text. This criteria type can be used to verify a series of numbers as potentially valid, e.g. credit card numbers.

- The Case Sensitive checkbox causes the scan to be case sensitive.
- The Use validation checkbox allows for Luhn or Mod 11 validation.
- The Analyze checkboxes allow criteria to be built to analyze Filename, File Metadata, and File Content.
- The textbox is where the expression is entered.
- The Number Slider indicates the number of matches from the list needed to classify a file as potentially sensitive.

### Keywords Criteria

Keywords criteria consist of a list of comma-separated words. If any word in the list is found in the file, it is considered a hit.

- If checked, the Case Sensitive checkbox causes the scan to be case sensitive.
- The Analyze checkboxes allow criteria to be built to analyze Filename, File Metadata and File Content.
- The textbox is where the keywords are entered.
- The A..z button will sort keywords alphabetically and automatically remove duplicates. If checked, the Distinct checkbox causes the scan to search for unique hits of criteria.
- The Number Slider indicates the number of keywords from the list needed to classify a file as potentially sensitive. If Distinct is checked, this is the number of unique keywords needed.

### Summary Criteria

Summary Criteria are designed as a way of combining Regular Expression Criteria and Keywords Criteria for reporting purposes. These results are calculated according to the selected comparison operator (Any of, All of, or At least, which uses the value of the Number Slider).

- Check the desired criteria from My Criteria, System Criteria, or both.
- A *Summary Query* statement builds at the bottom with the appropriate comparison operator.

Select the radio button for the desired comparison operator. If At least is selected, a Number Slider appears to set the minimum number of criteria matches.

---

## Entitlement Optimization

Entitlement Optimization mediates between the role of the DBA in providing users the entitlements that are required to perform their jobs efficiently, and the role of Security in keeping entitlements as accurate and as minimal as possible to prevent system vulnerabilities.

Situations naturally arise during day to day management of the system that result in vulnerabilities, for example:

- Over-generalized access
- A privilege that was given to a user needed for one-time use but not removed afterward
- Changes over time of users and tables, resulting in dormant users and tables
- Privileges that are passed from one user to another

Entitlements require constant ongoing vigilance. For example, advanced persistent threats (APT) usually originate with one of these back door entries into the system.

Entitlement optimization constantly analyzes users' privileges and actions, and produces recommendations that pinpoint specific actions that aim to minimize user access to only that which is required. The analysis is entirely performed by the system. The admin reviews the results, examines each case, and takes the appropriate actions, for example, removing privileges from a DB user, or deleting dormant roles.

You can also investigate entitlement changes over the past week, a complete list of users and roles, data source privileges alongside their actual usage, and a simulated justification of a specific user-role combination. These views provide information relevant to the recommendations, and are also starting points for other investigations.

The advantages of entitlement optimization over Guardium reports is that it consolidates information for all database types (that appears in multiple Guardium reports), and it adds new analyses into its own comprehensive and consolidated reports, simplifying entitlement management, and thereby increasing system security.

Entitlement optimization supports database types: Microsoft SQL Server, Oracle. It does not support SQL Contained Databases. (Guardium reports are per database type.)

Entitlement optimization activity monitoring is limited to the data currently monitored by Guardium. The accuracy of the Recommendations, Entitlement browse and What if analyses depend on the relevance of the monitored data. To fully maximize the potential of this tool, configure the userScope and objectScope parameters, and consider modifying the security policy.

Users that are dormant from the time you start monitoring with Entitlement optimization are not included in the entitlement optimization reports. To watch a specific user that is monitored but doesn't have any recommendations, manually check the activity of the user either through entitlement browse or any of the other Guardium activity monitoring tools. The tools have the full information if the policy is correctly defined.

Entitlements analysis is per Collector, and operates only on the data sources that you configure by grdapi.

The **must gather** feature supports entitlement optimization. See [Basic information for IBM Support](#).

Access entitlement optimization from Discover > Database Entitlements > Entitlement Optimization

- [Enable and configure entitlement optimization](#)  
Use GuardAPI commands to enable and configure entitlement optimization.
- [Entitlement Optimization What's New](#)  
The What's New tab summarizes the additions and changes that are made to the system over the calendar week, from Sunday to Sunday.
- [Entitlement Optimization Users and Roles](#)  
The Users and Roles tab lists all users and their roles for all data sources that are enabled for Entitlement Optimization on this collector.
- [Entitlement Optimization Recommendations](#)  
Recommendations pinpoint specific actions that aim to minimize user access to only that which is required.
- [Entitlement Optimization Browse entitlements](#)  
Use the views and filters in this window to see the activity level of entitlements, and the lineage of the entitlements.
- [Entitlement Optimization What If](#)  
What If shows the probable justification for entitlement of a specific user with one or more specific verbs on a specific object (regardless of whether or not the entitlement exists).

## Enable and configure entitlement optimization

Use GuardAPI commands to enable and configure entitlement optimization.

All commands are run on the collector, and use already defined Guardium data sources. First, enable the feature on the collector, and then specify the data sources and enable the specific features.

The most accurate results are obtained by fine-tuning the data that is included in the entitlement optimization.

Users and Roles, and Browse entitlements, are enabled by default, however you must set extractActivity and extractEntitlement to `true` to extract the relevant data. The other three features (What's New, Recommendations, What If) are enabled individually. For example, you can enable Recommendations while leaving What If disabled.

Entitlement recommendations uses a subset of data, filtered by the userScope and objectScope parameters. Browse Entitlements uses the userScope parameter to filter data. Both parameters specify one or more Guardium® groups. Most likely, you will create specific groups to use for this purpose. Define the groups to extract only the data you want, to minimize storage and processing. The groups should have Full Audit, so that all data is analyzed and the results are conclusive. When you use groups with Full audit, the Browse Entitlements shows all rights of all users, regardless of their activity. A user that is outside of the userScope definition appears in the window, but its activity count is "unknown."

The best practice is to carefully evaluate and design your data collection scheme such that you only rarely change it. This is for two reasons: every time you change the configuration, it takes a week to generate data for reports; the data is compared to data of the previous 3 weeks, and when you change the data definition the comparison is less meaningful for the first 3 weeks.

Data is present in each tab from the first Sunday after you enable the individual feature.

For more information about the entitlement optimization functions, see [Entitlement optimization APIs](#).

Prerequisites

- Investigation dashboard is enabled. (Required for What-if, Recommendations, and updating activity in Entitlement Browse.)
- The user that configures the entitlement optimization must have permission to all the meta data and schema tables that are in the configured datasources.

## Entitlement Optimization What's New

The What's New tab summarizes the additions and changes that are made to the system over the calendar week, from Sunday to Sunday.

Data is presented in the tab from the first Sunday after you enabled the feature.

The What's New tab presents:

- The number of new Users, Roles, Objects, and the number of databases associated with these additions
- The number of new Grantees and Grantors and the number of grants

### What to look for

Look for current trends, for example, by drilling-down to find:

- Unusual type or quantity of changes in the entitlements
- Most active grantors / grantees

Click Details in any topic to open a detailed table of the additions. For example, the details on new users are the server and service name.

## Entitlement Optimization Users and Roles

The Users and Roles tab lists all users and their roles for all data sources that are enabled for Entitlement Optimization on this collector.

Data is presented in the tab from the first Sunday after you enabled the feature.

This tab is based on the standard Guardium user and roles report that presents data on only one database type. It presents:

- Host
- Service Name
- DB type
- Grantee
- Grantee type
- Role

You can use the standard Query-Report Builder functions, which are accessed by the icons above the table.

## Entitlement Optimization Recommendations

Recommendations pinpoint specific actions that aim to minimize user access to only that which is required.

Data is presented in the tab from the first Sunday after you enabled the feature.

The system is continuously evaluating users and privileges. The weekly Entitlement recommendations report is based on the last 3 weeks of data (by default), such that each new report overlaps with data of the previous report. The Recommendations tab is equivalent to the Recommendations report in "Reports", which can be enabled as a distributed report.

If you customized the userScope parameter, the recommendations only include users from the specified user groups. The userScope and objectScope parameters are used in order to explicitly define the scope of recommendations. In order to maximize the accuracy of recommendations regarding users and objects, the users and objects in the specified groups should have Full Audit.

All recommendations must be thoroughly investigated by the admin, by drilling-down for specific server, database, object, and recommendation type, before implementation.

The top of the tab contains a pie graph that shows the recommendations by type. The table at the bottom of the window lists the recommendations. You can modify the recommendations report using the standard reports icons, export the report by clicking Export, and map to API by clicking Actions.

The recommendations types are:

Table 1. Recommendation Types

| Type                         | String                                                                        | Details                                                                                                                                                                                                                                                                                                                                |
|------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANOMAL USER                  | User {object} has anomalous activity within role {source}                     | User activity count within a specific role is anomalous. This means the user is either much more active or much less active than other users.                                                                                                                                                                                          |
| ALERT ACTIVITY (Ad-hoc user) | User {source} used the privilege {verb}-{object} but no entitlement was found | A typical ad hoc user gives itself permission, performs an action, and then removes the permission. Users can be erroneously identified as ad hoc due to the time differences between the entitlement changes and their activities. Use the Guardium Activity Monitoring Tools to determine whether or not the privilege is justified. |
| DORMANT_USE_R                | Remove inactive or empty user{object}                                         | User has no assigned privilege or had no activity within the given interval.                                                                                                                                                                                                                                                           |
| DORMANT_ROLE                 | Remove inactive or empty role{role}                                           | No users, no activity by any users, or empty privileges                                                                                                                                                                                                                                                                                |
| REVOKE_FROM_USER             | Revoke{verb}-{object} from user {source}                                      | User did not perform any activity on the relevant object, verb.                                                                                                                                                                                                                                                                        |
| REVOKE_FROM_ROLE             | Revoke{verb}-{object} from role {source}                                      | ALL the users within the specific role didn't perform any activity on object, verb.                                                                                                                                                                                                                                                    |
| REMOVE_FROM_ROLE             | Remove user{object} from role{source}                                         | User didn't use any of the privileges granted to him by the role.                                                                                                                                                                                                                                                                      |
| INACTIVE DATABASE            | Database has no activity                                                      | If the unused database cannot be justified, remove it.                                                                                                                                                                                                                                                                                 |

## Entitlement Optimization Browse entitlements

Use the views and filters in this window to see the activity level of entitlements, and the lineage of the entitlements.

Data is presented in the tab from the first Sunday after you enabled the feature. After the first Sunday, the activities are updated daily.

This information is useful for general entitlement investigation, and to further evaluate recommendations in the Recommendations report. The default view in this window is a bar chart of the datasources with the highest rates of unused privileges.

Entitlement browse shows all the entitlements of the data sources defined in the grdAPI that have extractEntitlement available. This is true if the activity collection is off, and if the user scope and object scopes are defined. You can always search and see the permissions of all the users.

The activity count field results are affected by the userScope parameter, as follows:

- Users that are included in the userScope:
  - Active users appear green and have numerical results in the activity count column
  - Non-active users appear red and the activity count is "Not active"
- Users that are not included in the userScope:
  - Active users appear green and have numerical results in the activity count
  - Non-active users appear gray and the activity count is "unknown"

Typical investigations are:

- Determine which objects a user has permissions for and whether he uses them
- Determine whether a user utilized his permission on an object at the specific time it was permitted
- Are there permissions that are used more than expected?
- Are there permissions that are used only once?
- What is the lineage of the permissions that have been unusually utilized: explicit, or implicit, inherited from a parent role, or role hierarchy?

To get more details on how a specific privilege is used, with full SQL, you can search for Data Activity (Investigate > Search for Data Activity), right-click the DB User or Source program in the Results Table, and select Full SQL by DB User.

Unused entitlements are typically one of:

- Action rarely performed, but a valid entitlement, for example generating a quarterly report
- Unused and therefore not justified (point of vulnerability)

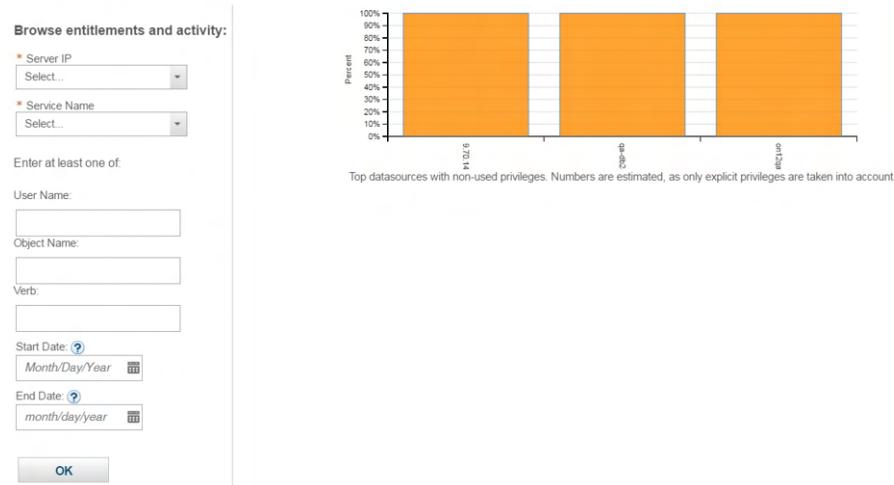

To view entitlement usage on a specific service on a specific server:

1. On the left side, select a server IP and service.
2. Filter by one or more of: Name, Object Name.
3. Optionally enter a Verb or date range.

Figure 1. Selecting entitlement criteria

To explore entitlement breakdown in a datasource instance, specify either user, object, or verb. The default bar chart shows Top datasources with non-used privileges.

Data shown may be incomplete due to data collection policy.

The table presents the Grantee type, Grantee, Verb, Name, Activity count, and Lineage. A user can have multiple privilege lineages: explicit, or implicit, inherited from a parent role, or role hierarchy.

## Entitlement Optimization What If

What If shows the probable justification for entitlement of a specific user with one or more specific verbs on a specific object (regardless of whether or not the entitlement exists).

Data is available in this tab from the first Sunday after you enabled the feature.

Guardium analyzes the behavior of similar users to produce the probable justification, which is some cases provides highly relevant information. The analysis can be useful when you examine unused entitlements, and the REVOKE\_FROM\_USER recommendation. It is a general indication, and should be used together with other entitlement optimization functions.

Enter these details and click OK to generate the probability:

- User name
- Object name
- Verb (one or more)
- Server IP

- Service name

Possible responses are:

- The probability that this DB user will use this privilege is **n%**. Probability of 100% indicates that the user used the activity at least once.
- Failed to find data source on server.
- Object and DB user are not in scope.
- No sufficient evidence found for DB user and privilege: either the User / Object / Verb does not exist in the selected database, or no activity is found for the user, or no activity has been found for the object, verb tuple. Possible fixes: wait for activity collection to run; make sure the input is entered correctly.

## Protect

After you identify databases and file systems that contain sensitive data, you can take several steps to protect that data. Protection options include masking data, alerting personnel based on data access, and establishing policies that enforce access restrictions.

- **[Active Threat Analytics](#)**  
The Active Threat Analytics dashboard shows potential security breach cases, based on the outlier mining process and on identified attack symptoms. In this dashboard, you can view and investigate cases, and take actions on individual cases.
- **[Risk Spotter](#)**  
Risk Spotter is a First of its Kind technology, changing the security paradigm to an Artificial Intelligence Data Protection Policy. It uses a holistic algorithm to dynamically assess risk factors, and it uses a smart algorithm to identify potential risks across your entire system.
- **[Outliers detection](#)**  
Enable and start auditing outlier detection in two easy steps, letting Guardium do the work of identifying abnormal server and user behavior, and providing early detection of possible attacks.
- **[Real-time trust evaluator](#)**  
The Real-time Trust Evaluator (RTTE) evaluates the application connections that are monitored by Guardium®. Connections are classified as "untrusted", "evaluated" or "trusted". Trust scores (value from 0 - 100) are assigned to each classified connection. Connections that are not classified as trusted or untrusted are classified as evaluated.
- **[Policies](#)**  
Policies are sets of rules and actions applied in real time to the database traffic observed by a Guardium system. Policies define which traffic is ignored or logged, which activities require more granular logging, and which activities should trigger an alert or block access to the database.
- **[Managing correlation alerts](#)**  
An alert is a message that indicates that an exception or policy rule violation was detected. Create and manage correlation alerts from the Add Alert page.
- **[Incident Management](#)**  
The Integrated Incident Management (IIM) application provides a business-user interface with workflow automation for tracking and resolving database security incidents.
- **[How to manage the review of multiple database security incidents](#)**  
Incident management - track and resolve database security incidents.
- **[Query rewrite](#)**  
Query rewrite functionality provides fine-grained access control for databases by intercepting database queries and rewriting them based on criteria defined in security policies.
- **[File Activity policies for UNIX and Windows file servers](#)**  
File activity policies are used to protect sensitive data on UNIX file servers, Windows file servers,
- **[File activity policies for network-attached storage \(NAS\) and SharePoint](#)**  
Set up file activity monitoring for NAS devices and SharePoint by defining policies and rules in the Policy Builder for Files.
- **[Configuring consolidation of FAM MS Office events](#)**  
Use the FAM monitor Office event consolidation feature to filter out the extraneous, irrelevant MS Word, Excel, and PowerPoint file activities.

## Active Threat Analytics

The Active Threat Analytics dashboard shows potential security breach cases, based on the outlier mining process and on identified attack symptoms. In this dashboard, you can view and investigate cases, and take actions on individual cases.

Active Threat Analytics runs on central managers and stand-alone units.

Prerequisite: Threat finder and DAM Outlier mining are enabled. Click the Active Threat Analytics Setup link to enable Threat finder and DAM Outlier mining. Active Threat Analytics shows results for all collectors on which DAM Outlier mining is enabled.

Access Active Threat Analytics from the Welcome page or from Protect > Uncover threat vectors > Active Threat Analytics.

The first row of results tabulates all cases and all open cases per: databases, DB users or OS users, file systems and file user. The cases in each category are identified by their risk level: high, medium, and low. If a database, database user, file system, or OS user is associated with multiple cases, that database or user is only counted one time.

For example, assume there are 40 cases. 10 of which are associated with database NN, 10 of which are associated with user XX, and the remaining 20 associated with various databases or users. In this case, the total of database and file server cases and database and file user cases would be 22, and not 40.

By default, data is presented for the last day. You can change the time period from the drop-down list.

The table shows violations, outliers, errors, and activities over the same period of time.

The table lists all cases (in descending order of severity), including the type of threat, the observed activity on which the case is based, and the source details. Active Threat Analytics identifies potential security breaches by case type, listed in [Threat descriptions](#).

Click Databases, DB users, File Systems, and OS users to open a summary of the entities with open cases. From there, you can click View Profile to open the Behavioral Analytics for the specific database or user, and view all cases that are associated with this entity, the distribution of working hours, and the distribution of verbs. For database users, you can also click User Risk Indicators to open the Risk Details window, showing the Risk Spotter risk indicator scores.

Attention: Each high severity case is a suspected threat that should be investigated immediately. High severity cases can also be caused by a patch installation. In this case, you would close the case. Low severity cases can be anomalies. If so, consider closing the case.

When you are investigating cases:

- Get a clear picture of whether this is an isolated incident, or one of many on the source.
- Change the time frame or filters for a narrower or broader cross section, and look for patterns or other unusual behavior.
- Look at the distribution of activity per verb, distribution over time, average activities, errors, and so on.
- For database users, look at the risk score and analysis.

In the Cases table, you can:

- Click the  next to the case number to open the Case Analysis page, giving a detailed analysis of the case from a few perspectives. This is the starting point of your investigation:
    - Case details: time, type, observations, details specific to the case type, and a link to the following reports.
      - SQL Report  
SQL statements with limited information.
      - Full SQL Report - Full SQL statements  
Available only if the Log full details rule action applies according to the installed policy. The default time period for the Full SQL report is one hour.  
When you are investigating cases, also look at shorter time periods, and earlier time periods.
      - SQL Exceptions Report  
SQL exceptions, including the SQL statement that caused the exception.
    - Source details: statistics and activities on the source, distribution of activities by time period, history of cases, and types that were opened (and closed) on this source.
    - Exploration: Five sets of tables that give context to this case, and provide a deep-dive into your investigation.
- Where  
More details on the server and database, for example, number of databases (and their types) on the server, number of cases of the same type seen on the database.
- When  
Time period details: work hours, off-work hours, weekends, what else happened during this time.
- What  
Details of similar cases: Case statistics, sensitive objects accessed (and by which commands), other occurrences of this case (and where).
- Who  
Statistics on the users that accessed the database, users that normally access this database (OS users, DB users), and from which client hosts. For OS users: the client hosts this user accesses from, and when it was first used (as recorded in Guardium).
- How  
Statistics on the applications used to access the database. Applications that were used during the case time window, applications that are normally used, First record of use of application (as recorded in Guardium).

You can also take actions on individual cases:

- Assign case: Assign the case to a role, an email, a user group, or a user. Roles and groups are preferable, since individual users and emails can change.
  - Add to group: Select either Server IP, database, DB user, file system, or file user and add it to either an existing group or a new group. This is useful for tracking users and activity. You can use these groups in policies, reports, and alerts for enhanced monitoring over your system.
  - Close case: If the observed behavior is acceptable, consider closing the case. Before you close the case, you can also assign the case a threat category and severity level based on your own input by completing the Actual threat category and Actual severity fields.
  - Add a comment.
  - Open case dashboard: Opens the Investigation Dashboard, filtered for the selected case. Drill down for details of symptoms, compare to other databases and users, and view activity over time. See [Investigation Dashboard](#).
  - Add items to an exclusion list. For more details, see [Excluding items from Active Threat Analytics](#).
- Filter the entire table by threat category by using the drop-down menu or the free text field.
  - Filter the entire table by severity level (high, medium, or low).
  - Filter the table to show either only unassigned cases only or only cases assigned to an audit process or an external ticketing system, such as ServiceNow.

The threat cases are not copied to the secondary central manager. In the case of a failover, there are no known threat cases in the new primary central manager.

- [Threat descriptions](#)  
Understand the different types of threats identified by Active threat analytics.
- [Creating threat categories from policy rules](#)  
You can use your policies' rules to create active threat analytics case types, by setting a threshold on specific violation policy rules.
- [Excluding items from Active Threat Analytics](#)  
Exclude items from the Active Threat Analytics process.
- [Active Threat Analytics setup](#)  
Enable and disable, and monitor, the active threat analytics processes, both across your entire system (recommended), or on individual managed units.

## Threat descriptions

Understand the different types of threats identified by Active threat analytics.

#### Account takeover

A nonauthorized user accesses an account.

A case is opened when an account is accessed by a new connection profile. For example, a known user is connecting from a different source IP or is using a different source program. Errors or exceptions that are associated with the source are also reported.

#### Anomaly

Anomalies are behaviors that are contrary to "normal" behavior in any aspect of tracked activity.

Guardium® identifies anomalies by using outlier mining (including the volume of outliers, severity of individual events, and predicted volume of outliers at specific times of day), and an anomaly detection algorithm.

#### Brute force attack

Suspected failed login attacks cover many scenarios. The failed logins are usually by one database user or by multiple database users on one database. The factors that are considered include the user, the timing, the frequency, and other actions taken by the suspicious user.

#### Cross-site scripting

Cross-site scripting (XSS) attacks attempt to insert malicious JavaScript code into the server through client input fields and APIs. When such a script is in place, it is persistent and activated every time that a user accesses the affected page. A typical scenario inserts JavaScript through a web page and then runs every time that page is accessed.

Guardium constantly monitors for XSS patterns in database requests.

#### Data tampering

A data tampering attack attempts to change or delete information. This type of attack typically exhibits a high volume of data deletion or removal.

Guardium observes whether errors are generated by the data deletion and whether the removal or deletion actions affected sensitive data.

#### Denial of Service

A denial of service attack attempts to impact service availability by creating excessively high demands on memory or resources or by causing server unavailability.

One means of identifying these attacks is by a high volume of outliers and weighted anomalies. The volume of outliers in this case is high enough to impact availability: for example, a thousand times the average activity.

#### Insider threat: possible data leak

This attack is an attempt to retrieve data for unauthorized use.

Data leaks are identified by abnormally high data retrieval activity. The activity can be either the number of activities or the number of records that are affected, depending on whether records affected tracking is enabled in the Guardium environment.

#### Malicious stored procedure

A malicious stored procedure is a block of SQL code that is designed to evade detection and to run complex attacks over an extended time period. The stored procedure can be run repeatedly, change its behaviors over time, or remain dormant for long periods of time, all of which makes it harder to identify its activities as suspicious. For example, a stored procedure that caused unusual activity to be identified in an audit can go dormant and be forgotten by the time of the next audit. A malicious stored procedure can be used to disguise the drop of an important table or to extract the contents of a table. Examples of suspicious activity include:

- The creation of a stored procedure with a DROP statement that affects sensitive objects.
- SQL exceptions that are caused by missing objects.
- A procedure that is dormant for an extended time period but is then modified.

Guardium finds malicious stored procedures by tracking the activity around individual stored procedures and, together with outlier mining data, correlating the symptoms and users.

#### Massive grants

Symptoms of massive grant attacks include granting many new privileges to various users and permissions that are being granted by users that don't usually grant permissions.

Guardium identifies and flags such behaviors.

#### New grants

Granting privileges to users is a normal procedure. However, grants can also transfer privileges to users to stage attacks under a different username. Guardium opens a case if it identifies suspicious behavior of a user with recently granted privileges.

#### OS command injection

These attacks are attempts to run commands on the operating system, from a client to a process. For example, inserting operating system commands to erase files or, in Guardium, to set outlier mining parameters with the goal of preempting the identification of attack symptoms. The attacker usually does not know whether the attack succeeded and uses tools like ping to check communication between its client and the server.

Guardium observes patterns of operating system commands that an attacker might attempt to run on the target server.

#### Schema tampering

Schema tampering is characterized by changes to database elements such as tables, views, or stored procedures.

Guardium identifies these changes and correlates them with other factors such as whether the changes generated errors or were performed by a privileged user.

#### SQL injection (general)

SQL injection attacks attempt to exploit application vulnerabilities by concatenating user input with SQL queries. If successful, these attacks can run malicious SQL commands that use the legitimate application connection. SQL injection attacks can be difficult to identify because the individual steps of an attack, analyzed independently of the other steps, might be considered legitimate. Using threat detection analytics, Guardium identifies potential SQL injection attacks by capturing the individual steps and analyzing them as part of a single complex attack.

Typical symptoms of SQL injection attacks that Guardium identifies include:

- An attacker tries to identify the structure of a dynamic SQL query: for example, the number of columns queried.
- An unusually large quantity of new queries, specifically queries that are uniquely or unusually structured.
- Access to tables that contain information about the database structure.

#### SQL Injection: Tautology

In a tautology type attack, code is injected that uses the conditional operator OR and a query that evaluates to TRUE. Tautology-based SQL injection attacks usually bypass user authentication and extract data by inserting a tautology in the "WHERE" clause of an SQL query. The SQL query results transform the original condition into a tautology that causes, for example, all the rows in a database table to be open to an unauthorized user.

Guardium prevents this type of attack by identifying multiple variations on tautological expressions in the database requests.

#### SQL Injection: Side channel

SQL injection attacks often result in a general error with no indication of the reason for failure. In side channel attacks, the attacker typically inserts code that has a "side effect" like sleeping for 2 seconds if an attack is successful. This technique allows the attacker to measure the side effect and determine whether the attack was successful. For example, the injected code might sleep for 2 seconds if the MySQL version is 5.6: if the request takes more than 2 seconds to return, the attacker confirms that the server is running MySQL 5.6.

Guardium finds side channel attacks by identifying the use of commands such as sleep and comments in the database requests.

#### SQL Injection: Denial of Service

A denial of service attack attempts to impact service availability by creating excessively high demands on memory or resources or by causing server unavailability. Guardium identifies these attacks, for example, by analyzing the syntax used in the database requests.

# Creating threat categories from policy rules

You can use your policies' rules to create active threat analytics case types, by setting a threshold on specific violation policy rules.

## About this task

You can set thresholds on violation rules that have a severity of high in the rule definition, and the rule action is alert per match.

When the rule threshold is exceeded in any 1 hour, a case is created. The case type is the name of the rule. Cases that are created from a policy rule threshold appear in the active threat analytics cases table, and are treated like any other case.

Changes to installed policies are applied according to the policy schedule. When adding a threshold to a rule in an installed policy, cases are created for violations (according to the threshold) only after the policy is reinstalled.

Use the API to define thresholds on rules. You cannot define thresholds in the GUI.

## Procedure

1. Identify which policy and which rule you want to use. Use the API commands `list_policy` and `list_policy_rules`.
2. Add or modify the threshold by using the API command `add_threshold_to_rule` or `update_threshold_in_rule`. For example, to add the threshold 25 to ruleNNN in policyAAA:

```
grdapi add_threshold_to_rule policy_name=policyAAA rule_name=ruleNNN threshold=25
```

## Results

From the next day (after the policy has been updated), when the rule threshold is exceeded in a timeframe of one hour, a case is created.

# Excluding items from Active Threat Analytics

Exclude items from the Active Threat Analytics process.

## About this task

You might want to exclude certain sources and activities from the Active Threat Analytic processes altogether to optimize resources and reduce false positives. For example, test data or activities run by automated processes.

Excluding sources from Active Threat Analytics:

A source is a database, a database user (DB user), or an operation system user (OS user).

You can exclude sources from the analytics process based on the following attributes:

- Server IP
- Database
- Database user
- Operation system user

Each such row is called an exclude item, though it might match several sources. You can use the asterisk character as a wildcard that replaces any string. The sources are excluded from all Active Threat Analytic processes – Outlier mining, Threat finder, and Threat diagnostics.

Examples of exclude items:

Example 1  
Server IP=130.23.45.55

Result: all the databases on this server and all the DB users of these databases are excluded from analytics.

Example 2  
Server IP=130.23.\*

Database=QA\_\*

Result: all the databases that start with “QA\_” on all the servers in subnet 130.23 are excluded from analytics and all DB users of these databases are excluded as well.

Example 3

Database user=QATEST

Result: database user "QATEST" is excluded from analytics in all the databases

You can also choose to exclude sources only from a specific category. For example, to exclude a database only from the "New grants" category. The database is analyzed for all other categories.

Excluding activities from Outlier mining:

You can exclude activities and exceptions from the Outlier mining process only, based on the source program (application) or object. This capability can be used, for example, to exclude temporary tables or activities that are run by trustworthy applications to reduce false positives.

Excluding sources and activities from Active Threat Analytics on a temporary basis:

Specify start and end dates on the exclude item to exclude sources and activities temporarily.

Note: You can set dates in the future only and cannot use the exclude list to remove cases already created.

Restriction:

The following limitations affect only managed units that are working with Guardium versions that are earlier than 12.0, while their central manager is upgraded to version 12.0 or later:

- The managed unit is not updated when you update or delete an exclusion item.
- Items excluded temporarily, that is, items with an end date selected, do not take effect on the managed units.
- When you enter a future start date on an exclude item, the exclusion starts immediately on the managed units.
- Cases cannot be excluded based on their category when the cases are created from the managed unit.
- Cases that are created from the managed unit are not excluded based on their category.

## Procedure

1. You can view the exclude list as a whole from Active Threat Analytics setup. Go to **Manage > Maintenance > Active Threat Analytics Setup > Analytics exclusion section**, or click Active Threat Analytics setup from the main Active Threat Analytics page.
2. After you access the exclude list from either of these paths, you can edit the list by adding new items or removing existing items. To add an item, click the  icon and select a period start in the window that appears. You can then also select a period end, but it is not required. These 2 fields define the window of time that the case is excluded. (Step 3 addresses the other fields in this window). Remove an item by selecting it and clicking the  icon.  
You can also add new items to the exclude list (but not remove items or view or edit the exclude list as a whole) from some other places in the UI.
  - To add items to the exclude list from Active Threat Analytics, click Active Threat Analytics from the Welcome page or from **Protect > Uncover threat vectors > Active Threat Analytics**. Select a case whose source you want to exclude and click **Actions > Add to exclude list**. Or click  to view a case's details and then click **Actions > Add to exclude list**. Define the period start as usual.
  - To add items to the exclude list from the Investigation Dashboard, go to **Welcome > Investigation dashboard > Outliers tab**. In the Outliers table, right-click the wanted outlier and select **Add to analytic exclude list**. Define the period start as usual.
3. From all paths described thus far, you can view and adjust the exclusion parameters for an existing item. Select the case that you want to make edits for and click 
  - Add, remove, or edit the values for the fields in the window that appears. Define a Server IP, Database, Database user, and Operating system user to exclude in the respective fields (if relevant). Use an asterisk in these fields to mark things you want to ignore as a wildcard.
  - The Category field defines specific threat categories to exclude, and you can use it in tandem with the Server IP, Database, Database user, and Operating system user fields. You can read more about each threat category in [Threat descriptions](#).
  - If you do not want to see any cases from a specific category, you can deactivate the entire category. In the Categories section of Active threat Analytics setup, choose the categories that you want to deactivate and click **Actions > Inactivate**
  - The Source program and Object fields define specific activities and exceptions to exclude. These fields are only intended for cases that stem from the Outlier mining process only and they cannot be selected in tandem with the Category field.
  - Add a comment in the Comment field to remind yourself or other users why you are making the current exclusion selections.

## Active Threat Analytics setup

Enable and disable, and monitor, the active threat analytics processes, both across your entire system (recommended), or on individual managed units.

The Active threat analytics processes are the Threat finder and DAM outlier mining. Best practice is to enable all processes across all Guardium® systems. If required, you can enable processes selectively.

To open the Active Threat Analytics Setup, go to **Maintenance > Active Threat Analytics Setup**. There are three sections, each with a modules status.

### Enable all processes

Prerequisite for Threat finder: Quick search is enabled.

Click **Enable all processes** to enable Threat finder and DAM outlier mining on all managed units in your environment. The system responds with one message on the Threat finder status, and one message on the DAM outlier mining status.

### Enable threat finder

Prerequisite for Threat finder: Quick search is enabled.

Click **Enable** to enable Threat finder either on a central manager or stand-alone system. The system responds with a status message.

## Enable DAM outlier mining

---

When viewed on an aggregator this window presents details of the specific aggregator's collectors.

When viewed on a collector, only that collector is detailed.

To enable or disable outlier mining on all managed units in your environment: click **Enable All / Disable All**. To enable outlier on individual units: select them and click **Enable / Disable** from the Actions drop-down list. Best practice: Enable outlier mining for your entire environment. If you need to enable selectively, enable on aggregators in preference to collectors.

View the enable and disable history by clicking Outlier mining enable/disable history. Details include the collectors that send data to the aggregator, or if the collectors do not send data to the aggregator, and why not.

This table describes the DAM outlier mining section, and the recommended user actions.

| Column                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                   | Actions                                                                                                                                                                                                                                          |

If an error repeats, contact technical support. For processes that did not end successfully, click Details to view more information. |
| Learning Since                                                                         | Date and time at which the outlier mining process was enabled. The process learns the resource's behavior since this time.                                                                                                                                                                                                                                                                                    | NA                                                                                                                                                                                                                                               |
| Quick Search on/off                                                                    | Indicates whether Quick Search and Solr are enabled on the managed unit. When Quick Search is disabled, this machine's data is not included in the Investigation Dashboard.                                                                                                                                                                                                                                   | See <a href="#">Enabling and disabling the Investigation Dashboard</a>                                                                                                                                                                           |
| Last Info. Update                                                                      | Last date and time the information in this row was updated. Data is usually updated in intervals of about 5 minutes.                                                                                                                                                                                                                                                                                          | NA                                                                                                                                                                                                                                               |
| Configured to Send Outlier Mining Data                                                 | Collectors only in multi-CM environment. Indicates whether a collector is configured to send data to an aggregator. (If not, either it is running outliers detection locally, or it's not configured to send data.)                                                                                                                                                                                           | NA                                                                                                                                                                                                                                               |
| Outliers data last received                                                            | Collectors only in multi-CM environment. Indicates when an aggregator last received data from collectors.                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                  |

## Predefined alert

---

There is a predefined alert Outlier Analysis Failure, that is triggered by failure of the outlier mining process. You need to configure it in the Alert Builder.

## Risk Spotter

---

Risk Spotter is a First of its Kind technology, changing the security paradigm to an Artificial Intelligence Data Protection Policy. It uses a holistic algorithm to dynamically assess risk factors, and it uses a smart algorithm to identify potential risks across your entire system.

Configure and enable the required and optional Guardium and Risk Spotter modules, then enable Risk Spotter itself.

## Risk Spotter functions

Learn how Risk Spotter identifies risky users across your entire system.

Risk Spotter runs on central managers and on stand-alone systems. All collectors must be running V11.0 or later.

The Risk Spotter implements a dynamic risk assessment, considering multiple risk factors, including:

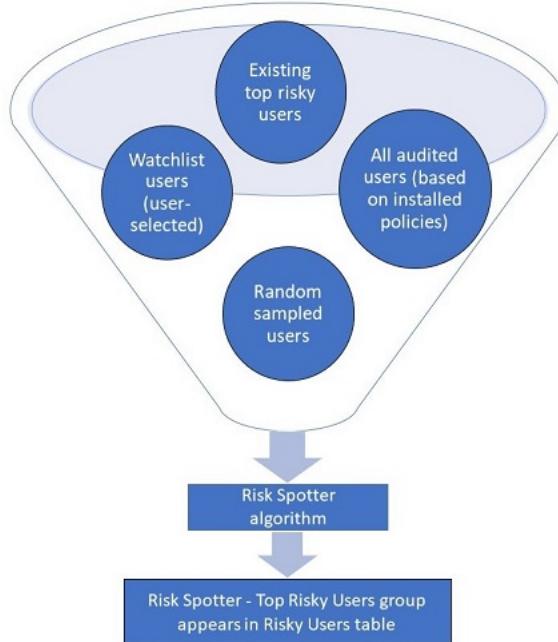

- Vulnerabilities and violations that are associated with the user
- Errors
- Threat Analytics findings
- Activity during off-work hours (defined by AFTER HOURS WORK and BEFORE HOURS WORK in the Time Period Builder page, and distributed from the central manager to its managed units.)
- Data access volume
- Volume of activities
- Access to sensitive data
- Type of commands the user ran (DML, DDL, SYSTEM, and so on)

The Risk Spotter algorithm uses Guardium modules to analyze the risk indicators and to identify risky users. Each user's risk overall risk score is calculated daily, based on the audited data. Risk Spotter assigns each user a score in the range 0 - 10. The detailed risk data is presented in the Risky Users table in the Risk Spotter page.

To maximize the Risk Spotter benefits, implement your own Risk Spotter Dynamic Auditing policy that uses the Risk Spotter - Audited Risky Users group. When you implement a Dynamic Auditing policy:

- Guardium® adds three types of users to the Risk Spotter - Audited Risky Users group, and audits the group continuously. The three types of users are:
  - Top risky users: Users identified by the Risk Spotter algorithm, together with your installed policies. Users in this group are carried over from day to day if their risk score warrants it. (The top risky users list is not copied to the secondary central manager. In the case of a failover, the Top risky users list is empty in the new primary central manager.)
  - Watchlist users: The Watchlist is a group of users that you populate, for further observation or investigation. You can add any user to the watchlist. These users remain in the Watchlist group in subsequent Risk Spotter daily iterations, regardless of their risk score.
  - Random sampled users: Risk Spotter continuously scans across your system, beyond your policy radar, evaluating non-audited users and identifying potential risky users.
- Risk Spotter updates the Risk Spotter - Audited Risky Users group members and reinstalls the policy during its daily process (1:00-2:00), effectively updating any policy that uses it.
- Guardium constantly monitors resources. If a managed unit's resources are overloaded for any reason, Guardium automatically uninstalls the Dynamic Auditing policy on the overloaded managed units. Uninstalling the policy does not impact the members of the Risk Spotter - Audited Risky Users group or Risk Spotter - Watchlist group. A user that is only audited by the Dynamic Auditing policy is not audited on the day the policy is uninstalled. New risky users on a collector that does not have the policy installed are not added to the Risk Spotter – Audited Risky Users group, and the risk score of existing users is not updated. Click Logs and Status to open the Risk Spotter events log to see which managed units do not have the policy installed.

## Risk Spotter risk indicators

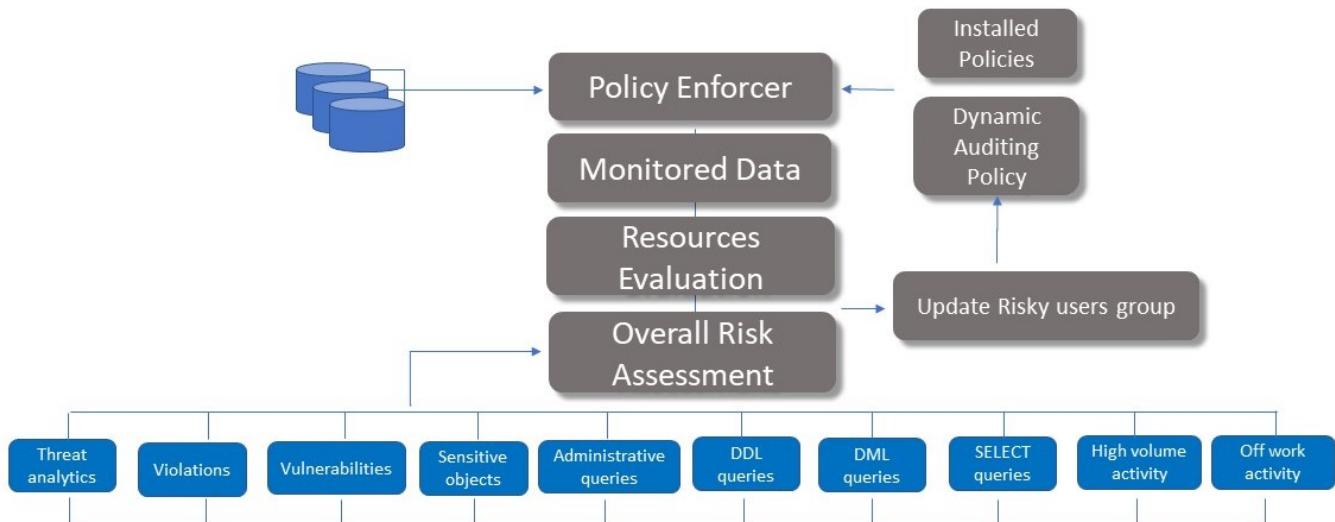

Guardium® applies the Risk Spotter algorithm to the audited data modules, to analyze multiple risk indicators and to calculate the overall risk scores of risky users.

The Risk spotter algorithm includes relevant weights of each risk indicator.

Table 1. Risk indicators used to derive total risk score per user

| Risk indicator         | Description                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------|
| Threat Analytics       | Identified high and medium potential risks from Guardium Advanced Threat Analytics.                 |
| Violations             | The number of high and medium severity violations related to the DB user.                           |
| Vulnerability          | The number of failed vulnerability assessments for a user.                                          |
| Sensitive objects      | The number of queries on sensitive data related to the DB user.                                     |
| Administrative queries | The relative number of administrative queries related to the DB user, out of the total activity.    |
| DDL queries            | The relative amount of DDL queries related to the DB user, out of the total activity.               |
| DML queries            | The relative amount of DML queries related to the DB user, out of the total activity.               |
| Select queries         | The relative number of select queries related to the DB user, out of the total activity.            |
| High volume activity   | DB Users that have high volume activity as compared to the average of all entities of similar type. |
| Off-work activity      | Activity related to the DB user that occurred in non-work hours.                                    |

[Figure 1](#) shows how the various modules and Guardium data interact in the Risk Spotter process.

## Use the Risk Spotter results

The Risk Spotter page presents risk data over your entire system, with a few graphs and tables. Learn how to use the Risk Spotter data in your daily Guardium activities.

A typical flow includes:

- View the top potential risky users.  
The Risky Users table lists the top potential riskiest users, as identified by the Risk Spotter algorithm and the Watchlist. Users from the watchlist are indicated by the eye symbol (👁) in the From Watchlist column.

With the default Latest period of time (the previous calendar day) Risk spotter shows the risk details of 50-100 users based on their activity during the previous calendar day: 50 from the Top Risky Users (highest risk score or highest potential for causing damage) and up to 50 from the Watchlist. In this scenario, the Max Risk is the same as Current Risk.

If you select Last 3 days, there are up to 150 users from the Top Risky Users group since they are aggregated over the selected time period; and up to 150 Watchlist users. In this scenario, the Max Risk column shows the highest risk for the DB user over the time period. There is one row per user. Multiple instances of both Risky User and Watchlist are aggregated into one row.

Hover over the colored risk level to see the individual risk indicators. Sort the columns to view and compare multiple occurrences of database users or databases.

- Investigate risky users in the investigation dashboard.
- If a user was added to the risky users but it seems unwarranted, add it to the Trusted users group. Henceforth, Risk Spotter only audits the user with your installed policies.
- Do you suspect other users in your system but they are not in the Risky users list? Add them to the Watchlist. Continue adding and removing users to and from the Watchlist, as relevant. View the Watchlist report, looking at maximum scores per day. Consider creating new groups and new reports for continued observation.
- Watch the Risk Spotter page, looking for trends, and unusual changes.

Auditing can be temporarily stopped for one day if system resources are low on an individual managed unit. Check the Risk Spotter log to see whether auditing was suspended.

Select one or more users from the table, and select from the Actions drop-down menu:

- View risk details: opens a window with the relative weights of the risk indicators that are currently associated with the user, for example, violations, outliers, vulnerability. The gray bars reflect the maximum score for each risk indicator based on its relative weight, and the yellow bars show the actual score. When a risk indicator reaches its maximum score, there is no gray visible. Click a risk indicator to open the [Investigation Dashboard](#), filtered for this user, database server, and verb group (if relevant), for the selected date. Click Threat Analytics in the Latest Risk or Max Risk window to open the associated Threat Analytics DB User Behavioral Analytics window.
- View max risk details: Opens a window with the relative weights of the risk indicators for the maximum identified risks that were posed by this user during the selected timeframe. Click a risk indicator to open the [Investigation Dashboard](#), filtered for this user, database server, and verb group (if relevant), for the selected date.
- Investigate: opens the [Investigation Dashboard](#), filtered for this DB user and server, for the selected date. You can investigate the specific activities that resulted in the high risk score. You can also view specific details, activities, and you can compare to other users, dates, databases. Consider adding a rule to your installed policies to quarantine the user by blocking its access on next entry.
- Assign risky user: Appears if there is no configured external ticketing system. Opens a ticket in Guardium to review specific users. (If you are logged in with the User role, add permission for the report Active Risk Spotter - Risky User before assigning a risky user.)
- Create ticket: Appears if an external ticketing system is configured. Opens a ticket in ServiceNow. See more details in [Configure an external ticketing system](#).
- Add user to Watchlist: Use the Watchlist to maintain a group of users that you want to monitor. If you try to add a user to the Watchlist, but it's currently in the Trusted Users group, the user remains in the Trusted Users group. Guardium responds with a message that at least one user was found in the Trusted Users group and was ignored. To add it to the Watchlist, you need to delete it from the trusted users group. Changes to this group are effective from the next run of the Risk Spotter.
- Add to "Risk Spotter - Trusted Users" group: Users in this group are not added to the Top Risky Users group and not monitored by the Risk Spotter policy, though they continue to be monitored by your installed policies. If you identify a false positive, consider adding the database user to the Trusted Users group. If you try to add a user to the Trusted Users group, and it's currently in the Watchlist, it's deleted from the watchlist, and added to the Trusted Users group. Changes to this group are effective from the next run of the Risk Spotter.
- Add DB users to group: Add the DB user to a group that is already defined, or create a new group. The Add DB User to Group window is prefiltered for the user. Consider adding a DB user group to a specific policy to audit these users at a higher resolution, by setting the Log Full Details option. Groups can also be used to keep watching these users with an automatic workflow process, or a specific alert. And you can use these groups in policies, and reports.
- Add server IPs to group: Add the server IP to a group that is already defined, or create a new group. The Add Server IP to Group window is prefiltered for the server IP. Consider adding a server IPs to a specific policy to audit these servers at a higher resolution, by setting the Log Full Details option. Groups can also be used to keep watching these servers with an automatic workflow process, or a specific alert. And you can use these groups in policies, and reports.

Use the Actions on risky users menu to perform:

- Audit process all risky users: This pre-defined audit process sends the Active Risk Spotter - Risky Users Scores report to the users you define. See [Building audit processes](#).
- Investigate risky users: Opens the investigation dashboard, which is filtered for the Risk Spotter - Risky Users Index group (similar to the Risk Spotter - Top Risky Users group), for the selected dates. In the Investigation Dashboard, you can look for trends over all the users. Change the time period or filters for a narrower or broader cross section, and look for patterns or other unusual behavior. Look at the distribution of activity per verb, activity over time, average activities, and errors. And drill down on specific users. See [Investigation Dashboard for data](#).
- Edit groups: where you can manage your watchlist and trusted users group – to add, remove and view members.
- View report: view one of the reports, showing data for the selected date:
  - Risky Users - Connection profiling list: the Connection profiling list report filtered for risky users
  - Risky Users - SQL Errors report: the SQL Errors report filtered for risky users
  - Risky Users - Policy Violation report: the Policy Violation report filtered for risky users
  - Active Risk Spotter - Risky Users Scores: This report lists users, DBs, total risk, and individual risk indicator scores.
  - Active Risk Spotter - Watchlist Snapshot: This report lists users, DBs, total risk, and individual risk indicator scores for the users in the Watchlist.
- Export risky users to PDF: A handy PDF, as a snapshot, or for distribution. It lists users, DBs, total risk, and individual risk indicator scores. It has the same details as the Risky Users table.
- Export risky users to CSV: A handy Excel, as a snapshot, or for distribution. It lists users, DBs, total risk, and individual risk indicator scores. It has the same details as the Risky Users table.

## Create a Dynamic Auditing policy

Learn how to create and install a policy for Dynamic Auditing, to maximize your Risk Spotter results.

### Procedure

1. Access the Policy Builder for Data.
2. Filter for Risk Assessment Dynamic Policy Selective [template], and click . The Create New Policy window opens.
3. Modify and save the policy as relevant:
  - There must be one rule with Session level criteria: Client IP/Source application/Database user/Server IP/Service name = Risk Spotter – Risky Audited Users group. This rule is included in the Risk Assessment Dynamic Policy Selective [template]. Recommended actions are Audit only or Log full details
  - Best practice: To make sure Risk spotter audits as many risky users as possible without overloading your system resources, include a rule to ignore users with high volume activity (like app users), by limiting the number of activities that are audited per user. See [limit count rule guideline](#). This rule is included in the Risk Assessment Dynamic Policy Selective [template].
  - Clear the Selective audit trail check box (in the Name and properties section) if your installed policies do not use Selective audit trail. See [Selective audit trail](#).
  - Make any other required changes.
4. Install the policy.
  - a. In the Policy Builder, select the policy and click **Install > Install**. The **Install policy** window opens.
  - b. Select an Installation action. By default the policy is installed as the last policy on the target collectors. The correct position of the risk spotter policy is based on the specific details of each installed policy. **Make sure you understand your policy details before installing the risk spotter policy.**
    - Installing the risk spotter dynamic policy first might overload system by overriding the basic session level criteria rule described in step 3.
    - Installing the risk spotter dynamic policy last might result in some risky users being ignored by prior ignore policies.

- c. Select the collectors on which to install the policy.
- d. Click OK. The system responds with a message indicating success, or not.

- [Policies](#)

## Configure and enable Risk Spotter

Configure and enable the required and optional Guardium® and Risk Spotter modules, then enable Risk Spotter itself.

### Before you begin

---

- All collectors must be running V11.0 or later.
- Ports 8983 and 9983, on both the collectors and the central manager, are opened when you enable enterprise search. Verify that these ports are not blocked by any firewall.
- On the central manager or standalone system: Enter the GuardAPI command: **grdapic restart\_solv**.
- On the central manager: Enterprise search should be enabled by default. To check the Enterprise search status enter the following GuardAPI command:

```
grdapic get_quick_search_info
```

If it isn't enabled, enter the following GuardAPI command:

```
grdapic enable_quick_search schedule_interval=2 schedule_units=MINUTE all=true includeViolations=true
```

- Some Guardium modules must be enabled or configured before you can enable Risk Spotter. They are included in this task. You can enable the Risk Spotter process without enabling the optional Guardium modules. You get the best protection by enabling both the required and optional modules.
- Enabling Risk Spotter only activates risk assessment for users audited by your installed policies. To dynamically audit risky users with Dynamic Auditing, create and install a Risk Spotter policy. See [Create a Dynamic Auditing policy](#) and [Using the Policy Installation tool](#).

### About this task

---

Configure Risk Spotter on the central manager or on a stand-alone Guardium system. In a central manager environment, enable all modules once on the central manager only. If you install a Risk Spotter policy, this is also managed from the central manager.

Important: To maximize your Risk Spotter results, enable the optional modules.

The required modules are:

- Enterprise search: Queries data across the entire Guardium environment. It is enabled by default.
- Unit utilization data processing: Assesses resource utilization of each Guardium system in your environment to maximize user auditing. See step [3](#)
- S-TAP and buffer usage monitoring: Enables the central manager to get updated information on unit utilization and on its managed units. (Not relevant for standalone Guardium systems.) See step [4](#)

The recommended modules are:

- Dynamic Auditing: To get the most comprehensive risk assessment, configure Dynamic Auditing; create, install, and select a policy that incorporates the Risk Spotter – Audited Risky users group. This policy audits identified risky users and users in the Risk Spotter watchlist, and it samples users beyond your policy radar to identify additional risks. For details on creating the policy, see [Create a Dynamic Auditing policy](#).
- The Database Protection Subscription service (DPS) publishes updates to known vulnerabilities (known risks). The DPS file is not mandatory but without it, the risk scores are less accurate. (Best practice is to subscribe to this service whether you use Risk Spotter or not.) See step [5](#)
- Active Threat Analytics identifies various types of suspected attacks. These findings are incorporated into the Risk Spotter analysis. See step [6](#)

Click Logs and Status to open the Risk Spotter events log. This log has details of, for example: start and end of the Risk Spotter processes, if/when the risk spotter policy was uninstalled.

Note: All steps are relevant for a central manager and standalone systems unless noted otherwise.

## Procedure

---

1. Open the Risk Spotter page: go to Protect > Uncover Threat Vectors > Active Risk Spotter, and click Policy and related modules.
2. Optional: **Recommended: Dynamic Auditing**
  - a. Click Dynamic Auditing. The Configure Dynamic Auditing window opens.
  - b. Select your Dynamic Auditing policy, then click Save. The system responds: Saved. Install the policy if it's not already installed. (Only policies that use the Risk Spotter - Audited Risky Users group can be saved in this window.)
  - c. Install the policy if it's not already installed.
3. To configure Unit utilization data processing from the Active Risk Spotter UI, follow the steps in this section. Enable unit utilization to assess resource utilization of each Guardium system in your environment, and enable central manager buffer usage monitoring to assess the available bandwidth over the entire system.
  - a. Go to Manage > Unit Utilization > Unit Utilization Levels.
    - i. Configure:
      - Schedule By = Day
      - Select Days = Every Day
      - Repeat every = 1 hour
      - Each day, begin repeating at = 12:00 AM (default)
      - Select Activate Schedule
    - ii. Click Save.
    - iii. Click Run Once Now.

- b. On the central manager only (not relevant for standalone systems): Go to Reports > Report Configuration Tools > Custom Table Builder. (You must have Custom Table Builder access rights to perform this step.)
- i. In the Custom Tables page, select CM Buffer Usage Monitor and click Upload Data.
  - ii. Under Scheduling, click Modify Schedule.
    1. Leave Start time at the default 12 a.m. (midnight) ..
    2. Set Restart to every hour.
    3. Leave Repeat at Do not repeat.
    4. Set Schedule by... to Day/Week and click Every Day.
    5. Click Save.
    6. Click Back.
    7. Click Run Once Now.
  - iii. Click Back to return to the Custom Tables page.
4. To configure S-TAP information from the Active Risk Spotter UI, follow the steps in this section. On the central manager only (not relevant for standalone systems): enable S-TAP information to assess the available bandwidth over the entire system. (You must have Custom Table Builder access rights to perform this step.)
- a. Go to Reports > Report Configuration Tools > Custom Table Builder
  - b. Select S-TAP info and click Upload Data.
  - c. Under Scheduling, click Modify Schedule.
    - i. Leave Start time at the default 12 a.m. (midnight) ..
    - ii. Set Restart to every hour
    - iii. Leave Repeat at Do not repeat.
    - iv. Set Schedule by... to Day/Week and click Every Day.
    - v. Click Save.
    - vi. Click Back.
    - vii. Click Run Once Now.
5. Optional: **Recommended:** If the Database Protection Subscription service (recommended) is gray, click Upload file to open the Customer Uploads page and import a DPS file: Guardium\_V11\_Quarterly\_2019\_Q1\_20190227.enc or higher. See [Customer Uploads](#) for details on uploading and importing DPS files. (The DPS file is not mandatory, but **risk scores are partial without it.**) The DPS file can take a long time to install. If you restart the browser, the install stops. Either keep the Customer Upload window open until you see a status message, or enter the CLI command `show dps` to check install status. (DPS files are downloaded from [Fix Central](#) and [Passport Advantage](#).)
6. Optional: **Recommended:** On the central manager, enable Active Threat Analytics:
  - In the Risk Spotter page, click Configure in Active Threat Analytics Setup, expand the Active Threat Analytics processes section, and click Enable all processes. For more information, see [Active Threat Analytics setup](#).
7. Enable Risk Spotter. In the Risk Spotter page, click Enable opposite Risk Spotter process. (This button is enabled only when all required modules are enabled.)

## Results

---

It can take up to 10 minutes for the Risk Spotter page to update the number of managed units running enterprise search; or whether Active threat analytics is enabled. Go to another page, then return to this page to refresh the display.  
After the first run of the risk score process (between 01:00-02:00 daily), the Risk Spotter page shows results. The risky users are added incrementally according to the available collector resources.

## Outliers detection

Enable and start auditing outlier detection in two easy steps, letting Guardium do the work of identifying abnormal server and user behavior, and providing early detection of possible attacks.

An outlier is behavior by a particular source (in DAM either a database or a particular user on a database, and in FAM either a server or an OS user), in a particular time period or scope that is outside of the “normal” time frame or scope of the particular database or user's activity. Outliers can indicate a security violation that is taking place, even if the activities themselves do not directly violate an existing security policy.

User activity that is identified as a suspected outlier includes:

- User accessing a table for the first time
- User selecting specific data in a table that he has never selected before
- Exceptional volume of errors. For example, an application generates more SQL errors than it has in the past. This could indicate that there is a SQL injection attack in progress.
- Activity that itself is not unusual, but its volume is unusual
- Activity that itself is not unusual, but the time of activity is unusual. For example, a DBA is accessing a particular table more frequently than in the past. This could indicate that the DBA is slowly downloading small amounts of data over time.

Database activity that is identified as a suspected outlier includes:

- Exceptional volume of errors
- Activity that itself is not unusual, but its volume is unusual
- Activity that itself is not unusual, but the time of activity is unusual

Outlier Mining findings are available from the Investigation Dashboard (Quick Search) and in Reports.

Outlier mining operates on data that is already audited by a security policy. Make sure that the data you want evaluated for outliers is already audited by a security Policy.

Outlier detection can run on:

- A central manager, with data from its aggregators' collectors (except a collector that is running outliers detection locally).
- A collector, using only its own data.
- A central manager that receives data from aggregators that are managed by another CM. This is the multi-CM environment.

12.1 and later A predefined alert 'Outlier with anomaly score 90 and above', if activated, then it alerts about the outliers with anomaly score greater than or equal to 90. For more information on predefined alerts, see [Predefined alerts](#).

- [Quick start for outlier detection](#)  
Learn how to enable outliers, and start receiving alerts in a few simple steps.
- [Enabling and disabling outliers detection](#)  
Enable/disable outliers detection from any unit in a centralized environment, a multi-CM environment, or on a stand-alone collector.
- [Interpreting data outliers in the investigation dashboard](#)  
Guardium provides a convenient graphical interface for identifying and responding to outliers detected by the algorithm.
- [Interpreting file activity outliers in the investigation dashboard](#)  
View file activity monitoring outliers in the Investigation Dashboard Activity Chart and Results Table (investigation dashboard must be enabled), or review the Analytic Outlier List report.
- [Switching DB and OS users](#)  
Outlier mining, by default, tracks two types of sources: databases and database users. The behavior baseline and hourly activities are compared for each source. If your system typically has a high number of users per application, then tracking activity by DB user might not be specific enough. In this case, you can switch outliers detection user mode to evaluate by OS user. In this scenario, sources are databases and OS users. User mode is configured on the central manager for the entire system.
- [Grouping users and objects for outliers detection](#)  
Find out how to add groups, for example user or object groups, to the default outlier detection algorithm.
- [Outliers detection clustering](#)  
User clustering divides the system's users into clusters based on their activity. During the outliers scoring process, outliers detection compares the activity of the users in a group. Analyzing groups of users increases the accuracy of the results, and decreases the number of false positives.

## Quick start for outlier detection

Learn how to enable outliers, and start receiving alerts in a few simple steps.

### About this task

Outliers detection can run on any number of aggregators. However, it's recommended to start with one aggregator, refine the configuration, and then expand to additional aggregators. Before you start, decide on the available resources to investigate outliers. Then limit the number of outliers reported daily to an amount you can investigate. The Guardium algorithm provides you with the most important events to investigate, not just the "top 10," for example.

Outlier detection is a separate process from security policy rules and enforcement, so you cannot set up real-time alerts on outliers. However, because outlier data is included in reports, you can create a correlation alert. A correlation alert is triggered by a query that looks back over a specified time period to determine whether the alert threshold has been met.

### Procedure

1. Enable outliers. See [Enabling and disabling outliers detection](#), or [Active Threat Analytics setup](#).
2. Optionally fine tune the outlier definition. See [Grouping users and objects for outliers detection](#) and [Excluding events from outliers detection](#).
3. Create a query.
  - a. Navigate to Reports > Report Configuration Tools > Query-Report Builder.
  - b. Set Domain=analytic, Query name=Analytic Outliers List or Analytic Outliers Summary by Date. All other settings can be left at their defaults.
  - c. Click Create Report.
4. Create an Audit process.
  - a. Navigate to Comply > Tools and Views > Audit Process Builder.
  - b. Name the process and add the task (the report you just created).
  - c. Define receivers. Decide what kind of notifications you want. You can set up alerts, add to the to-do list, and assign users to review and justify the findings.
  - d. Schedule the process as daily, and Save.
5. For easy viewing, add the outliers reports to My Dashboard.

### Results

When the learning period is complete, there should be data in the reports, and alerts are sent.

## Enabling and disabling outliers detection

Enable/disable outliers detection from any unit in a centralized environment, a multi-CM environment, or on a stand-alone collector.

### Before you begin

- Guardium strongly recommends that you enable outliers only on 64-bit aggregators with a minimum of 24 gigabytes of memory.

### About this task

Restriction: Outliers detection and Data Level Security cannot be enabled concurrently.

Outliers detection is disabled by default. You can enable outliers detection by either of the following two ways:

- In the Maintenance > Active Threat Analytics Setup page. See [Active Threat Analytics setup](#).
- Two API commands, `enable_outliers_detection` and `disable_outliers_detection`, are used for enabling and disabling outliers detection on any Guardium system, in any topology.

The outliers detection commands affect the Guardium systems differently, depending on their setup.

#### Single CM environment

Enable outliers detection on a CM to enable/disable outliers detection on all managed units, and on all units registered to the CM thereafter, by running the API command with no additional parameters. Alternatively, you can limit the enable/disable to a list of units. Similarly, disabling outliers detection on a CM disables it on all units that are registered with the CM.

Enable outliers detection on a collector that extracts data to an aggregator. Outliers detection is enabled on the aggregator (if not already enabled) and the collector starts sending data to the aggregator. When disabling on a collector, if this is the only collector sending data to the aggregator, then the collector stops sending data, and outliers detection is disabled on the aggregator.

#### Multi-CM environment

Enable/disable outliers detection on a CM to enable/disable outliers detection on all managed units, and on all units registered to the CM thereafter, by running the API command with no additional parameters. Alternatively, you can limit the enable/disable to a list of units. Similarly, disabling outliers detection on a CM disables it on a unit registered with the CM.

When enabling on a collector that extracts data to an aggregator that is not in the same CM environment as the collector, the collector starts sending data to the aggregator, and the API responds with the name of the aggregator that needs to be enabled for outliers detection.

When enabling on an aggregator, outliers detection is enabled and collectors in the same CM environment start sending data. If the aggregator receives data from collectors in a different CM environment, the API responds with a list of all collectors that need to be enabled for outliers detection.

To enable on individual aggregators or collectors, use the commands [enable\\_outliers\\_detection\\_cross\\_cm\\_agg](#) and [enable\\_outliers\\_detection\\_cross\\_cm\\_collector](#).

#### Single Collector

Run the command on a collector that does not extract data to an aggregator to enable/disable it locally.

## Procedure

---

1. Log in to the Guardium system as a user or administrator with the CLI role.

2. To enable the outliers detection on all the units under the CM and on all units that are registered to the CM thereafter, enter: **grdapi enable\_outliers\_detection**

Optional parameters are:

- `outliers_detection_enabling`: group ID of an existing group. Relevant and optional on a CM.
- `managed_units_hostnames`: comma separated list of units. Relevant and optional on a CM.
- `FAM_DAM` is an optional parameter that specifies the type of outliers. The default is DAM.

The parameters `schedule_interval` and `schedule_units` are ignored.

3. To disable the outliers detection function, enter the command, with or without the optional parameters:

```
grdapi disable_outliers_detection
```

## Results

---

When enabling, the system starts collecting outlier data. After the learning completes(14 days), outliers data is available in the Investigation Dashboard ([Interpreting data outliers in the investigation dashboard](#) and [Interpreting file activity outliers in the investigation dashboard](#)) and the Outlier Analytic List Report.

## Interpreting data outliers in the investigation dashboard

---

Guardium provides a convenient graphical interface for identifying and responding to outliers detected by the algorithm.

Quick Search must be enabled (**grdapi enable\_quick\_search**) to see outlier detection data in the investigation dashboard.

Let's say you have an outlier that shows an exceptional number of errors for user X. Some of the points you want to investigate are:

- Look at the history, is this the first time the user has outliers? The first time the user has this type of outlier?
- Comparing this user to other users, is this error type unique for this user?
- Check the error types
- Is the number of errors standard for this user?
- Look at the sensitivity of the tables accessed by the user
- Compare the actions to other DBs

Let's walk through a flow of investigating an outlier.

1. Open the investigation dashboard by selecting Data or from the User Interface drop-down, and clicking Enter; or by entering quick search in the search field and clicking Search for Data Activity, and add the Activity Chart (Add chart > Activity Chart). (You can change the time interval of the charts at the top of the window.) Red indicators reflect highly anomalous events requiring immediate attention. Yellow indicators represent less extreme anomalies that warrant attention as part of other or related investigations.

2. Hover over the outlier icon to view further details in a popup. Here you can click Show details to filter the Results Table to activities or outliers that occurred during the same time period.

3. Click the outlier to open the Summary tab of the Outlier View, which shows the number of sources that had outliers during the selected time period, and the high and medium outliers.

- Filter the data in the table either using the facets list, an individual search result, or the right-click menu.
- Use the right-click menu in the outliers table to show related activity, show related exceptions, show related violations.

4. Try monitoring only privileged users to eliminate the data and improve focus.

- You can get good insights into the patterns and usage of the privileged user activity. You might see:
  - Users that should NOT be accessing certain data.
  - SQL activity that looks abnormal, which could be privileged users that are disguising their activity with SQL attacks. See also [Characteristics of an SQL injection attack](#).

- Look for Time Of Day Outliers

5. Try monitoring only sensitive objects to eliminate the data and improve focus.

- You can get good insights into the patterns and usage of the users that access these sensitive objects. You might see unusual patterns of access to these objects.
- Look for Time Of Day Outliers.
- Look at which utilities (source programs) accessed these objects.

The Outliers tab in the Results Table has two views:

- Summary has one row per source per hour in which an outlier was found, with an anomaly score and one or more reasons. Note that not every outlier presented in the Summary Tab has further details in the Details tab.
- Details is a sample of events that occurred, with one row per event with a reason (except diverse, see table) and other details (source program, object, verb, etc.). For example, for high volume, the sampling presents the events with the highest score. You can configure the number of samples (rows) that appear in the Details Tab, per each outlier in the Summary tab.

This table describes the columns in both the Summary and Details views:

| Column name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Further Action                                                                                                                                                                                                                                      |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Anomaly Score           | Summary Tab: A calculated aggregate value based on the volume of outliers, the severity of individual events, the predicted volume of outliers for a given time of day, and other factors. For example, on a system that typically identifies 0 outliers at 1am and 5-10 outliers at 1pm during weekdays, the presence of two additional outliers (of 2 outliers at 1am or of 12 outliers at 1pm) is more significant, and weighted more heavily, than the hourly total itself. Details Tab: The anomaly score is only relevant for a high volume event. | Right-click the score to open a menu with additional actions you can perform. In the Details tab the score can be 0, indicating that the individual events are not suspicious on their own, but the accumulated events in that hour are suspicious. |
| Textual Description     | Description of the outlier activity; may include, for example, database name, user name, object.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                     |
| High volume Outlier     | True or False. High volume of activities of some type, for example on an object, of a DB user.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                     |
| Vulnerable obj. Outlier | High volume anomaly in the activities on objects that are members of the “Temporary objects” group.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                     |
| New Outlier             | True or False. Unusual volume of object/verb activities that are not normal when compared to previous activity. For example an admin uncharacteristically creates a high number of new tables; or a user selects a number of objects and performs updates, when never performed updates earlier                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                     |
| Diverse Outlier         | Summary view only. True or False. High volume of different types of activities, for example a DB user performs many more activities than usual, or performs them at an unusual time. A sample of the diverse events does appear in the Details tab, they can be identified by the database user. Although Diverse is not a column in the details tab, they may have other reasons assigned to them. Otherwise they appear without a reason.                                                                                                              | See the Activity table for more details.                                                                                                                                                                                                            |
| Error Outlier           | True or False. High volume of errors                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                     |
| Ongoing Outlier         | Summary view only. True or False. Event in the last few hours that was not high enough to create an outlier, but does raise suspicions.                                                                                                                                                                                                                                                                                                                                                                                                                  | There are no specific events to view. See the Activity table, filter by the database in the facet list, at the time of the suspicious behavior.                                                                                                     |
| Sensitive Object        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                                                                                                                                     |
| Number of Instances     | Details view only. Number of times this particular event has been seen in the hour.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                     |
| Records affected        | Number of records affected by the particular event. Appears as a negative number if the event does not, by definition, have affected records.                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                     |

## Interpreting file activity outliers in the investigation dashboard

View file activity monitoring outliers in the Investigation Dashboard Activity Chart and Results Table (investigation dashboard must be enabled), or review the Analytic Outlier List report.

Quick Search must be enabled (grdapi enable\_quick\_search) to see outlier detection data in the investigation dashboard.

General workflow guidelines:

1. Open the investigation dashboard by selecting File or from the User Interface drop-down, and clicking Enter; or by entering quick search in the search field and clicking Search for File Activity, and view the outliers in the Activity Chart. (You can change the time interval of the chart at the top of the window.) Red indicators reflect highly anomalous events requiring immediate attention. Yellow indicators represent less extreme anomalies that warrant attention as part of other or related investigations.
2. Hover over an outlier icon to view detailed information about outliers detected during that time period.
3. Filter the Results Table to activities or outliers that occurred during the same time period by clicking Show details.
4. Click the outlier to open the Summary tab of the Outlier View, which shows the number of sources that had outliers during the selected time period, and the high and medium outliers.
  - Filter the data in the table either using the facets list, an individual search result, or the right-click menu.
  - Use the right-click menu in the outliers table to show related activity, show related exception, show related violations, and more.
5. Try monitoring only privileged users to eliminate the data and improve focus.
  - You can get good insights into the patterns and usage of the privileged user activity. You might see:
    - Users that should NOT be accessing certain data.
    - Look for Time Of Day Outliers
6. Try monitoring only sensitive objects to eliminate the data and improve focus.

- You can get good insights into the patterns and usage of the users that access these sensitive objects. Do this, for example, by creating a Group of file servers with sensitive data. You might see unusual patterns of access to these objects.
  - Look for Time Of Day Outliers.
  - Look at which utilities (source programs) accessed these objects.
7. Continue monitoring.
- Alerts Setting: Set alerts for the Anomaly Hours (based on Analytic Outliers Summary report)
  - Auditing: define Review Outliers (Define Audit Process on Analytic Outliers List report) and assign to the appropriate Roles / User-Groups

The Outliers tab in the Results Table has two views:

- Summary has one row per source per hour in which an outlier was found, with an anomaly score and one or more reasons. Note that not every outlier presented in the Summary Tab has further details in the Details tab.
- Details is a sample of events that occurred, with one row per event with a reason and other details. For example, for high volume, the sampling presents the events with the highest score. You can configure the number of samples (rows) that appear in the Details Tab, per each outlier in the Summary tab.

This table describes the columns in both the Summary and Details views:

| Column name         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Further Action                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Anomaly Score       | Summary Tab: A calculated aggregate value based on the volume of outliers, the severity of individual events, the predicted volume of outliers for a given time of day, and other factors. For example, on a system that typically identifies 0 outliers at 1am and 5-10 outliers at 1pm during weekdays, the presence of two additional outliers (of 2 outliers at 1am or of 12 outliers at 1pm) is more significant, and weighted more heavily, than the hourly total itself. Details Tab: The anomaly score is only relevant for a high volume event. | Right-click the score to open a menu with additional actions you can perform. In the Details tab the score can be 0, indicating that the individual events are not suspicious on their own, but the accumulated events in that hour are suspicious. |
| High volume Outlier | True or False. High volume of activities of some type, for example on an object, of a DB user.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                     |
| New Outlier         | True or False. High volume of activities on new objects, for example an admin uncharacteristically creates a high number of new tables.                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                     |
| Error Outlier       | True or False. High volume of errors                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                                                                                                                                                                                     |
| Ongoing Outlier     | Summary view only. True or False. Event in the last few hours that was not high enough to create an outlier, but does raise suspicions.                                                                                                                                                                                                                                                                                                                                                                                                                  | There are no specific events to view. See the Activity table, filter by the database in the facet list, at the time of the suspicious behavior.                                                                                                     |

## Switching DB and OS users

Outlier mining, by default, tracks two types of sources: databases and database users. The behavior baseline and hourly activities are compared for each source. If your system typically has a high number of users per application, then tracking activity by DB user might not be specific enough. In this case, you can switch outliers detection user mode to evaluate by OS user. In this scenario, sources are databases and OS users. User mode is configured on the central manager for the entire system.

## About this task

All managed units that report to one central manager use the same mode.

You usually switch user mode only once on your system, preferably before you enable outliers detection. When you switch user mode, all the statistical modeling on the DB users is discarded, and the system starts over again, collecting details on the OS user.

In a cross-CM environment, you need to switch the mode on both central managers (or all central managers that share a collector-aggregator link).

If you have managed units that are running a version earlier than V11.2, they continue to accumulate data for DB users. They are identified in the Active Threat Analytics Setup page by the text User Mode change requires V11.2+.

If you are already running outliers detection, and specific events are excluded from the outliers detection algorithm (the Ignore option in the investigation dashboard), then:

- The value of each ignored field is maintained when you switch between DB and OS user.
- The ignored field is now the OS user and not the DB user.

You must evaluate each Ignore statement and decide whether you want to keep it or not. Since DB users and OS users rarely, if ever, have the same names, excluded events are usually deleted, and new ones defined. In the Analytic User Feedback, rows that have a value for DB user now show a value for OS user.

## Procedure

---

1. Evaluate each Ignore statement and decide whether it's relevant for an OS user.
  - a. Open the Analytic User Feedback report to view ignored events.
  - b. To delete an ignored event, double-click the event, and select Invoke > delete\_analytic\_user\_feedback.
2. On the central manager, switch to OS users by running the API command **set\_outliers\_user\_detection\_mode mode=OS**  
This command disables outlier mining on all units in the system, switches the user mode, and enables outlier mining on all units that were running outliers mining before the switch. The mode is listed in the Active Threat Analytics Setup page.
3. If a managed unit was unavailable when you switched users, as seen in the Active Threat Analytics Setup page, disable outlier mining on that unit, and then enable outlier mining. The mode switches.

## Grouping users and objects for outliers detection

---

Find out how to add groups, for example user or object groups, to the default outlier detection algorithm.

## About this task

---

By default, there are two groups of users and objects that are weighted or scored more heavily by Guardium® machine-learning algorithm: Admin Users and Sensitive Objects. However, you may have already established additional groups that would also be useful for outlier detection. For example, you may have a group of Suspicious Users or you may have several different groups of sensitive objects that are aligned with different applications.

## Procedure

---

1. This task requires that you know the internal group ID to use with the grdapi command. To get the group ID, you can use the following command: `grdapi list_group_by_desc desc=[group name]`. For example, if you have a group named BadGuys, you can enter the following command to get its internal group ID:  
`grdapi list_group_by_desc desc="BadGuys"`
2. Once you know the desired ID, add it as privileged user group for a boosted score as follows (note that you must also include the default group 1 if you want to boost scores for that as well). To add a group with the ID 1234: `grdapi set_outliers_detection_parameter parameter_name="privUsersGroupIds" parameter_value=1,1234`
3. To add sensitive objects with the IDs 333 and 156: `set_outliers_detection_parameter parameter_name="sensitiveObjectGroupIds" parameter_value=5,333,156`

## Results

---

The specified groups or sensitive objects are added to the outlier detection and are given additional weight by the algorithm.

## Outliers detection clustering

---

User clustering divides the system's users into clusters based on their activity. During the outliers scoring process, outliers detection compares the activity of the users in a group. Analyzing groups of users increases the accuracy of the results, and decreases the number of false positives.

When a user's activity is unusually high, or has many errors, Guardium compares its activity with its cluster's activity and changes the user scores, as relevant.

The clustering algorithm runs periodically, moving users into a different cluster group as relevant. The outlier log /opt/IBM/Guardium/analytic/outlier\_out/outlier.log details changes in the outliers scoring process. (The userClustering.log, also in this folder, is used by support only.)

User clustering is enabled by default. It's recommended to leave the configuration at its default. The configuration is controlled with the API command `set_outliers_detection_parameter` parameters.

- `clusteringScheduleIntervals`: The frequency, in hours, at which the clustering algorithm runs.
- `minNumIntervalsForFirstClustering`: the number of periods, in hours, until the initial clustering of users.

To disable the user clustering, set both of these parameters = 0.

## Real-time trust evaluator

---

The Real-time Trust Evaluator (RTTE) evaluates the application connections that are monitored by Guardium®. Connections are classified as "untrusted", "evaluated" or "trusted". Trust scores (value from 0 - 100) are assigned to each classified connection. Connections that are not classified as trusted or untrusted are classified as evaluated.

The trust evaluator release consists of the following main modules:

1. Security incident policies that are capable of detecting denial-of-service attacks, credential stuffing attacks, password-spraying attacks, and connection authentication vulnerabilities.  
Note: You cannot modify the trust evaluator policies.
2. Probabilistic engine (Probability engine), based on a Bayesian machine learning model. This model requires a long training period. The training status is displayed in the user interface so that you can follow it.
3. Anomaly detection, based on a special machine learning model. Visually, anomaly detection is represented as a list of anomaly conditions. This model requires a short training period and training status is not displayed.

All three modules evaluate application connections in parallel.

The evaluated application connections are collected. The trust evaluator is integrated with session level policies. Thus, a session level policy installed outside the trust evaluator can be used to alert customers of security breaches, create security exceptions, and terminate connections if necessary. For more information, see [Session-level policies](#).

Note: The trust evaluator is available from central manager and standalone machines only. In addition, all collectors must be at Guardium 11.4 or later. When using the trust evaluator, it's best to manage policies from the central manager. This avoids situations where enabling the trust evaluator causes the central manager to overwrite policies that may have been updated on managed units but not yet synced to the central manager. If you must manage policies from managed units, wait until any policy changes are synced to the central manager before enabling the trust evaluator.

## Getting started

---

To get started with the real-time trust evaluator, browse to Protect > Security Policies > Real-Time Trust Evaluator from a central manager and click Enable.

When the trust evaluator starts up, it installs security incidents policies, and begins to evaluate incoming connections. At the same time, the probability engine enters its first training phase.

Here's what you need to know:

- You can view the evaluated application connections from the connections window. For more information, see [Configuring the connections table](#).
- When you click Enable, the trust evaluator installs the security incident policies. You can use the default, **Real-time trust evaluator: incidents related to all users**, or select a different policy from the Configuration section. For more information, see [Configuring the trust evaluator](#).
- When you click Disable, the trust evaluator stops and uninstalls the security incidents policy.
- For anomaly detection, you can select anomalies from the [Anomalies tab](#).

The remainder of this topic provides more information about how the trust evaluator works, configuration information, and details about the connection table and information graphs.

## How the trust evaluator works

---

When you first start the trust evaluator, it begins to evaluate application connections by using installed security incident policies. At the same time, probability engine and anomaly detection modules start their training phases.

At this point, trust evaluator can detect untrusted application connections. Untrusted application connections include security violating connections such as communicating with plain passwords, performing denial-of-service credential stuffing or password-spraying attacks, administrative communicating with not encrypted information, and so on. The trust evaluator sets low trust scores to detected untrusted connections.

When the probability engine finishes its training, it starts to evaluate application connections as well. Connections can be evaluated as "untrusted", "evaluated" or "trusted".

When the anomaly detection module finishes its training, it also starts to evaluate application connections. Connections can be evaluated as "evaluated".

## Trusted versus untrusted connections

---

The trust evaluator identifies a connection as trusted when it meets one of the following criteria:

- The connection matches the criteria of the trusted connection group.
- The probability engine deems that the connection is sufficiently common.

A connection is identified as untrusted in the following circumstances:

- A connection that is identified by a security incident policy as a threat.
- A user-supplied untrusted group.
- In addition, there can be multiple factors and parameters that identify the trustworthiness of a connection. The probability engine can assign an untrusted score if it is not similar to known data, or if other trust evaluator components identify issues for that connection. For example, you might have a case where the probability engine identifies a connection as trusted, but an anomaly or incident is identified for the connection. In this case, the connection is identified as untrusted.
- [Configuring the trust evaluator](#)  
When you configure the trust evaluator, you can choose to monitor either all connections (the default) or administrator connections.
- [Viewing trust evaluator status](#)  
The Status window shows the progress of the probability engine as it learns the typical behaviors of traffic for your system.
- [Adding post-training automation](#)  
After your system is trained and running, the trust evaluator continues to monitor all of your connections, and displays them in the connections table.
- [Configuring the connections table](#)  
From the connections table, you can manage and view information about your connections.

## Configuring the trust evaluator

---

When you configure the trust evaluator, you can choose to monitor either all connections (the default) or administrator connections.

From the Configuration section of the Real-Time Trust Evaluator window, you can see the current settings for the trust evaluator. The default settings are shown on the trust evaluator page. Each setting is associated with one of the configuration tabs.

- Learn patterns from scratch.
- Run on all collectors.
- Evaluate all sessions for all users.
- Use default trust thresholds.
- Evaluate 12 of 12 anomalies.

To change the default settings, click Configure to open the Configure trust evaluator window. From here, you can use the following tabs to configure your system. However, you can also choose to use the defaults and click Enable to install the **Real-time trust evaluator: incidents related to all users** policy and start the training.

When you are done configuring the trust evaluator, click Save to save your changes. At this point, you can click Enable from the trust evaluator main page to begin training your system.

## Inputs tab

From Inputs, you can specify groups of explicitly trusted or untrusted connections. When you add an existing group, the trust evaluator adds those connections to the specified list.

- If you select a group from the Trusted connections list (for example, Risk Spotter - Trusted Users) the trust evaluator continues to monitor the connections. If a connection encounters a security incident, it is removed from the trusted connections and added to untrusted connections.
- If you select a group from the Untrusted connections list (for example, Risk Spotter - Top Risky Users) the trust evaluator assumes that the connections are never trusted. The trust evaluator does not include the connections that are specified as untrusted in the training.

Select Do not consider client IP as part of connection analytics to ignore client IP addresses during trust-score evaluation. This option is useful when the client IP address changes frequently, for example if your site uses dynamic or virtual IP addresses.

## Systems tab

From Systems, you can make the following changes:

- Select the collectors that you want to include in the trust evaluator. The trust evaluator runs only on a central manager, the Systems page displays the related collectors. You can select one of the following system groups:
  - All Collectors: Display all of the collectors associated with this central manager.
  - All Units group: Display all available machines associated with this central manager.
- Alternatively, also use the filter box to find and display specific machines by name or number.
- After you select the machines that you want to include in the trust evaluator training, you can take one of the following steps:
  - Click Collectors to include all of the selected machines.
  - Select each machine that you want to include.

## Incidents tab

From Incidents, you can choose incidents that are related to all users or only incidents that are related to administrators.

For each type of incident (administrator or all users), Guardium® surfaces a read-only policy that you can view from the Security Policies page (Policies > Security Policies > Policy Builder for Data). Depending on your selection, the trust evaluator uses one of the following session-level security incident policies.

Each policy provides a number of rules that track and report on possible security incidents that might be encountered at run time:

- **Real-time trust evaluator: incidents related to all users**
- **Real-time trust evaluator: incidents related to administrative users**

The rules for each policy are described under [Security incident policies](#).

- For information about incidents related to all users, see [All users](#).
- For information about incidents related to administrative users, see [Administrative users and applications](#).

When you enable the trust evaluator, Guardium installs the selected policy before training.

From Incidents, you can select and modify groups against which to run the trust evaluator. If you do not select any groups here, the trust evaluator runs against all server IP addresses associated with the selected S-TAP.

Note: If you select Incidents related to administrators, make sure that the groups you select include only populated groups. If you select an empty group, there are no members of the group to test against. Therefore, the trust evaluator cannot find security incidents for the empty group, but does not provide any indication that the group is not populated.

## Thresholds tab

From Thresholds, you can view or change the trust-score thresholds that the trust evaluator uses to mark connections as trusted, untrusted, or evaluated (that is, not trusted or untrusted). As you start to understand your system, you can tweak the default trust scores (90 or greater for trusted, 10 or lower for untrusted) to help ensure that your system is protected.

## Anomalies tab

When training begins, the anomalies engine tracks unique connections. The trust evaluator starts to recognize anomalies after it sees a sufficient number of unique connections. When any anomalies are found, they are logged in the **Connection Exceptions** report.

Note: The number of "sufficient connections" to detect anomalies is based on your environment and set without user involvement, but it is always greater than 1000 connections.

From Anomalies, select some or all of the anomaly conditions. The trust evaluator uses the read-only Real-time trust evaluator: Security anomalies policy, where each rule represents an anomaly type. For more information about the Security anomaly policy, see [Security anomalies](#).

## Viewing trust evaluator status

The Status window shows the progress of the probability engine as it learns the typical behaviors of traffic for your system.

Click View status to open the Status window.

Note: The status includes PAUSED or IDLE when no traffic is seen for at least 15 minutes. When Guardium detects traffic again, the trust evaluator restarts, the status updates.

Table 1. Status types

| Status                | Meaning                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FIRST STAGE LEARNING  | The initial 7-day learning period.                                                                                                                                                                                                                                    |
| SECOND STAGE LEARNING | The secondary 24-hour contiguous learning period                                                                                                                                                                                                                      |
| TRAINED               | Training is complete. Guardium is issuing trust scores.                                                                                                                                                                                                               |
| RETRAINING            | Issuing trust scores using current learning data. However, Guardium is training a secondary model in the background. When learning completes the old model is quietly replaced.                                                                                       |
| IMMEDIATE RETRAINING  | Guardium discards the current training data and begins the training from the first stage. This status generally indicates that Guardium found too many anomalous connections. The probability engine will discard the current training data and retrain from scratch. |

## Adding post-training automation

After your system is trained and running, the trust evaluator continues to monitor all of your connections, and displays them in the connections table.

For a trained system, you can determine the actions to take when connections are marked as trusted, untrusted, or evaluated (but not categorized as trusted or untrusted).

- Select Automation, and then, for each category type, select an appropriate action and an optional group.  
If you specify an existing group, or add a new group, the identified connections (trusted or untrusted) are automatically added to that group.  
For more information about the available actions, see [Policy rule actions](#).
- When you are done, click Save to save your changes and close the Automation window.

Deciding when to use automation depends on how your site is configured. However, some guidelines for automation are as follows:

- Before you enable automation, review all of your connections to ensure that both trusted and untrusted connections align with your expectations.
- Guardium suggests that you ignore trusted connections only for trusted group input connections or for trusted connections that you review regularly.
- If you set untrusted connections to one of the S-GATE Session *Terminate* actions, be aware that your users may notice if some connections are terminated.

## Configuring the connections table

From the connections table, you can manage and view information about your connections.

While the trust evaluator runs (either during or after training), you can use Time frame to set the number of days of connections to display in the connections table.

From the connections table, you can take the following steps:

- Select the type of connections you want to view (Trusted, Evaluated (but not categorized as trusted or untrusted), or Untrusted).  
Note: If the real-time trust evaluator encounters multiple incidents for the same connection (for example, an administrator who uses the same password for multiple accounts), then only the first incident might be recorded in the connections table.
- Use the Filter box within connection types to create a subset of connections.
- Click  to download information about all of the connections that are shown in the connections table.
- Select one or more connections from the table and then select Actions. You can add the selected connections to the Trusted connections group, the untrusted connections group, or to a custom group.  
If you select Add to custom group, the Add to custom group window displays. The group type must be *Tuples*, but you can either select an existing group or create a new group. For more information about tuple groups, see [Groups overview](#).

After you save and close the custom group, the selected connections are added to the group.

- Select Hide connections in trusted groups (or Hide connections in untrusted groups) to hide any connections that match existing members in a trusted or untrusted group. When you select this option, only the trusted (or untrusted) connections found by the trust evaluator display in the connections table. The results reason

shows as **Trusted as input from user** or **Untrusted as input from user**.

In addition, two graphs display the data from the connections table.

- The Connections seen or evaluated graph displays the total number of connections that have been seen or evaluated by the trust evaluator. The graph includes connections that are known to be untrusted (and therefore not evaluated), as well as connections that are not yet evaluated (new connections). The number in the center of the graph reflects one of the following numbers:
  - If your mouse is not in the graph, the number reflects the total number of connections that were seen or evaluated in the selected timeframe.
  - If you hover your mouse over one of the graph elements, the number reflects the number of connections that are represented by the graph element (that is: new, trusted, evaluated, or untrusted).
- The Trust scores assigned graph shows the number of connections in each trust score category and the percentage of connections in each category. Categories are labeled as 0 - 10, 11 - 20, and so on). This graph does not include new connections that are not yet evaluated.

## Policies

Policies are sets of rules and actions applied in real time to the database traffic observed by a Guardium system. Policies define which traffic is ignored or logged, which activities require more granular logging, and which activities should trigger an alert or block access to the database.

- **[Understanding policies](#)**  
A security policy contains an ordered set of rules to be applied to the observed traffic between database clients and servers. Each rule can apply to a request from a client, or to a response from a server. Multiple policies can be defined and multiple policies can be installed on a Guardium appliance at the same time.
- **[Session-level policies](#)**  
Session-level policies and advanced session-level policies create new possibilities for detecting suspicious behavior of users of services as well as security incidents. Session-level policies are created using the Policy Builder for Data, and advanced session level policies are created as scripts using the SR language and uploaded to Guardium using the Policy Builder for Data.
- **[Policy rule actions](#)**  
Define blocking, alerting, or logging actions to take when policy rules are matched.
- **[Creating and installing a policy and policy rules](#)**  
Use the Policy Builder for Data to manage policies and policy rules.
- **[Tagging policy rules](#)**  
Guardium provides predefined policy rule tags and supports custom tagging of rules. Use tags to quickly create and manage policies aligned with specific compliance standards, reporting and auditing requirements, or geographies.
- **[Using the Policy Installation tool](#)**  
Learn how to install a policy on your Guardium system.
- **[Running policy analyzer and reviewing results](#)**  
Policy analyzer provides insights that help identify frequently fired rules, optimize rule order, and evaluate rule changes.
- **[Security incident policies](#)**  
Guardium® provides several session level policy templates that encapsulate security problems that are frequently found at run time.

## Understanding policies

A security policy contains an ordered set of rules to be applied to the observed traffic between database clients and servers. Each rule can apply to a request from a client, or to a response from a server. Multiple policies can be defined and multiple policies can be installed on a Guardium appliance at the same time.

Each rule in a policy defines a conditional action or several actions. The condition tested can be a simple test - for example it might check for any access from a client IP address that does not belong to an Authorized Client IPs group. Or the condition tested can be a complex test that considers multiple message and session attributes (database user, source program, command type, time of day, etc.), and it can be sensitive to the number of times the condition is met within a specified time frame.

The action triggered by the rule can be a notification action (e-mail to one or more recipients, for example), a blocking action (the client session might be disconnected), or the event might simply be logged as a policy violation.

A policy violation is logged each time that an alert or log-only action is triggered. Optionally, the SQL that triggered the rule (including data values) can be recorded with the policy violation. Policy violations can be assigned to incidents, either automatically by a process, or manually by authorized users (for more information, see [Incident Management](#)).

Attention: Correlation alerts can also be written to the policy violations domain (for more information, see [Managing correlation alerts](#)).

In addition to logging violations, policy rules can affect the logging of client traffic, which is logged as constructs and construct instances.

- Constructs are prototypes of requests that Guardium® detects in the traffic. The combinations of commands, objects and fields included in a construct can be very complex, but each construct represents a specific type of access request. The detection and logging of new constructs begins when the inspection engine starts, and by default continues (except as described) regardless of any security policy rules.
- Each instance of a construct detected in the traffic is also logged, and each instance is related to a specific client-server session. No SQL is stored for a construct instance, except when a policy rule requests the logging of SQL for that instance, or for a particular client/server session of instances (with or without values).

In addition to controlling the inclusion of SQL in client construct instances, a security policy rule can disable the logging of constructs and instances for the remainder of a session.

In heavy volume situations, the parsing and aggregating of information into constructs and instances can be deferred by using the Log Flat (Flat Log) option. When used, the production of alerts and reports will be delayed until the logged information has been aggregated.

To completely control the client traffic that is logged, a policy can be defined as a selective audit trail policy. In that type of policy, audit-only rules and an optional pattern identify all of the client traffic to be logged.

Data-monitoring policies are installed from Protect > Security Policies > Policy Builder for Data or from Protect > Security Policies > Policy Installation.

Attention: On a new installation only (not on upgrades), a default policy is installed. It contains one rule, and the policy name is Default - Ignore Data Activity for Unknown Connections.

- **[Rule types, categories, classifications](#)**  
Within a policy, rules are evaluated in the order in which they appear as each element of traffic is analyzed.
- **[Minimum counts and reset intervals](#)**  
Some activities are normal and acceptable when they occur less than a certain rate but require attention when the rate exceeds a tolerable threshold.
- **[Continue to next rule](#)**  
By default, the evaluation of access and exception rules for a unit of traffic ends when a rule is triggered provided there are not multiple actions in one rule. In cases where it is necessary to take multiple actions for the same or similar conditions, enable the Continue to next rule setting for that rule.
- **[Record values with policy violation](#)**  
When using the Record values setting, the actual construct causing the rule to be satisfied will be logged in the SQL string attribute and is available in reports.
- **[Values and groups of values in rules](#)**  
For many policy rule criteria, you can specify a single value or a group of values. It is also possible to simultaneously specify both a single value and a group of values.
- **[Matching patterns with regular expressions](#)**  
Use regular expressions to search traffic for complex data patterns.
- **[Special pattern tests](#)**  
You can use these special pattern tests to identify sensitive data that is contained in the traffic that flows between the database server and the client.
- **[Log flat](#)**  
Log flat allows Guardium to log information without immediately parsing it.
- **[Rules on flat](#)**  
The rules on flat setting changes the way Guardium processes policy rules.
- **[Selective audit trail](#)**  
When you create or edit a policy, click Selective audit trail to limit the amount of logging on the Guardium system.
- **[Analyzer rules](#)**  
Certain rules can be applied at the analyzer level.
- **[Character sets](#)**  
You can use character set codes in extrusion rules.

---

## Rule types, categories, classifications

Within a policy, rules are evaluated in the order in which they appear as each element of traffic is analyzed.

There are three types of rules:

- An access rule applies to client requests. For example, it might test for UPDATE commands issued from a specific group of IP addresses.
- An exception rule evaluates exceptions returned by the server (responses). For example, it might test for five login failures within one minute.
- An extrusion rule evaluates data returned by the server (in response to requests). For example, it might test the returned data for numeric patterns that could be social security or credit card numbers.

For each rule, an optional Category and Classification can be assigned. These are used to group policy violations for both reporting and incident management.

---

## Minimum counts and reset intervals

Some activities are normal and acceptable when they occur less than a certain rate but require attention when the rate exceeds a tolerable threshold.

For example, if interactive database access is allowed, a consistent but relatively low rate of login failures might be expected. However, a sharply higher rate might indicate an attack is in progress.

To deal with thresholds, a minimum count and a reset interval can be specified for each policy rule. For example, this can be used to trigger the rule action after the count of login failures exceeds 100 (the minimum count) within one minute (the reset interval). If omitted, the default is to execute the rule action each time the rule is satisfied.

---

## Continue to next rule

By default, the evaluation of access and exception rules for a unit of traffic ends when a rule is triggered provided there are not multiple actions in one rule. In cases where it is necessary to take multiple actions for the same or similar conditions, enable the Continue to next rule setting for that rule.

The Continue to next rule setting applies to access rules following access rules and to exception rules following exception rules. It does not apply to an exception rule following an access rule or an access rule following an exception rule.

Extrusion rules will be processed regardless of the end of an access or exception rule preceding the extrusion rule.

In the session level policies, Continue to next rule setting applies to the rules that have alerting and logging actions.

---

## Record values with policy violation

When using the Record values setting, the actual construct causing the rule to be satisfied will be logged in the SQL string attribute and is available in reports.

When the Record values setting is not used, no SQL statement is logged.

To include the full values in the policy violation, set the Record values parameter to 1 - Log full SQL in policy violation for that rule.

Attention: The full SQL with values will be available only in the policy violation record within the policy violations reporting domain. It will not be available in the client traffic log or on reports from the data access domain. To include full SQL (with or without data values) in the client traffic log, use the Log Full SQL rule action.

## Values and groups of values in rules

For many policy rule criteria, you can specify a single value or a group of values. It is also possible to simultaneously specify both a single value and a group of values.

Be aware that a group member may contain wildcard (%) characters, so each member of a group may match multiple actual values.

- Negative rules: use the != or Not in group operators to create a negative rule. For example, not the specified Application user or not any member of the selected group. It is also possible to exclude both single values and a group of values. For example, define two negative Application user rule criteria, one using != for a specific user and another using Not in group to exclude members of a selected group.
- Empty value: enter the special value `guardium://empty` to test for an empty value in the traffic. This is allowed only in the following fields: Application event text, Application user, Database name, Database user, Event type, Event user name, Operating system user, and Source application.
- Define a new group to be tested: select the In group or Not in group operator and click the  icon to define a new group.
- Match any value: select the = operator and leave the value field blank.
- Match a specific value: select the = operator and enter the value to match in the text field.
- Match any member of a group: select the In group operator, select the group from the list of groups. If the minimum count is greater than one, there will be a single counter, and it will be incremented each time any member of the group is matched.
- Match an individual value or any member of a group: define two rule criteria, one using the = operator to match a specific value and another using In group to match members of a selected group. If the minimum count is greater than one, there will be a single counter, and it will be incremented each time the individual value or any member of the group is matched.
- If the minimum count is greater than one, count each individual value separately: select the = operator and enter a period (.) in the value field. Note that the period option cannot be used for the Service name or Network protocol criteria.
- If the minimum count is greater than one, count each member of a group separately: select the In group operator and select a group from the list.

## Matching patterns with regular expressions

Use regular expressions to search traffic for complex data patterns.

The Guardium implementation of regular expressions conforms with PCRE, which differs from the UNIX implementation of regular expressions. Regular expressions are allowed in any field that is followed by the  button.

Restriction: Guardium does not support regular expressions for non-Latin character sets.

However, if your database uses UTF-8 encoding for Unicode, you can use the |xnn pattern to extend regex patterns in Unicode data, to, for example, scrub data written in non-Latin character sets. Technically, you can now scrub any data that you can represent with |xnn byte patterns. However, there are some limitations, as follows:

- Each database has its own encoding scheme. You need to know which Unicode encoding your database uses.
- The replacement character in scrub might not appear the same as defined in the scrub pattern, especially with 2-byte encoding schemes.
- To limit the scrub, specify the length of the data to scrub as prefix. Otherwise, you might override the query metadata, which can lead to a failure or crash.

Tip: You can also use regular expressions with the following criteria by typing the special value `guardium://regexp/(regular expression)` in the value field: Database user, Application user, Source application, Field name, Object, Application event values text.

Notes:

- If a complex regex statement fails (for example, a statement that uses recursive stack matching up to the maximum depth of the stack), criteria matching stops and the error is logged to the snif log. However, one error is logged at most every 30 minutes (and not for each failed statement).
- Redact policies that use regular expressions can only scrub null-terminated data types.

For more information about using regular expressions, see [Regular Expressions](#). For more information about troubleshooting with REDACT and regex, see [REDACT function causes overly masked result](#) and [REDACT - Working with regex on Windows DB servers](#).

## Special pattern tests

You can use these special pattern tests to identify sensitive data that is contained in the traffic that flows between the database server and the client.

Each policy rule can include a single special pattern test. To use one of these tests, begin the rule name with one of the special pattern test names, followed by a space and one or more additional characters to make the rule name unique. For example, if you are searching for Social Security numbers of your employees, you could name the rule `guardium://SSEC_NUMBER_employee`. You can still specify all other components of the rule, such as specific client and server IP addresses.

These tests match a character pattern, and that match does not guarantee that the suspected item, such as a Social Security number, has been encountered. There can be false positives under a variety of circumstances, especially if longer sequences of numeric values are concatenated in the data.

`guardium://CREDIT_CARD`

Detects credit card number patterns. It tests for a string of 16 digits or for four sets of four digits, with each set separated by a blank. This special pattern test also works with American Express 15-digit credit card number patterns (first digit 3 and second digit either 4 or 7). For example: **1111222233334444** or **1111 2222 3333 4444**

When a rule name begins with "guardium://CREDIT\_CARD", and there is a valid credit card number pattern in the Data pattern field, the policy uses the Luhn algorithm, a widely-used algorithm for validating identification numbers such as credit card numbers, in addition to standard pattern matching. The Luhn algorithm is an additional check and does not replace the pattern check. A valid credit card number is a string of 16 digits or four sets of four digits, with each set separated by a blank. There is a requirement to have both the `guardium://CREDIT_CARD` rule name and a valid [0-9]{16} number in the Search Expression box in order to have the Luhn algorithm involved in this pattern matching.

`guardium://PCI_TRACK_DATA`

Detects two patterns of magnetic stripe data. The first pattern consists of a semi-colon (;), 16 digits, an equal sign (=), 20 digits, and a question mark (?), such as:

**;1111222233334444=11112222333344445555?**

The second pattern consists of a percent sign (%), the character B, 16 digits, a carat (^), a variable-length character string terminated by a forward slash (/), a second variable-length character string terminated by a carat (^), 31 digits, and a question mark (?), such as:

**%B1111222233334444^xxx/xxxx x^1111222233334444555566667777888?**

guardium://SSEC\_NUMBER

Detects numbers in Social Security number format: three digits, dash (-), two digits, dash (-), four digits, such as **123-45-6789**. The dashes are required.

guardium://CPF

The Cadastro de Pessoas Físicas (CPF), a Brazilian personal identifier. It contains 11 digits of the format **nnn.nnn.nnn-nn**, where the last two digits are check digits. Check digits are computed from the original nine digits to provide verification that the number is valid. The formatting characters within the expression are optional. If there is a match on the expression, the check digits are validated.

guardium://CNPJ

Cadastro Nacional de Pessoas Jurídicas (CNPJ), an identification number used for Brazilian companies. It contains 14 digits of the format **00.000.000/0001-00** where:

- The first eight numbers show the registration.
- The next four numbers identify the entity branch. 0001 is the default value for head quarters.
- The last 2 numbers are the check digits.

The formatting characters within the expression are optional. If there is a match on the expression, the check digits are validated.

12.1 and later

guardium://CANSIN

Detects Canadian Social Insurance Number (SIN) pattern.

When a rule name begins with 'guardium://CANSIN', and there is a valid SIN number pattern in the data pattern field, the policy uses the Luhn algorithm, a widely-used algorithm for validating identification numbers such as credit card numbers, in addition to standard pattern matching.

## Log flat

Log flat allows Guardium to log information without immediately parsing it.

This saves processing resources, so that a heavier traffic volume can be handled. The parsing and merging of that data to Guardium's internal database can be done later, either on a collector or an aggregator unit.

There are two Guardium features involving the Flat Log Process - Flat Log by policy definition and Flat Log by throttling mechanism.

Flat Log by throttling mechanism - This is the feature implemented by running the CLI command, store alp\_throttle 1. The same policy that is applicable to real-time S-TAP traffic is used to process traffic that was logged into the GDM\_FLAT\_LOG table.

For Flat Log by throttling mechanism, the Flat Log checkbox should NOT be checked in Policy Builder.

Flat Log by policy definition - Selection of this feature involves the Policy Builder menu in Setup >Tools and Views and Flat Log Process menu in Manage > Activity Monitoring.

Note: Rules on flat does not work with policy rules involving a field, an object, SQL verb (command), Object/Command Group, and Object/Field Group. In the Flat Log process, "flat" means that a syntax tree is not built. If there is no syntax tree, then the fields, objects and SQL verbs cannot be determined.

The following actions do not work with rules on flat policies: LOG FULL DETAILS; LOG FULL DETAILS PER SESSION; LOG FULL DETAILS VALUES; LOG FULL DETAILS VALUES PER SESSION; LOG MASKED DETAILS.

When the Log Flat (Flat Log) checkbox option listed in the Policy Definition screen of the Policy Builder is checked,

- Data will not be parsed in real time .
- The flat logs can be seen on a designated Flat Log List report.

## Rules on flat

The rules on flat setting changes the way Guardium processes policy rules.

When Rules on flat is checked:

- Session-Level rules will be examined in real-time.
- No rules will be evaluated when the offline processing does takes place.

When Rules on flat is NOT checked:

- Policy rules will fire at processing time using the current installed policy.

Note: Rules on flat does not work with policy rules involving a field, an object, SQL verb (command), Object/Command Group, and Object/Field Group. In the Flat Log process, "flat" means that a syntax tree is not built. If there is no syntax tree, then the fields, objects and SQL verbs cannot be determined.

The following actions do not work with rules on flat policies: LOG\_FULL\_DETAILS; LOG\_FULL\_DETAILS\_PER\_SESSION; LOG\_FULL\_DETAILS\_VALUES; LOG\_FULL\_DETAILS\_VALUES\_PER\_SESSION; LOG\_MASKED\_DETAILS.

## Selective audit trail

When you create or edit a policy, click Selective audit trail to limit the amount of logging on the Guardium system.

A selective audit trail is appropriate in the following circumstances.

- The traffic of interest is a relatively small percentage of the traffic that the inspection engines.
- All of the traffic you might ever want to report upon can be completely identified.

For any Guardium collector, if Selective audit trail is specified for one policy, then all policies for that collector use a selective audit trail. In this case, multiple policies are treated as a single policy, where rules are applied in the order that the policies are installed.

Without a selective audit trail policy, the Guardium appliance logs all traffic that the inspection engines accept. Each inspection engine on the appliance or on an S-TAP is configured to monitor a specific database protocol (Oracle, for example) on one or more ports. In addition, the inspection engine can be configured to accept traffic from subsets of client/server connections, which tends to capture more information than a selective audit trail policy. However, it might cause the Guardium appliance to process and store more information than is needed to satisfy your security and regulatory requirements.

When a selective audit trail policy is installed, only the traffic that the policy requests is logged. Traffic is identified in two ways:

- Specify a string to use to identify the traffic of interest in the Audit Pattern box of the Policy Definition window. You might identify a database or a group of database tables, for example. An audit pattern is a pattern that is applied (via regular expression matching) to EACH SQL that the logger processes to see whether it matches. This pattern match is strictly a string match. It does not match against the session variables (such as DB name) the way the policy rules do.
  - Specify Audit Only or any of the Log actions (except for Log Full Details Per Session) for one or more policy rules in a Rule Definition window. With policy rules you can be precise, specifying exact values, groups, or patterns to match for every conceivable type of attribute (such as DB Type, DB Name, or User Name).
- Note: The Log Full Details Per Session action is not supported for policies that use selective audit trail. Because you are selectively auditing the data, full details are not available.

When a Selective audit trail is enabled for a Guardium security policy:

- If you create a rule on a group of objects, the string on each element in the group is checked. If a match is found, a decision is made to log the information and continue.
- If you create a rule on a group of objects that use a NOT designation on the object group, Guardium still needs to check the string on each element in the group, and decide to log and continue only if none of the elements match. NOT designated rules behave the same as normal rules when used with selective audit trail.

These rules include

- OR situations such as rules based on multiple objects or commands.
- Situations with two NOT conditions (for example, NOT part of a group of objects and NOT part of a group of commands).
- Situations with one NOT condition and one YES condition (for example, a NOT part of a group of objects and a YES part of a group of commands).

Note: Any select statements with query hints, such as `SELECT /*+ ORDERED USE_MERGE(m)`

`*/, SELECT /*+ ORDERED */`, or `SELECT /*+ all_rows */` are allowed to pass through the parser and logged regardless of the rule definition to skip them (at least with selective audit mode). A selective audit policy should not prevent logging of certain SQLs that might be needed for other functions, like application user translation.

## Selective Audit Trail and Application Events API

---

When a selective audit trail policy is used, and application users or events are being set via the Application Events API, the policy must include an Audit Only rule that fires whenever a set/clear application event, or set/clear application user command is encountered. For more information about setting the application user via the Application Events API, see [Identify Users with API](#).

## Selective Audit Trail and Application User Translation

---

When a selective audit trail policy is used, an Application User Translation is also used:

- The policy ignores all of the traffic that does not fit the application user translation rule (for example, not from the application server).
- Only the SQL that matches the pattern for that policy is available for the special application user translation reports.

## Selective Audit Trail and specifying an empty group

---

An empty tuple group attached to a rule does not cause a rule action to match.

## Analyzer rules

---

Certain rules can be applied at the analyzer level.

Examples of analyzer rules are: user-defined character sets, source program changes, and issuing watch verdicts for firewall mode. Rules applied at the analyzer level means decisions can be made at an earlier stage.

## Character sets

---

You can use character set codes in extrusion rules.

## Session-level policies

Session-level policies and advanced session-level policies create new possibilities for detecting suspicious behavior of users of services as well as security incidents. Session-level policies are created using the Policy Builder for Data, and advanced session level policies are created as scripts using the SR language and uploaded to Guardium using the Policy Builder for Data.

Session-level policies create new possibilities for detecting suspicious service user behavior as well as security incidents. Session-level policies can detect issues such as credential stuffing, denial of service (DoS) attacks, password spraying attacks, data exfiltration, and administrative security breaches. Session-level policies include machine learning algorithms for security anomaly detection. Use session-level policy rules to effectively tailor analyzed traffic for security processing and information event management (SIEM) in real time, and evaluate the level of session trust.

The quality of a security system depends on its ability to detect suspicious behavior of service users. As Data Security Standards (DSS) and Data Protection Regulations (DPR) are updated and become more stringent, session-level policies cover important data security requirements.

Employing session-level policies is the first phase in checking the security of incoming network traffic. The policies act based on the outcome of the security check. Various types of actions are available. For example, an action might terminate the offending connection, make data transformations that are useful for reporting, or alert and warn of various security violations.

Multiple session-level policies can be used at the same time, which is installed in a user-defined order. Each session-level policy can contain multiple rules. Rules are sets of conditions with one or more associated actions. Session-level policies can be imported, exported, and managed both locally and from a central manager.

Guardium provides a number of session-level policies from the Policy Builder for Data page. Policies are in the form of templates; you can view templates, but you cannot change them. To create a session-level policy to meet your requirements, you can either create a new policy, or copy an existing template, as described in [Creating session-level policies](#).

Learn how to create and install session-level and advanced session-level policies.

- [Using session-level and advanced session-level policies](#)

Use session-level policies or advanced session-level policy scripts to validate incoming packets and define actions based on the result. This guide describes the criteria, actions, and other elements available for creating session level policies and advanced session level policies.

- [Criteria](#)

- [Tuples](#)

- [Actions](#)

- [Action parameters](#)

- [Session-level policy examples](#)

To help you understand session-level policies, Guardium provides a number of examples with descriptions. The examples include both the Guardium UI and SR language methods.

- [Known limitations](#)

The following known limitations apply to session-level policies and advanced session-level policies.

## Creating session-level and advanced session-level policies

Learn how to create and install session-level and advanced session-level policies.

- [Creating session-level policies](#)

Use the Policy Builder for Data to create and install session-level policies.

- [Creating advanced session-level policies](#)

Use advanced session-level policy scripts to validate incoming packets and define actions based on the result. The action can send the request back to the S-TAP, transform the runtime data for the analyzer, and prepare the data for the parser or logger.

## Creating session-level policies

Use the Policy Builder for Data to create and install session-level policies.

### About this task

The overall workflow for defining session-level policies is the same as for standard data-security policies. For information about defining policies, see [Creating and installing a policy and policy rules](#). This procedure focuses on unique aspects of creating session-level policies.

### Procedure

1. Navigate to Protect > Security Policies > Policy Builder for Data.
2. Create a new policy or clone an existing policy.

- To create a new policy, click the  icon.

- To clone a policy, select an existing session level policy template from the Security Policies window and then click the  icon.

- Important: Policies that are installed from the central manager to an aggregator might appear in the aggregator UI as not installed because you cannot install policies on an aggregator. To determine whether a policy is installed, run the [list\\_installed\\_policies](#) API or check in the Policy Builder for Data page for each aggregator.

The Create New Policy window displays.

3. For a new policy, from the Name and properties pane, set the policy type to Session level policy and define a policy name.

Attention: After a policy is saved as a session-level policy, you cannot change it to a data-security policy.

4. Click the Rules pane to begin working with policy rules, then create a new rule by clicking the  icon.

- a. From the Rule definition pane of the Create New Rule window, define a Rule name.

For session-level policies, the Rule type field is predefined to Session.

- b. Click the Rule criteria pane and begin defining rule parameters and values.

- Use the menus to select individual parameters and define selection operators, and then specify values or groups to match.

- Use the  and  icons to add or remove criteria from the rule.

For more information about rule criteria, see [Rule definition fields](#) and [Values and groups of values in rules](#)

Attention: Unlike standard data-security policies, all rule criteria available for session-level policies are based on the session.

- c. Click the Rule action pane to begin working with rule actions, then create a new rule action by clicking the  icon and selecting an action. If further configuration is necessary, use the Add New Action window to define the action. For more information about available actions, see the [Actions](#) section of the [Using session-level and advanced session-level policies](#).
- d. When finished defining the rule, click OK to return to the Rules pane.  
Continue working with rules as needed.

5. When finished defining the policy and its rules, click OK to save the policy and return to the Security Policies table.

## What to do next

Install policies by selecting a policy from the Security Policies window and clicking  Install. Select the Installation action you want and click OK to install the policy.

Installed policies are indicated by a  in the Installed column.

- [Creating tuple parameters for session-level policies](#)

Combine several session-level policy parameters into a single parameter known as a tuple. Compared to using multiple single parameters, where each parameter matches any value in a group, tuple parameters allow finer control by defining only specific combinations of values to match.

## Creating tuple parameters for session-level policies

Combine several session-level policy parameters into a single parameter known as a tuple. Compared to using multiple single parameters, where each parameter matches any value in a group, tuple parameters allow finer control by defining only specific combinations of values to match.

### Before you begin

Create or edit a session-level policy using the Policy Builder for Data, and begin creating or editing a policy rule. This procedure begins with either the Create New Rule or Edit Rule window open.

### Procedure

1. From the Rule criteria panel, select Tuples from the Session level criteria menu.
2. Define a new group or select and edit an existing group to use with the tuple.
  - To define a new group:
    - Use the  icon to open the Create new group dialog.
    - Use the Description field to provide a name for the group.
    - Use the General tab to configure the group. For more information, see [Using the group builder](#).
    - Use the Tuple parameters menu to select parameters to include in the tuple. Use the  icon to specify the tuple order.
  - To edit an existing group, select the group from the menu and use the  icon to open the Edit group dialog. If you do not need to edit the existing group, simply select it and continue defining criteria for the session-level policy.
3. Select the Members tab to populate and work with group members.  
Use the , , and  icons to add, edit, or remove group members. When adding members, the Add member dialog displays fields matching the tuple criteria.  
Note:  
An empty member matches any value. Use GUARDIUM://empty to match an empty value.

## Creating advanced session-level policies

Use advanced session-level policy scripts to validate incoming packets and define actions based on the result. The action can send the request back to the S-TAP, transform the runtime data for the analyzer, and prepare the data for the parser or logger.

### About this task

This procedure describes how to install advanced session-level policies from the Policy Builder for Data. It assumes that you are familiar with creating advanced session-level policies using the SR language or have completed SR scripts ready to import.

### Procedure

1. Open Protect  Security Policies  Policy Builder for Data.
2. Use the  icon to create a new policy.
3. From the Create New Policy window, set the Type to Advanced session level policy and enter a Name for the new policy.
4. Optional: Use the Roles button to assign roles to the policy.
5. Open the Rule panel.
6. Edit or import an advanced session-level policies script.
  - Edit a script:
    - Use the  icon to begin editing an advanced session-level policies script.
    - Use the Check syntax button at any time to validate the script.
    - When you have finished editing the script, click OK.
  - Import a script:
    - Use the Import from file button to open the Select an advanced session level policies script to upload dialog.

- Use the Browse button and select a file to upload. The script file should be plain text and include a valid advanced session level policies script.
  - Use the Upload button to import the script. If there is an existing script, either Append the new script or Replace the existing scripts.
  - You can continue editing the script directly in the Guardium UI. Use the Check syntax button at any time to validate the script.
  - When you have finished editing the script, click OK.
7. If the script validates, the policy is saved and can be installed from the Security Policies table. If the script fails to validate, review the error message and update the script.
- 

## Using session-level and advanced session-level policies

Use session-level policies or advanced session-level policy scripts to validate incoming packets and define actions based on the result. This guide describes the criteria, actions, and other elements available for creating session level policies and advanced session level policies.

In the SR language examples, you can map the parameters (that is, parameter = *variable*) directly to most UI examples. Take for example the following SR language snippet:

```
SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' SOURCE_PROGRAM = 'JAVA%' SERVER_IP = '20.20.20.20')
 {
 IGNORE_SESSION
 }
 IF (*)
 {
 IGNORE_SESSION PACKETS_LIMIT = 50
 }
}
```

- CLIENT\_IP criteria in the SR language maps to Client IP address in the UI
- SERVER\_IP maps to Server IP address.
- SOURCE\_PROGRAM maps to Source application.

In addition, the { IGNORE\_SESSION } code in the SR language maps to the IGNORE SESSION rule action in the UI.

In this guide, you can find the mappings between the SR language and UI elements.

In the guide, the UI name is generally on the left, and the SR language name is on the right. The SR language name is shown in parentheses. For example, looking at search parameters:

Request types available for actions with search parameters:

```
LOGIN FAILED (LOGIN_FAILED)
PREPARED STATEMENT (PREP_STAT)
RPC (RPC)
SQL (SQL)
SQL ERROR (SQL_ERROR)
SQL SUCCESS (SQL_SUCCESS)
```

LOGIN FAILED in the UI maps to LOGIN\_FAILED in the SR language, PREPARED STATEMENT in the UI maps to PREP\_STAT in the SR language.

- [Wildcards](#)
- [Tokens](#)  
Tokens expand to the values of the token name for the current session.
- [IPv6 support](#)  
Session-level and advanced session-level policies support both IPv4 and IPv6 addresses. Any IPv6 notation is supported.
- [Groups](#)  
Groups are combinations of parameters that can be used in rule conditions.
- [Grammar](#)  
Overall syntax and grammar used for creating advanced session-level policies.
- [Unsupported databases for session-level policies](#)

## Wildcards

Session-level policies and the SR language support wildcards:

- % matches zero or more characters
- ? matches a single character

The % wildcard is slower than the ? wildcard.

Wildcards are allowed for the following parameters:

- Groups
- Session-level criteria
- Search pattern (SEARCH\_PATTERN)
- Search prefix (SEARCH\_PREFIX)
- Tuples

This example has the following rule and rule actions, and uses wildcards for session-level criteria.

- Session level criteria
  - Database type = ORA%
  - Database user = ?SCOTTt%
  - Client host name = rh7u6x64t.%

- Rule action
  1. *TRANSFORM SOURCE PROGRAM NAME*
    - Source = *SOURCE PROGRAM NAME*
    - Search prefix = *SQL PLUS*
    - Output format = *PEREL\_PROGRAM*
  2. *DISCARD SESSION*
    - a. Request type = *SQL*
    - b. Search prefix = *SYSTEM*

SR Language example:

```
SR_POLICIES
{
 IF (DB_TYPE = 'ORA%' DB_USER = '?COTT%' CLIENT_HOST_NAME = 'rh7u6x64t.%')
 {
 TRANSFORM_SOURCE_PROGRAM SEARCH_PREFIX = 'SQLPLUS' OUTPUT_FORMAT = 'PEREL_PROGRAM'
 DISCARD_SESSION REQ_TYPE = SQL SEARCH_PATTERN = 'SYSTEM'
 }
}
```

The following values match:

- **DB\_TYPE** matches ORACLE
- **DB\_USER** matches SCOTT
- **CLIENT\_HOST\_NAME** matches rh7u6x64t.domain.name.com

## Tokens

Tokens expand to the values of the token name for the current session.

Supported tokens:

- \$(ACTUAL\_CLIENT\_IP)\$
- \$(ANALYZED\_CLIENT\_IP)\$
- \$(AUTH\_TYPE)\$
- \$(CLIENT\_HOST\_NAME)\$
- \$(CLIENT\_OS\_NAME)\$
- \$(CLIENT\_IP)\$
- \$(CLOGIN\_FAILURES)\$
- \$(COMMAD)\$
- 12.1 and later \$(COLLECTOR\_HOST\_NAME)\$
- \$(CSESSIONS)\$
- \$(CTIMEZONE)\$
- \$(DATETIME)\$
- \$(DB\_NAME)\$
- \$(DB\_TYPE)\$
- \$(DB\_USER)\$
- \$(ERROR)\$
- \$(NET\_PROTOCOL)\$
- \$(OS\_USER)\$
- \$(PE\_EXCEPTION)\$
- \$(SENDER\_IP)\$
- \$(SERVER\_DESCRIPTION)\$
- \$(SERVER\_HOST\_NAME)\$
- \$(SERVER\_IP)\$
- \$(SERVER\_OS\_NAME)\$
- \$(SERVICE\_NAME)\$
- \$(SESSION\_INFO)\$ (return format: client\_ip:client\_port <-> server\_ip:server\_port)
- 12.1 and later \$(SESSION\_KEY)\$
- \$(SOURCE\_PROGRAM)\$
- 12.1 and later \$(STATEMENT\_KEY)\$

Tokens are allowed in:

- Exception message (EXC\_MSG)
- Output format (OUTPUT\_FORMAT)
- Search pattern (SEARCH\_PATTERN)
- Search prefix (SEARCH\_PREFIX)

Example:session\_level\_policies\_actions\_transform

```
SR_POLICIES
{
 IF(OS_USER = 'SALLY')
 {
 TRANSFORM_OS_USER SOURCE = CLIENT_HOST_NAME SEARCH_PATTERN = '$(SERVER_HOST_NAME)$' OUTPUT_FORMAT = (DB_USER)
 }
}
```

If CLIENT\_HOST\_NAME is the same as SERVER\_HOST\_NAME, replace OS\_USER with DB\_USER only when OS\_USER = 'SALLY'.

## IPv6 support

Session-level and advanced session-level policies support both IPv4 and IPv6 addresses. Any IPv6 notation is supported.

Example:

```
SR_POLICIES
{
 IF (CLIENT_IP = '::ffff:150.49.108.36')
 {
 TRANSFORM_SOURCE_PROGRAM MATCH_PATTERN = '^.*$' OUTPUT_FORMAT = 'SPECIAL JDBC'
 }
}

SR_POLICIES
{
 IF (CLIENT_IP = '150.49.108.36')
 {
 TRANSFORM_SOURCE_PROGRAM MATCH_PATTERN = '^.*$' OUTPUT_FORMAT = 'SPECIAL JDBC'
 }
}
```

This shows two logically equal rule conditions using IPv6 and IPv4 notation.

Example:

```
SR_POLICIES
{
 IF (SERVER_IP = ('',1) SERVER_PORT = 1521)
 {
 TRANSFORM_SOURCE_PROGRAM MATCH_PATTERN = '^.*$' OUTPUT_FORMAT = 'SPECIAL JDBC'
 }

 GROUP_ID = 1 TYPE = IP_ADDRESS SIZE = 2 #CLIENT_IP GROUP
 {
 '150.49.108.36' '2002:920:C000:3146::6'
 }
}
```

This example shows a policy for a database server with dual IPv4 and IPv6 addresses.

Example:

```
SR_POLICIES
{
 IF (CLIENT_IP = '::FFFF:DCCC:ED91' CLIENT_NET_MASK = '::FFFF:DCCC:0000' SENDER_IP = '2002:920:C000:3146::6')
 {
 TRANSFORM_OS_USER MATCH_PATTERN = '^.*$' OUTPUT_FORMAT = 'SPECIAL OS_USER'
 }
}
```

This shows how network masks for IPv6 addresses are supported in a format similar to IPv4.

Example:

```
SR_POLICIES
{
 IF (CLIENT_IP = '0.0.0.0' SERVER_IP = '9.70.157.177' ANALYZED_CLIENT_IP = '9.70.144.184' ANALYZED_CLIENT_NET_MASK = '255.255.255.0')
 {
 TRANSFORM_SERVER_DESC SEARCH_PREFIX = '9.' SOURCE = ANALYZED_CLIENT_IP OUTPUT_FORMAT = '(.*)'
 }
}

SR_POLICIES
{
 IF (CLIENT_IP = '0.0.0.0' SERVER_IP = '9.70.157.177' ANALYZED_CLIENT_IP = '::ffff:9.70.144.184' ANALYZED_CLIENT_NET_MASK = '::ffff:0000:0000')
 {
 TRANSFORM_SERVER_DESC SEARCH_PREFIX = '9.' SOURCE = ANALYZED_CLIENT_IP OUTPUT_FORMAT = '(.*)'
 }
}
```

This shows using ANALYZED\_CLIENT\_IP as condition with IPv4 and IPv6 addresses. The rule copies the value from the column ANALYZED\_CLIENT\_IP into the column SERVER\_DESC of table GDM\_ACCESS.

## Groups

Groups are combinations of parameters that can be used in rule conditions.

Multiple groups can be used in one rule.

Session level policy groups are defined like any other policy group using the Policy builder for data.

Advanced session-level policy groups are defined using the SR language as shown in the following examples.

Note:

- To specify a group within the policy, include one element of the group followed by the group ID. In the following example, `admin` is one of the elements in group 1. Specify the remaining group elements at the end of the policy.
- Group contents are always put at the end of policy snippets.

Example:

```
SR_POLICIES
{
 IF (DB_USER != ('admin',1) { VERDICT_ATTACH }

 GROUP_ID = 1 SIZE = 3 { 'root' 'sys' 'system' }
}
```

In this example, the condition includes `DB_USER`, `admin`, and all users from `GROUP_ID = 1`. Here `IF(*)` represents no condition

Example:

```
SR_POLICIES
{
 IF (CLIENT_IP != '192.168.0.1' DB_USER = 'SCOTT') { VERDICT_ATTACH SELECT_SESSION }

 IF (CLIENT_IP != ('192.168.0.2',176) DB_USER = 'SCOTT') { VERDICT_DETACH }

 IF (CLIENT_IP != '192.168.0.3' DB_USER = ('',177) { VERDICT_TERMINATE }

 IF (*) { IGNORE_SESSION_PACKETS_LIMIT = 30 }
 IF (*) { TRANSFORM_SOURCE_PROGRAM MATCH_PATTERN = '' OUTPUT_FORMAT = 'SPECIAL JDBC' }

 GROUP_ID = 176 TYPE = IP_ADDRESS SIZE = 8
 {
 '192.168.0.2' '192.168.0.3' '192.168.0.4'
 '192.168.0.5' '192.168.0.6' '192.168.0.7'
 '192.168.0.8' '192.168.0.9'
 }

 GROUP_ID = 177 SIZE = 2 { 'LEONID' 'SA' }
}
```

In this example, the groups represent different data types and `''` represents no condition.

## LIKE and NOT LIKE operator for groups

In the SR language used for advanced session-level policies, groups support the LIKE and NOT LIKE operators to search for wildcard values.

Example:

```
SR_POLICIES
{
 IF (CLIENT_IP NOT LIKE ('192.168.0.2',176) DB_USER = 'SCOTT') { VERDICT_DETACH }

 IF (CLIENT_IP != '192.168.0.3' DB_USER LIKE ('',177) { VERDICT_TERMINATE }

 GROUP_ID = 176 TYPE = IP_ADDRESS SIZE = 2
 {
 '192.168.%' '192.168.%'
 }

 GROUP_ID = 177 SIZE = 2 { 'LEON%' 'SA%' }
}
```

CIDR notation is supported for LIKE and NOT LIKE groups.

Examples:

```
192.168.1% Matches any IP starting with 192.168.1
2002:0920:C000:3146% Matches any IP starting with 2002:0920:C000:3146
192.168.128.1/17 11111111 11111111 10000000 00000000
 Allows 32K-2 (hosts) in the subnet(15 bits for the hosts)
 Similar to subnet mask of 255.255.128.0
2002:0920:C000:3146::0/61 11111111 11111111 11111111 11111111 11111111 11111111
 11111000 00000000 00000000 00000000 00000000 00000000
 00000000 00000000
 Allows 2^67 hosts on subnet 2002:0920:C000:3146::0/61
```

Note: For session-level policies created using the policy builder, use the following keywords to have a UI group considered as LIKE or NOT LIKE by default:

- `&#like:yes`
- `&#like:no`

## Grammar

Overall syntax and grammar used for creating advanced session-level policies.

Write advanced session-level policies using the basic format:

```
SR_POLICIES {
```

```

[TUPLES _ GROUP1, ... TUPLES _ GROUPn]

#RULE 1
IF (<conditions>)
{
 ACTION1

 ACTIONn
}

.....
#RULE m
IF (<conditions>)
{
 ACTION1

 ACTIONm
}

[GROUP1, GROUPk]

```

The complete advanced session-level policies scripting language (SR language) is expressed as:

- Mandatory fields: <...>
- Optional fields: [...]
- Allowed values separated by: |
- Rules, conditions, actions, tuples, and groups may contain one or more values.

To view the scripting language grammar, take the following steps:

1. Browse to the Guardium Security Policies > Create New Policy page.
2. Click Advanced session level policy.
3. Enter a new name for the policy and then click Rules.
4. From the top of the scripting worksheet, click Show Grammar.

## Unsupported databases for session-level policies

Databases and protocols that do not support session-level policies:

- CIFS
- Data Sets on z/OS
- Db2 on z/OS
- FTP
- IBM System i
- IMS

## Criteria

Criteria supported by session-level policies and advanced session-level policies include:

- Analyzed client IP address (ANALYZED\_CLIENT\_IP)  
Use this option when sessions are decrypted and the client IP address is not available.  
Restriction: Criteria ANALYZED\_CLIENT\_IP is the result of correlation encrypted and not encrypted sessions. This criteria is not always available.
- Analyzed client net mask (ANALYZED\_CLIENT\_NET\_MASK) (only supports = operator)  
Analyzed client net masks are possible additions to the IP address criteria. They represent the criterion IP address as a range of values.
- Application user (APP\_USER)
- Authentication type (AUTH\_TYPE)  
Use to differentiate by authentication methods. Allowed values:
  - WINDOWS
  - DATABASE
  - KERBEROS
  - ACTIVE\_DIRECTORY
  - NO\_AUTH
  - PLAIN
  - HTTP\_BASIC
  - BEARER
  - FEDERATION
  - GSSAPI
  - SCRAMSHA1
  - SCRAMSHA256
  - OS
  - SAML
  - LDAP
  - COOKIE
- Client host name (CLIENT\_HOST\_NAME)
- Client IP address (CLIENT\_IP)
- Client net mask (CLIENT\_NET\_MASK) (only supports = and != operators)

Client net mask is only available when using the client IP address parameter.

- Client operating system (CLIENT\_OS\_NAME)
- Command (COMMAND)

Search from the beginning of the SQL and do not use parser output. For example, with the statement `select sysdate from dual`, select will be recognized as the command.

When session-level policies use SQL criteria like command, object, or field, Guardium invokes the parser for these items before processing session-level criteria. If SQL criteria are not present in the policy, Guardium processes session-level criteria first and invokes the parser afterward.

- Client time zone (CTIMEZONE)

Use to limit the rule to a specific time zone of the client.

- Database name (DB\_NAME)

- Database protocol (DB\_PROTOCOL)

Use to differentiate databases by type and by the protocol version a database is using.

- Database type (DB\_TYPE)

- Database user (DB\_USER)

- Error (ERROR)
  - LOGIN\_FAILED

Use to search for specific database errors. Can be used to check for LOGIN\_FAILED.

- REQUEST\_ERROR

Use REQUEST\_ERROR in Tuples. It is not recommended to use REQUEST\_ERROR in Groups.

Note:

- Error criteria will be set to true for any error except LOGIN\_FAILED.

- Session level policy's ERROR criteria REQUEST\_ERROR is equivalent to Data Security Policy's Exception type criteria SQL\_ERROR.

- Field (FIELD)

When session-level policies use SQL criteria like command, object, or field, Guardium invokes the parser for these items before processing session-level criteria. If SQL criteria are not present in the policy, Guardium processes session-level criteria first and invokes the parser afterward.

- Incident (INCIDENT) (only supports = and != operators)

This detects problems related to protocol-level security. Allowed values:

- CREDENTIAL\_STUFFING

- PLAIN\_PASSWORD

Check if password is sent in plain text.

- WEAK\_PASSWORD

Check if password uses weak encryption.

- Label (LABEL) (supports = and != operators, and can contain tokens)

Use with LABEL actions to trigger actions based on a text string (the label). For more information, see [Label action and criteria](#).

- Literal (LITERAL) (supports =, !=, IN GROUP and NOT IN GROUP operators)

Use LITERAL to look for a specific value, or group of values, in a SQL statement.

- Network protocol (NET\_PROTOCOL)

The Policy Builder for Data provides a menu of valid network protocol values as well as supporting user-entered text values.

- Object (OBJECT)

When session-level policies use SQL criteria like command, object, or field, Guardium invokes the parser for these items before processing session-level criteria. If SQL criteria are not present in the policy, Guardium processes session-level criteria first and invokes the parser afterward.

- Operating system user (OS\_USER)

- Sender IP address (SENDER\_IP)

- Sender net mask (SENDER\_NET\_MASK) (only supports = and != operators)

Sender net mask is only available when using the sender IP address parameter.

- Server description (SERVER\_DESC)

Use for optional description of the database server. For example, from Guardium® Data Protection version 12.1 and later Server Description displays the cluster name of the Cloudera Data Platform.

- Server host name (SERVER\_HOST\_NAME)

- Server IP address (SERVER\_IP)

- Server net mask (SERVER\_NET\_MASK) (only supports = and != operators)

Server net mask is only available when using the server IP address parameter.

- Server operating system (SERVER\_OS\_NAME)

- Server port (SERVER\_PORT)

Use server port to differentiate multiple instances of the same database type on a single host.

- Service name (SERVICE\_NAME)

- Session (SESSION) (only supports = and != operators)

Allowed values:

- ADMIN

Check for administrator privileges. Supported for Oracle, PostgreSQL, Vertica, GreenPlum, Aster, and DB2 (DAS).

- ENCRYPTED

- FAILOVER

- FLAT\_LOG

- GET\_USERNAME\_PROBLEM

Applies when the Oracle Analyzer has identified a database user name retrieval issue.

- HIGH\_TRUST  
Apply actions to all sessions marked with HIGH TRUST\_LEVEL(GDM\_SESSION).
- LOCAL
- LOGGED
- LOGIN\_MISSED
- LOGIN\_RESTORED
- LOW\_TRUST  
Apply actions to all sessions marked with LOW TRUST\_LEVEL(GDM\_SESSION).
- MID\_STREAM
- NOT\_SUPPORTED\_PLATFORM
- PE\_ANOMALY  
Create rules when there is an exception identified by the probability engine.
- SENSITIVE  
Identify if session matches an extrusion pattern.
- SNIF\_LOGIN\_NOT\_COMPLETE
- STAP\_LOGIN\_NOT\_COMPLETE  
For UNIX S-TAP only: This criterion is supported for Linux-UNIX S-TAP only.  
A flag that indicates that priority packets were dropped within the first *N* packets of the session, where *N* is configured by the priority\_count parameter in the S-TAP guard tap.ini file.  
To track losses by S-TAPs or K-TAPs in reports, the transmit\_session\_losses\_metadata guard\_tap.ini parameter must be enabled (set to 1).
- For more information, see the [transmit\\_session\\_losses\\_metadata](#) and [priority\\_count](#) guard\_tap.ini parameters.
- STAP\_PACKETS\_DROPPED  
For UNIX S-TAP only: This criterion is supported for Linux-UNIX S-TAP only.  
A flag that indicates that packets were dropped within a session on the S-TAP side.
- TAP\_DECRYPTED
- U\_STAP
- W\_STAP
- SERVER\_DATA  
Supports patterns to search in server responses. Criteria can contain configuration parameters in the form of a set of bits, a search pattern in the form of a string (with wildcards), or a regular expression.  
Restriction:
  - Cannot be used with groups and tuples.
  - Only supports = operator.
  - This criterion can be configured to send data values to the logger.
  - For performance reasons, this criterion is checked last after all other criteria in the rule.
  - If built-in configuration options are set, then they have precedence over parameters defined in action CONFIGURE.

Syntax:

```
SERVER_DATA [$(configuration)$]<string_pattern|guardium_regex>
```

Where *configuration* is one of the following. Except where noted, the default is no.

- *count* - For regular expressions only. Data values are not provisioned. Counts only the number of matches.
- *values* - For regular expressions only. The number of matches is counted, and the data values are extracted.
- *sensitive* - Sets the rule session parameter as SENSITIVE, so that subsequent SESSION criteria can trigger specific actions related to SENSITIVE sessions.
- *masked* - For regular expressions only. Masks data values. (The data is masked with the "\*" character, leaving the last 4 characters unchanged).
- *luhn* - For regular expressions only. Applies a LUHN verification to extracted data. Used by default for credit card patterns. For other cases default is no.
- *greedy* - Sets the SERVER\_DATA criteria to verify all server response packets from the point when the first pattern was found, even if COMMAND or STATEMENT criteria do not match. When set to greedy, COMMAND and STATEMENT criteria of the rule are not verified.
- *lazy* - Disables the rule with a SERVER\_DATA criterion for the session where first 20 packets (priority packets) were checked.

The Policy Builder for Data provides controls for defining the server data configuration options.

In addition, <guardium\_regex> is one of the patterns described in [Guardium regex patterns](#).

- Session start time range (SESSION\_START) (only supports = and != operators)

This executes rules within a specific time range, for example to avoid logging and processing data from known periods of database optimization or back-up. For more information and detailed examples, see [Scheduling with SESSION\\_START examples](#).

- Source application (SOURCE\_PROGRAM)
- Statement (STATEMENT)

Use with wildcards to search the SQL statement.

Statement can be specified in the following format:

```
[Length] [Pattern] Length := $(integer[-integer])$
Pattern := <string>|<string with wildcards>|<guardium_regex>]
```

Where <guardium\_regex> is one of the patterns described in [Guardium regex patterns](#).

The Policy Builder for Data provides controls for defining the statement criteria based on maximum length, minimum length, length unit, and whether to check for bind variables.

Use the STATEMENT criterion with the SERVER.

Note: Session level policy's STATEMENT criteria is equivalent to the Data security policy's PATTERN criteria.

- Tuple (TUPLES)

Note:

- Check for empty criteria using either != '%' or = 'guardium://empty'.

- Hex values can be matched using \hd<xx> in criteria, patterns, group members, or tuple elements. For example: \hdf~~f~~OPERO matches <0xff>OPERO
- Identify binary non-ASCII symbols using the following: DB\_USER != 'GUARDIUM://LATIN'
- 

## Guardium regex patterns

---

Some criteria support <guardium\_regex>, which indicates a special regular expression that can include one of the following patterns:

- GUARDIUM://CREDIT\_CARD/MASTERCARD
- GUARDIUM://CREDIT\_CARD/VISA
- GUARDIUM://CREDIT\_CARD/AMEX
- GUARDIUM://CREDIT\_CARD/DINERS
- GUARDIUM://CREDIT\_CARD/DISCOVER
- GUARDIUM://CREDIT\_CARD/JCB
- GUARDIUM://CREDIT\_CARD/UNIONPAY
- GUARDIUM://CREDIT\_CARD/[MASTERCARD][|VISA][|AMEX][|DINERS][|DISCOVER][|JCB][|UNIONPAY]
- GUARDIUM://CREDIT\_CARD – Combines all 7 types of credit cards.
- GUARDIUM://PCI\_TRACK\_DATA

---

## Tuples

If several groups represent a union of parameters, create a tuple group to represent an intersection of parameters. Only one tuple group is allowed per rule.

Supported **TYPE** options:

- Analyzed client IP address (ANALYZED\_CLIENT\_IP)
- Application user (APP\_USER\_NAME)
- Authentication Type (AUTH\_TYPE)
- Client host name (CLIENT\_HOST\_NAME)
- Client IP address (CLIENT\_IP)
- Client operating system (CLIENT\_OS\_NAME)
- Command (COMMAND)
- C Time Zone (CTIMEZONE)
- Database name (DB\_NAME)
- Database protocol (DB\_PROTOCOL)
- Database type (DB\_TYPE)
- Database (DB\_USER)
- Error (ERROR)
- 12.1 and later Field (FEILD)
- Incident (INCIDENT)
- Network protocol (NET\_PROTOCOL)
- 12.1 and later Object (OBJECT)
- Operating system user (OS\_USER)
- 12.1 and later Literal (LITERAL)
- Sender IP address (SENDER\_IP)
- Server description (SERVER\_DESC)
- Server host name (SERVER\_HOST\_NAME)
- Server IP (SERVER\_IP)
- Server operating system (SERVER\_OS\_NAME)
- Server port (SERVER\_PORT)
- Service name (SERVICE\_NAME)
- Session (SESSION)
- Source application (SOURCE\_PROGRAM)
- Statement (STATEMENT)

Advance session-level policy examples

Example 1

```
TUPLES_GROUP_ID = 1 TYPE = (DB_USER OS_USER) SIZE = 5
{
 'sys%+oracle%' 'qa+q_a'
 '%scott+admin' 'guardium+guardium_%'
 '%system+admin'
}
```

This is an example of a 2-tuple group with five members.

Example 2

```
IF (SERVER_PORT = 1521 TUPLES = ('',1))
{
 TRANSFORM_DB_USER WHERE SOURCE = OS_USER OUTPUT_FORMAT = 'OPS$(.*)'
```

This is an example with tuples represented as parameters where the rule refers to **tuples\_group\_id = 1**. The **TRANSFORM\_DB\_USER** action takes the **OUTPUT\_FORMAT** and writes it to the **DB\_USER** field, where **OUTPUT\_FORMAT = 'OPS\$(.\*)'** means **OPS\$** plus all data from the field **OS\_USER**. **OUTPUT\_FORMAT** is a string, and it may include plain text, a regular expression result group, or the entire source string.

Example 3

```

SR_POLICIES
{
 TUPLES_GROUP_ID = 1 TYPE = (DB_USER OS_USER) SIZE = 6
 {
 '%sys+oracle%' 'qa+qa' 'sc??t+syb%'
 'sc??t+oracle%' 'system+admin' '%sc%+spo%'
 }
 TUPLES_GROUP_ID = 2 TYPE = (DB_USER OS_USER) SIZE = 4
 {
 '%sys+oracle%' 'qa+qa'
 '%sc%+spo%' 'OPS%+spo%'
 }

 IF (DB_USER != ('',1) { VERDICT_ATTACH }

 IF (SERVER_PORT = 1521 TUPLES = ('',1))
 {
 TRANSFORM_DB_USER SOURCE = OS_USER OUTPUT_FORMAT = 'OPS(.*)'
 }

 IF (TUPLES = ('',2))
 {
 TRANSFORM_CLIENT_HOST_NAME SEARCH_PREFIX = 'ENCORE' OUTPUT_FORMAT = 'PEREL'
 }

 GROUP_ID = 1 SIZE = 5 { 'root' 'sys' 'sa' 'admin' 'system' }
}

```

This is an example of tuples and groups used in the same policy. There can be multiple tuple groups in the same policy, but one rule can use only one tuple group. Create additional rules if you need to use additional tuple groups.

## Actions

Define audit, alerting, parsing and other actions to take when session-level policy rules are matched.

- [Audit and ignore session actions](#)  
Selective audit actions are triggered in analyzers before the parser/logger starts to receive session requests. Selective audit can save sniffer resources by reducing the load on relatively slower modules that limit sniffer performance.
- [Mark session actions](#)  
Mark session (MARK\_SESSION) is used to set a trust-level score from session-level policies or to control the learning of the real-time trust evaluator.
- [Alert and Log actions](#)
- [Parse actions](#)
- [Configure actions](#)  
The configure action is used to adjust analyzer settings or activate session-level policy features.
- [Transform actions](#)
- [Exception actions](#)
- [Extrusion actions](#)  
Use the REDACT and GET\_SERVER\_DATA actions to manage sensitive data.

## Audit and ignore session actions

Selective audit actions are triggered in analyzers before the parser/logger starts to receive session requests. Selective audit can save sniffer resources by reducing the load on relatively slower modules that limit sniffer performance.

### Audit only

This action is only available for policies that use the Selective Audit Trail setting. Audit Only logs the construct that triggered the rule. For a Selective Audit Trail policy, no constructs are logged by default, so use this selection to indicate which constructs you want to log. For example, for the Application Events API, if you want to log database usernames for reporting, use this action (otherwise, in this example, the username is blank).

### Discard session (DISCARD\_SESSION)

Discard session filters out the entire session. It sends a request to the S-TAP to ignore the session and not forward network traffic to the collector, for example encrypted data. Discard session supports search parameters and works with all supported traffic.

The following examples compare ignore session to discard session:

```

SR_POLICIES
{
 IF (DB_USER = 'SQLUSER1' SOURCE_PROGRAM = 'Vault')
 {
 DISCARD_SESSION
 }
}

SR_POLICIES
{
 IF (DB_USER = 'SQLUSER1' SOURCE_PROGRAM = 'Vault')
 {
 IGNORE_SESSION
 }
}

```

```
 }
```

During the login handshake, the S-TAP sends the initial DB\_USER and SOURCE\_PROGRAM values. Later, another packet might have the correct values for DB\_USER and SOURCE\_PROGRAM. The rule conditions for ignore session are checked earlier than the conditions for discard session, meaning that the discard session action is triggered later than the ignore session action.

## Ignore session (IGNORE\_SESSION)

Ignore session filters out the entire session. It sends a request to the S-TAP to ignore the session and not forward network traffic to the collector, for example encrypted data. Filtered sessions are not created, processed, or logged. Use ignore session with criteria that are known from the start of the session, for example database type, client IP address, or server IP address.

The following example filters out Hadoop traffic.

```
SR_POLICIES
{
 IF (DB_TYPE = 'HADOOP')
 {
 IGNORE_SESSION
 }
}
```

The following example uses (\*) to unconditionally ignore any sessions that are not logged after the first 50 packets arrive at the collector.

```
SR_POLICIES
{
 IF (*)
 {
 IGNORE_SESSION PACKETS_LIMIT = 50
 }
}
```

## Ignore request (IGNORE\_REQUEST)

Ignore requests that match search parameters.

This example ignores any SELECT statement that contains the pattern WARNING.

```
IGNORE_REQUEST WHERE REQ_TYPE = SQL SEARCH_PREFIX = 'SELECT' SEARCH_PATTERN = 'WARNING'
```

Note: For an Oracle data source, if you specify an IGNORE\_REQUEST action for a DBMS\_SESSION statement that updates some session parameters after parsing, then those session fields might not be set correctly for subsequent requests.

## Select session (SELECT\_SESSION)

Select session is the opposite of the ignore session action. It allows easy filtering and does not send a request to the S-TAP.

This example allows all sessions where the DB\_TYPE is not Hadoop. If the session is Hadoop, it is filtered by the sniffer.

```
IF (DB_TYPE != 'HADOOP')
{
 SELECT_SESSION
}
```

This example allows the collector to work only on the specified group of IPV6 S-TAPs.

```
IF (SENDER_IP = 'ad:f0:e1::1' SENDER_NET_MASK = 'ad:f0:e1::0')
{
 SELECT_SESSION
}
```

## Soft discard (SOFT\_DISCARD)

Soft discard is the same as discard session but does not send a command to the S-TAP and all processing is done on the collector. This provides something like a revocable discard that is available on a per-session basis. Soft discard is good for short sessions.

## Stop soft discard (STOP\_SOFT\_DISCARD)

Used for revoking the soft discard action, stop soft discard can revoke soft discard for individual sessions based on search parameters.

## Log access only (LOG\_ACCESS\_ONLY)

Log access forwards only the first required number of packets to the logger. No command is sent to the S-TAP. Log access allows only the following to pass to the logger: ACCESS\_INFO, FIRST\_REQUEST, LOGIN\_FAILED, ERRORS, TYPE\_UPDATE, TYPE\_LOGOUT, and TYPE\_LOGOUT\_TIMEOUT.

## Stop log access only (STOP\_LOG\_ACCESS\_ONLY)

Used for revoking the log access only action, stop log access can revoke log access only for individual session based on search parameters.

## Mark session actions

Mark session (MARK\_SESSION) is used to set a trust-level score from session-level policies or to control the learning of the real-time trust evaluator.

The mark session (MARK\_SESSION) action requires the as (AS) parameter. The as (AS) parameter supports the following values:

- Skip ML training phase (SKIP\_ML\_TRAINING\_PHASE)
- Skip ML evaluation (SKIP\_ML\_EVALUATION)
  - With (WITH)
- ML trusted (ML\_TRUSTED)
  - With (WITH)
  - Exception message (EXC\_MSG)
  - Track (TRACK)
    - True (TRUE)
    - False (FALSE)
  - Distinct (DISTINCT)
  - Label (LABEL)
- Set trust (SET\_TRUST)
  - With (WITH)
  - Exception message (EXC\_MSG)
  - Track (TRACK)
    - True (TRUE)
    - False (FALSE)
  - Distinct (DISTINCT)
  - Label (LABEL)

---

## Alert and Log actions

### Alert actions

---

Alert actions are only available through the policy builder for data UI for session-level policies and are not supported for advanced session-level policies. The following alert actions are available:

- Alert daily
- Alert once per session
- Alert only
- Alert per match
- Alert per time granularity

Alert actions allow an *exception message* that is added as part of the last error description in the alert message. Some alert actions also support the [distinct \(DISTINCT\) parameter](#).

Note: Alerting actions are not available for advanced session-level policies created using the SR language.

### Log actions

---

- 12.1 and later Audit only
- Log access only
- Log exception
- Log full details
- 12.1 and later Log full details with replaced values
- 12.1 and later Log masked details
- 12.1 and later Log Extrusion Counter
- 12.1 and later Log Masked Extrusion Counter
- 12.1 and later Log only

---

## Parse actions

The following parse actions are available:

- No parse (NO\_PARSE)
- Quick parse (QUICK\_PARSE)
- Quick parse no fields (QUICK\_PARSE\_NO\_FIELDS)

Parsing granularity is per-request.

---

## Configure actions

The configure action is used to adjust analyzer settings or activate session-level policy features.

The configure (CONFIGURE) parameter accepts the following options:

- ANALYZER\_PARSER:<ON|OFF>  
Disable to require processing session-level criteria before invoking the parser, regardless of whether SQL criteria like command, object, or field are used in the policy.

- CHARSET:guardium://char\_set?<hint|force>=<int>  
Use alternative character set.
- CREDENTIAL\_STUFFING:<ON>|[PMAX=<float>]|,[CONFIDENCE=<float>]  
Start credential stuffing attack detector.
- 12.1 and later DISABLE\_CACHE:ALL|[HOSTNAME][,SERVICENAME][,OSNAME]  
Disables caching of Host names, Service names, OS names separately or all together.
- IFX\_IGNORE:OFF  
Tell Informix analyzer to stop ignoring sessions.
- IGNORED\_FLAG:<ON|OFF>  
Enable to log sessions otherwise ignored with the following actions: DISCARD SESSION, SOFT DISCARD SESSION, LOG ACCESS ONLY, STOP LOG ACCESS ONLY, STOP SOFT DISCARD. This setting is not required with the LOG ACCESS ONLY action. The default value is OFF.
- 12.1 and later LARGE\_RESULTSET:<ON|OFF>  
Removes size limits for database responses. The default value is ON.
- LOG\_PARSER\_ERRORS:<ON|OFF>  
Enable or disable logging parser errors. The default value is ON.
- LOG\_CONSTRUCT\_ERRORS:<ON|OFF>  
Enable or disable logging construct errors. The default value is OFF.
- MARK\_BATCH:<ON|OFF>  
Enable to mark SQL execution as part of a batch. The default value is OFF.
- ORA\_BIND\_TYPE:<SELECT|INSERT|UPDATE|DELETE>  
Oracle bind variable type.
- ORA\_CHECKSUM:<MD5|SHA1|SHA256|SHA384|SHA512|int>  
Type of Oracle hash used in Oracle data integrity.
- ORA\_SESSION\_INFO:<session\_info\_string>  
Oracle session platforms.
- ORA\_TOKEN\_OFFSET:<TNS314|TNS315>  
Token format for calculating Oracle statement size.
- QUERY\_REWRITE:<ON|OFF>  
Enable to attach or detach based on session-level criteria.
- RAW\_STATEMENT\_MAP\_SIZE:<integer>  
Change the number of raw statements stored in the analyzer. The default value is 1024 raw statements per session.
- SELECTIVE\_AUDIT:ON  
Selective audit actions are triggered in analyzers before the parser/logger starts to receive session requests.
- SERVER\_DATA:[OFF]|[MAX\_HITS=<integer>]|[CONFIDENCE=<integer>]|[EXFILTRATION=<integer>]  
Used in combination with other criteria, the SERVER\_DATA criteria allows limiting the scope of extrusion rules to improve performance.
  - OFF - Turn off checking the criteria according to its CONFIGURE abilities.
  - MAX\_HITS - Applies to regular expressions only and refers to the maximum number of pattern matches in a packet. The default value is 1, meaning SERVER\_DATA is used as the usual criteria for finding at least one match.
  - CONFIDENCE - Applies to regular expressions only using the COUNT or VALUE flags, it refers to the number of checks before deciding that matches are not false positives. The default value is 1.
  - EXFILTRATION - Applies to regular expressions only and limits the number of hits per request. If the session is SENSITIVE, exceeding this limit may indicate exfiltration of sensitive data. In this case, SENSITIVE\_DATA\_EXFILTRATION is set.
- SESSION\_TRUST:<OFF>|[LOW=<float>]|,[HIGH=<float>]  
Exclude sessions from session trust evaluation or change LOW/HIGH trust limits.
- STRICT\_USERNAME:<replacement\_value>  
Where <replacement\_value> is any value that you choose. If Guardium finds a problem with the username, it is replaced with the specified value.
- TDS\_SWAP\_LIMIT:<number between 10,000 and 100,000>  
MS SQL analyzer related to records affected calculation.
- TYPE\_STATUS:<ON|OFF>  
Disable to prevent logging sessions with artificial activities.

## Transform actions

Available transform actions:

- TRANSFORM ANALYZED CLIENT IP (TRANSFORM\_ANALYZED\_CLIENT\_IP)
- TRANSFORM APP USER NAME (TRANSFORM\_APP\_USER)
- TRANSFORM CLIENT HOST NAME (TRANSFORM\_CLIENT\_HOST\_NAME)
- TRANSFORM CLIENT OS NAME (TRANSFORM\_CLIENT\_OS\_NAME)
- TRANSFORM DB NAME (TRANSFORM\_DB\_NAME)
- TRANSFORM DB USER (TRANSFORM\_DB\_USER)
- TRANSFORM OS USER (TRANSFORM\_OS\_USER)
- TRANSFORM SERVER DESCRIPTION (TRANSFORM\_SERVER\_DESC)

- TRANSFORM SERVER HOST NAME (TRANSFORM\_SERVER\_HOST\_NAME)
- TRANSFORM SERVER OS NAME (TRANSFORM\_SERVER\_OS\_NAME)
- TRANSFORM SERVICE NAME (TRANSFORM\_SERVICE\_NAME)
- TRANSFORM SOURCE PROGRAM NAME (TRANSFORM\_SOURCE\_PROGRAM)
- TRANSFORM STATEMENT (TRANSFORM\_STATEMENT)

## Transform action examples in the UI

---

For an example of how to use the TRANSFORM ANALYZED CLIENT IP action, see [Hostname caching example](#).

For an example of how to use the TRANSFORM DB NAME action, see [Add DB name on failed login example](#).

For some examples of how to use the TRANSFORM STATEMENT action, see [Query masking examples](#).

For more information about creating session level policies in the UI, see [Understanding the UI examples](#).

## Transform action examples using the advanced session-level policy language

---

Example:

```
TRANSFORM_SERVER_DESC SEARCH_PREFIX = 'SERVER_DESCRIPTION:guardium://empty' OUTPUT_FORMAT = 'IBM VM'
```

This shows the use of tokens in a transform action such that if the SERVER\_DESCRIPTION field is empty for the session it is transformed to IBM VM.

Example:

```
SEARCH_PREFIX = 'DB_USER:SCOTT'
SEARCH_PATTERN = 'OS_USER:ORACLE19'
MATCH_PATTERN = 'SOURCE_PROGRAM:/(\w+)/(.*))'
```

These show the ability to use independent targets.

Example of using "not found" (NOT), which is available in SEARCH\_PREFIX, SEARCH\_PATTERN, and MATCH\_PATTERN:

```
SEARCH_PREFIX = '(NOT):STATEMENT:grant' - means any not "GRANT ..." statement.
SEARCH_PREFIX = '(NOT):OS_USER:? - empty OS user.'
```

These show how to use SEARCH\_PREFIX to match any statement other than grant and an empty OS user, respectively.

Example:

```
TRANSFORM_DB_USER SEARCH_PREFIX = '(NOT):(DB_USER)' SOURCE = OS_USER OUTPUT_FORMAT = '$(SOURCE_PROGRAM)$\(.*)'
Initial GDM_ACCESS record:
DB_USER = *scott*. | OS_USER = oracle19 | SOURCE_PROGRAM = sqlplus

Transform result in GDM_ACCESS table:
DB_USER = sqlplus\oracle19 | OS_USER = oracle19 | SOURCE_PROGRAM = sqlplus
```

### Case 1:

#

Special handling for TRANSFORM actions:

According to EX. 1 CLIENT\_HOST\_NAME should be transformed into IP address and copied to ANALYZED\_CLIENT\_IP field, but in addition it is possible to check and do it only if analyzed client IP is empty:

```
TRANSFORM_ANALYZED_CLIENT_IP SEARCH_PREFIX = '(NOT):ANALYZED_CLIENT_IP:?' SOURCE = CLEINT_HOST_NAME OUTPUT_FORMAT = '(.*)'
```

### Case 2:

```
TRANSFORM_DB_USER WHERE OUTPUT_FORMAT = '<some string>' # copies <some string> into DB_USER, if DB_USER is empty (not copies if DB_USER is not empty)
```

### Case 3:

```
TRANSFORM_DB_USER WHERE SEARCH_PREFIX = '?' OUTPUT_FORMAT = '<some string>' # copies <some string> into DB_USER, if DB_USER is not empty (not copies if DB_USER is empty)'
```

Now it is possible to transform to some value to empty. For that in any transform action it is possible to put SEARCH\_PREFIX = '?' and OUTPUT\_FORMAT as 'guardium://empty'

## Specific behaviors for search parameters with transform actions

---

Transform actions using certain search parameters may have specific behavior, as illustrated by the following examples.

Example:

```
TRANSFORM_DB_USER WHERE SOURCE = OS_USER OUTPUT_FORMAT = '(.*)'
```

This always copies OS\_USER into DB\_USER, regardless of whether or not DB\_USER is empty.

Example:

```
TRANSFORM_ANALYZED_CLIENT_IP SEARCH_PREFIX = '(NOT):ANALYZED_CLIENT_IP:?' SOURCE = CLEINT_HOST_NAME OUTPUT_FORMAT = '(.*)'
```

This transforms CLIENT\_HOST\_NAME into an IP address and copies it to ANALYZED\_CLIENT\_IP only if ANALYZED\_CLIENT\_IP is empty.

Example:

```
TRANSFORM_DB_USER WHERE OUTPUT_FORMAT = '<some string>'
```

This copies <some string> into DB\_USER only if DB\_USER is empty. It will not copy the value if DB\_USER is not empty.  
Example:

```
TRANSFORM_DB_USER WHERE SEARCH_PREFIX = '?' OUTPUT_FORMAT = '<some string>'
```

This copies <some string> into DB\_USER only if DB\_USER is not empty. It will not copy the value if DB\_USER is empty.  
Example:

```
TRANSFORM_DB_USER WHERE SEARCH_PREFIX = '?' OUTPUT_FORMAT = 'guardium://empty'
```

This transforms DB\_USER to an empty value.

- [Transform parameters](#)

Transform actions support additional parameters not available with other actions.

---

## Transform parameters

Transform actions support additional parameters not available with other actions.

### Source (SOURCE)

Source is used as a filter to tell the action which value should be matched. Values include:

- ANALYZED CLIENT IP (ANALYZED\_CLIENT\_IP)
- APP USR NAME (APP\_USER\_NAME)
- CLIENT HOST NAME (CLIENT\_HOST\_NAME)
- CLIENT OS NAME (CLIENT\_OS\_NAME)
- DB NAME (DB\_NAME)
- DB USER (DB\_USER)
- OS USER (OS\_USER)
- SERVER DESCRIPTION (SERVER\_DESC)
- SERVER HOST NAME (SERVER\_HOST\_NAME)
- SERVER IP (SERVER\_IP)
- SERVER OS NAME (SERVER\_OS\_NAME)
- SERVICE NAME (SERVICE\_NAME)
- SOURCE PROGRAM NAME (SOURCE\_PROGRAM)
- STATEMENT (STATEMENT)

The source parameter defines the content used for search parameters in transform actions.

Example:

```
TRANSFORM_DB_USER SEARCH_PREFIX = 'CHE' SOURCE = OS_USER OUTPUT_FORMAT = '(.*)'
```

This copies the value of OS\_USER to DB\_USER if OS\_USER begins with the string CHE.

### Mask (MASK)

Mask uses the regular expression defined by the match pattern parameter to search the source and replace (mask) all matched occurrences using the value defined by the output format parameter. Use the mask parameter with match pattern (MATCH\_PATTERN) and output format (OUTPUT\_FORMAT). For example

Example:

```
TRANSFORM_OS_USER SEARCH_PREFIX = '?' MATCH_PATTERN = '\d' MASK_OUTPUT_FORMAT = '0'
```

This matches all digits and replaces them with 0, such that if OS\_USER is ORACLE19 it becomes ORACLE00.

### Output format (OUTPUT\_FORMAT)

Output format defines the output for transform actions. When source (SOURCE) is specified, the output format can be (.) to replace the transformed value with the source value. When used with match pattern, custom strings and the contents of regular expression groups like \1 can be used. Specify **guardium://empty** for empty output.

### Related concepts

- [Search parameters](#)
- 

## Exception actions

Available exception actions:

- Throw exception (THROW\_EXCEPTION)
- Log exception (LOG)

### Throw exception (THROW\_EXCEPTION)

Throw exception accepts an exception type that defines what type of processing happens on the logger side. Exception message (EXC\_MSG) allows customization of the message. Available exception types:

- Analyzer alert
- Security incident
  - Adds the exception to the Security incidents report.
- Session exception

## Log exception (LOG)

Log exception is the same as throw exception but can be used to log an exception even when the login is not made.

## Extrusion actions

Use the REDACT and GET\_SERVER\_DATA actions to manage sensitive data.

Available extrusion actions:

- REDACT
- GET\_SERVER\_DATA

## REDACT

The REDACT action requires *log record affected* and *inspect return data* to be enabled for the inspection engine. It is executed on analyzer level of sniffer processing and can prevent execution of the first SQL statement without redaction being applied with the firewall mode activated.

Attention: The REDACT action alters raw packets. Using broad regular expressions can inadvertently modify internal data structures sent by the server, potentially causing session disruptions. To avoid these issues, be sure to use precise regular expressions that avoid false positives. In addition, if patterns are spread across two physical network packets or their fragments, REDACT operations might be skipped, because S-TAP does not assemble these packets.

For more information about using REDACT, including additional restrictions, see [Redact](#) in [Logging or ignoring rule actions](#).

Note:

- Write the part of the pattern that you want to mask in parentheses.
- 12.1 and later Along with the list of predefined replacement symbols, you can enter any custom symbol as a replacement symbol.

## GET\_SERVER\_DATA

The Runtime Sensitive Object Identification policy uses the GET\_SERVER\_DATA action to retrieve and process sensitive data. This action is available only for use with the Runtime Sensitive Object Identification policy.

## Action parameters

- [Label action and criteria](#)  
Use the Label (LABEL) action parameter to assign a label to the triggered action, which you can then use as a criterion for subsequent rules.
- [Distinct parameter](#)  
The distinct (DISTINCT) parameter is a flexible way to group different sessions at runtime.
- [Track option](#)  
The track option allows you to trace the execution action of session-level policies.
- [Search parameters](#)  
Search parameters define additional conditions and can be used with different actions.

## Label action and criteria

Use the Label (LABEL) action parameter to assign a label to the triggered action, which you can then use as a criterion for subsequent rules.

You can use both the LABEL action and LABEL criteria as follows:

Within a policy, let's say you define a LABEL action as

```
LABEL = (DB_USER)
```

If this action is triggered for some session request (such as **DB\_USER** = SCOTT), then SCOTT is added to internal dynamic group.

In addition, let's say that you create a rule within the policy that has the following criteria:

```
LABEL = (DB_USER)
```

If a request comes in from a database user, then the LABEL criteria is triggered. If the database user (the DB\_USER) is, for example, SA, then that DB\_USER is not found in dynamic group, the criteria LABEL is validated to false, and the rule actions are not triggered. However, if the request comes the database user SCOTT, then SCOTT is found in the dynamic group, and the LABEL criteria is validate to true, which triggers the rule actions.

The LABEL parameter is available for the following actions:

- ALERT
- IGNORE\_REQUEST
- LOG
- MARK\_SESSION
- THROW\_EXCEPTION
- VERDICT\_TERMINATE

## Distinct parameter

The distinct (DISTINCT) parameter is a flexible way to group different sessions at runtime.

The distinct parameter is used with the following actions:

- ALERT\_ONCE\_PER\_SESSION
- ALERT\_ONLY
- ALERT\_PER\_MATCH
- DISCARD\_SESSION
- IGNORE\_REQUEST
- LOG
- MARK\_SESSION
- THROW\_EXCEPTION
- VERDICT\_TERMINATE

Syntax:

```
Syntax:
<distinct> ::= [MIN_COUNT=<number><space>] [PERIOD=<number><space>] [MAX_COUNT=<number><space>] [RESET_INTERVAL=<number>[:<number>]<space>] [composite key]$
<composite key> ::= [<key>|<FUNC|key|[condition key]>]
<FUNC> ::= <SUM>
<key> ::= [<token>...<token|>]
<condition key> ::= [<token>...<token|>]
<token> ::= $(<session parameter>)$
<session parameter> ::= <DB_USER|CLIENT_IP|CLIENT_HOST_NAME|SERVER_IP|SERVER_HOST_NAME|
 OS_USER|DB_NAME|DB_TYPE|SOURCE_PROGRAM|SERVICE_NAME|NET_PROTOCOL|
 ANALYZED_CLIENT_IP|COMMAND|ERROR|SENDER_IP>
```

```
MIN_COUNT value is any >0 and <= 65535.
PERIOD value is the number >0 and <=65535
MAX_COUNT value is any >0 and <= 65535.
RESET_INTERVAL measured in minutes.
CON_MIN_COUNT value is any >0.
CON_MAX_COUNT value is any >0.
```

Examples:

| CLIENT_IP         | DB_USER | SOURCE_PROGRAM | COUNT |
|-------------------|---------|----------------|-------|
| 9.70.2.3.1        | SCOTT   | SQLPLUS        |       |
| 19.70.2.3.1       | SCOTT   | TOAD           |       |
| 19.70.2.3.1       | SCOTT   | JDBC           |       |
| 19.70.2.3.1       | SYS     | JDBC           |       |
| 19.70.2.3.1       | ALICE   | TOAD           |       |
| 19.70.2.3.2       | SCOTT   | SQLPLUS        |       |
| 19.70.2.3.2       | BOB     | SQLPLUS        |       |
| 29.70.2.3.2       | BOB     | TOAD           | 1     |
| <hr/>             |         |                |       |
| TOTAL CONNECTIONS |         |                | 9     |
| TOTAL PROGRAMS    |         |                | 3     |
| TOTAL USERS       |         |                | 5     |
| TOTAL CLIENTS     |         |                | 2     |

- More than 2 connections from different users of same CLIENT\_IP during 1 minute (Client - 9.70.2.3.1, 3 Users - SCOTT, SYS, ALICE):
 

```
MIN_COUNT=3 MAX_COUNT=3 RESET_INTERVAL=1 SUM|(DB_USER)|$(CLIENT_IP)$$
```
- More than 3 connections from different users during 1 minute (4 occurrences: SCOTT,SYS,ALICE,BOB):
 

```
MIN_COUNT=4 MAX_COUNT=4 RESET_INTERVAL=1 SUM|(DB_USER)|$
```
- More than 3 connections from same users during 1 minute (User SCOTT):
 

```
MIN_COUNT=4 MAX_COUNT=4 RESET_INTERVAL=1 $(DB_USER)$$
```
- More than 2 connections from same user of same CLIENT\_IP during 1 minute (Client - 9.70.2.3.1, User - SCOTT and Client - 9.70.2.3.2, User - BOB):
 

```
MIN_COUNT=3 MAX_COUNT=3 RESET_INTERVAL=1 (DB_USER)|$(CLIENT_IP)$$
```
- More than 1 connection from different users and source programs of same CLIENT\_IP during 1 minute (Client - 9.70.2.3.1, Client - 9.70.2.3.2):
 

```
MIN_COUNT=2 MAX_COUNT=2 RESET_INTERVAL=1 SUM|(DB_USER)|$(SOURCE_PROGRAM)$|$(CLIENT_IP)$$
```
- More than 1 connection from same user, same program of same CLIENT\_IP during 1 minute (Client - 9.70.2.3.2, User - BOB, PROGRAM - SQLPLUS):
 

```
MIN_COUNT=2 MAX_COUNT=2 RESET_INTERVAL=1 (DB_USER)|$(SOURCE_PROGRAM)$|$(CLIENT_IP)$$
```
- Too many db users connecting from same client ip per period of time (SESSION != 'TAP\_DECRYPTED'):
 

```
MIN_COUNT=10 MAX_COUNT=10 RESET_INTERVAL=5 SUM|(DB_USER)|$(CLIENT_IP)$$
```
- Find user with reused password (DB\_USER!=%''):
 

```
MIN_COUNT=2 SUM|(DB_USER)|$(PASSWORD)$$
```

```
9. Too many Login failures from same Program and different DB users per period of time (5 in 3 minutes).
MIN_COUNT=5 MAX_COUNT=5 RESET_INTERVAL=3 SUM|$(DB_USER)|$(SOURCE_PROGRAM) $$
```

## Track option

The track option allows you to trace the execution action of session-level policies.

The track option is available for the following actions:

- Ignore session (IGNORE\_SESSION)
- Discard session (DISCARD\_SESSION)
- Log access only (LOG\_ACCESS\_ONLY)
- Stop log access only (STOP\_LOG\_ACCESS\_ONLY)
- Soft discard session (SOFT\_DISCARD\_SESSION)
- Stop soft discard session (STOP\_SOFT\_DISCARD\_SESSION)
- Mark session (MARK\_SESSION) when as (AS) value is not ML TRUSTED (ML\_TRUSTED)
- S-Gate session terminate (S-GATE\_SESSION\_TERMINATE)

## Search parameters

Search parameters define additional conditions and can be used with different actions.

### Request type (REQ\_TYPE)

Request type acts as a filter for transform actions. In non-transform actions with search parameters, request type provides a hint for where to search.

Request types available for actions with search parameters:

- LOGIN FAILED (LOGIN\_FAILED)
- PREPARED STATEMENT (PREP\_STAT)
- RPC (RPC)
- SQL (SQL)
- SQL ERROR (SQL\_ERROR)
- SQL SUCCESS (SQL\_SUCCESS)

Request types available for actions with transform parameters:

- LOGIN FAILED (LOGIN\_FAILED)
- PREPARED STATEMENT (PREP\_STAT)
- RPC (RPC)
- SQL (SQL)
- SQL ERROR (SQL\_ERROR)

Note: In the SR language, write request types without quotation marks.

### Search prefix (SEARCH\_PREFIX)

Search prefix matches the defined pattern at the beginning of a value.

Use search prefix with or without request type for transform actions and for regular actions with search parameters. Request type acts as a filter for transform actions. In non-transform actions with search parameters, request type provides a hint for where to search.

| Rule criteria used          |     |     |     |     |
|-----------------------------|-----|-----|-----|-----|
| Request type defined        | Yes | No  | Yes | No  |
| Search prefix defined       | Yes | Yes | No  | No  |
| Actions taken               |     |     |     |     |
| Search with search prefix   | Yes | Yes | No  | No  |
| Search with request type    | No  | No  | Yes | No  |
| Search in DB User (DB_USER) | No  | No  | No  | Yes |

Example:

```
IGNORE_REQUEST REQ_TYPE = SQL SEARCH_PREFIX = 'GAT'
```

This matches SQL requests with the prefix GAT.

Example:

```
IGNORE_REQUEST REQ_TYPE = SQL_ERROR SEARCH_PREFIX = 'TNS-'
```

This matches SQL errors with the prefix TNS-.

### Search pattern (SEARCH\_PATTERN)

Search pattern matches the defined pattern in any part of the value.

Example:

```
IGNORE_REQUEST REQ_TYPE = SQL SEARCH_PREFIX = 'SELECT' SEARCH_PATTERN = 'FROM SCOTT.'
```

This matches SELECT SQL requests that contain the pattern FROM SCOTT.

## Match pattern (MATCH\_PATTERN)

---

Match pattern is similar to search pattern but uses regular expressions to match the defined pattern in any part of the value.

Example:

```
SELECT * FROM SCOTT.A WHERE SECRET = '1234'
MATCH_PATTERN = '^.*FROM (.*)\\.A\\.*$'
OUTPUT_FORMAT = '\1'
```

This takes the first regular expression element in parenthesis and writes it to the output format.

## Search offset (SEARCH\_OFFSET)

---

Search offset works with search pattern and match pattern to cut the source string where the matched pattern is found. This can improve matching with regular expressions.

Example:

```
SELECT LAST_NAME FROM SCOTT.EMPLOYEES
TRANSFORM STATEMENT SEARCH_PREFIX = 'SELECT' SEARCH_PATTERN = 'FROM SCOTT.' SEARCH_OFFSET MATCH_PATTERN = '^(.*)\\. (.*)$'
OUTPUT_FORMAT = '\1.\2'
```

This finds the string defined by search pattern while search offset cuts off everything before it allowing match pattern to work more efficiently.

## Checking criteria for actions in search parameters

---

The default is `DB_USER:guardium://empty`, meaning that SEARCH\_PREFIX matches if the value is empty. Other criteria can be checked:

- ANALYZED\_CLIENT\_IP
- APP\_USER\_NAME
- AUTH\_TYPE
- CLIENT\_HOST\_NAME
- CLIENT\_IP
- CLIENT\_OS\_NAME
- COMMAND
- CTIMEZONE
- DB\_NAME
- DB\_USER
- DESCRIPTION
- ERROR
- OS\_USER
- SERVER\_DESCRIPTION
- SERVER\_HOST\_NAME
- SERVER\_IP
- SERVER\_OS\_NAME
- SERVICE\_NAME
- SOURCE\_PROGRAM
- STATEMENT

Examples:

- Search prefix = `DB_USER:NO_AUTH`
- Search pattern = `STATEMENT:SELECT%`
- Match pattern = `ERROR:%13%`

## Session-level policy examples

---

To help you understand session-level policies, Guardium provides a number of examples with descriptions. The examples include both the Guardium UI and SR language methods.

### Understanding the UI examples

---

These examples might help you understand how to design and build session-level policies.

For the UI examples, each example describes the actions that you need to take on each ribbon to re-create the example, as follows:

1. For the *Ignoring sessions example* policy, start with creating and naming the policy, as described in [Creating session-level policies](#). Select Session level policy and provide a name.

## Create New Policy

Name and properties  
Provide a unique name and optional properties

Type: Session level policy

Name: Ignore sessions

Roles: No roles assigned.

Rules: Number of rules: 0

2. Click the Rules ribbon and then click the icon to open the Create New Rule window. For this policy, you need to provide only the name of the first rule.

### Create New Rule

Rule definition  
Specify rule name and type

Rule type: Session

Rule name: Rule 1

Category: Enter rule category

Classification: Enter rule classification

Severity: Information

Rule criteria: No parameters specified

Rule action: Number of actions: 0

3. Click the icon to open the Create New Rule window. From here, you can add session-level criteria.

Note: In the examples, the criteria are labeled as Session level criteria. For example, in [Ignoring sessions example](#), this example is shown as:

#### Session level criteria

- Client IP address = 10.10.10.10
- Server IP address = 20.20.20.20
- Source application = JAVA%

Add criteria as needed by clicking the near the last criterion.

Figure 1. Rule criteria UI example

### Create New Rule

Rule definition: Rule 1

Rule criteria: Conditions where rule action will be triggered

Session level criteria

|                    |   |             |
|--------------------|---|-------------|
| Client IP address  | = | 10.10.10.10 |
| Client net mask    | = | 0.0.0.0     |
| Server IP address  | = | 20.20.20.20 |
| Server net mask    | = | 0.0.0.0     |
| Source application | = | JAVA%       |

Rule action: Number of actions: 0

4. When you are done adding criteria, click the Rule action ribbon, and then click the to begin adding actions.

Note: In the examples, the rule actions are labeled as Rule action. The example documentation describes only the criteria that you need to change for a specific example.

Figure 2. Add new action UI example

Create New Rule

Rule definition: Rule 1

Rule criteria: 3 session parameters specified

Rule action

Add New Action

\* Rule action: IGNORE SESSION

Packets limit: 1

Track: True False

OK Cancel

5. When you are done, your new policy looks similar to the following policy,

Figure 3. Session level policy with rules and actions

The screenshot shows a 'Session level policy' configuration screen. At the top, there are tabs for 'Name and properties' (selected) and 'Ignore sessions policy'. Below is a 'Rules' section with a 'Define policy rules' tab selected. A toolbar includes icons for add, edit, delete, import, reinstall, and uninstall. A 'Filter' button is also present. The main area displays two rules:

| Order | Rule type | Rule name | Tags | Criteria                                                                                                      | Actions        | Continue to next rule | Installed |
|-------|-----------|-----------|------|---------------------------------------------------------------------------------------------------------------|----------------|-----------------------|-----------|
| 1     | Session   | Rule 1    |      | Server IP address = 20.20.20.20, Client IP address = 10.10.10.10, Source application = JAVA%, Severity = Info | IGNORE SESSION |                       |           |
| 2     | Session   | Rule 2    |      | Severity = Info                                                                                               | IGNORE SESSION |                       |           |

In addition, each example includes an advanced session-level policy that is written in the SR language.

## Mapping the SR language examples

In the SR language examples, you can map the parameters (that is, parameter = *variable*) directly to most UI examples. Take for example the following SR language snippet:

```
SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' SOURCE_PROGRAM = 'JAVA%' SERVER_IP = '20.20.20.20')
 {
 IGNORE_SESSION
 }
 IF (*)
 {
 IGNORE_SESSION PACKETS_LIMIT = 50
 }
}
```

- CLIENT\_IP criteria in the SR language maps to Client IP address in the UI
- SERVER\_IP maps to Server IP address.
- SOURCE\_PROGRAM maps to Source application.

In addition, the { `IGNORE_SESSION` } code in the SR language maps to the IGNORE SESSION rule action in the UI.

In the [Using session-level and advanced session-level policies](#), you can find the mappings between the SR language and UI elements.

In the guide, the UI name is generally on the left, and the SR language name is on the right. The SR language name is shown in parentheses. For example, looking at search parameters:

Request types available for actions with search parameters:

```
LOGIN FAILED (LOGIN_FAILED)
PREPARED STATEMENT (PREP_STAT)
RPC (RPC)
SQL (SQL)
SQL ERROR (SQL_ERROR)
SQL SUCCESS (SQL_SUCCESS)
```

LOGIN FAILED in the UI maps to LOGIN\_FAILED in the SR language, PREPARED STATEMENT in the UI maps to PREP\_STAT in the SR language.

- [Ignoring sessions example](#)  
The [Ignore sessions](#) policy shows two different methods of ignoring certain policies.
- [Log LOGIN FAILED sessions only example](#)  
The [Log LOGIN FAILED sessions only](#) policy contains a single rule that logs an error if a login fails. Other types of errors that the session encounters are ignored.
- [REQUEST\\_ERROR example](#)  
REQUEST\_ERROR in the session level policies are SQL errors.
- [Add DB name on failed login example](#)  
The [Add DB name on failed login](#) policy solves a problem where the database name is not available if the login fails (with a LOGIN\_FAILED message). If the DB\_NAME value is empty, the policy adds a database name.
- [Get correct service name \(MS SQL Server\) example](#)  
For MS SQL server, some sites use a placeholder name for the SERVICE\_NAME. This example shows how to replace the placeholder with the actual service name.
- [Ignoring exceptions example](#)  
The [Ignoring exceptions](#) policy shows two ways to ignore certain exceptions.
- [Firewall and latency issues examples](#)  
If your site uses the Guardium® database firewall, you can encounter latency issues when Guardium reconnects. These examples show how to use session-level policies to prevent unwanted traffic.
- [Sniffer overload issues examples](#)  
In some circumstances, the Guardium sniffer can be overloaded with unnecessary traffic. These three examples show how to prevent the traffic that can overload the sniffer, while still allowing other traffic through.
- [Query masking examples](#)  
Analyzer query masking can be useful when used with non-relational databases such as MongoDB or Cassandra, or protocol frameworks such as the Google protocol buffer or Apache Thrift. The following examples show how to mask unencrypted data in non-relational databases.
- [Correct IP address \(Oracle\) example](#)  
When the Oracle connection manager handles the connection to the database server, the connection manager can insert the wrong IP address and other information. The following example shows how to ensure that Guardium has the correct information from Oracle.
- [Show SQL schema names example](#)  
You can use a session-level policy to find and display an SQL schema name. This example shows how to move the schema name to the `GDM_CONSTRUCT_INSTANCE.APP_USER_NAME` table and column so that it is available for reports.
- [Server and S-TAP IP addresses example](#)  
For some Guardium implementations, one collector serves multiple S-TAPs. In some cases, customers want to have separate sets of session-level policies for each S-TAP. Normally they can use SERVER\_IP and SERVER\_NET\_MASK rule conditions. However, the server IP address can be different from STAP IP address. In these cases, use a session-level policy to associate the session-level policies by S-TAP.

- [User authentication \(Oracle\) example](#)  
If your site uses Oracle OS authentication, the DB\_USER cannot be captured in network traffic and therefore is not logged. For this session-level policy, if the DB\_USER is empty, the policy copies the ORACLE\_USER name to DB\_USER.
- [Redacting data example](#)  
The REDACT rule action is similar to redaction in extrusion rules. Use REDACT to replace a matched pattern in SQL statements that are sent from client to server and mask the matched values.
- [Hostname caching example](#)  
This example shows how to manage hostnames that are stored in a cache file, where the cache is updated hourly.
- [Ignore specified users example \(MongoDB\)](#)  
This example ignores all requests that belong to the MongoDB users NO\_AUTH and \_SYSTEM.
- [Scheduling with SESSION\\_START examples](#)  
Use SESSION\_START to define when the session-level rules are active. The following examples show how to use the Session start time range parameter.
- [Logging access activity for trusted sessions example](#)  
You can change LOG\_ACCESS\_ONLY functionality by using IGNORE\_REQUEST as shown in the following examples.
- [Creating a custom exception message example](#)  
Create a custom exception message with the SR language THROW\_EXCEPTION or by selecting the LOG EXCEPTION action in the UI for a local session-level policy.
- [Find name in SQL query example](#)  
Create a session-level policy that sends an alert when a name is found in an SQL query.
- [Detect local admin example](#)  
Use this policy to attach local admin sessions.
- [Strict username example \(Oracle\)](#)  
Monitoring network traffic is subject to network packet loss. Losses can occur for various reasons, such as overloading S-TAP buffers on the peaks or insufficient collector power, S-TAP or sniffer restarts, or too many sessions are coming into the collector. Priority packets are the packets that contain metadata responsible for correctly extracting session information. Partial loss of priority packets can cause interpretation issues such as mangled usernames, source program names, and other important session information. This example shows how to provide a check on the username to ensure that it is correct. If the username is not correct, the username is replaced by a user-defined value.
- [Login information dump example](#)  
Use the `login information dump` session level policy to help resolve Sniffer connection issues.

  - [Creating session-level policies](#)
- 

## Ignoring sessions example

The **Ignore sessions** policy shows two different methods of ignoring certain policies.

The **Ignore sessions** policy contains two rules:

- The first rule ignores sessions that meet specific criteria (client IP, server IP, and source program language).

You can include specific criteria in a group.

- - Example- You can include specific criteria in a group
- The second rule ignores invisible binary traffic, for example, background encrypted SSL or TLS sessions, which are useless but can overload the sniffer. Setting the Packets limit to 50 on the IGNORE SESSION rule action states that if the session does not encounter a query within the first 50 packets, then ignore the session.

Rule 1:

- Session level criteria:
  - Client IP address = 10.10.10.10
  - Server IP address = 20.20.20.20
  - Source application = JAVA%
- Rule action = *DISCARD SESSION*

Rule 2:

- Session level criteria: None
- Rule action: *IGNORE SESSION*  
Packets limit = 50

## SR language example

---

```
SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' SOURCE_PROGRAM = 'JAVA%' SERVER_IP = '20.20.20.20')
 {
 DISCARD_SESSION
 }
 IF (*)
 {
 IGNORE_SESSION PACKETS_LIMIT = 50
 }
}
```

## Related concepts

---

- [Audit and ignore session actions](#)

## Log LOGIN\_FAILED sessions only example

The **Log LOGIN\_FAILED sessions only** policy contains a single rule that logs an error if a login fails. Other types of errors that the session encounters are ignored.

This policy has one rule and one rule action.

- Session level criteria: Error != LOGIN\_FAILED
- Rule action = SOFT DISCARD

## SR language example

```
SR_POLICIES
{
 IF (ERROR != 'LOGIN_FAILED')
 {
 SOFT_DISCARD_SESSION
 }
}
```

## Related concepts

- [Search parameters](#)

## REQUEST\_ERROR example

REQUEST\_ERROR in the session level policies are SQL errors.

You can use it when you want to:

- Trigger the rule on any error request
- Identify sessions with too many user errors
- Identify errors while accessing specific tables

Variants for ERROR criteria:

```
ERROR = 'GUARDIUM://EMPTY' - No error code detected.
ERROR = '%' - Any error including Login failure.
ERROR = '<error code|LOGIN_FAILED>' - Specific error or Login failure.
ERROR = 'LOGIN_FAILED' - Login failure
```

Variants for REQUEST\_ERROR criteria:

```
ERROR = 'REQUEST_ERROR' - Any error excluding Login failure.
```

## Add DB name on failed login example

The **Add DB name on failed login** policy solves a problem where the database name is not available if the login fails (with a LOGIN\_FAILED message). If the DB NAME value is empty, the policy adds a database name.

This example has one rule and one rule action.

- Session level criteria:
  - Server IP address = 20.20.20.20
  - Server port = 1433
- Rule action = TRANSFORM\_DB\_NAME
  - Source = DB NAME
  - Request type = LOGIN FAILED
  - Output format = NEWACCDB

## SR language example

```
SR_POLICIES
{
 IF (SERVER_IP = '20.20.20.20' SERVER_PORT = '1433')
 {
 TRANSFORM_DB_NAME REQ_TYPE = LOGIN_FAILED OUTPUT_FORMAT = 'NEWACCDB'
 }
}
```

## Get correct service name (MS SQL Server) example

For MS SQL server, some sites use a placeholder name for the SERVICE\_NAME. This example shows how to replace the placeholder with the actual service name.

In the **Get correct service name** policy, the MS SQL server instance uses a placeholder name, MS SQL SERVER for the SERVICE\_NAME. The service name and the server hostname are concatenated into SERVER\_HOSTNAME, separated by a backslash (\). For example:

| SERVICE_NAME  | SERVER_HOSTNAME        |
|---------------|------------------------|
| MS SQL SERVER | MY_SQL_SERVICE\MY_HOST |

This example has one rule and two rule actions.

- Session level criteria:
  - Server IP address = 20.20.20.20
  - Database type = MS SQL SERVER

- Rule actions:

1. **TRANSFORM SERVICE NAME**

This rule finds all instances of SERVER HOSTNAME that contain a backslash. The output (for SERVER HOSTNAME) is the data after the backslash.

- Source = SERVER HOSTNAME
- Match pattern = (.\*)\\(.\*)
- Output format = |2

2. **TRANSFORM SERVER HOSTNAME**

This rule moves the first part of the original SERVER HOSTNAME and moves it to the SERVICE NAME.

- Source = SERVER HOSTNAME
- Match pattern = (.\*)\\(.\*)
- Output format = |1

The final output is as follows:

| SERVICE_NAME   | SERVER_HOSTNAME |
|----------------|-----------------|
| MY_SQL_SERVICE | MY_HOST         |

## SR language example

```
SR_POLICIES
{
 IF (DB_TYPE = 'MS SQL SERVER' SERVER_IP = '20.20.20.20')
 {
 TRANSFORM_SERVICE_NAME SOURCE = SERVER_HOST_NAME MATCH_PATTERN = '(.*)\\(.*)' OUTPUT_FORMAT = '\2'
 TRANSFORM_SERVER_HOST_NAME MATCH_PATTERN = '(.*)\\(.*)' OUTPUT_FORMAT = '\1'
 }
}
```

## Related concepts

- [Transform parameters](#)

## Ignoring exceptions examples

The **Ignoring exceptions** policy shows two ways to ignore certain exceptions.

Rule 1: Ignore TNS errors that are logged as LOGIN\_FAILED.

- Session level criteria
  - Server IP address in Group where,
    - Group type = Server IP
    - Members = IP addresses
  - Database type = ORACLE
  - Server port = 1521
- Rule action = IGNORE REQUEST
  - Request type = LOGIN FAILED
  - Search prefix = TNS-

Rule 2: Ignore error 42702, which is caused by multiple SQL DROP TABLE and CREATE TABLE command pairs.

- Session level criteria
  - Database type = DB2
- Rule action = IGNORE REQUEST
  - Request type = SQL
  - Search prefix = 42702

## SR language examples

While both of the exceptions are managed with a single policy in the UI, two SR language policies are needed.

Example 1:

```
SR_POLICIES
{
 IF (SERVER_IP = ('', 20005) SERVER_PORT = 1521 DB_TYPE = 'ORACLE')
 {
```

```

 IGNORE_REQUEST REQ_TYPE = LOGIN_FAILED SEARCH_PREFIX = 'TNS-'
 }

 GROUP_ID = 20005 TYPE = IP_ADDRESS SIZE = 2
 {
 '20.20.20.20' '30.30.30.30'
 }
}

```

Example 2:

```

SR_POLICIES
{
 IF (DB_TYPE = 'DB2')
 {
 IGNORE_REQUEST REQ_TYPE = SQL_ERROR SEARCH_PREFIX = '42702'
 }
}

```

- [Audit and ignore session actions](#)

## Firewall and latency issues examples

If your site uses the Guardium® database firewall, you can encounter latency issues when Guardium reconnects. These examples show how to use session-level policies to prevent unwanted traffic.

In the following example, the application can automatically reconnect and restore a terminated session. In this case, a query that violates the rules is automatically sent at the begin of the session. Because the database firewall was too late, the violating query is sent to the database server.

In this example, the following steps occur within milliseconds:

1. The session is put under a firewall watch as soon as the user is verified in the analyzer.
2. The analyzer ends the session after the first query that contains the object CREDIT\_CARD.

The following session-level policy addresses this issue:

- Session level criteria:
  - Client IP address = 10.10.10.10
  - Client net mask = 255.255.255.0
  - Server IP address = 20.20.20.20
  - Database user = *Hermione*
  - Server port = 1521
- Rule actions:
  1. S-GATE SESSION ATTACH
    - ATTACH
    - ATTACH ON REQUEST
  2. S-GATE SESSION TERMINATE ON REQUEST
    - Request type = SQL
    - Search prefix = *SELECT*
    - Search pattern = *CREDIT\_CARD*

For the following example, Guardium attaches the session to the firewall for sessions when a database user tries to access database server objects for which they do not have permission. In this case, the Oracle database server issues error ORA-01031 – insufficient privileges.

Tip: Make sure that STAP\_FIREWALL\_DEFAULT\_STATE (Linux®-UNIX) or Firewall default state (Windows) S-TAP parameter is set to 2 to help prevent a security hole. If STAP\_FIREWALL\_DEFAULT\_STATE is set to 0 or 1, database clients that are not authorized by the security system database client can create database server sessions. A user can issue an SQL statement and the firewall reacts only after the first SQL statement (when a database session is already created).

The following session-level policy uses two rules to address this issue.

- Rule 1: Session level criteria
  - Server IP address = 20.20.20.20
  - Database user = *Bellatrix*
  - Server port = 1521
- Rule action = S-GATE SESSION ATTACH
  - Request type = *SQL ERROR*
  - Search prefix = *ORA-01031*
- Rule 2: Session level criteria
  - Server IP address = 25.25.25.25
  - Server port = 9160
- Rule action = S-GATE SESSION ATTACH ON REQUEST
  - Request type = *RPC*
  - Search prefix = *LOGIN*
  - Match pattern = *.\*bella.\*\$*

## SR language example

---

Example 1:

```

SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' CLIENT_NET_MASK = '255.255.255.0' SERVER_IP = '20.20.20.20' SERVER_PORT = 1521 DB_USER =
'Bellatrix')
 {
 VERDICT_ATTACH
 VERDICT_TERMINATE_REQ_TYPE = SQL SEARCH_PREFIX = 'SELECT' SEARCH_PATTERN = 'CREDIT_CARD'
 }
}

```

Example 2:

```

SR_POLICIES
{
 IF (SERVER_IP = '9.70.145.22' SERVER_PORT = 1521 DB_USER = 'SCOTT')
 {
 VERDICT_ATTACH REQ_TYPE = SQL_ERROR SEARCH_PREFIX = 'ORA-01031'
 }
}

```

## Sniffer overload issues examples

---

In some circumstances, the Guardium sniffer can be overloaded with unnecessary traffic. These three examples show how to prevent the traffic that can overload the sniffer, while still allowing other traffic through.

Example 1: Ignore any traffic from the SAP HANA statistics service.

- Session level criteria
  - Database type = *SAP HANA*
  - Source application = *STATISTICSERVICE*
- Rule action = *IGNORE SESSION*

Example 2: Optimized method to log only traffic from specified ports.

- Session level criteria - Server port *In Group* where:
  - Group type = *Server port*
  - Members = A list of the server ports to log.
- Rule action = *SELECT SESSION*

Example 3: Ignore traffic from Zabbix (a third-party product). This example requires three rules.

Rule 1 - If the session is not logged after 30 packets are received on the collector, then ignore this session.

- Session level criteria - No criteria
- Rule action = *IGNORE SESSION*
- Packets limit = 30

Rule 2 - Transform all dynamic source program strings that contain the phrase "ZABBIX" to the string ZABBIX.

- Session level criteria
  - Database type = *ORACLE*
  - Operating system user = *ZABBIX*
- Rule action = *TRANSFORM SOURCE PROGRAM NAME*
  - Source = *SOURCE PROGRAM NAME*
  - Match pattern = *.\*ZABBIX.\**
  - Output format = *ZABBIX*

Rule 3: Log any session where the source program is not ZABBIX. The first rule ignores the session if the session is not available within the first 30 packets. Since the session does not fall under the *SELECT\_SESSION* rule, it is not forwarded to the Logger and is ignored.

- Session level criteria - Source application = *ZABBIX*
- Rule action = *TRANSFORM SOURCE PROGRAM NAME*
  - Source = *SOURCE PROGRAM NAME*
  - Match pattern = *.\*ZABBIX.\**
  - Output format = *ZABBIX*

## SR language example

---

Example 1:

```

SR_POLICIES
{
 IF (DB_TYPE = 'SAP HANA' SOURCE_PROGRAM = 'statisticsService')
}

```

```

 {
 IGNORE_SESSION
 }
}

```

Example 2:

```

SR_POLICIES
{
 IF (SERVER_PORT = (1434, 1))
 { SELECT_SESSION }

 GROUP_ID = 1 TYPE = INTEGER SIZE = 3 { 1435 1436 1437 }
}

```

Example 3:

```

SR_POLICIES
{
 IF (*) { IGNORE_SESSION_PACKETS_LIMIT = 30 }

 IF (DB_TYPE = 'ORACLE' OS_USER = 'ZABBIX')
 {
 TRANSFORM_SOURCE_PROGRAM MATCH_PATTERN = '.*ZABBIX.*' OUTPUT_FORMAT = 'ZABBIX'
 }

 IF (SOURCE_PROGRAM == 'ZABBIX') { SOFT_DISCARD_SESSION }
}

```

## Query masking examples

Analyzer query masking can be useful when used with non-relational databases such as MongoDB or Cassandra, or protocol frameworks such as the Google protocol buffer or Apache Thrift. The following examples show how to mask unencrypted data in non-relational databases.

Example 1: Mask an unencrypted password from Cassandra.

- Session level criteria:
  - Server IP address = 20.20.20.20
  - Database type = CASSANDRA
- Rule action = *TRANSFORM STATEMENT*
  - Source = *STATEMENT*
  - Request type = *RPC*
  - Search prefix = *login*
  - Search pattern = *password*
  - Match pattern = *|x27|w+|x27|x7D|x7D|x29\$*
  - Mask = *True*
  - Output format = *|x27|x2A|x2A|x2A|x27|x7D|x7D|x7D|x29*

Example 2 : Mask the user credentials for a CouchBase REST query.

- Session level criteria: Server port *In Group* where:
  - Group type = *Server port*
  - Members = A list of server ports.
- Rule action = *TRANSFORM STATEMENT*
  - Source = *STATEMENT*
  - Request type = *SQL*
  - Search prefix = *\_CB POST /query/service*
  - Search pattern = *"pass": "*
  - Match pattern = *"pass": "[^"]{[^"]}\*[^"]"*
  - Mask = *True*
  - Output format = *"pass": "\*\*\*\*\*"*

## SR language examples

---

Example 1:

```

SR_POLICIES
{
 IF (SERVER_IP = '20.20.20.20' DB_TYPE = 'CASSANDRA')
 {
 TRANSFORM_STATEMENT REQ_TYPE = RPC SEARCH_PREFIX = 'login'
 SEARCH_PATTERN = 'password' MATCH_PATTERN = '\x27\w+\x27\x7D\x7D\x29$'
 MASK_OUTPUT_FORMAT = '\x27\x2A\x2A\x2A\x27\x7D\x7D\x29'
 }
}

```

Example 2:

```

SR_POLICIES
{
 IF (SERVER_PORT = (8091,100))
 {
 TRANSFORM_STATEMENT REQ_TYPE = SQL SEARCH_PREFIX = '_CB POST /query/service'
 SEARCH_PATTERN = '"pass":' MATCH_PATTERN = '"pass":[^"][^"]*'
 MASK_OUTPUT_FORMAT = '"pass":*****'
 }
 GROUP_ID = 100 TYPE = INTEGER SIZE = 1 { 8093 }
}

```

## Correct IP address (Oracle) example

When the Oracle connection manager handles the connection to the database server, the connection manager can insert the wrong IP address and other information. The following example shows how to ensure that Guardium has the correct information from Oracle.

This example has two rules.

Rule 1: If the session is not logged after 30 packets are received on the collector, then ignore this session.

- Session level criteria: No criteria
- Rule action = *IGNORE SESSION*
- Packets limit = 30

Rule 2: Map Oracle connection information correctly.

- Session level criteria:
  - Client IP address = *10.10.10.10*
  - Database type = *ORACLE*
  - Operating system user *In Group*, where:
    - Group type = *OS User*
    - Members = A list of allowed operating system users.
  - Server port = *1521*
  - Session = *LOCAL*
- Rule actions:
  - TRANSFORM SERVER HOST NAME*
    - Source = *SERVER HOST NAME*
    - Search prefix = *redwood*
    - Output format = *rh7u1-lenx01*
  - TRANSFORM ANALYZED CLIENT IP*
    - Source = *CLIENT HOST NAME*
    - Search prefix = *redwood*
    - Output format = *(.\*)*
  - TRANSFORM SERVER DESCRIPTION*
    - Source = *ANALYZED CLIENT IP*
    - Search prefix = *10*
    - Output format = *WITH ORACLE CONNECTION MANAGER*

## SR language example

---

```

SR_POLICIES
{
 IF (*) { IGNORE_SESSION_PACKETS_LIMIT = 30 }

 IF (CLIENT_IP = '10.10.10.10' SESSION = 'LOCAL' OS_USER = ('',1) DB_TYPE = 'ORACLE' SERVER_PORT = 1521)
 {
 TRANSFORM_SERVER_HOST_NAME SEARCH_PREFIX = 'redwood'
 OUTPUT_FORMAT = 'rh7u1-lenx01'

 TRANSFORM_ANALYZED_CLIENT_IP SEARCH_PREFIX = 'redwood'
 SOURCE = CLIENT_HOST_NAME OUTPUT_FORMAT = '(.*)'

 TRANSFORM_SERVER_DESC SEARCH_PREFIX = '10'
 SOURCE = ANALYZED_CLIENT_IP OUTPUT_FORMAT = 'WITH ORACLE CONNECTION MANAGER'
 }
 GROUP_ID = 1 SIZE = 1 { 'or18cl' }
}

```

## Show SQL schema names example

You can use a session-level policy to find and display an SQL schema name. This example shows how to move the schema name to the `GDM_CONSTRUCT_INSTANCE.APP_USER_NAME` table and column so that it is available for reports.

This policy contains one rule with two rule actions. The rule actions work as follows:

1. Copy the prefix `:SC=` and the value of DB USER into `GDM_CONSTRUCT_INSTANCE.APP_USER_NAME`.
2. Extract the schema name from SQL statements and copy it to `GDM_CONSTRUCT_INSTANCE.APP_USER_NAME` too.

Note: If the second rule action does not find the MATCH\_PATTERN, the policy does not override the result of the first action.

- Session level criteria:
  - Client IP address = 10.10.10.10
  - Server IP address = 20.20.20.20
  - Database type = SAP HANA
- Rule actions:
  1. `TRANSFORM APP USER NAME`
    - Source = `DB USER`
    - Output format = `:SC=(*)`
  2. `TRANSFORM APP USER NAME`
    - Source = `STATEMENT`
    - Request type = `SQL`
    - Search prefix = `SELECT`
    - Search pattern = `.M_DATABASE`
    - Match pattern = `.*(.*)\M_DATABASE`
    - Output format = `:SC=|1`

## SR language example

```
SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' SERVER_IP = '20.20.20.20' DB_TYPE = 'SAP_HANA')
 {
 TRANSFORM_APP_USER SOURCE = DB_USER OUTPUT_FORMAT = ':SC=(.*)'

 TRANSFORM_APP_USER REQ_TYPE = SQL SEARCH_PREFIX = 'SELECT' SEARCH_PATTERN = '.M_DATABASE'
 SOURCE = STATEMENT MATCH_PATTERN = '.*(.*)\M_DATABASE' OUTPUT_FORMAT = ':SC=|1'
 }
}
```

## Related concepts

- [Transform actions](#)

## Server and S-TAP IP addresses example

For some Guardium® implementations, one collector serves multiple S-TAPs. In some cases, customers want to have separate sets of session-level policies for each S-TAP. Normally they can use SERVER\_IP and SERVER\_NET\_MASK rule conditions. However, the server IP address can be different from STAP IP address. In these cases, use a session-level policy to associate the session-level policies by S-TAP.

You can manage this issue with either a group of IP addresses or by using a SENDER\_NET\_MASK. The two examples show both methods.

In the first example, the rule condition is set to check SENDER\_IP, which is the STAP IP address on the database server and to check that the database user is SCOTT.

If the conditions are met, the rule action is triggered. In this example, the action transforms the APP\_USER\_NAME in GDM\_CONSTRUCT\_INSTANCE table to match the SERVER\_HOSTNAME. In the OUTPUT\_FORMAT field, the action inserts the value SERVER\_HOSTNAME into the APP\_USER\_NAME field.

You can use a SENDER\_IP condition if you have multiple S-TAPs that are installed on the database server. Use the SENDER\_IP (which is the S-TAP IP address) to create a rule for one or more specified S-TAPs.

Specify S-TAP IP addresses in the GROUP of IP address. For example, to specify a single IP address in a group:

```
SENDER_IP = ('20.20.20.20',1)
```

Where: 1 is the number of members in the group.

For the second example, any NET\_MASK is triggered on the subnet in the group, rather than on a specific IP address (as described for the first example). For this example, the .20 IP address is related to SENDER\_IP, and .0 subnet IP is related to NET\_MASK condition.

Example 1: Use a group of IP addresses.

- Session level criteria:
  - Database User = `fred@example.com`
  - Server IP address In Group, where:
    - Group type = `Sender IP`
    - Members = A list of IP addresses.
- Rule actions:
  1. `TRANSFORM SOURCE PROGRAM NAME`
    - Source = `SOURCE PROGRAM NAME`
    - Search prefix = `Microsoft`
    - Output format = `GEORGE ODBC`
  2. `TRANSFORM SOURCE PROGRAM NAME`
    - Source = `SOURCE PROGRAM NAME`

- Output format = *GEORGE ODBC*

Example 2: Use a subnet mask:

- Session level criteria:
  - Server IP address *In Group*, where Group type = *Sender IP*  
Members = A list of IP addresses.
  - Subnet mask = 255.255.255.0
- Rule action: *TRANSFORM APP USER NAME*
  - Source = *SERVER HOST NAME*
  - Output format = (.\*)

## SR language examples

---

Example 1:

```
SR_POLICIES
{
 IF (SENDER_IP = ('20.20.20.1',1) DB_USER = 'fred@example.com')
 {
 TRANSFORM_SOURCE_PROGRAM SEARCH_PREFIX = 'Microsoft' OUTPUT_FORMAT = 'GEORGE ODBC'
 TRANSFORM_SOURCE_PROGRAM OUTPUT_FORMAT = 'GEORGE ODBC'

 }

 GROUP_ID = 1 TYPE = IP_ADDRESS SIZE = 8 #SENDER_IP GROUP
 {
 '20.20.20.2' '20.20.20.3' '20.20.20.4' '20.20.20.5' '20.20.20.6' '20.20.20.7' '20.20.20.8' '20.20.20.9'
 }
}
```

Example 2:

```
SR_POLICIES
{
 IF (SENDER_IP = ('20.20.20.20',1) DB_USER = 'SCOTT' SENDER_NET_MASK = '255.255.255.0')
 {
 TRANSFORM_APP_USER SOURCE = SERVER_HOST_NAME OUTPUT_FORMAT = '(.*)'

 }

 GROUP_ID = 1 TYPE = IP_ADDRESS SIZE = 2 #SENDER_IP GROUP
 {
 '20.20.20.1' '20.20.20.0'
 }
}
```

## Related concepts

## User authentication (Oracle) example

---

If your site uses Oracle OS authentication, the DB\_USER cannot be captured in network traffic and therefore is not logged. For this session-level policy, if the DB\_USER is empty, the policy copies the ORACLE\_USER name to DB\_USER.

- Session level criteria:
  - Client IP address = 10.10.10.10
  - Server IP address = 20.20.20.20
  - Database type = *ORACLE*
  - Server port = 1521
- Rule action: *TRANSFORM DB USER*
  - Source = *OS USER*
  - Output format = (.\*)

## SR language example

---

```
SR_POLICIES
{
 IF (CLIENT_IP = '10.10.10.10' SERVER_IP = '20.20.20.20' DB_TYPE = 'ORACLE' SERVER_PORT = 1521)
 {
 TRANSFORM_DB_USER SOURCE = OS_USER OUTPUT_FORMAT = '(.*)'
 }
}
```

## Related concepts

---

## Redacting data example

---

The REDACT rule action is similar to redaction in extrusion rules. Use REDACT to replace a matched pattern in SQL statements that are sent from client to server and mask the matched values.

In this example, any 13-16 digit number matches the regular expression and is masked by asterisks. The purpose is to mask credit card numbers, which usually meet the criteria.

- Session level criteria: None.
- Rule action: *Redact*
  - Data pattern =  $(\b(?\:\d[-]?)^{13,16}\b)$
  - Replacement symbol = *STAR\_SIGN*
  - 12.1 and later Replacement symbol = *Any*

Notes:

- The pattern to mask must be within parentheses ( ).
- The replacement symbol *STAR\_SIGN* is an asterisk (\*).
- 12.1 and later Along with the list of predefined replacement symbols, you can enter any custom symbol as a replacement symbol. If you enter multiple replacement symbols, then only the last symbol is used as the replacement symbol.

## SR language example

---

```
SR_POLICIES
{
 IF (*)
 {
 REDACT MATCH_PATTERN = '(\b(?\:\d[-]*?)^{13,16}\b)' REPLACEMENT_SYMBOL = STAR_SIGN
 }
}
```

## Related concepts

---

- [Extrusion actions](#)

## Hostname caching example

---

This example shows how to manage hostnames that are stored in a cache file, where the cache is updated hourly.

The cache is stored as *IP\_ADDRESS HOST\_NAME*. Use a TRANSFORM action to move the IP address in the cache to *HOST NAME*, which you can then use as the output value for all *IP\_ADDRESS TRANSFORM* actions.

- Session level criteria: None.
- Rule action: *TRANSFORM ANALYZED CLIENT IP*
  - Source = *CLIENT HOST NAME*
  - Search prefix = ?
  - Output format = (.\*)

## SR language example

---

```
SR_POLICIES
{
 IF (*)
 {
 TRANSFORM_ANALYZED_CLIENT_IP SEARCH_PREFIX = '?' SOURCE = CLIENT_HOST_NAME OUTPUT_FORMAT = '(.*)'
 }
}
```

## Related concepts

---

- [Transform actions](#)

## Ignore specified users example (MongoDB)

---

This example ignores all requests that belong to the MongoDB users NO\_AUTH and \_SYSTEM.

MongoDB allows users to connect to the database without authentication. When a user logs in, it is NO\_AUTH. If authentication never occurs, then it is just an extra record for each connection in the tables.

In another scenario, the user uses data security policies, which ignore S-TAP sessions.

In this case, the data security policy ignores the NO\_AUTH username. When the data security policy receives the real username, it is too late to ignore. This session-level policy avoids forwarding such connections only sessions to Logger, so the security policy does not ignore relevant sessions.

- Session level criteria:
  - Database user *Not in Group*, where Group type = *USERS*  
Members = A list of the users to ignore (that is, NO\_AUTH and \_SYSTEM).

- Subnet mask = 255.255.255.0
- Rule action: *SELECT SESSION*

## SR language example

---

```
SR_POLICIES {
 IF (DB_USER != ('',1) DB_TYPE = 'MONGODB')
 {
 SELECT_SESSION
 }
 GROUP_ID = 1 SIZE = 2
 {
 'NO_AUTH' '__SYSTEM'
 }
}
```

## Related concepts

---

## Scheduling with SESSION\_START examples

---

Use SESSION\_START to define when the session-level rules are active. The following examples show how to use the Session start time range parameter.

## SR language examples

---

Example 1: Ignore any session that starts outside of normal working hours (in this case after 7 PM and before 8 AM) and is labeled as a NIGHT\_JOB.

- Session level criteria:
  - Session start time range != [08:00..19:00]
- Rule action = *IGNORE REQUEST*
  - Request type = *SQL*
  - Search pattern = *NIGHT\_JOB*

Example 2: In many configurations, the database server and the collector are located in different time zones. For example, suppose that the database server is installed in San Francisco (Pacific time, which is UTC-8) and the collector is installed in Boston (Eastern Time, UTC-5). In this case, you need to specify both the session range and the time zone offset (as Coordinated Universal Time [UTC]).

- Session level criteria:
  - Session start time range = [08:00..19:00, -8]
- Rule action = *SELECT SESSION*

Example 3. Discard any session that runs between 8:00 PM and 8:30 PM that also meets all of the following criteria:

- The session comes from an S-TAP with IP address 25.25.25.25.
- The server port is 1422 (an MS SQL instance).
- The database user is Sirius.
- Session level criteria:
  - Database user = *Sirius*
  - Server port = 1433
  - Sender IP address = 25.25.25.25
  - Session start time range = [20:00..20:30]
- Rule action = *DISCARD SESSION*

## SR language examples

---

Example 1:

```
SR_POLICIES
{
 IF (SESSION_START = [08:00..19:00, -8])
 {
 SELECT_SESSION
 }
}
```

Example 2:

```
SR_POLICIES
{
 IF (SESSION_START != [08:00..19:00])
 {
 IGNORE_REQUEST REQ_TYPE = SQL SEARCH_PATTERN = 'NIGHT_JOB'
 }
}
```

Example 3:

```
SR_POLICIES
{
```

```

 IF (SENDER_IP = '25.25.25.25' SERVER_PORT = 1433 DB_USER = 'sirius' SESSION_START = [20:00..20:30])
 {
 DISCARD_SESSION
 }
}

```

## Related concepts

---

- [Audit and ignore session actions](#)

## Logging access activity for trusted sessions example

You can change LOG\_ACCESS\_ONLY functionality by using IGNORE\_REQUEST as shown in the following examples.

## SR language examples

---

The following example contains three if statements:

1. If the initial OS\_USER is ORACLE19, then transform the OS user from ORACLE19 to SIRIUS.
2. Log access only for all sessions where FRED is the database user.
3. If the OS\_USER is SIRIUS, stop logging access if any user runs a statement that contains \* FROM.

```

SR_POLICIES
{
 IF(OS_USER = 'ORACLE19')
 {
 TRANSFORM_OS_USER_SEARCH_PREFIX = '?' OUTPUT_FORMAT = 'SIRIUS'
 }
 IF(OS_USER = 'SIRIUS')
 {
 LOG_ACCESS_ONLY_SEARCH_PREFIX = 'DB_USER:FRED'
 }
 IF(OS_USER = 'SIRIUS')
 {
 STOP_LOG_ACCESS_ONLY_SEARCH_PREFIX = 'STATEMENT:/* FROM%'
 }
}

```

The following example performs a soft discard, with an option to revert the discard if sysdate is found in the sent statement.

The second action reverts the soft discard if any user runs a statement that contains \* FROM.

```

SR_POLICIES
{
 IF(*)
 {
 SOFT_DISCARD_SESSION_SEARCH_PREFIX = 'STATEMENT:sysdate'
 STOP_SOFT_DISCARD_SESSION_SEARCH_PREFIX = 'STATEMENT:/* FROM%'
 }
}

```

## Related concepts

---

## Creating a custom exception message example

Create a custom exception message with the SR language THROW\_EXCEPTION or by selecting the LOG EXCEPTION action in the UI for a local session-level policy.

- Session level criteria:
  - Session = LOCAL
  - Database type = ORACLE
- Rule action = LOG EXCEPTION
  - Exception type = SECURITY INCIDENT
  - Exception message = *Restricted local connection \${SESSION\_INFO}\$*

Note: The exception message is logged only once per session.

## SR language examples

---

In the following example, if the analyzer encounters a PLAIN\_PASSWORD security incident, it logs a custom message.

```

SR_POLICIES
{
IF (INCIDENT = 'PLAIN_PASSWORD')
{
 THROW_EXCEPTION EXC_TYPE = SECURITY INCIDENT EXC_MSG = 'Unencrypted database connection'
}

```

```
 }
In this
```

## Related concepts

---

- [Exception actions](#)

## Find name in SQL query example

Create a session-level policy that sends an alert when a name is found in an SQL query.

You can use a session-level policy from the UI to create an alert when a name, or other specific information, is found in an SQL query.

- Session level criteria: Statement *In Group*, where Group type = *FIELDS*.  
Members = A list of the names for which you want to send an alert, for example:

```
%Jane%Doe%
%Doe%Jane%
```

- Rule action: *ALERT PER MATCH*
  - Message Template = *Default*
  - Notification Type = *SYSLOG*
  - Exception message = *DB user \$(DB\_USER)\$ has searched for name in database \$(DB\_NAME)\$*
  - Distinct = *blank*

## SR language examples

---

Alerts are not available in the SR language. To use the SR language to do a similar action, use the LIKE parameter and THROW\_EXCEPTION action, for example:

```
SR_POLICIES
{
 IF (STATEMENT LIKE ('', 20010))
 {
 THROW_EXCEPTION EXC_TYPE = SECURITY INCIDENT EXC_MSG = 'DB user (DB_USER) has searched for name in database
$(DB_NAME) $$'
 }

 GROUP_ID = 20010 SIZE = 2
 {
 '%Jane%Doe%' '%Doe%Jane%'
 }
}
```

- [Exception actions](#)

## Detect local admin example

Use this policy to attach local admin sessions.

The following example uses a 1-parameter tuple. For more information about tuples, see [Tuples](#).

Session level criteria:

- Session *In Group*, where Group type = *Tuples*
  - Tuple parameters = *Session*
  - Members = A list of IP addresses
- Rule action: *S-GATE SESSION ATTACH*

## SR language example

---

```
SR_POLICIES
{
 TUPLES_GROUP_ID = 20008 TYPE = (SESSION) SIZE = 1
 {
 'ADMIN'
 }
 IF (TUPLES = ('', 20008) SESSION = 'LOCAL')
 {
 VERDICT_ATTACH
 }
}
```

## Related concepts

## Strict username example (Oracle)

Monitoring network traffic is subject to network packet loss. Losses can occur for various reasons, such as overloading S-TAP buffers on the peaks or insufficient collector power, S-TAP or sniffer restarts, or too many sessions are coming into the collector. Priority packets are the packets that contain metadata responsible for correctly extracting session information. Partial loss of priority packets can cause interpretation issues such as mangled usernames, source program names, and other important session information. This example shows how to provide a check on the username to ensure that it is correct. If the username is not correct, the username is replaced by a user-defined value.

Note: This example is available only for Oracle databases.

This example has two rules.

Rule 1: ORACLE - Set the database type to Oracle and configure the STRICT\_USERNAME option.

- Session level criteria = Database type = *ORACLE*
- Rule action = CONFIGURE = *STRICT\_USERNAME:<replacement\_value>*  
Where *<replacement\_value>* is any value that you choose. If Guardium finds a problem with the username, it is replaced with the specified value.

Rule 2: Throw exception - Throw an exception if a problem is found with the username.

- - Session level criteria:
    - Database type = *ORACLE*
    - Session = *GET\_USERNAME\_PROBLEM*
  - Rule action = THROW EXCEPTION = *SESSION EXCEPTION*
  - Exception message = *Session \${SESSION\_INFO}\$. PROBLEM TO GET USERNAME. PLACEHOLDER USERNAME - \${DB\_USER}\$, CLIENT OS - \${CLIENT\_OS\_NAME}\$, SERVER OS - \${SERVER\_OS\_NAME}\$*

## Related concepts

- [Configure actions](#)

## Login information dump example

Use the **login information dump** session level policy to help resolve Sniffer connection issues.

When you work with Guardium technical support to solve Sniffer issues, your support person might ask you to configure and run the slon looper or the **login information dump** session level policy. The slon looper and **login information dump** policy work together as follows.

The **login information dump** is a standard session-level policy template. To use this policy, click  to make a copy of the policy and make changes as needed. For example, you can specify a database username, an IP address, or other information.

Let's say that you have a scenario in which the username is empty, but packets aren't dropped in either the S-TAP or in Sniffer. One cause might be that the login sequence was encrypted or garbled and was sent more than 1 hour before the session's first statement. If the session received the login sequence, but timed out after an hour, then no information is available to log. In this case, the first incoming statement opens new session without login information and an error occurs. The **login information dump** session-level policy can help find these kinds of issues.

This example has two rules:

- Rule 1: Configure a login dump (CONFIGURE DUMP LOGIN)
  - Session level criteria: None.
  - Rule action: CONFIGURE Option =*DUMP\_LOGIN:ON*
- Rule 2: Create the login dump (DUMP LOGIN)
  - Session level criteria: None.
  - Rule action: LOG EXCEPTION = *SESSION EXCEPTION*
  - Exception message = *DUMP\_LOGIN:DUMP\_LOGIN: Session \${SESSION\_INFO}\$*

## SR language example

This example creates a login dump for an Oracle database.

```
SR_POLICIES
{
 IF (DB_TYPE = 'ORACLE')
 {
 CONFIGURE OPTION = 'DUMP_LOGIN:ON'
 }
 IF (DB_TYPE = 'ORACLE' STATEMENT LIKE 'BEGIN%')
 LOG EXC_TYPE = SESSION_EXCEPTION EXC_MSG = DUMP_LOGIN:DUMP_LOGIN: Session ${SESSION_INFO}$. Packets logged.
}
```

## Related tasks

- [Creating session-level policies](#)
- [Running the slon looper utility](#)

## Known limitations

The following known limitations apply to session-level policies and advanced session-level policies.

- Session-level policies apply on new database sessions opened after installing the session-level policy. When updating or removing session-level policies, existing sessions continue using the original policies until the sessions have finished their work.
- In some protocols, SERVICE\_NAME does not exist and is replaced by SERVER\_TYPE as a placeholder. For example, Microsoft SQL Server. In this case it is better to avoid using SERVICE\_NAME and to use DB\_TYPE instead.
- The Microsoft SQL Server username for local connections can be set to OS user and replaced later. Consider this when creating session-level policy rules.
- NET\_PROTOCOL can change during sessions and is not recommended for use.
- In rare cases, session information can be correlated in the logger (e.g. Oracle Kerberos authentication). Session parameters correlated in the logger should not be used as session-level policy rule conditions.
- When session-level policies use SQL criteria like command, object, literal or field, the following limitations apply:
  - The ANTLR3 parser is required.
  - Session-level policy processing is done on parsed context and constructs that do not have parser errors.
  - Some actions are not allowed with SQL criteria: TRANSFORM STATEMENT, NO PARSE, QUICK PARSE, QUICK PARSE NO FIELDS, MARK SESSION, CONFIGURE, LOG ACCESS ONLY, LOG EXCEPTION, and some TRANSFORM actions.
- Wildcards are allowed in session-level rule criteria, tuples, search parameters (except MATCH\_PATTERN), and groups (or LIKE groups when using advanced session-level policies). Regular expressions are allowed in rule criteria, groups and tuples. CIDR masking for IP addresses allowed in groups and tuples.
- IP address network masks are not applied to IP address groups. Mask IP address group members before creating the group and add them to the group in subnet form. If CLIENT\_NET\_MASK, SERVER\_NET\_MASK, or SENDER\_NET\_MASK used when CLIENT\_IP, SERVER\_IP, or SENDER\_IP contain a group, add the related subnet members directly to the group. Consider using CIDR notation in groups when it is needed.
- If session level policies are reinstalled, sessions are validated with the new policy rules.
- Regular expression use Perl syntax. The maximum size of regular expressions is 255 symbols. Note that Guardium checks regular expression syntax but does not check semantics. The regular expression language has advanced features and is recommended for use only by experienced users. Otherwise, regular expressions can lead to serious degradation of performance and available resources.
- Only one tuple per rule is allowed. Multiple tuples are allowed in the policy.
- For advanced session level policies only:
  - The size specified in the header of any group (including groups of tuples) must match the number of group member values specified in the body of the group. For example, in a six-tuple group with seven tuples, the seventh tuple will be disregarded.
  - Imported session rules only work with actions supported by advanced session level policies.
  - Advanced session level policies cannot be created with empty groups: at least one group member must be specified.
  - Importing session rules imports all currently installed session level policies and rules at once. If you need rules from a single policy, install that policy before importing so it will have only rules from that policy.
- Criteria ANALYZED\_CLIENT\_IP is the result of correlation encrypted and not encrypted sessions. This criteria is not always available.
- Rules that use the CONFIGURE action can use the following criteria: CLIENT\_IP\_ADDRESS, CLIENT\_NET\_MASK, SERVER\_IP\_ADDRESS, SERVER\_NET\_MASK, SERVER\_PORT, SENDER\_IP, SENDER\_NET\_MASK, DB\_TYPE, SESSION\_START\_TIME\_RANGE, NET\_PROTOCOL, SESSION(OPTIONS: LOCAL, TAP\_ENCRYPTED, ALL\_ENCRYPTED, W\_STAP, U\_STAP, E\_STAP, MID\_STREAM).
- For performance reasons, use fewer than 500 session-level rules across all installed policies.

## Policy rule actions

Define blocking, alerting, or logging actions to take when policy rules are matched.

Note: Consider that you have created a security policy that contains both access rules and extrusion rules. If the SQL request triggers the access rule actions and the SQL responses match the extrusion rules, you can use the [store skip extrusion on sql access rule match](#) CLI command to determine how or which extrusion rule actions may be skipped or executed. Use the CLI to help reduce duplicate logged data or alerts.

- [\*\*Blocking rule actions\*\*](#)  
This section describes S-TAP Terminate and S-GATE rule actions.
- [\*\*Alerting rule actions\*\*](#)  
Alert actions send notifications to one or more recipients.
- [\*\*Logging or ignoring rule actions\*\*](#)  
Logging actions control the level of logging based on the observed traffic.

Details about how data is handled when using ignore actions in policy rules.
- [\*\*Log full details\*\*](#)  
With log full details, Guardium logs data for each separate request and with unmasked values. Log full details also provides exact timestamps.
- [\*\*Set character set\*\*](#)  
You can use an action under a policy extrusion rule in order to attach alternative character sets to the session.
- [\*\*Rule definition fields\*\*](#)  
You can use these fields when you define policy rules.

## Blocking rule actions

This section describes S-TAP Terminate and S-GATE rule actions.

### S-TAP Terminate

The S-TAP Terminate action terminates a database connection (a session) and prevents additional requests on that session. This action is available in the S-TAP regardless of whether S-GATE is used.

Note: With S-TAP Terminate, the triggering request is not usually blocked but additional requests from that session are blocked. With a high request rate, sometimes more than one request may go through before the session is terminated.

## S-GATE

---

S-GATE provides database protection via the S-TAP for both network and local connections. When S-GATE is available, all database connections (sessions) are evaluated and tagged for monitoring in one of the following S-GATE modes:

- Attached (S-GATE is "on"): S-TAP is in firewalls mode for that session, and it holds the database requests and waits for a verdict on each request before releasing its responses. Latency is expected in this mode, but it ensures that rogue requests are blocked.
- Detached (S-GATE is "off"): S-TAP is in normal monitoring mode for that session, and it passes requests to the database server without any delay. Latency is not expected in this mode.

S-GATE configuration in the S-TAP itself defines the default S-GATE mode for all sessions, as well as other defaults related to S-GATE verdicts when the collector is not responding. For more information, see [Linux and UNIX systems: S-TAP firewall parameters](#) and [Windows: S-TAP firewall parameters](#).

It is possible to alter the default S-GATE configuration in real time using the following S-GATE policy rule actions:

- S-GATE Attach: sets S-GATE mode to "Attached" for a specific session. Intended for use when a certain criteria is met that raises the need to closely watch (and if needed block) the traffic on that session.
- S-GATE Detach: sets S-GATE mode to "Detached" for a specific session. S-GATE Detach is intended for use on sessions that are considered safe or sessions that cannot tolerate any latency.
- S-GATE Terminate: applies only when the session is attached, S-GATE Terminate drops the reply of the firewalled request and terminates the session on some databases. The S-GATE TERMINATE policy rule action causes a previously watched session to terminate.

Notes:

- S-TAP and S-GATE Terminate actions do not work on a client IP group whose members have wild-card characters. S-TAP and S-GATE Terminate only work with a single IP address. Wildcards should be handled by groups if the customer wants to use multiple IP entries. Customer can create groups of trusted or untrusted users/clients to handle their business needs in the policies.
- There are limitations for using S-GATE with A-TAP with older Linux kernels. For S-TAP V10.1.2 and higher, S-GATE is supported everywhere except Linux with A-TAP using kernels earlier than 2.6.36.
- For MySQL databases, the default command line connection is `mysql -u <user> -p <pass> <dbname>`. In this mode, MySQL first maps all the objects and fields in the database to support tab-key auto-completion. A terminate rule on any object or field involved in this mapping immediately disables the connection session. To avoid this, connect to MySQL with the `-A` flag, which disables the auto-complete feature and will not trigger the terminate rule. Another option is to fine-tune the rule and not terminate on any access to these objects or fields, instead defining a narrower criteria that does not trigger the rule on the login sequence.

---

## Alerting rule actions

Alert actions send notifications to one or more recipients.

For each alert action, multiple notifications can be sent, and the notifications can be a combination of one or more of the following notification types:

- Email messages: You can specify a Guardium user email, or an external email. Emails are sent using the SMTP server configured for the Guardium system. Additional receivers for email notification are the invoker (the user that initiated the actual SQL command that caused the trigger of the policy) and the owner (the owner of the database). The invoker and owner are identified by retrieving user IDs (IP-based) configured via Guardium APIs. To view these mappings, log in as `accessmgr` and go to Data Security > User-DB Association or use the `list_db_user_mapping` API command.
- SNMP traps: alerts the trap community configured for the Guardium system.
- Syslog messages: generates messages that are written to the syslog.  
Attention: The `%%RecordsAffected` variable does not return values when used in a message template for `alert only` rule actions that specify the `syslog` notification type.
- Custom notifications: user-created notification handlers implemented as Java classes.

Attention: Alert definitions and notifications are not subject to data-level security for the following reasons: alerts are not evaluated in the context of users, alerts may be related to databases associated with multiple users, and to avoid situations where no one receives the alert notification.

---

## Alert messages

The contents of an alert are defined by message templates. Navigate to Setup > Global Profile, locate the Named template field, and click Edit. Use the Named Template Finder to create, review, and modify message templates.

---

## Alert behaviors

There are several types of alert actions, including the following:

- Alert Daily: sends notifications only the first time the rule is matched each day.
- Alert Once Per Session: sends notifications only once for each session in which the rule is matched. This action might be appropriate in situations where you want to know that a certain event has occurred, but not for every instance of that event during a single session. For example, you may want a notification sent when a certain sensitive object is updated, but if a program updates thousands of instances of that object in a single session, you would not want thousands of notifications sent to the receivers of the alert.
- Alert Only: when Alert Only is used with the syslog notification type, messages go directly to `/var/log/messages`. For other notification types, Alert Only sends messages to the MESSAGE table. Alert Only does not notify of policy violations.  
Attention: The `%%RecordsAffected` variable does not return values when used in a message template for `alert only` rule actions that specify the `syslog` notification type.
- Alert Per Match: sends notifications each time the rule is satisfied. This is appropriate for a condition requiring attention each and every time it occurs.
- Alert Per Time Granularity: sends notifications once per logging granularity period. For example, if the logging granularity is set to one hour, notifications are sent for only the first match of the rule during each hour.

Tip: The Guardium administrator sets logging granularity using the [Manage > Activity Monitoring > Inspection Engines](#) tool.

## Logging or ignoring rule actions

Logging actions control the level of logging based on the observed traffic.

Access rules, exception rules, and extrusion rules differ in which actions are available. For example, Log and Ignore actions are available for most policies, but the Audit Only action is only available for policies that use the Selective Audit Trail setting.

### Audit Only

This action is only available for policies that use the Selective Audit Trail setting.

Audit Only logs the construct that triggered the rule. For a Selective Audit Trail policy, no constructs are logged by default, so use this selection to indicate which constructs you want to log. For example, for the Application Events API, if you want to log database usernames for reporting, use this action (otherwise, in this example, the username is blank).

### Allow

When matched, log the matching construct but do not log a policy violation. If the Allow action is selected, no other actions can be added to the rule.

### Log Only

Log the policy violation. Except for the Allow action, a policy violation is logged each time that a rule is triggered unless the rule action suppresses logging.

### Log Masked Details

This action is available for access rules and extrusion rules.

Log the full SQL for the request, replacing values with question marks (?).

### Log Full Details

Log the full SQL string and the exact timestamp for the request.

### Log Full Details with Values

Like Log Full Details, but each value is stored as a separate element such that the values are parsed and logged in to a separate table in the database. This log action uses more system resources as it logs the specific values of the relevant commands. Use this log action only when you need to generate reports with specific conditions on these values.

Attention: Consult technical services to access this log action.

### Log Full Details per Session

Log the full SQL string and exact timestamp for this request and for the remainder of the session.

### Log Full Details with Values per Session

See the descriptions for Log Full Details with Values and Log Full Details per Session.

Attention: Consult technical services to access this log action.

### Skip Logging

When matched, do not log a policy violation and stop logging constructs. This action is similar to the Allow action, but it also stops the logging of constructs. This action is used to eliminate the logging of constructs for requests that are known to be of no interest. This feature also applies for exception rules that concern database error codes only, allowing users to not log errors when an application generates a large and unavoidable quantity of errors.

Note: GDM\_CONSTRUCT is logged sometimes because parsing and logging of the construct occurs before the rule is applied, but the construct is included in the session.

### Ignore Responses per Session

Responses for the remainder of the session are ignored. This action does not log a policy violation, but it stops analyzing responses for the remainder of the session. This behavior is useful in cases where you know that the database response is of no interest. This action works when data is sniffed from an S-TAP, but it does not work when data is sniffed from a SPAN port.

Note: For Ignore Responses per Session, since the sniffer does not receive any response for the query or it is ignored, the values for COUNT\_FAILED and SUCCESS are the default. In this case, the values are COUNT\_FAILED=0 and SUCCESS=1.

### Ignore Session

The current request and the remainder of the session are ignored. This action does not log a policy violation. But it stops the logging of constructs and does not test for policy violations of any type for the remainder of the session. This action might be useful if the database includes a test region and you do not need to apply policy rules against that region of the database. The S-TAP or sniffer discards or disregards activity from individual sessions due to the execution of an ignore session rule action.

Important: Connection (login and logout) information is always logged, even if the session is ignored.

### Ignore S-TAP Session

The current request and the remainder of the S-TAP session are ignored. This action is done in combination with specifying specific systems, users, or applications that are producing a high volume of network traffic. This action is useful in cases where you know that the database response from the S-TAP session is of no interest.

- If no SQL is recorded for a session, then the "Ignore S-TAP Session" NEVER fires - and hence the **Session:Session Ignored** flag is recorded as No.
- If a session has 1 or more SQL statements, then the **Session:Session Ignored** flag recorded as Yes.

Use Ignore S-TAP Session as follows:

- IGNORE S-TAP SESSION: A "hard" ignore that cannot be revoked.
  - IGNORE STAP SESSION (REVOCABLE): A "soft" ignore; this rule action can enable the session traffic to be sent again without requiring a new connection to the database.
  - REVOKE Ignore - Resumes the sessions that are ignored by IGNORE\_S-TAP\_SESSION (REVOCABLE) action, which means that traffic is sent to the Guardium system after the S-TAP receives the **REVOKE Ignore** command. This command is sent from the S-TAP Control page using Revoke All Ignored Sessions.
- Note: The Revoke Ignore command persists for the S-TAP host in one sniffer process. New sessions opened after the S-TAP is in the revoked ignore state are not ignored even if the rule IGNORE\_STAP\_SESSION (REVOCABLE) is triggered.

Tip: Use IGNORE S-TAP SESSION (REVOCABLE) only when some of your IGNORE S-TAP SESSION actions need to be revoked. Otherwise, use IGNORE S-TAP SESSION because it's simpler and faster.

#### Ignore SQL per Session

Do not log SQL for the remainder of the session. Exceptions are still logged, but the system might not capture the SQL strings that correspond to the exceptions.

#### Log Extrusion Counter

This action is only available for extrusion rules.

Update the counter but do not log any of the returned data. This action saves disk space when the counter value is more important than the returned values.

#### Log Masked Extrusion Counter

This action is only available for extrusion rules.

Update the counter and log the SQL request, replacing values with question marks (?). This action does not log the returned values.

#### Quarantine

This action is available for access, exception, and extrusion rules.

Prevent the same user from logging in to the same server for a specified time period. To use the Quarantine rule action, you must also specify a duration for the quarantine with the Quarantine for (minutes) setting. If the session is watched (S-GATE), the action sends a drop verdict. If the session is not watched (S-TAP Terminate), the action has the S-TAP stop the session.

Quarantine timestamps are calculated by taking the current time and adding the number of minutes from the reset interval field. The new timestamp, which is sorted by timestamp, is kept in a structure along with server IP, server type, DB username, service name, and a flag that indicates whether the session is watched.

#### No Parse

Do not parse the SQL statement.

#### Quick Parse

This action is for access rules.

Do not parse the SQL statement for the remainder of the session. This action reduces parsing time. In this mode, all objects that are accessed can be determined but the exact object instances are unknown.

#### Note:

If you are using the universal connector, this action is only available for plug-ins that delegate the language syntax parsing to Guardium Data Protection. These cases usually occur when Guardium Data Protection supports that language natively. This action is not available if you are using a plug-in that parsed the language syntax by itself and does not delegate the syntax parsing to Guardium Data Protection.

#### Quick Parse No Fields

Do not parse fields in the SQL statement. Quick parse rules are only applied if SQL string is greater than 100 characters.

#### Quick Parse Native

This action is used only for Guardium S-TAP for Db2 on z/OS.

Use this rule action to improve performance in an environment where heavy traffic is overloading the Guardium sniffer.

#### Redact

This action is for extrusion rules.

Mask portions of database query output in reports for certain users, for example credit card numbers. Define the masking character by the Replacement character of the Data pattern parameter of the extrusion rule. If output produced by the extrusion rule matches the regular expression of the Data pattern, the portions that match subexpressions between parenthesis ( and ) are replaced by the masking character. Predefined regular expressions can also be used. For more information, see Data Pattern in [Rule definition fields](#).

#### Restriction:

- Redaction does not work on open sessions after an S-TAP live upgrade.
- Redaction does not work on tables that are created with field and number type.
- Redaction is available only with unencrypted traffic.
- Redaction is supported only with ANSI character sets.
- Delay in redaction is proportional to the amount of data returned by the query.
- The following restrictions apply only to regular (non-session-level) policies:
  - SQL Pattern is not supported for redaction rules.
  - Set redaction rules on the session level (attributes like IP addresses or users) and not on the SQL level (attributes like OBJECT\_NAME or VERB). If you set redaction rules on the SQL that needs to be scrubbed, it can take a few milliseconds for the scrub instructions to reach the S-TAP. In this case, some results might go though unmasked.

To guarantee that all SQL is redacted, set the S-TAP's default S-GATE mode to "attach" for all sessions that use the guard\_tap.ini file. This step guarantees that the rules engine, which holds each request and waits for the policy's verdict on the request, inspects all commands. This deployment introduces some latency but makes sure that data is 100% scrubbed.

In the Informix database, when you use char data type, columns do not have null termination at the end. All four columns are captured in the sendmsg system call as one piece, and K-TAP always tries to redact whatever data it captures. This behavior is a limitation when you use redaction with Informix.

- For more information about issues with redact, see the troubleshooting tips under [Policies](#).

#### Record Values Separately

#### Do Not Record Values Separately

This action is a session-based access rule. Used in replay functions to distinguish between transactions.

#### Mark as Auto-commit ON

#### Mark as Auto-commit OFF

This action is a session-based access rule. Used in replay function due to various auto-commit models for different databases.

#### z/OS Audit

This action is used only for datasets, Db2, and IMS collection profile policy rules that specify which traffic to collect on a z/OS server.

Traffic that meets the filtering criteria is sent to the collector. Only this action can be specified on a collection profile rule.

## Understanding ignore actions

Details about how data is handled when using ignore actions in policy rules.

#### Ignore session

The current request and the remainder of the session will be ignored. This action does not log a policy violation, but it stops the logging of constructs and will not test for policy violations of any type for the remainder of the session. This action might be useful if, for example, the database includes a test region, and there is no need to apply policy rules against that region of the database.

Table 1. Ignore session

| Data logged or ignored between client and DB Server/S-TAP | Data sent from DB Server/S-TAP to Collector                                                                                                                                                                                                              | Data from Span Port/ Network TAP to Collector                                                                                                  |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Ignore - SQL commands, SQL errors, Result Sets            | Log in/ Log out<br>Sniffer to S-TAP - One signal to S-TAP to stop sending activity for this session. If additional activity is sent by S-TAP, it is ignored at the sniffer level only.<br>Ignore SQL commands<br>Ignore SQL errors<br>Ignore Result Sets | Ignore – SQL commands, SQL errors, Result Sets.<br>SQL commands and errors coming from a Span Port or Network TAP are filtered at the Sniffer. |

#### Ignore S-TAP session

The current request and the remainder of the S-TAP session will be ignored. This action is done in combination with specifying in the policy builder menu screen of certain machines, users or applications that are producing a high volume of network traffic. This action is useful in cases where you know the database response from the S-TAP session will be of no interest.

Table 2. Ignore S-TAP session

| Data logged or ignored between client and DB Server/S-TAP | Data sent from DB Server/S-TAP to Collector                                                                                                                             | Data from Span Port/ Network TAP to Collector                                                                     |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Ignore - SQL commands, SQL errors, Result Sets            | Log in/ Log out Sniffer to S-TAP - One signal to S-TAP to stop sending activity for this session. Additional signals to S-TAP to stop sending activity to this session. | Not Applicable<br>If there is a need to ignore traffic from a Span Port/ Network TAP, use Ignore session instead. |

#### 12.1 and later Ignore responses per session

Responses for the remainder of the session will be ignored. This action does not log a policy violation, but it stops analyzing responses for the remainder of the session. This action is useful in cases where you know the database response will be of no interest.

Note: For ignore response per session, since the sniffer does not receive any response for the query or it is ignored, then the values for COUNT\_FAILED and SUCCESS are whatever the default for the table says they are, in this case COUNT\_FAILED=0 and SUCCESS=1.

Table 3. Ignore responses per session

| Data logged or ignored between client and DB Server/S-TAP | Data sent from DB Server/S-TAP to Collector                                                                                                                                          | Data from Span Port/ Network TAP to Collector                     |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| Log – SQL commands Ignore - SQL errors, Result Sets       | Log in/ Log out SQL Commands Sniffer to S-TAP - One signal to S-TAP to stop sending activity for this session. Additional signals to S-TAP to stop sending activity to this session. | Not applicable<br>This rule action is S-TAP-only implementations. |

#### Ignore SQL per session

No SQL will be logged for the remainder of the session. Exceptions will continue to be logged, but the system may not capture the SQL strings that correspond to the exceptions.

Table 4. Ignore SQL per session

| Data logged or ignored between client and DB Server/S-TAP | Data sent from DB Server/S-TAP to Collector                                                                                                                                                                                                 | Data from Span Port/ Network TAP to Collector                              |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Ignore - SQL commands                                     | Log in/ Log out                                                                                                                                                                                                                             | Ignore – SQL commands                                                      |
| Log - SQL errors, Result Sets                             | Sniffer to S-TAP - One signal to S-TAP to stop sending activity for this session. If additional activity is sent by S-TAP, it is ignored at the sniffer level only.<br>SQL commands<br>SQL errors<br>Result Sets, if using extrusion rules. | Log - SQL errors, Result Sets<br>SQL commands are filtered at the Sniffer. |

#### Selective Audit Trail

Use a Selective Audit Trail policy to limit the amount of logging on the appliance. This is appropriate when the traffic of interest is a relatively small percentage of the traffic being accepted by the inspection engines, or when all of the traffic you might ever want to report upon can be completely identified.

It is important to note that Ignore Session rules are still very important to include in the policy even if using a Selective Audit Trail. Ignore Session rules decrease the load on a collector considerably because by filtering the information at the S-TAP level, the collector never receives it and does not have to consume resources analyzing traffic that will not ultimately be logged. A Selective Audit Trail policy with no Ignore Session rules would mean that all traffic would be sent from the database server to the collector, causing the collector to analyze every command and result set generated by the database server.

Table 5. Selective Audit Trail

| Data logged or ignored between client and DB Server/S-TAP | Data sent from DB Server/S-TAP to Collector                                                                                                           | Data from Span Port/ Network TAP to Collector                              |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Ignore - SQL commands                                     | Log in/ Log out                                                                                                                                       | Ignore – SQL commands                                                      |
| Log - SQL errors, Result Sets                             | Ignore SQL commands, except for those defined by Audit-Only or Log Full Details rules.<br>Log SQL errors<br>Log Result Sets, if using extrusion rules | Log - SQL errors, Result Sets<br>SQL commands are filtered at the Sniffer. |

## Log full details

With log full details, Guardium logs data for each separate request and with unmasked values. Log full details also provides exact timestamps.

By default the Guardium® collector masks all values when logging an SQL string. For example

```
insert into tableA (name,ssn,ccn) values ('Bob Jones', '429-29-2921','29249449494949494')
```

is logged as `insert into tableA (name,ssn,ccn) values (?, ?,?)`. This is the default behavior for two reasons:

1. Values should not be logged by default because they may contain sensitive information.
2. Logging without values can provide for increased system performance and longer data retention within the appliance. Very often, database traffic consists of many SQL requests, identical in everything except for their values, repeated hundreds, thousands, or even millions of times per hour. By masking the values, Guardium is able to aggregate these repeated SQL requests into a single request, called a "construct". When constructs are logged, instead of each individual SQL request/construct being logged separately, it is only logged once per hour (per session) with a counter of how many times the construct was executed. This can save a tremendous amount of disk space because, instead of creating a hundreds (or millions) of lines in the database, only one new line is added.

With Log Full Details, Guardium logs the data with the values unmasked and each separate request. Log Full Details also provides the exact timestamp whereas logging without details provides the most recent timestamp of a construct within the logging granularity time period (usually 1-hour).

Important: When using log full details, if the inspection engine is not configured with inspect returned data enabled, the success or failure of SQL statement is not updated correctly. For more information about configuring inspection engines to inspect returned data, see [Inspection Engine Configuration](#).

Ignore S-TAP Session - Ignore S-TAP Session causes the collector to send a signal to the S-TAP instructing it to stop sending all traffic, except for the logout notification, for specific sessions. For example, if you have a rule that says `where`

```
DBUserName?=?scott, Ignore S-TAP Session:
```

- When Scott logs into the database server, S-TAP sends the connection information to the collector.
- The collector logs the connection. Session information (log in/log outs) are always logged.
- The collector sends a signal to S-TAP to stop sending any more traffic from this specific session. This means that any commands run by Scott against the database server and any responses (result sets, SQL errors, etc.) sent by the Database server to Scott will be discarded by S-TAP and will never reach the collector.
- When Scott logs out of the database server, S-TAP will send this information to the collector (log in/log out information is always tracked even if the session is ignored).
- When Scott logs in again, these steps are repeated. The logic on which sessions should be ignored is maintained by the collector, not the S-TAP.

It is important to note that Ignore Session rules are still very important to include in the policy even if using a Selective Audit Trail. Ignore Session rules decrease the load on a collector considerably because by filtering the information at the S-TAP level, the collector never receives it and does not have to consume resources analyzing traffic that will not ultimately be logged. A Selective Audit Trail policy with no Ignore Session rules would mean that all traffic would be sent from the database server to the collector, causing the collector to analyze every command and result set generated by the database server.

## Using MS-SQL or Sybase batch statements

There is a limitation where the success or failure of SQL commands in MS-SQL or Sybase batch statements may not show correctly.

MS-SQL or Sybase SQL batch statements are primarily used when creating complex procedures. When executing SQL statements separately, the status of each statement is tracked separately and will have the correct success or failure value. However, when a batch of SQL statements (used in MS-SQL or Sybase) are executed together, the status returned is the single status of the last transaction in the batch.

For example:

```
[Start of SQL batch]
SQL 1 statement - failed
SQL 2 statement - failed
SQL 3 statement - success
[End of SQL batch]
```

In the Guardium application, only the success or failure of the last SQL statement is reported in a MS-SQL or Sybase batch statement. In this case, success is reported for the MS-SQL or Sybase batch statement, even though SQL 1 and SQL 2 failed.

## Set character set

You can use an action under a policy extrusion rule in order to attach alternative character sets to the session.

Example of extrusion rule (with hint):

Character set EUC-JP (code 274).

Extrusion rule pattern: `guardium://char_set?hint=274`

As a result an extrusion rule is attached to the session and Analyzer will use EUC-JP in the session, if there is no other character set.

Example of extrusion rule (with force) :

Character set EUC-JP (code 274).

Extrusion rule pattern: `guardium://char_set?force=274`

As a result an extrusion rule us attached to the session and Analyzer will use EUC-JP character set in the session in any case. Character set used before will be substituted by EUC-JP.

Keep in mind that extrusion rules usually attach to the session with some delay. Therefore short sessions or the beginning of the session are not immediately changed by a character set change. The schema works for: Oracle, Sybase, MY SQL, and MS SQL.

## Rule definition fields

You can use these fields when you define policy rules.

Table 1. Reference Table of Rule Definition Fields

| Field                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Action                                                   | Indicates the action to be taken when the rule is true. For a comprehensive description of all rule actions, see Rule Actions Overview.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| App Event Exists                                         | Match for an application event only. See the App Event Note.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| App Event Values                                         | Match the specified application event Text, Numeric, or Date values. Also allow a Group to be chosen for the event string as an option. See the App Event Note.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| (App) Event Type                                         | Match the specified application event. See the App Event Note.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| (App) Event User Name                                    | Match the specified application event username only. | App. User                                                | Application User. For more information, see <a href="#">Values and groups of values in rules</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Category                                                 | An arbitrary label that can be used to group policy violations for reporting purposes. A default category can be specified in the policy definition, but the default can be overridden for each rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Classification                                           | An arbitrary label that can be used to group policy violations for reporting purposes. A default classification can be specified in the policy definition, but the default can be overridden for each rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client Info                                              | DB2® client information: For access rules only. For z/OS® only, a CLIENT INFO field (and CLIENT_INFO_GROUP_ID) is visible if DB_TYPE is either Db2, Db2 COLLECTION Profile or VSAM COLLECTION Profile.<br><br>The type of information that can be placed in this field is USER=x; WKSTN=y; APPL=z.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Client IP                                                | <p>Clear the Not box to include, or mark the Not box to exclude:</p> <ul style="list-style-type: none"> <li>Any client: Leave all client fields blank. The count is incremented every time that any client satisfies the rule. (You cannot leave all fields blank if the Not box is marked.)</li> <li>All clients that are selected by an IP address and mask: Enter a client IP address in the first box and network mask in the second box. The count is incremented each time that any of the specified clients satisfies the rule. For example, to select all clients in subnet 192.168.9.x, enter 192.168.9.1 in the first box and 255.255.255.0 in the second box.</li> <li>A group of clients: Select a group of client IP addresses from the Group list, or click Groups to define a new group and then select that group. The count is incremented each time that any member of the selected group satisfies the rule.</li> <li>All clients that are selected by an IP address and mask AND a group of clients: Use both the Client IP and Group fields. The count is incremented each time that any client is specified who uses either method that satisfies the rule.</li> </ul> <p>Allow wildcard in IP address. Wildcard % is permitted in a policy for Client IP group.</p> |
| Client IP/Source Program/DB User/ Server IP/Service Name | <p>7-tuple group - Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB<br/>5-tuple group type available for access, exception, and extrusion rules.<br/>A tuple allows multiple attributes to be combined together to form a single group member.<br/>Tuple supports the use of one slash and a wildcard character (%). It does not support the use of a double slash.<br/>Wildcard % is permitted in a policy for Client IP/Source Program/DB User/ Server IP/Service Name group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client MAC                                               | <p>To make the rule sensitive to a single client MAC address, you can take one of the following steps:</p> <ul style="list-style-type: none"> <li>Enter the address in nn:nn:nn:nn:nn:nn format, where each n is a hexadecimal digit (0-F).</li> <li>Enter a dot (.) in the Client MAC box to indicate to maintain a separate count for each client MAC address.</li> <li>Leave the Client MAC box empty to ignore client MAC addresses.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Command                                                  | <p>The command. You can have situations in which a command group cannot be edited, and the and/or Group label changes to Collect Only, indicating that commands from only the selected group are to be selected. For more information, see <a href="#">Values and groups of values in rules</a>.</p> <p>If the Every member in group option is selected, all fields of the SQL statement must be a member of the defined group. However, the SQL statement does not need to contain all members of the group. For example, for the group <b>DB_TABLES_PROD</b> with members <b>students</b>, <b>module</b>, <b>marks</b>:</p> <ul style="list-style-type: none"> <li>For the query <b>select * from students;</b>, the object <b>students</b> is in the group and triggers the rule.</li> <li>For query <b>select * from students, module, marks;</b>, all three objects are in the group, which triggers the rule.</li> <li>For the query <b>select * from students, test;</b>, the object <b>test</b> is not in the group and does not trigger the rule when the Every member in group option is selected. However, it triggers the rule if the In group option is selected, since <b>students</b> is a member of the group.</li> </ul>                                                  |
| Continue to Next Rule                                    | If marked, rule testing will continue with the next rule, regardless of whether this rule is satisfied. This means that multiple rules can be satisfied (and multiple actions taken) by a single SQL statement or exception. If not marked (the default), no additional rules are tested for the current transaction when this rule is satisfied.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |          |            |                |             |                |                   |             |                |                      |                     |                        |                         |                     |                        |                     |                 |                |                        |                  |                |                        |                 |                |                           |                |                |        |          |            |                |             |                |                   |             |                |                      |                     |                |                         |                     |                |                     |                 |                |                        |                  |                |                       |                 |                |                          |                  |                |

| Data Pattern              | <p>Every type of rule (Access, Exception, Extrusion) can have Data pattern, but it is required for Extrusion rules.</p> <p>For use in defining Extrusion Rules - A regular expression to be matched, in the Data Pattern box. Click Regex to open the Build Regular Expression tool, which allows you to enter and test regular expressions. This enables more complex masking patterns. Put parentheses around the section that you want to mask. Use this function to mask data retrieved from the database.</p> <p>For example,</p> <pre><b>Windows S-TAP:</b> ([0-9][0-9][0-9][0-9[-, ]?[0-9][0-9][0-9][0-9][-, ]?[0-9][0-9][0-9][0-9][-, ]?) [0-9][0-9][0-9][0-9][0-9]</pre> <pre><b>Unix S-TAP:</b> ([0-9]{4}[-, ]?[0-9]{4}[-, ]?[0-9]{4}[-, ]?) [0-9]{4}[ ]{0,20}</pre> <p>Additional regular expressions (Regex) for use only in Data Patterns with an action of Redact (Scrub):</p> <pre><b>For Windows S-TAP</b></pre> <table border="1"> <thead> <tr> <th>Name :</th> <th>Pattern:</th> <th>Masked to:</th> </tr> </thead> <tbody> <tr> <td>SCRUB_SSN_ANSI</td> <td>AAA-AA-AAAA</td> <td>****-****-AAAA</td> </tr> <tr> <td>SCRUB_SSN_UNICODE</td> <td>UUU-UU-UUUU</td> <td>****-****-UUUU</td> </tr> <tr> <td>SCRUB_CC_SPACES_ANSI</td> <td>AAAA AAAA AAAA AAAA</td> <td>***** ***** ***** AAAA</td> </tr> <tr> <td>SCRUB_CC_SPACES_UNICODE</td> <td>UUUU UUUU UUUU UUUU</td> <td>***** ***** ***** UUUU</td> </tr> <tr> <td>SCRUB_CC.Solid_ANSI</td> <td>AAAAAAAAAAAAAAA</td> <td>**********AAAA</td> </tr> <tr> <td>SCRUB_CC.Solid_UNICODE</td> <td>UUUUUUUUUUUUUUUU</td> <td>**********UUUU</td> </tr> <tr> <td>SCRUB_CC_AX.Solid_ANSI</td> <td>AAAAAAAAAAAAAAA</td> <td>**********AAAA</td> </tr> <tr> <td>SCRUB_CC_AX.Solid_UNICODE</td> <td>UUUUUUUUUUUUUU</td> <td>**********UUUU</td> </tr> </tbody> </table><br><pre><b>UNIX S-TAP</b></pre> <table border="1"> <thead> <tr> <th>Name :</th> <th>Pattern:</th> <th>Masked to:</th> </tr> </thead> <tbody> <tr> <td>SCRUB_SSN_ANSI</td> <td>AAA-AA-AAAA</td> <td>****-****-AAAA</td> </tr> <tr> <td>SCRUB_SSN_UNICODE</td> <td>UUU-UU-UUUU</td> <td>****-****-UUUU</td> </tr> <tr> <td>SCRUB_CC_SPACES_ANSI</td> <td>AAAA AAAA AAAA AAAA</td> <td>**********AAAA</td> </tr> <tr> <td>SCRUB_CC_SPACES_UNICODE</td> <td>UUUU UUUU UUUU UUUU</td> <td>**********UUUU</td> </tr> <tr> <td>SCRUB_CC.Solid_ANSI</td> <td>AAAAAAAAAAAAAAA</td> <td>**********AAAA</td> </tr> <tr> <td>SCRUB_CC.Solid_UNICODE</td> <td>UUUUUUUUUUUUUUUU</td> <td>**********UUUU</td> </tr> <tr> <td>SCRUB_AMEX.Solid_ANSI</td> <td>AAAAAAAAAAAAAAA</td> <td>**********AAAA</td> </tr> <tr> <td>SCRUB_AMEX.Solid_UNICODE</td> <td>UUUUUUUUUUUUUUUU</td> <td>**********UUUU</td> </tr> </tbody> </table> <p>Regex with Redact - Use of Regular expressions (regex) in the IBM® Guardium® solution (including masking in the policy) runs on the appliance, and allows advanced regex capabilities.</p> <p>However, the regex library for use with Redaction runs in the kernel of the database server and is limited to most basic regex. Only basic regex patterns can be used with Redaction.</p> <p>For example, the regular expression nomenclature [0-9]* cannot be used to indicate any number of digits. Use basic regular expression nomenclature, for example, [0-9]-[0-9]-[0-9]... to specify a sequence of digits.</p> <p>Note: S-TAP accepts only the predefined SCRUB pattern names; ignoring any other name.<br/>Access rule, data pattern, and replacement character - Using a data pattern such as <code>[a-z,2]{3}([_][0-9]{1,2})</code> with a replacement character of * changes the values between the parentheses in the data pattern to ***. Use this function to mask values.</p> <p>User-Defined Character Sets</p> <p>Available for Oracle, Sybase, MySQL, and MSSQL and for extrusion rules only, users can influence the character set used by defining special extrusion rules. These character set policy rules are only used to set the character set a user wants to convert traffic to, setting an action is irrelevant. To have an action for that traffic, the user needs to define additional rules after that character set rule. Two examples of setting a character set rule are possible (hint or force) as defined in the following examples:</p> <p>Example of extrusion rule (with hint).</p> <p>Converts the traffic by character set as defined in the extrusion rule of the installed policy ONLY if the regular conversion failed.</p> <p><b>Character set EUC-JP (code 274) .</b></p> <p>Extrusion rule pattern: <code>guardium://char_set?hint=274</code></p> <p>Example of extrusion rule (with force).</p> <p>Converts the traffic by character set as defined in the extrusion rule of the installed policy for ALL data.</p> <p><b>Character set EUC-JP (code 274) .</b></p> <p>Extrusion rule pattern: <code>guardium://char_set?force=274</code></p> <p>Note: Keep in mind that extrusion rules usually attached to the session with delay. Therefore short sessions or beginning of a session might not be immediately affected by character set change.</p> | Name :                 | Pattern: | Masked to: | SCRUB_SSN_ANSI | AAA-AA-AAAA | ****-****-AAAA | SCRUB_SSN_UNICODE | UUU-UU-UUUU | ****-****-UUUU | SCRUB_CC_SPACES_ANSI | AAAA AAAA AAAA AAAA | ***** ***** ***** AAAA | SCRUB_CC_SPACES_UNICODE | UUUU UUUU UUUU UUUU | ***** ***** ***** UUUU | SCRUB_CC.Solid_ANSI | AAAAAAAAAAAAAAA | **********AAAA | SCRUB_CC.Solid_UNICODE | UUUUUUUUUUUUUUUU | **********UUUU | SCRUB_CC_AX.Solid_ANSI | AAAAAAAAAAAAAAA | **********AAAA | SCRUB_CC_AX.Solid_UNICODE | UUUUUUUUUUUUUU | **********UUUU | Name : | Pattern: | Masked to: | SCRUB_SSN_ANSI | AAA-AA-AAAA | ****-****-AAAA | SCRUB_SSN_UNICODE | UUU-UU-UUUU | ****-****-UUUU | SCRUB_CC_SPACES_ANSI | AAAA AAAA AAAA AAAA | **********AAAA | SCRUB_CC_SPACES_UNICODE | UUUU UUUU UUUU UUUU | **********UUUU | SCRUB_CC.Solid_ANSI | AAAAAAAAAAAAAAA | **********AAAA | SCRUB_CC.Solid_UNICODE | UUUUUUUUUUUUUUUU | **********UUUU | SCRUB_AMEX.Solid_ANSI | AAAAAAAAAAAAAAA | **********AAAA | SCRUB_AMEX.Solid_UNICODE | UUUUUUUUUUUUUUUU | **********UUUU |

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |          |            |                |             |                |                   |             |                |                      |                     |                        |                         |                     |                        |                     |                 |                |                        |                  |                |                        |                 |                |                           |                |                |        |          |            |                |             |                |                   |             |                |                      |                     |                |                         |                     |                |                     |                 |                |                        |                  |                |                       |                 |                |                          |                  |                |
| DB Type                   | <p>Supported DB Types</p> <p>For access rule: Cassandra, CIFS, CouchDB, Db2, Db2 COLLECTION PROFILE* (only for use with z/OS), FTP, GreenPlumDB, Hadoop, HTTP, IBM INFORMIX (DRDA), IBM iSeries, IMS, IMS COLLECTION PROFILE (only for uses with z/OS, Informix®, MongoDB, MS SQL SERVER, MYSQL, NETEZZA, Oracle, PostgreSQL, Sybase, TERADATA, VSAM, or VSAM COLLECTION PROFILE* (only for use with z/OS)).</p> <p>For exception and extrusion rules: Cassandra, CIFS, CouchDB, Db2, FTP, GreenPlumDB, Hadoop, IBM INFORMIX (DRDA), IBM iSeries, Informix, MongoDB, MS SQL SERVER, MYSQL, NETEZZA, Oracle, PostgreSQL, Sybase, or TERADATA. Note: Informix supports two protocols SQLEXEC (native Informix protocol) or DRDA (IBM protocol). These protocols are automatically identified for Informix traffic with no additional settings. The Server Type attribute shows INFORMIX (for SQLEXEC protocol) and IBM INFORMIX (DRDA) (for DRDA protocol).</p> <p>Note: TERADATA has a silent login and allows clients to auto-reconnect. To block Teradata statements in a policy, use the S-TAP firewall function with default state ON and unwatch safe users.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                        |          |            |                |             |                |                   |             |                |                      |                     |                        |                         |                     |                        |                     |                 |                |                        |                  |                |                        |                 |                |                           |                |                |        |          |            |                |             |                |                   |             |                |                      |                     |                |                         |                     |                |                     |                 |                |                        |                  |                |                       |                 |                |                          |                  |                |

| Field                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Pattern                    | A regular expression to be matched, in the Pattern box. You can enter a regular expression manually, or click theRegex) button to open the Build Regular Expression tool, which allows you to enter and test regular expressions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Time Period                | To make the rule sensitive to a single time period, select a pre-defined time period from the Period list or click thePeriod) button to define a new time period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Rec. Vals.                 | When marked, the actual construct causing the rule to be satisfied will be logged, and available in reports, in the SQL String attribute. For a policy violation only, if not marked, no SQL statements will be logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Records Affected Threshold | <p>Access rule only. Set a threshold value for matched records. For example: Let 100 instances take place before taking action.</p> <p>This field affects the rule output rather than the rule definition (that is, what happens when it is triggered, rather than when should it trigger).</p> <p>You can select how to calculate the records affected threshold. The choices are as follows:</p> <ul style="list-style-type: none"> <li>Per session</li> <li>Per single query</li> <li>By the exceeded row count, that is, when the number of affected records exceeds the number of records that the Guardium sniffer is configured to process at one time)</li> </ul> <p>If the threshold reaches the specified number, and any other rule criteria are matched, the defined rule actions are triggered.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Replacement Character      | <p>Define a masking character.</p> <p>Should the output produced by the extrusion rule match the regular expression, the portions that match sub-expressions between parenthesis '(' and ')' will be replaced by the Masking character.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Reset Interval             | Used only if the Min. Ct. field is greater than zero. This value is the number of minutes after which the condition met counter will be reset to zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Response length threshold  | <p>For access rules: Tracks the size of data packets, in bytes, returned from the server for a successful SQL query. You can set the response length and the response length threshold as follows:</p> <ul style="list-style-type: none"> <li>Per session (calculates the sum of all response lengths in the session)</li> <li>Per single query (stores the response length for each SQL query)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Revoke                     | This checkbox appears on extrusion rules only. It allows you to exclude from logging a response that has already been selected for logging by a previous rule in the policy. In most cases you can accomplish the same result more simply by defining a single rule with one or more NOT conditions to exclude the responses you do not want, while logging the remaining ones that satisfy the rule. (The Revoke checkbox pre-dates NOT conditions, and is provided mainly for backward compatibility to support existing policies.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Field                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Rule Description                   | <p>The name of the rule. To use a special pattern test in the rule, enter the special pattern test name followed by a space and one or more additional characters to make the rule name unique, for example: guardium://SSEC_NUMBER employee. (See Special Pattern Tests for more information.)</p> <p>When displayed, the name will be prefaced with the rule number and the label Access Rule, Exception Rule, or Extrusion Rule, to identify the rule type. If the rule was generated using the Suggest From DB function, the generated name is in the format: Suggested Rule &lt;n&gt;_mm-dd hh:mm, consisting of the following components</p> <p>n is sequence number for the generated rule</p> <p>mm-dd is the month and day the rule was generated</p> <p>hh:mm is the time the rule was generated</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Server IP                          | <p>Clear the Not box to include, or mark the Not box to exclude:</p> <ul style="list-style-type: none"> <li>Any server: Leave all server fields blank. The count will be incremented every time any server satisfies the rule. (You cannot leave all fields blank if the Not box is marked.)</li> <li>All servers selected by an IP address and mask: Enter a server IP address in the first box, and network mask in the second box. The count will be incremented each time that any of the specified servers satisfies the rule. For example, to select all servers in subnet 192.168.3.x, enter 192.168.3.1 in the first box, and 255.255.255.0 in the second box.</li> <li>A group of servers: Select a group of server IP addresses from the Group drop-down list or click the Groups button to define a new group and then select that group. The count will be incremented each time that any member of the specified group satisfies the rule.</li> <li>All servers selected by an IP address and mask AND a group of servers: Use both the Server IP and Group fields. The count will be incremented each time that any server specified using either method satisfies the rule.</li> </ul> <p>Allow wildcard in IP address. Wildcard % is permitted in a policy for Server IP group.</p> |
| Service Name                       | The service name. | Full_SQL return values using MSSQL | In MSSQL, sp_cursoropen and sp_cursorfetch stored procedures are used for SELECT database queries.<br>Sp_cursoropen holds the original statement, while the FULL_SQL return value in an Extrusion rule will appear as sp_cursorfetech instead of Select * from _____.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Creating and installing a policy and policy rules

Use the Policy Builder for Data to manage policies and policy rules.

### About this task

The Policy Builder for Data provides a single solution for creating and modifying policies, policy rules, and policy rule actions. This procedure describes an end-to-end workflow for creating and installing a policy.

Note: After you update a policy (such as changes to group members, policy rules, or actions), you must reinstall the policy. You can either reinstall the policy on a managed unit, or select **Policy installation schedule** from the configuration profile. Use the **Policy installation schedule** to schedule a distribution that pushes the policy from the central manager to specified managed units. For more information, see [Working with configuration profiles](#).

Important: Policies that are installed from the central manager to an aggregator might appear in the aggregator UI as not installed because you cannot install policies on an aggregator. To determine whether a policy is installed, run the [list\\_installed\\_policies](#) API or check in the Policy Builder for Data page for each aggregator.

### Procedure

1. Navigate to Protect > Security Policies > Policy Builder for Data.
2. Create a policy or clone an existing policy or policy template.

- To create a new policy, click the  icon.
  - To clone an existing policy, select an existing policy or policy template from the Security Policies window and click the  icon.  
Tip: Guardium provides templates of predefined policies that you can use to build similar policies. Clone the [template] version and customize it as needed.
- a. From the Name and properties ribbon of the Create New Policy page, specify a policy Type and policy Name.  
Note: The policy name must not exceed 255 characters.
  - b. Optional: For data-security policies, specify additional settings.
    - Use the Category field to provide an arbitrary label for grouping policy violations for reporting purposes. The category that is specified here is used as the default category for each rule and can be overridden in individual rule definitions.
    - Click Show advanced options to work with the following settings:
      - [Log flat](#)
      - [Rules on flat](#)

- [Selective audit trail](#)
3. Click the Rules ribbon to begin working with policy rules.
- To create a new rule, click the  icon.
  - To clone a rule, select an existing rule and click the  icon.
  - To edit a rule, select an existing rule and click the  icon.
- a. From the Rule definition ribbon of the Create New Rule window, specify a Rule type and Rule name.  
 Note: The rule name must not exceed 255 characters.  
 For access and exception rules, optionally specify Category and Classification values for reporting purposes, and define the rule Severity.
- b. Click the Rule criteria ribbon and begin defining rule parameters and values.  
 Some rule criteria are only available for specific rule types or are only available after other criteria are defined. The policy builder manages these dependencies for you: criteria are available for use only in valid contexts.
- Use the menus to select individual parameters and define selection operators before you specify values or groups to match.
  - Use the  and  icons to add or remove criteria from the rule.
- For more information about rule criteria, see [Rule definition fields](#) and [Values and groups of values in rules](#).
- c. Optional: After defining criteria on the Rule criteria ribbon, select the Continue to next rule checkbox.  
 Use this setting in cases where it is necessary to take multiple actions for the same or similar conditions. For more information, see [Continue to next rule](#).
- d. Click the Rule action ribbon to begin working with rule actions.
- To create a new rule action, click the  icon and select an action. If further configuration is required, use the Add New Action window to define the action.
  - To edit a rule action, select an existing action and click the  icon and use the Edit Action window to update the rule action configuration.
- For more information about available actions, see [Policy rule actions](#).
- e. When you finish defining the rule, click OK to return to the Rules ribbon.  
 Continue creating, cloning, and editing rules as needed.
4. When you finish defining the policy and its rules, click OK to save the policy and return to the Security Policies table.

## What to do next

To install policies, select a policy from the Security Policies window and click [Install > Install](#). Select the Installation action you want and click OK to install the policy.

Installed policies are indicated by a  in the Installed column.

You can also install policies by using [Protect > Security Policies > Policy Installation](#). For more information, see [Using the Policy Installation tool](#).

Note: From Security Policies title bar, you can begin to create a IBM® Knowledge Catalog - Guardium® integration by clicking Configure WKC. For more information, see [Integrating with IBM Knowledge Catalog for federated data protection](#).

## Tagging policy rules

Guardium provides predefined policy rule tags and supports custom tagging of rules. Use tags to quickly create and manage policies aligned with specific compliance standards, reporting and auditing requirements, or geographies.

## Procedure

1. Open [Protect > Security Policies > Policy Builder for Data](#).
2. Use the  icon to create a new policy, or select an existing policy and use the  icon to edit.
3. In the Rules section of the policy builder, begin working with tags.
  - **[Importing rules by tag](#)**  
 Use one or more tags to add collections of policy rules to a policy. This includes predefined rules and tags provided by Guardium as well as custom rules and tags created for your organization. Importing rules by tags allows you to easily create policies that support your specific reporting and auditing requirements, for example by combining Guardium's predefined rules for GDPR with a set of custom rules.
  - **[Adding tags while defining policy rules](#)**  
 It is easy to add tags while creating or editing policy rules. Tagging allows you to add rules to Guardium's predefined collections or establish your own collections of rules. It's also possible to include the same rule in multiple collections by applying multiple tags.
  - **[Managing policy rule tags](#)**  
 Easily manage policy rule tags directly from the policy builder for data.

## Importing rules by tag

Use one or more tags to add collections of policy rules to a policy. This includes predefined rules and tags provided by Guardium as well as custom rules and tags created for your organization. Importing rules by tags allows you to easily create policies that support your specific reporting and auditing requirements, for example by combining Guardium's predefined rules for GDPR with a set of custom rules.

## Before you begin

Open the Policy Builder for Data and begin working with the Rules section of a specific policy.

## Procedure

1. From the Rules section of the Policy Builder for Data, click Import.

2. From the Import rules from policy dialog, select Import by tags.
3. Use the Select a tag menu to select one or more tags.
4. Optional: Use the Show only template rules check box to hide or show custom rules.
5. Use the check boxes to select the rules to import.
6. Use the Import after rule menu to define where to add the rules in the policy.
7. Click OK to import the rules into the policy.

---

## Adding tags while defining policy rules

It is easy to add tags while creating or editing policy rules. Tagging allows you to add rules to Guardium's predefined collections or establish your own collections of rules. It's also possible to include the same rule in multiple collections by applying multiple tags.

### Before you begin

Open the Policy Builder for Data and begin working with the Rules section of a specific policy.

### Procedure

1. From the Rules section of the Policy Builder for Data, use the  icon to create a new rule, or select an existing rule and use the  icon to edit.
2. From the Rule definition section, use the Tags menu to add or remove tags on the rule.
  - Use the check boxes to select to deselect tags.
  - Use the  icon to create new tags.
3. Continue working with rule definition, rule criteria, and rule action.
4. Click OK to save the rule and apply the tags.

---

## Managing policy rule tags

Easily manage policy rule tags directly from the policy builder for data.

### Before you begin

Open the Policy Builder for Data and begin working with the Rules section of a specific policy.

### Procedure

1. From the Rules section of the Policy Builder for Data, use the check boxes to select one or more rules.
2. Click Tag.
3. From the Manage tags for policy rules dialog, use the Tags menu to add or replace tags for the rules.
  - Use the menu to select an existing tag.
  - Use the  icon to create a new tag.
4. Define the tagging action.
  - Select Replace existing policy rule tags to replace all existing tags on the rules with the selected tag.
  - Select Add to existing policy rule tags to add the selected tag to the existing tags on the rules.
5. Click Save to update the tags on the rules.

---

## Using the Policy Installation tool

Learn how to install a policy on your Guardium system.

### Install a policy

1. Go to Protect > Security Policies > Policy Builder for Data to open the Security Policies page.
2. Select the policy to be installed.
3. Click Install > Install. The Install policy window opens.
4. Select an Installation action.
  - Install and override: delete all installed policies and install the selected one instead.
  - Install first: install the selected policy as the first one in the sequence (before all currently installed policies).
  - Install last: install the selected policy as the last one in the sequence (after all currently installed policies, which gives it the lowest priority).
5. Select the collectors on which to install the policy.
6. Click OK. The system responds with a message indicating success, or not.
7. Optionally, go to the Policy Installer and click Modify Schedule to open the scheduling utility, to schedule recurring installation.

### Multi-policy support

More than one installed policy is permitted at the same time. All installed policies are available for action. There are two limitations: policies defined as selective audit policies can not be mixed with policies not defined as selective audit policies, and policies defined as flat log cannot be mixed with policies not defined as flat log. If trying

to mix policies, an error message results when installing these mixed policies.

The order of appearance can be controlled during the policy installation, such as first, last, or somewhere in between. But the order of appearance can not be edited at a later date.

On the Security Policies page, click  to remove an installed policy.

The first installed policy has a special meaning, as it sets the value of the global policy parameters. These parameters are: Global pattern; Is it a selective audit; Client and Server net mask; Tagged Client and Server group ID.

This multi-policy support is available through the GUI (Setup > Tools and Views > Policy Installation) and through GuardAPI.

## View policy rules for the installed policy

---

In the Currently Installed Policies page, any user can view the rules of the installed policy, and in addition, authorized users can open the policy for editing.

1. Go to Protect > Security Policies > View Installed Policy to open the Currently Installed Policies page.
2. Click View Details Report to see a detailed list of installed policies and rules.
3. Click  to edit the policy and its rules.

## Related concepts

---

- [Scheduling](#)
- [Job dependencies](#)

## Running policy analyzer and reviewing results

---

Policy analyzer provides insights that help identify frequently fired rules, optimize rule order, and evaluate rule changes.

## Before you begin

---

Policy analyzer works with standalone Guardium systems or managed units in a centrally managed environment and requires currently installed policies to evaluate traffic.  
Note:

- The policy analyzer supports up to 128 rules across all installed policies. This restriction applies to the policy analyzer only.
- Policy analyzer does not support push-down policies from z/OS S-TAPs.

## About this task

---

There are two policy analyzer modes: continuous and ad hoc. Continuous analysis records and evaluates data at predefined intervals and is useful for observing longer-term trends in policy activity. Ad hoc analyses run once, at a time you define, and are useful for evaluating specific policy changes.

## Procedure

---

1. Begin by navigating to Protect > Security policies > Policy builder for data and clicking the Analyze menu.
2. Confirm that policy analyzer is running. If necessary, start policy analyzer by clicking the Start policy analyzer link.
3. Optional: Configure the continuous analysis interval by clicking the Change policy analyzer settings link and specifying an interval.
4. Optional: Start an ad hoc analysis by clicking the Run ad hoc analysis link.
  - a. On the Run ad hoc analysis dialog, use the Start date fields to define a date and time to begin the analysis.
  - b. Use the Duration fields to define how long to run the analysis.

Tip:

  - Use the time and duration settings to evaluate traffic before and after modifying a policy to better understand the impact of the policy change.
  - The schedules for ad hoc policy analyzer jobs are not editable and cannot overlap.
  - c. Click OK to begin the ad hoc analysis.
5. View policy analyzer results by clicking the View results link and selecting either Ad hoc analysis or Continuous analysis.  
For continuous analysis, use the Time frame setting to change how much data is displayed. For ad hoc analysis, use the Start time menu to view a specific set of ad hoc results.  

The % fired among transactions for each rule chart shows what percentage of all transactions cause each rule to fire. Because not all transactions fire a rule, the total will not always equal 100%.

The Top rules (fire count) chart shows the number of times that a rule fired during the continuous analysis period or during the ad hoc analysis. Click the chart to see a key that identifies the chart contents. Click the Top rules (fire count) label and select Change selected rules to hide or show specific rules in the chart.

The Details for all policy rules table summarizes activity for policies, rules, and rule actions.

  - Use the % fired among transactions column to see how often rules are firing, expressed as a percentage of all transactions evaluated in the specified time frame.
  - Use the % fired among rules column to see which rules are firing the most, expressed as a percentage of all rules that have fired during the specified time frame.
6. Investigate specific results.
  - a. Click a bar in the % fired among transactions chart to select the corresponding row in the Details for all policy rules table or click to select any row in the table.
  - b. Investigate the selected row by clicking Actions > Full SQL log details or Violation log details.  
The details view provides information about the specific clients, users, and programs triggering the selected policy rule.

# Security incident policies

Guardium® provides several session level policy templates that encapsulate security problems that are frequently found at run time.

Each of the security incident policies contains rules that find and report on a specific type of security incident.

Many of the rules within these policies are also used by the real-time trust evaluator policies. For more information, see [Real-time trust evaluator](#).

Note: While the security incidents policies use many of the same rules as the real-time trust evaluator, they are separate entities.

The following security incident policies trigger relevant runtime actions.

- **Security anomalies**

An anomaly is behavior by a particular source that is outside of the “normal” timeframe or scope of the particular database or user's activity. Anomaly detection can indicate a security violation, even if the activities themselves do not directly violate an existing security policy.

- **Access to unaudited sensitive data**

The **Security incidents: access to unaudited sensitive data** identifies situations where either a user accesses a table that contains sensitive data, or sensitive data is improperly labeled (for example, is not in a **Sensitive data** group).

- **Administrative user accessing sensitive data**

The **Security incidents: Administrative user accessing sensitive data** identifies situations where an unauthorized administrative user tries to access sensitive data.

- **Administrative users and applications**

The **Security incidents: administrative users and applications** template provides a number of rules that track and report on possible security incidents that might be encountered at run time. You can choose which rules you need for your security scenario.

- **All users**

The **Security Incidents: all users** template provides a number of rules that track and report on possible security incidents that might be encountered at run time. You can choose which rules you need for your security scenario.

- **Credential stuffing attack**

Credential stuffing is method of hacking a system by injecting breached username and password pairs in an attempt to fraudulently gain access to user accounts. The **Security Incidents: credential stuffing attack** policy helps identify possible credential stuffing attacks.

- **Repeated failed logins or possible denial of service attack**

The **Security Incidents: repeated failed logins or possible denial of service attack** template looks for repeated failed logins or possible denial of service attacks for both database and administrative users.

- **Suspicious user activity with sensitive data (user not privileged)**

The **Security incidents: Suspicious user activity with sensitive data (user not privileged)** policy identifies situations where an unauthorized user tries to access sensitive data.

- **Quarantine users with multiple failed logins**

12.1 and later In the multiple failed login quarantine method, users are allowed five failed login attempts before they are locked out of the system and quarantined for 30 minutes. Use the **Multiple Failed Login Quarantine[template]** to create this policy.

## Security anomalies

An anomaly is behavior by a particular source that is outside of the “normal” timeframe or scope of the particular database or user's activity. Anomaly detection can indicate a security violation, even if the activities themselves do not directly violate an existing security policy.

Each rule, except for **Server encounter first time in the audit**, sets the TRUST LEVEL score to MEAN in the **Session** report. For all rules, the messages are generated in the **Connection Exceptions** report when a suspicious activity is found.

Note: The **Connection Exceptions** report data displays in managed user environments, unless you populate the Exception table on the central manager.

In addition, anomaly detection begins after Guardium detects a sufficient number of unique connections. The number of “sufficient connections” to detect anomalies is based on your environment and set without user involvement, but it is always greater than 1000 connections.

The **Security anomalies** policy contains the following rules:

Suspicious client connection

This rule identifies when new client connects to a server. Any unknown client hostname that is encountered after Guardium® detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique CLIENT\_HOST\_NAME that is identified as suspicious.

Suspicious DB user connection

The S-TAP encountered an unknown or unexpected database type. Any unknown DB user connection that is encountered after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique DB\_USER identified as suspicious.

Suspicious OS user and DB user combination connection

An unexpected combination of OS user and database user was detected. Any new combination of DB User and OS User after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique OS\_USER and DB\_USER combination that is identified as suspicious.

Suspicious OS user connection

A new OS user connected to a server. Any unknown OS user that is encountered after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique OS\_USER that is identified as suspicious.

Unexpected DB type per server IP identification

A new database user connected to a server. Any unknown database user that connects to a specific server after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique DB\_TYPE that is identified as suspicious.

Unexpected command on connection start

An unexpected command was used at the connection start. Any new command on connection start that is seen after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique command on connection start that is identified as suspicious.

Unexpected error on connection start

An unexpected error occurred at the connection start. Any new error on connection start that is seen after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique error on connection start that is identified as suspicious.

#### Unexpected client time zone

Any client connection from a new time zone that is seen after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique client time zone that is identified as suspicious.

#### Unexpected authentication type

Client connected by using an unexpected authentication type. Any new authentication type for this client that is seen after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each unique authentication type that is identified as suspicious.

#### Unexpected authentication type for this DB type

Unexpected authentication type used for this database. Any new authentication type for this database type that is seen after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each new unique authentication type for this DB type that is identified as suspicious.

#### Unexpected client OS name

A new OS client connected to a server. Any unknown client OS name that is encountered after Guardium detects a sufficient number of connections is considered suspicious.

This rule generates exception messages in the **Connection Exceptions** report for each new unique Client OS name that is identified as suspicious.

#### Server encounter first time in the audit

An unknown S-TAP is found for this server IP address. The first time a previously unseen server connects is considered an anomaly.

This rule generates exception messages in the **Connection Exceptions** report each time that a new server is identified. In addition, this rule sets the TRUST LEVEL score to 0.7 in the **Session** report.

---

## Access to unaudited sensitive data

### The **Security incidents: access to unaudited sensitive data**

This identifies situations where either a user accesses a table that contains sensitive data, or sensitive data is improperly labeled (for example, is not in a **Sensitive data** group).

#### The **Security incidents: access to unaudited sensitive data** contains the following rules:

##### Configure server data to detect sensitive data exfiltration

This rule configures the server to detect when an unauthorized user accesses a table that contains sensitive data.

##### Identify sensitive data that has not been previously audited

This rule identifies sensitive data (in this case, credit card data) that is not properly labeled as sensitive.

##### Generate a security incident exception

This rule generates an exception message in the **Security Incident** report when an unauthorized database user attempts to access the sensitive data.

---

## Administrative user accessing sensitive data

### The **Security incidents: Administrative user accessing sensitive data**

This identifies situations where an unauthorized administrative user tries to access sensitive data.

#### The **Security incidents: Administrative user accessing sensitive data** contains the following rules:

##### Identify access to sensitive data by administrative user

This rule configures the server to detect when an unauthorized administrative user accesses a table that contains sensitive data.

##### Generate security incident

This rule generates an exception message in the **Security Incident** report when an unauthorized administrative user attempts to access the sensitive data.

---

## Administrative users and applications

### The **Security incidents: administrative users and applications**

This template provides a number of rules that track and report on possible security incidents that might be encountered at run time. You can choose which rules you need for your security scenario.

Some rule definitions are tagged as either PCI or GDPR. These tags indicate that the rule can help meet compliance with either payment card information (PCI) or General Data Protection Regulation (GDPR) rules.

By default, each rule includes the MARK SESSION action, which sets the trust for this session to LOW and generates an exception in the Security Incidents report.

Note: The security incident policies analyze authentication methods, but do not log or analyze passwords.

#### The **Security incidents: administrative users and applications** contains the following rules:

##### Admin user using plain text password

This rule identifies when plain-text passwords are used in the authentication process for admin users. Any connection to a database that uses a driver or a database that allows sending a password in clear text over the network generates a security incident.

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and SERVER\_IP.

Prerequisite: Admin users group.

##### Administrative program using plain text password

This rule identifies when plain-text passwords are used in the authentication process for applications and programs. Any program or application that allows sending a password in clear text over the network generates a security incident.

This rule generates exception messages in the **Security Incident** report for each unique CLIENT\_IP and SOURCE\_PROGRAM.

Prerequisite: Admin programs group.

#### Unencrypted administrative session

This rule checks that the session is not encrypted and the user is part of the administrative group. This rule generates a security incident for unencrypted administrative sessions.

This rule generates exception messages in the **Security Incident** report for each unique CLIENT\_IP, DB\_USER, and SOURCE\_PROGRAM.

Prerequisite: Admin users group.

#### Unencrypted administrative program

This rule checks that the session is not encrypted and the program is part of the administrative group. This rule generates a security incident only for unencrypted administrative programs, rather than the entire session.

This rule generates exception messages in the **Security Incident** report for each unique CLIENT\_IP and SOURCE\_PROGRAM.

Prerequisite: Admin programs group.

#### Suspicious administrative activity

This rule finds and reports on users with administrative privileges who connect to a database, but either do not have administrative privileges or are not members of the administrative group. These activities can indicate an intrusion into the database.

This rule generates a security incident when a user might have inappropriate admin privileges.

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER, SOURCE\_PROGRAM, and SERVER\_IP.

Prerequisite: Admin users group.

#### Suspicious administrative program activity

This rule generates a security incident when it finds connections to a database by a program that has administrative privileges, but either the program does not have administrative privileges or it was not accounted for in the administrative group. These activities can indicate an intrusion into the database.

Prerequisite: Admin programs group

#### Repeated failed login per server IP and admin user (5 in 3 minutes)

Repeated failed log-ins by an admin user (specified as five logins within 3 minutes) generate a security incident.

Note: This rule is similar to the **User Activity Monitoring** policy *Failed Login - Alert if repeated* rule. However, the rule triggers only when a user unsuccessfully attempts to log on to the same server five times within 3 minutes (rather than logging in to multiple servers within 5 minutes).

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and SERVER\_IP.

Prerequisite: Admin users group.

#### Password sent using vulnerable encryption method for admin user

Guardium® generates a security incident when passwords are sent using insufficiently secure methods. For example, when a database uses a driver with outdated encryption methods or a database sends passwords that use outdated or vulnerable encryption methods over the network.

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER, CLIENT\_IP, and SOURCE\_PROGRAM.

Prerequisite: Admin users group.

#### Repeated login failures from same Program and different Admin DB users per period of time (5 in 3 minutes)

Repeated failed log-ins by an admin user (specified as five log ins within 3 minutes) generate a security incident.

Note: This rule is similar to the **User Activity Monitoring** policy *Failed Login - Alert if repeated* rule. However, the rule triggers only when a user unsuccessfully logs on to the same server five times within 3 minutes (rather than logging in to multiple servers within 5 minutes).

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and SERVER\_IP.

Prerequisite: Admin users group.

#### Admin users re-using passwords

Reusing passwords across multiple sites poses serious security risks. If an attacker can steal credentials and gain access to one account, they can also log in to any other account that uses the same password.

This rule generates exception messages in the **Security Incident** report when at two or more DB\_USERS use identical passwords.

Prerequisite: Admin users group.

#### Failed login for admin user re-using passwords

This rule generates exception messages in the **Security Incident** report when two identical or similar passwords are found for different DB\_USER login failures on the same server.

Prerequisite: Admin users group.

---

## All users

The **Security Incidents: all users** template provides a number of rules that track and report on possible security incidents that might be encountered at run time. You can choose which rules you need for your security scenario.

Some rule definitions are tagged as either PCI or GDPR. These tags indicate that the rule can help meet compliance with either payment card information (PCI) or General Data Protection Regulation (GDPR) rules.

Many rules include the MARK SESSION action, which sets the trust for this session to LOW and generates an exception in the Security Incidents report.

Note: The security incident policies analyze authentication methods, but do not log or analyze passwords.

The **Security Incidents: all users** contains the following rules:

#### DB user using plain text password

This rule identifies when plain-text passwords are used in the authentication process for database users. Any connection to a database that uses a driver or a database that allows sending a password in clear text over the network generates a security incident.

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and SERVER\_IP.

#### Password spraying attack detection

This rule identifies when an attacker attempts to gain unauthorized access to user accounts or systems by systematically trying commonly used passwords or a small set of passwords against multiple user accounts. This rule generates an exception message when more than 10 connection attempts are made by different users with the same password.

#### Source application using plain text password

This rule identifies when plain-text passwords are used in the authentication process for applications and programs. Any program or application that allows sending a password in clear text over the network generates a security incident.

This rule generates exception messages in the **Security Incident** report for each unique CLIENT\_IP and SOURCE\_PROGRAM.

#### Repeated failed login per server IP and user (5 in 3 minutes)

This rule generates a security incident for repeated failed log-ins.

Note: This rule is similar to the **User Activity Monitoring** policy *Failed Login - Alert if repeated* rule. However, the rule triggers only when a user unsuccessfully attempts to log on to the same server five times within 3 minutes (rather than logging in to multiple servers within 5 minutes).

This rule generates exception messages in the report for each unique DB\_USER and SERVER\_IP.

Repeated login failures from same Program and different DB users per period of time (5 in 3 minutes)

Repeated failed log-ins by a database user (specified as five log-ins within 3 minutes) generates a security incident.

Note: This rule is similar to the **User Activity**

**Monitoring** policy *Failed Login - Alert if repeated* rule. However, the rule triggers only when a user unsuccessfully logs on to the same server five times within 3 minutes (rather than logging in to multiple servers within 5 minutes).

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and SERVER\_IP.

Data exfiltration setup

Data exfiltration that exceeds a defined threshold during a session or in a session generates a security incident. This rule sets the thresholds for session and response exfiltration. In the CONFIGURE rule action, define the thresholds for SESSION, RESPONSE, or both.

Prerequisite: The *Session Data Exfiltration* or *Response Data Exfiltration* rules must be installed.

Session data exfiltration

This rule identifies data exfiltration by monitoring the amount of information that is extracted from the database during a single session.

This rule generates the following exception message in the **Security Incident** report when the data exfiltration threshold is reached:

**SESSION DATA EXFILTRATION: DATA EXCEEDED (SESSION\_EXFILTRATION\_LIMIT)**.

Prerequisite: The data exfiltration threshold for SESSION is defined by the *Data exfiltration setup* rule.

Response data exfiltration

This rule identifies data exfiltration by monitoring the amount of information that is extracted from the database from a specified response.

This rule generates the following exception message in the **Security Incident** report when the data exfiltration threshold for a response is reached:

**RESPONSE DATA EXFILTRATION: DATA EXCEEDED (RESPONSE\_EXFILTRATION\_LIMIT)**.

Prerequisite: The data exfiltration threshold is defined by the *Data exfiltration setup* rule.

## Credential stuffing attack

Credential stuffing is method of hacking a system by injecting breached username and password pairs in an attempt to fraudulently gain access to user accounts. The **Security Incidents: credential stuffing attack** policy helps identify possible credential stuffing attacks.

The **Security Incidents: credential stuffing attack** contains the following rules:

Prerequisite - Configure credential stuffing attack detection

This rule configures the credential stuffing attack detection.

Prerequisite: Server IP address in the Production Server group must be populated. By default, group is set to %.

Note: If you populate the group your own environment info, remove the % from the production server IP groups.

Credential stuffing attack detection

This rule detects credentials stuffing attacks and if an attack is found, the rule generates a security incident.

This rule generates exception messages in the **Security Incident** report when the number of login failures within the overall number of monitored sessions reaches a calculated threshold.

## Repeated failed logins or possible denial of service attack

The **Security Incidents: repeated failed logins or possible denial of service attack** template looks for repeated failed logins or possible denial of service attacks for both database and administrative users.

Many rules include the MARK SESSION action, which sets the trust for this session to LOW and generates an exception in the Security Incidents report.

Note: The security incident policies analyze authentication methods, but do not log or analyze passwords.

The **Security Incidents: repeated failed logins or possible denial of service attack** template contains the following rules:

Populate analyzed client IP if both client IP and analyzed client IP are empty

This rule uses a TRANSFORM action to move the IP address from HOST NAME to ANALYZED\_CLIENT\_IP.

Populate analyzed client IP if both client IP and analyzed client IP are empty and session identified as local

This rule uses a TRANSFORM action to move the IP address from SERVER IP to ANALYZED\_CLIENT\_IP.

Repeated failed login per Actual client IP and user (5 in 3 minutes)

This rule generates a security incident for repeated failed log-ins.

This rule generates exception messages in the **Security Incident** report for each unique DB\_USER and ACTUAL\_CLIENT\_IP.

Possible denial of service attack (20 in 1 minute)

A shared machine used as a client for multiple users can indicate a denial of service (DOS) attack and generates a security incident.

This rule requires that the populate rules (*Populate ANALYZED\_CLIENT\_IP if both CLIENT\_IP and ANALYZED\_CLIENT\_IP are empty* and *Populate ANALYZED\_CLIENT\_IP if both CLIENT\_IP and ANALYZED\_CLIENT\_IP are empty and session identified as local*) are also installed.

This rule generates exception messages in the **Security Incident** report when 20 DB\_USERS connect from a single ACTUAL\_CLIENT\_IP to a single SERVER\_IP within a 1-minute period.

Possible admin user denial of service attack (20 in 1 minute)

A shared machine used as a client for multiple users can indicate a denial of service (DOS) attack and generates a security incident.

This rule requires that the populate rules (*Populate ANALYZED\_CLIENT\_IP if both CLIENT\_IP and ANALYZED\_CLIENT\_IP are empty* and *Populate ANALYZED\_CLIENT\_IP if both CLIENT\_IP and ANALYZED\_CLIENT\_IP are empty and session identified as local*) are also installed.

This rule generates exception messages in the **Security Incident** report when 20 DB\_USERS connect from a single ACTUAL\_CLIENT\_IP to a single SERVER\_IP within a 1-minute period.

Prerequisite: Admin users group.

## Suspicious user activity with sensitive data (user not privileged)

The **Security incidents: Suspicious user activity with sensitive data (user not privileged)** policy identifies situations where an unauthorized user tries to access sensitive data.

The **Security incidents: Suspicious user activity with sensitive data** policy contains the following rules:

Identify access to sensitive data by unauthorized user

This rule configures the server to detect when an unauthorized user accesses a table that contains sensitive data.

Generate security incident exception

This rule generates an exception message in the **Security Incident** report when an unauthorized database user attempts to access the sensitive data.

## Quarantine users with multiple failed logins

12.1 and later In the multiple failed login quarantine method, users are allowed five failed login attempts before they are locked out of the system and quarantined for 30 minutes. Use the **Multiple Failed Login Quarantine [template]** to create this policy.

The **Multiple Failed Login Quarantine** policy contains the following rules:

Identify Multiple Failed Login

This rule identifies the users to quarantine due to multiple login failures.

Quarantine previously failed login connections

This rule uses the S-GATE SESSOIN TERMINATE action to enforce the quarantine policy and end the login session. Multiple failed logins are violation of the Payment Card Industry (PCI) data security compliance.

Tip: Ensure to populate production server group members for this policy to work as expected.

## Managing correlation alerts

An alert is a message that indicates that an exception or policy rule violation was detected. Create and manage correlation alerts from the Add Alert page.

Alerts are triggered in two ways:

- A *correlation alert* is triggered by a query that looks back over a specified time period to determine whether the alert threshold is met. The Guardium anomaly detection engine runs correlation queries on a scheduled basis. By default, correlation alerts do not log policy violations, but they can be configured to do that.
- A *real-time alert* is triggered by a security policy rule. The Guardium inspection engine component runs the security policy as it collects and analyzes database traffic in real time. For more information about real-time alerts, see [Understanding policies](#) and [Alerting rule actions](#).

Regardless of how they are triggered, Guardium logs all alerts the same way: the alert information is logged in the Guardium internal database. The amount and type of information that is logged depends on the specific alert type. The Guardium Alerter component, which also runs on a scheduled basis, processes each new alert, passing the logged information for each alert to any combination of the following notification mechanisms:

- MAIL - A Guardium user role email (User), or an external email (Email).  
When MAIL is selected, you can now tick the checkbox for Attach alert reports as CSV. Select User or Email. If Email is selected proceed to type in receivers email address. Otherwise if User is selected a user menu is displayed, choose wanted user.  
Select Save to add a receiver, or Back to exit Alert Receiver Selection window.
- SNMP - The SNMP (network information and control) server. When SNMP is selected for an Alert Notification, the Alerter passes all alert messages of that type to the single trap community for which the Alerter was configured.
- Syslog - The alert is written to syslog on the Guardium appliance (which might be configured by the Guardium Administrator to write syslog messages to a remote system).  
Note: For SNMP or SYSLOG, the maximum message length is 3000 characters. Any messages longer than that are truncated.
- Custom - A user written Java™ class to handle alerts. The Alerter passes an alert message and timestamp to the custom alerting class. You can have multiple custom alerting classes, and one custom alerting class can be an extension of another custom alerting class.
- Ticket - An external ticketing service

Note: Alerts definition and notification are not subject to Data Level Security for the following reasons,

- Alerts are not evaluated in the context of user.
- The alert might be related to databases that are associated with multiple users.
- To avoid situations where no one gets the alert notification.

Note: If an alert uses a query that contains 30 or more fields (including counters) the anomaly detection fails with an `Array out of bound exception` error message. Queries with 30 columns (or more) cannot be used for alerts. Such queries do not appear in the list of available queries for threshold alerts.

## Alerting tasks for administrators

Guardium administrators perform the following tasks:

- Customize the alert message template from the global profile.
- Configure and start thealerter, which delivers messages to SMTP, SNMP, Syslog, or custom alerting classes.
- Start and stop the anomaly detection engine, which runs the correlation alerts according to the schedules defined.

- Upload custom alerting classes to the Guardium system.

## Alerting tasks for users

---

Guardium users (and administrators) can perform the following tasks for correlation alerts,

- Define queries that can be used for correlation alerts.
- Define correlation alerts.
- Write custom alerting classes.

## Creating a correlation alert

---

A correlation alert is based on a query in any of the reporting domains. The query must be defined before you can define the alert. The query must contain at least one date field to be available to a correlation alert.

1. Click Protect->Database Intrusion Detection->Alert Builder to open the Alert Finder.
2. Click New in the Alerts Finder page to open the Add Alert page.
3. Under Settings, enter the following information
  - Name - Enter a unique name for the alert. Do not include apostrophe characters in the alert name.
  - Description - Enter a short sentence that describes the alert.
  - Category - Enter an optional category.
  - Classification - Enter an optional classification.
  - For Recommended Action, add free text as the recommended action for the specific alert.
  - Message Template - As with real-time alerts, you can choose a template for the message that is sent in case the threshold alert fires. The template uses a predefined list of variables that are replaced with the appropriate value for the specific alert. For more information about the message template, see [The alert message template](#).
  - Severity - Select a severity level from the Severity list. For an email alert, if the alert is set to HIGH, then the email is also flagged as HIGH. For more information on how severity affects syslog facility and priority, see [Facility and priority of syslog messages](#).
  - Run Frequency - Enter the number of minutes between runs of the query.
  - Select Active to activate the alert, or clear the box to save the alert definition without starting it running (it can be activated later). In a central manager environment, the alert is activated (or stopped) on all managed units when this box is marked (or cleared). To disable the alert on a specific appliance in a central manager environment, use the Anomaly Detection page of the Administrator Console.
  - Select Log Policy Violation to log a policy violation when this alert is triggered. By default, correlation alerts are logged in the Alert Tracking domain only. By marking this box, correlation alerts and real-time alerts (issued by the data access security policy) can be viewed together, in the Policy Violations domain.
  - Select View in deployment health dashboard if you want to include this alert in the deployment health dashboard.
4. Under Alert Definition, enter the following information.
  - Query - Select the query to run for this alert. The list of queries that are displayed includes all queries that meet the following criteria,
    - Contain at least one date field (timestamp).
    - Contain a Count field.
    - Can be accessed by your Guardium user account.

If the selected query contains runtime parameters, a Query Parameters window displays in the Alert Definition page. Supply appropriate parameter values for your application.

### Troubleshooting tips

- If a custom query was created in the Query-Report Builder, but the query does not appear in the Query list, then make sure that the custom query has a timestamp (date field).
- If you select a query from the Query list that needs editing, but you cannot edit the query, go to the Query-Report Builder to make the changes you need.
- Accumulation Interval - Enter the length of the time interval (in minutes) that the query examines the audit repository, counting back from the current time (for example, enter 10 to examine the last 10 minutes of data).
- Move interval window earlier by - GBDI data is not available immediately. Use this field to move the accumulation interval backwards in time, in minutes, so that the entire time interval of your query has data. Usually 120 minutes is sufficient.  
Note: Alerts that run on aggregators are based only on data within the defined merge period.
- Select Log Full Query Results to have the full report logged with the alert.
- Column - If the selected query contains one or more columns of numeric data, select a column to use for the test. The default is the last column for the query, which is always the count of occurrences aggregated in that row.
- 5. Under Alert Threshold, define the threshold at which a correlation alert is to be generated, as follows:
  - Threshold - Enter a threshold number that applies as described by the remaining fields in the window.
  - Alert condition - Select an operator that indicates how the report value relates to the threshold to produce an alert. Choose from > (greater than), >= (greater than or equal to), <= (less than or equal to), or < (less than).
  - Threshold Evaluated - Select per report if the threshold number applies to a report total, Select per line if the threshold applies to a single line of the report (the report contains the output of the selected query, which looks back over the specified accumulation time).
- If there is no data during the specified Accumulation Interval:
  - If the threshold is per report, the value for that interval is 0 (zero), and an alert is generated if the threshold condition is met. For example, if the condition specified is "Alert when value is < 1".
  - If the threshold is per line, no alert is generated, regardless of the specified condition (because there are no lines of output).
- Threshold Used - Select As absolute limit to indicate that the threshold entered is an absolute number. Select As a percentage change within period to indicate that the threshold represents a percentage of change within the time period that you select in From and To.
- As percentage change within period for the same Accumulation Period on a relative time - One relative date is entered and the alert runs the query for the current period and for the relative period (using the same interval), and checks the values as a percentage of the base period value.  
Note: If you use a relative period, each time the alert is checked it runs the query twice; once for the current period and once for the relative period.
- 6. Notification Frequency - Indicate how often (in minutes) to notify alert receivers when the alert condition is satisfied.
- 7. Under Managed Units, you can assign or exclude correlation alerts to individual managed units or managed unit groups from the central manager.
 

Under Select Units, select the managed units that you want to include for this alert,

  - This Central Manager - By default, the central manager receives alerts. Clear the checkbox to exclude the central manager.
  - All - Send alerts to all managed units.
  - Single Unit - Send alerts to the specified unit only.
  - Exclude Single Unit - Send alerts to all managed units except for the specified unit.

- Managed Unit Group - Click Select Group to select a managed unit group (or create a new group). Send alerts to all units in the specified managed unit group.
  - Exclude Managed Unit Group - Click Select Group to select a managed unit group (or create a new group). Send alerts to all managed units except for the units specified in this group.
8. Under Alert Receivers, you can optionally designate one or more persons or groups to notify when this alert condition is satisfied. To add a receiver, click Add Receiver to open the Alert Receiver Selection page.  
 Note: If the receiver of an alert is the admin user, then admin must have an assigned email address for the alert to fire.  
 Note: An additional receiver for threshold alerts is Owner (the owner/s of the database). If the query associated with the alert contains Server IP and Service name and if the alert is evaluated Per Row, then the receiver can be Owner. The Alert Notification must have: Alert Notification Type: Mail, Alert User ID: 0, Alert Destination: Owner. For more information, see [Alerting rule actions](#).
9. Optionally click Add Comments to add comments to the definition or click Roles to assign roles for the alert.  
 10. Click Apply and then Done to save your alert.

## Modifying a correlation alert

---

1. Click Protect > Database Intrusion Detection > Alert Builder to open the Alert Finder.
2. Select the correlation alert that you want to modify in the Alert Finder page.
3. Click Modify to open the Modify Alert window.
4. Modify the alert definition as needed.
5. Click Apply.

## Removing a correlation alert

---

1. Click Protect > Database Intrusion Detection > Alert Builder to open the Alert Finder.
2. Select the correlation alert that you want to remove in the Alerts Finder window.
3. Click Delete. You are prompted to confirm the action.

## Incident Management

---

The Integrated Incident Management (IIM) application provides a business-user interface with workflow automation for tracking and resolving database security incidents.

It simplifies incident management by allowing administrators to group a series of related policy violations into a single incident and assign them to specific individuals. This reduces the number of separate policy violations that oversight teams need to review.

Incident generation processes can be defined and scheduled to read the policy violations log and generate new incidents. From an incident generation process, each selected incident is:

- Assigned a unique incident number
- Assigned to a user
- Assigned a severity code
- Assigned to a category

In addition, policy violations can be assigned manually (by authorized users) to new incidents or existing incidents from the Policy Violations / Incident Management report.

Once an incident has been generated, administrators and other users work with incidents from the Incident Management tab, which is included on both the admin and user portals. From there, all other tasks can be performed (assign incidents, send notifications, assign status, and so forth).

The Incident Management functions can be accessed from the drill-down menus of the Incident Management reports. Each user may only have a subset of reports or functions available, depending on the security roles assigned to the user account.

You can create your own copies of the Incident Management reports, but those copies will not have all of the capabilities available from the pre-configured reports on the Incident Management tab. To assign incidents, severity codes, and so forth, use the reports on the Incident Management tab.

## Define an Incident Generation Process

---

An incident generation process executes a query against the policy violations log and generates incidents based on that query. Only the first 5,000 violations are included with an incident. When there are more than 5,000 violations, a new incident is created each time the process runs, and that incident includes the next 5,000 violations. By default, the definition and scheduling of incident generation processes is restricted to users with the admin role.

1. Click Comply > Tools and Views > Incident Generation to open Incident Generation Processes.
2. Click Add Process to open the Edit Incident Generation Process panel.
3. Select a query from the Query list. There are several restrictions that apply to queries used in an incident generation process. We suggest that you open the query in the Query-Report Builder to verify that it satisfies the following criteria:
  - The query must be from the Policy Violations domain.
  - The query must have the Count check box checked. See [Selecting the column display](#) for more information.
  - The main entity for the query must be the Policy Rule Violation entity.
  - The query fields for the query must not include a SQL string (from either the SQL entity or the Full SQL String attribute of the Policy Rule Violation entity).
4. Select a Severity for the incident (defaults to Info).
5. Optionally enter a Category for the incident (defaults to none).
6. Optionally enter a Threshold for generating the incident. The default is one, meaning every row returned by the query will generate an incident.
7. From the Assign to User list, select the user to whom the incident will be assigned.
8. Enter the From and To Dates for the query. For a scheduled query, use relative dates (for example: now -1 day and now).
9. Click Save to save the process definition. You cannot run or schedule the process until it has been saved.
10. To run the query now, click Run Once Now.
11. To schedule the query, click Modify Schedule to open the general-purpose scheduling utility.

## Assign/Reassign to Incident

---

1. Double-click the policy violation to be assigned or reassigned, in one of the Incident Management reports.
2. Select Assign/Reassign to incident from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of open incidents (for example, Assign to Incident #123), and one additional option: Assign to a new incident.
3. Select an incident to assign this violation to, or select Assign to a new incident to assign this Policy Violation to the next incident number available (they are numbered in sequence).  
A message is displayed when the change has been completed, and the Incident Management panel will be refreshed. If a new incident has been created, it will be listed first in the Open Incidents report.

## Assign to User

---

1. Double-click the incident to be assigned to another user, in one of the Incident Management reports.
2. Select Assign to user from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of users, and one additional option: Unassign.
3. Select a user, or select Unassign to remove the current user assigned. When a user is assigned, the Status Description will be Assigned, and when unassigned the Status Description will be Open.  
A message is displayed when the change has been completed, and the Incident Management panel will be refreshed.

## Change Severity

---

1. Double-click the incident on which the severity is to be changed, in one of the Incident Management reports.
2. Select Change Severity from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of severity codes: Info, Low, Med, and High.
3. Select the new severity code.  
A message is displayed when the change has been completed, and the Incident Management panel will be refreshed.

## Notify

---

1. Double-click the incident a user is to be notified about, in one of the Incident Management reports.
2. Select Notify from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of users.
3. Select a user.  
A message is displayed when the user has been a notification.

## Change Status

---

1. Double-click the incident on which the status is to be changed, in one of the Incident Management reports.
2. Select Change Status from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of status codes:
  - ASSIGNED - Once an incident has this status, it cannot have additional policy violations added to it. To add policy violations, change the incident status back to Open, add the violations, and then change the status back to Assigned.
  - CLOSED - Once an incident is marked Closed it cannot be modified, and is no longer listed.
  - OPEN - This is the initial status for a new incident.
3. Select the new status code.  
A message is displayed when the change has been completed, and the Incident Management panel will be refreshed.

## Add Comments

---

1. Double-click the incident to which comments are to be added, in one of the Incident Management reports.
2. Select Comments from the drill-down menu, to open the User Comment window. For instructions on how to add comments, see [Comments](#).

## How to manage the review of multiple database security incidents

---

Incident management - track and resolve database security incidents.

### About this task

---

Administrators can group a series of related policy violations into a single incident and assign to specific individuals. This reduces the number of separate policy violations that oversight teams need to review.

#### Prerequisites

- Create a Policy (See Policies).
- Start inspection engines (See Inspection Engine Configuration).

A security policy contains an ordered set of rules to be applied to the observed traffic between database clients and servers.

A policy violation is logged each time that a rule is triggered. Policy violations can be assigned to incidents, either automatically by a process, or manually by authorized users (see Incident Management).

#### Summary of Steps

1. Click Comply > Tools and Views > Incident Generation to open Incident Generation Processes.
2. Edit Incident Generation Process (Query, Severity, Threshold, Scheduling).
3. Go to Incident Management tab for reports.

## Incident Management

The Incident Management application provides a business-user interface with workflow automation for tracking and resolving database security incidents.

Incident generation processes can be defined and scheduled to read the policy violations log and generate new incidents. From an incident generation process, each selected incident is:

- Assigned a unique incident number.
- Assigned to a user.
- Assigned a severity code.
- Assigned to a category.

In addition, policy violations can be assigned manually (by authorized users) to new incidents or existing incidents from the Policy Violations / Incident Management report.

Once an incident has been generated, administrators and other users work with incidents from the Incident Management tab, which is included on both the admin and user portals. From there, all other tasks can be performed (assign incidents, send notifications, assign status, and so forth).

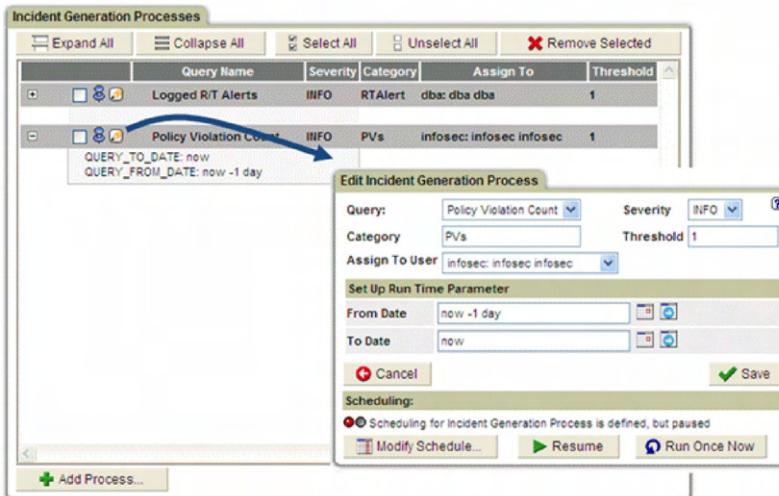

The Incident Management functions can be accessed from the drill-down menus of the Incident Management reports. Each user may only have a subset of reports or functions available, depending on the security roles assigned to the user account.

### Define an Incident Generation Process

An incident generation process executes a query against the policy violations log, and generates incidents based on that query. By default, the definition and scheduling of incident generation processes is restricted to users with the admin role.

## Procedure

- Click Comply > Tools and Views > Incident Generation to open Incident Generation Processes.
- Click the Add Process button to open the Edit Incident Generation Process panel.
- Select a query from the Query list. There are several restrictions that apply to queries used in an incident generation process. Open the query in the Query-Report Builder to verify that it satisfies the following criteria:
  - The query must be from the Policy Violations domain.
  - The query must have the Count check box checked. See [Selecting the column display](#) for more information.
  - The main entity for the query must be the Policy Rule Violation entity.
  - The query fields for the query must not include a SQL string (from either the SQL entity or the Full SQL String attribute of the Policy Rule Violation entity).
- Select a Severity for the incident (defaults to Info).
- Optionally enter a Category for the incident (defaults to none).
- Optionally enter a Threshold for generating the incident. The default is one, meaning every "row" returned by the query will generate an incident.
- From the Assign to User list, select the user to whom the incident will be assigned.
- Enter the From and To Dates for the query. For a scheduled query, use relative dates (for example: now -1 day and now).
- Click Save to save the process definition. You cannot run or schedule the process until it has been saved.
- To run the query now, click Run Once Now.
- To schedule the query, click Modify Schedule to open the scheduling utility. For instructions on how to use the scheduler, see Scheduling.

- Assign/Reassign to Incident - Double-click on the policy violation to be assigned or reassigned, in one of the Incident Management reports.
- Select Assign/Reassign to Incident from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of open incidents (for example, Assign to Incident #123), and one additional option: Assign to a new incident.
- Select an incident to assign this violation to, or select Assign to a new incident to assign this Policy Violation to the next incident number available (they are numbered in sequence). A message displays when the change has been completed, and the Incident Management panel will be refreshed. If a new incident has been created, it will be listed first on the Open Incidents report.

From the Incident Policy Violations / Incident Management report, users can:

- Assign/Reassign to Incident (create an incident from this policy violation).
- Change the severity of the incident.
- Notify one or more users about the incident.
- View reports of Client IP Activity, User Activity, or SQL from the incident.

| Violation Log Id | Timestamp           | Category Name                    | Access Rule Description | Client IP      | Server IP    | DB User Name | Full SQL String                 | Severity Description | Incident Number | Count of Policy Rule Violations |
|------------------|---------------------|----------------------------------|-------------------------|----------------|--------------|--------------|---------------------------------|----------------------|-----------------|---------------------------------|
| 52               | 2007-05-01 15:39:11 | Alert when abdiel accesses robin |                         | 192.168.20.204 | 192.168.2.45 | SA           | select @@trancount              | INFO                 | 0               | 1                               |
| 51               |                     | Assign/Reassign to Incident...   |                         |                |              |              | select * from guardium_borrower | HIGH                 | 1               | 1                               |
| 50               |                     | Change Severity...               |                         |                |              |              | select * from guardium_borrower | HIGH                 | 2               | 1                               |
| 45               |                     | Notify...                        |                         |                |              |              | set showplan_text off           | INFO                 | 0               | 1                               |
| 46               |                     | Client IP Activity Summary       |                         |                |              |              | set noexec off                  | INFO                 | 3               | 1                               |
|                  |                     | User Activity Summary            |                         |                |              |              |                                 |                      |                 |                                 |
|                  |                     | Show SQL                         |                         |                |              |              |                                 |                      |                 |                                 |

15. Assign to User - Double-click on the incident to be assigned to another user, in one of the Incident Management reports.
16. Select Assign to user from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of users, and one additional option: Unassign.
17. Select a user, or select Unassign to remove the current user assigned. When a user is assigned, the Status Description will be Assigned, and when unassigned the Status Description will be Open.
- A message displays when the change has been completed, and the Incident Management panel will be refreshed.
18. Change Severity - Double-click on the incident on which the severity is to be changed, in one of the Incident Management reports.
19. Select Change Severity from the drill-down menu. When selected, this menu will be replaced by a new menu containing a list of severity codes: Info, Low, Med, and High.
20. Select the desired severity code.

A message displays when the change has been completed, and the Incident Management panel will be refreshed.

Once a policy violation has been assigned to an incident the incident displays in the Open Incidents report. From the Open Incidents report, users can perform the actions shown:

| Open Incidents / Incident Management                          |                     |          |               |                    |            |           |               |       |                        |  |
|---------------------------------------------------------------|---------------------|----------|---------------|--------------------|------------|-----------|---------------|-------|------------------------|--|
| Start Date: 2007-04-26 09:31:57 End Date: 2007-05-04 09:31:57 |                     |          |               |                    |            |           |               |       |                        |  |
| Incident Number                                               | Timestamp           | Severity | Category Name | Status Description | First Name | Last Name | # of Comments | Count |                        |  |

## Query rewrite

Query rewrite functionality provides fine-grained access control for databases by intercepting database queries and rewriting them based on criteria defined in security policies.

The modification of queries happens transparently and on-the-fly, such that a user issuing queries seamlessly receives results based on rewritten SQL statements.

Query rewrite functionality is implemented through a combination of query rewrite definitions indicating how queries should be changed or augmented and a run-time context indicating the specific circumstances where the query rewrite definitions should be applied.

Rewriting database queries on the fly allows administrators to implement several types of access control, as illustrated by the following examples.

Table 1. Examples of access control with query rewrite.

| Access control                                                                        | Original SQL                     | Rewritten SQL                               |
|---------------------------------------------------------------------------------------|----------------------------------|---------------------------------------------|
| Limiting access to rows by adding a WHERE clause                                      | <code>SELECT C from T</code>     | <code>SELECT C from T WHERE [values]</code> |
| Limiting access to columns by modifying the SELECT list                               | <code>SELECT C1 from T</code>    | <code>SELECT C2 from T</code>               |
|                                                                                       | <code>SELECT C1,C2 from T</code> | <code>SELECT C2 from T</code>               |
| Restricting database activities by rewriting SQL statements to do nothing.            | <code>SELECT EMAIL from T</code> | <code>SELECT++ EMAIL from T</code>          |
| Restricting what users can do by modifying query verbs (SELECT, INSERT, UPDATE, etc.) | <code>DROP TABLE T</code>        | <code>UPDATE T SET [values]</code>          |
| Restricting what users can do by modifying query objects (TABLE, VIEW, COLUMN, etc.)  | <code>SELECT C from T1</code>    | <code>SELECT C from T2</code>               |

The ability to seamlessly rewrite database queries provides an extremely powerful and flexible form of access control that allows organizations to quickly address a wide range of security concerns. For example, query rewrite definitions can be developed to accomplish any of the following:

- Enforcing security in multi-tenancy scenarios where multiple users and applications share a single database, but where not all users and applications should have access to all data.
- Exposing a database to a production environment for testing purposes without exposing the entire database.
- Rapidly correcting critical security vulnerabilities while permanent solutions are developed at the database or application level.

Review the following sections to learn more about how query rewrite works and how to configure it for use within your Guardium® environment.

Note: If the S-TAP is set for `firewall_default_state=1`, the default state for Query Rewrite, `qrw_default_state=1` cannot be set at the same time.

- [How query rewrite works](#)  
Learn how Guardium implements query rewrite functionality.
- [Using query rewrite](#)  
Learn how to enable and use query rewrite functionality.

## How query rewrite works

Learn how Guardium® implements query rewrite functionality.

### Overview

Once query rewrite has been enabled on the S-TAP for supported database servers (see [Enabling query rewrite](#)), query rewrite functionality is implemented through three policy rule actions:

These rule actions are installed as access policy rules. The access policy rules specify both query rewrite definitions that indicate how queries should be rewritten and a run time context that indicates when those definitions should be applied.

Once query rewrite rules have been specified, sessions are handled as follows:

1. An SQL request triggers a QUERY REWRITE: ATTACH rule, and all subsequent activity in the session is watched by query rewrite.
2. While sessions are being watched by query rewrite, traffic is held at the S-TAP and the session information is checked against access policy rules.
3. If a query in the watched session matches a QUERY REWRITE: APPLY DEFINITION rule, the query is rewritten according to the definition and sent to the S-TAP.
4. The S-TAP releases the rewritten query to the database server.
5. When a QUERY REWRITE: DETACH rule is triggered, query rewrite stops watching activity for the remainder of the session or until another QUERY REWRITE: ATTACH rule is triggered.

## Requirements and limitations

Query rewrite is intended to work with the following database servers:

- Oracle
- Db2
- Microsoft SQL

Important: Query rewrite does not support encrypted traffic with Windows S-TAP. Active sessions may be terminated if they are encrypted.

For information about supported database servers and any associated restrictions, see [System requirements](#). For detailed information about database client support for query rewrite, contact IBM Guardium support.

Note: When query rewrite is watching a session, the sniffer is required to send engine verdicts to the S-TAP for each SQL request in the session. This process is asynchronous and introduces latency between the sniffer and S-TAP. Create query rewrite rule conditions that avoid attaching to sessions for performance-sensitive or trusted applications.

## Handling large SQL statements from an MSSQL Server database

Query rewrite does not mask the data when the overwritten SQL is larger than negotiated packet size. In these cases Guardium issues an alert. If the query is too long either a transport-level error occurs or the data in the query is shown as unmasked. If Guardium misses the login packet with the negotiated packet size, then Guardium uses the default packet size as 4K Use the predefined alert QWR Exceptions Alert to be notified of this situation. The alert fires once per session when the query returns more than the negotiated packet size. For more information, see [Predefined alerts](#).

There is a default report QRW Exceptions that provides details of such sessions.

## Enabling query rewrite

Learn how to configure an S-TAP for query rewrite functionality.

## Before you begin

---

The query rewrite feature is available only when you enable query rewrite in the guard\_tap.ini file and query rewrite policy rules exist and are triggered by session traffic.

## About this task

---

Query rewrite is controlled by a query rewrite parameter in the [TAP] section of the S-TAP guard\_tap.ini file.

## Procedure

---

1. Log on to the database server system using the root account.
2. Stop the S-TAP.
3. Make a backup copy of the guard\_tap.ini configuration file.
  - For Windows - \Program Files\IBM\Windows S-TAP\Bin\
  - For UNIX - /usr/local/guardium/guard\_stap/guard\_tap.ini
4. Open guard\_tap.ini in a text editor.
5. Locate the query rewrite parameter and edit it as required. Set the parameter to 1 to enable it or to 0 to disable it.
  - For Windows - QUERY\_REWRITE\_INSTALLED
  - For UNIX - qrw\_installed
6. Save your changes to guard\_tap.ini.
7. Restart the inspection engines either by navigating to Manage > Activity Monitoring > Inspection Engines and clicking on Restart Inspection Engines; or by logging in to the CLI as user, and restarting the inspection engines using the **restart\_inspection\_engines** CLI command.

## Results

---

When you are done, query rewrite functionality is enabled and responds to policy rules that contain query rewrite actions. For more information about query rewrite parameters, see [Query rewrite parameters](#) for UNIX or [Query rewrite parameters](#) for Windows.

---

## Creating query rewrite definitions

Learn how to create query rewrite definitions for data masking and access control scenarios.

## Procedure

---

1. Go to Protect > Security Policies > Query Rewrite Builder.
2. Provide a unique and meaningful name for the query rewrite definition in the Name field.
3. Create and parse a model query.
  - a. Provide a model query in the Enter a model query field.

For example, to create a rewrite definition preventing the use of **SELECT \* from** statements, enter **SELECT \* from EMPLOYEE** as a model.

- b. Click the DB Type menu and select a SQL parser to use with the model query.
- c. Click Parse to process the model query.

Your model query will be broken down into individual components with each actionable component highlighted with underlined text.

4. Define how to rewrite specific components of the model query.

- a. Click on an underlined component of the parsed query that you would like to rewrite. A dialog opens to help create your query rewrite definition.  
Options:

- Select and modify an individual verb, field, or object from the parsed query
- Add a component to the query (shown as gray underlined text next to the parsed query)
- Rewrite the entire query by clicking the gray underlined [R] next to the parsed query

In the example **SELECT \* from EMPLOYEE** where we want to prevent the use of **SELECT \* from** statements, click the **\*** to provide rewrite content.

- b. The Change from field indicates what will be rewritten.

- c. The To field defines the rewritten component.

For example, to prevent the use of **SELECT \* from** statements, replace the **\*** component with a list of specific objects: **EMPNO, FIRSTNAME, MIDINIT, LASTNAME, WORKDEPT, PHONENO, HIREDATE, JOB, EDLEVEL, SEX**.

Important: Rewrite definitions are based on syntax, so any statement with the form **SELECT \* from [OBJECT]** will match the example. For instance, both **SELECT \* from DEPARTMENT** and **SELECT \* from EMPLOYEE** statements match our example. Query rewrite definitions can be restricted to specific objects using access policy rules. See [Defining a security policy to activate query rewrite](#) for instructions.

- d. Click Save to save the rewrite definition, then click Back to close the dialog.

5. Review the output of the query rewrite definition using the Real time preview field and make any changes as needed.

Using our example, **SELECT \* from EMPLOYEE** is rewritten as **SELECT EMPNO, FIRSTNAME, MIDINIT, LASTNAME, WORKDEPT, PHONENO, HIREDATE, JOB, EDLEVEL, SEX from EMPLOYEE**.

6. When you are satisfied with the results, click Save to save your query rewrite definition.

Your query rewrite definition is saved and displayed in the list of available query rewrite definitions in the Query Rewrite Builder.

## What to do next

---

Continue working with query rewrite definitions:

- Create additional definitions by clicking New and repeating the steps in this task.
- Edit an existing query rewrite definition by double-clicking an item in the list of available query rewrite definitions.
- Copy and edit an existing query rewrite definition by selecting the item in the list of available query rewrite definitions and clicking Clone.
- Delete an existing query rewrite definition by selecting the item in the list of available query rewrite definitions and clicking Delete.

When you are finished working with query rewrite definitions, continue to the next step in this sequence to test and implement your definitions.

## Testing query rewrite definitions

---

Learn how to test query rewrite definitions against sample input and verify that the rewrite definitions behave as expected.

### Before you begin

---

To complete this task, you need to have created one or more query rewrite definitions.

### Procedure

---

1. Open Protect > Security Policies > Query Rewrite Builder.
2. Click Set Up Test to open a dialog and select query rewrite definitions for testing.
  - a. Drag and drop items from the Available query rewrite definitions field to the Test query rewrite definitions field.
  - b. Drag and drop items with the Test query rewrite definitions field to order multiple definitions as you would within an access policy.
  - c. Click Save to close the dialog when you are finished.

3. Type or paste test queries into the test field.

For example, to test a rewrite definition preventing the use of **SELECT \* from** statements (see [Creating query rewrite definitions](#)), enter sample queries such as:

```
SELECT * from DEPARTMENT
SELECT * from EMPLOYEE
SELECT FIRSTNAME, case
when SALARY > 150000 then 'high'
when SALARY > 100000 then 'medium'
when SALARY > 80000 then 'fair'
else 'poor'
end from EMPLOYEE
```

```

DELETE from EMPLOYEE where EMPNO=100
INSERT into TEMP_EMP SELECT * from EMPLOYEE

```

4. Click Run Test to process the sample queries and review the results.

For example, the sample queries provided in the previous step return the following results:

Table 1. Query rewrite test results

| Original SQL                                                                                                                                             | Rewritten SQL                                                                                                                                            | Changed |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| SELECT * from DEPARTMENT                                                                                                                                 | SELECT EMPNO, FIRSTNAME, MIDINIT, LASTNAME, WORKDEPT, PHONENO, HIREDATE, JOB, EDLEVEL, SEX from DEPARTMENT                                               | YES     |
| SELECT * from EMPLOYEE                                                                                                                                   | SELECT EMPNO, FIRSTNAME, MIDINIT, LASTNAME, WORKDEPT, PHONENO, HIREDATE, JOB, EDLEVEL, SEX from EMPLOYEE                                                 | YES     |
| SELECT FIRSTNAME, case when SALARY > 150000 then 'high' when SALARY > 100000 then 'medium' when SALARY > 80000 then 'fair' else 'poor' end from EMPLOYEE | SELECT FIRSTNAME, case when SALARY > 150000 then 'high' when SALARY > 100000 then 'medium' when SALARY > 80000 then 'fair' else 'poor' end from EMPLOYEE | NO      |
| DELETE from EMPLOYEE where EMPNO=100                                                                                                                     | DELETE from EMPLOYEE where EMPNO=100                                                                                                                     | NO      |
| INSERT into TEMP_EMP SELECT * from EMPLOYEE                                                                                                              | INSERT into TEMP_EMP SELECT * from EMPLOYEE                                                                                                              | NO      |

Important: Rewrite definitions are based on syntax, so any statement with the form `SELECT * from [OBJECT]` will match the example. For instance, both `SELECT * from DEPARTMENT` and `SELECT * from EMPLOYEE` statements match our example. Query rewrite definitions can be restricted to specific objects using access policy rules. See [Defining a security policy to activate query rewrite](#) for instructions.

5. Continue entering sample queries to test your rewrite definitions.

Click Set Up Test to change or reorder the rewrite definitions used for the test.

## What to do next

When you are satisfied with the test results, create a security policy to begin using your query rewrite definitions with live queries.

Previous topic: [Creating query rewrite definitions](#)

Next topic: [Defining a security policy to activate query rewrite](#)

## Related tasks

- [Defining a security policy to activate query rewrite](#)

## Defining a security policy to activate query rewrite

Learn how to create access policy rules using your query rewrite definitions with live queries.

## Before you begin

To complete this task, you need to have created and tested one or more query rewrite definitions, and you need to be familiar with creating security policies.

## Procedure

1. Open Protect>Security Policies>Policy Builder.
2. Create a new policy or modify an existing policy to use your query rewrite definitions.  
Tip: Consider creating a new policy for testing query rewrite definitions. Add your rewrite rules to existing security policies once you are satisfied with the behavior of the test policy.
3. Click Edit Rules to begin adding rewrite rules to the selected policy, then select Add Rules>Add Access Rule.  
Note: Query rewrite rules are always classified as access rules.
4. Add a rule with a QUERY REWRITE: ATTACH rule action. Be sure to check the Continue to next rule checkbox. This rule identifies the specific session parameters that must be matched in order to trigger a query rewrite session, for example a specific database user name or client IP address.
5. Add a rule with one or more QUERY REWRITE: APPLY DEFINITION rule actions and select the query rewrite definition(s) you would like to apply. This rule identifies the specific objects or commands that must be matched in order to apply the rewrite definitions and modify the source query.  
For example, you can limit the data that displays back to a user when a `SELECT * from EMPLOYEE` query is issued. To do so, set the Object field to `EMPLOYEE` and create a query rewrite definition to replace the `*` with a list of defined columns for the data you want the user to have access to.
6. Add a rule with a QUERY REWRITE: DETACH rule action. This detaches the query rewrite session and prevents further monitoring of session traffic. The conditions set for the detach rule should not be the same as the attach rule.
7. To install the new policy, return to the Policy Finder, select your security policy, and choose Select an installation action>Install and Override. Click OK when asked to confirm installation of the policy.
8. Log in to your database server and run test queries to verify that your access policy rewrite rules are functioning as intended.
  - a. Log in to your database server.
  - b. Issue queries that should trigger (or should not trigger) the installed access policy rules and match the criteria of your query rewrite definitions.  
For example, if you set the Object to `EMPLOYEE` and you issue `SELECT * from EMPLOYEE`, you should only see results for the columns you defined for `*` in the query rewrite definition. In contrast, if you issue a `SELECT * from DEPARTMENT`, you should see all column data returned for the `DEPARTMENT` object.
  - c. Verify that the results reflect the rewritten SQL.

## Creating a custom report to validate query rewrite results

---

Learn how to create a query rewrite tracking report for auditing query rewrite activity.

### Before you begin

---

To complete this task, you need to have created and installed access policy rules that apply query rewrite definitions, and you need to be familiar with creating reports.

### About this task

---

A query rewrite tracking report helps validate query rewrite actions in both test and production environments.

### Procedure

---

1. Follow instructions in [Using the Query-Report Builder](#) to create a new query.
2. Select one of the main entities:
  - Query Rewrite Log
  - Client/Server
  - Session
  - Access Period
3. Include the following items as a starting point for your query rewrite report:
  - Client/Server: Timestamp
  - Client/Server: DB User Name
  - Client/Server: Server Type
  - Query Rewrite Log: Applied QR Definition Names
  - Query Rewrite Log: Input SQL
  - Query Rewrite Log: Output SQL
4. Save the report when complete.
5. Click Add to My Custom Reports to add the report to your custom reports.
6. Open Reports > My Custom Reports and select the report you created to view a report of query rewrite actions.

A file activity monitoring policy specifies how Guardium handles different file activity events. Each policy consists of a set of ordered rules. Each rule in a policy defines a conditional action that is taken when the rule matches. The conditional test can be simple, for example a user accesses a specific location, or a complex test that considers multiple conditions. The action ranges from nothing to blocking the event. Multiple grouping and alerting actions can be combined and ordered to create sophisticated responses to matched rules.

You can, for example, define policies for these cases:

- Log a policy violation if John writes into the CONFIDENTIAL folder
- Block a group of users from deleting the file SALARIES.XLS
- Send an e-mail to Krishna if JENNY reads from any files that begin with the name sample\*
- Audit all accesses to any file that has been classified as containing sensitive data related to PCI

### Groups

Guardium uses the concept of groups for policy and report creation.

Guardium groups are created and maintained on the Guardium collector or Central Manager. Do not confuse Guardium groups with file system groups.

It is recommended that you consider a naming strategy for your groups, including groups of data sources (file servers), groups of files (such as by sensitivity level or combination of sensitivity level and application), groups of users (a list of all known users, "authorized" users, users with special privileges).

Guardium groups are created and maintained on the Guardium collector or Central Manager. Do not confuse Guardium groups with file system groups.

#### Rule Guidelines

- A overly broad rule (a rule that monitors too many files) can overload the system and increase processing and response time.
- A FAM rule can have more than one pattern in it. To protect both a directory and its contents, define a rule with two patterns /FAMtest/\* and /FAMtest.
- A group comprised of file paths: each path must be unique irrespective of case. For example, these two paths can co-exist in a group: C:\ABC and C:\abcdef. However, these two paths cannot co-exist in a group C:\ABC and C:\abc. The Group builder is not case sensitive. It is not required to input members with all upper case characters or all lower case characters. However, in UNIX, which is case sensitive, the path /IBM/Guardium is different from the path /ibm/guardium. If the user wants to monitor both of these paths, the current Group builder has a limitation and will not see them as two paths.
- The ordering of rules in the security policy is very important. The rules are sent to the S-TAP as a set and are processed strictly in order. Any given user activity is checked against each rule in the policy in order. The first rule that meets the criteria of this file access is applied and subsequent rules are ignored. In most cases, put the most specific rule first and the most general rule last. For example, you have two rules:
  - **Rule A:** audit only all access to /data/\*
  - **Rule B:** block, log violation and audit user 'joe' from accessing /data/salaries

If you put Rule A first, and Joe tries to read /data/salaries, there is no need to go to the next rule, and Joe will be audited. If you put Rule B first, Joe is blocked from accessing /data/salaries and there is no need to go to the next rule.

#### Rule attributes

##### Rule name

A unique name.

##### Datasource

The datasource can be:

- Datasource selected from drop-down list
- Group selected from drop-down list
- Group created from selected groups in the Create New Rule window
- Manually entered path

##### Rule Action

The rule action is the action taken when the criteria are met. Actions are defined for:

- One action for any file access that matches the rule criteria
- Multi-action rule comprised of multiple actions, each one is per a specified command category or a specified group. Note that **Continue to next rule** is not supported when using Multi-action rules.

The rule actions are:

- Alert and audit: Send an alert directly generated from the sniffer with specific behavior, and log the event.
- Audit only: Log the event in GDM tables
- Block, log violation, and audit: Block access to the object, log a policy violation, and log the event. A blocking action requires an alert configuration as well.
- Ignore: No action taken.
- Log as violation and audit: Log this as a policy violation and log the event.

#### Notification types

- Email messages: You can specify a Guardium user email, or an external email. Emails are sent using the SMTP server configured for the Guardium system.
- SNMP traps: alerts the trap community configured for the Guardium system.
- Syslog messages: generates messages that are written to the syslog.
- Custom notifications: user-created notification handlers implemented as Java classes.

##### Rule criteria

For any given file access, rule criteria are used to evaluate whether a particular action should be taken. For any datasource or group of datasources (file servers), the rule criteria that you can specify include:

**User:** The OS user who is accessing files. This can also be a group of users, as defined in a Guardium group. If this is left blank then the rule applies to all users (except root).

**File Path:** This can be a Windows or UNIX file path, an individual file path, or a group of file paths, as defined in a Guardium group. This cannot be blank (except when removable media is selected). You can also select to monitor the subdirectories in the file path.

Wild cards in the name specification:

- The '\*' character matches any number of any characters
- The '?' character matches one single character
- For UNIX, use back slash to escape \* and ?

Tip: Wild cards take extra processing. Excessive use of wild cards impacts performance.

This matches. The file name, FAM.output, matches the name, FAM, and is located in a subdirectory of the given directory '/'.

#### UNIX

Usage:

- To match all files on disk, enter /\*
- To match /tmp/My\*File.txt exactly , use /tmp/My\\*File.txt
- To match any file with a .txt extension in /tmp, use /tmp/\*.txt

Example: The FAM rule pattern is: /FAM\*

meaning

- Directory: /
- File name: FAM\*

The rule in place has subdirectories selected: (Subdirs: Yes)

The file accessed is: /guardium/modules/SUPERVISOR/10.0.0/FAM.output

**Windows:** For Windows, you must specify the drive, such as C:\

Usage:

- To monitor all files on the C drive, enter C:\ and mark the Monitor subdirectories checkbox.
- To match any file with a .txt extension in C:\tmp, use C:\tmp\\*.txt

GuardAPI examples: create policy with two rules

```
grdapi create_policy ruleSetDesc=policy1 isFam=true
grdapi create_fam_rule policyName=policy1 ruleName=rule1 serverHost="x.x.x.x" filePath="/famtest/*" command="DELETE"
actionName="Alert and Audit" notificationType="SYSLOG"
grdapi create_fam_rule policyName=policy1 ruleName=rule2 serverHost="x.x.x.x" filePath="/famtest/*" command="READ"
actionName="Alert and Audit" notificationType="MAIL"

policy1 -> rule1 -> "DELETE" -> "Alert and Audit" -> "SYSLOG"
policy1 -> rule2 -> "READ" -> "Alert and Audit" -> "MAIL"
```

GuardAPI examples: create policy with multi-Action Rule

Multi-Action Rule for FAM - Multi-action rules are comprised of multiple actions, each one is per a specified command category or a specified group. The commands in a FAM context are: Read, Write, Delete, Execute and File Operation. If the system does not support Multi-Action Rules, it ignores the rule and continues to the next rule.

```
grdapi create_policy ruleSetDesc=policy1 isFam=true
grdapi create_fam_rule policyName=policy1 ruleName=rule1 serverHost="x.x.x.x" filePath="/famtest/*"
add_action_to_fam_rule policyName=policy1 ruleName=rule1 command="DELETE, READ" actionName="Alert and Audit"
notificationType="SYSLOG"
add_action_to_fam_rule policyName=policy1 ruleName=rule1 command="WRITE" actionName="Alert and Audit"
notificationType="MAIL"

policy1 -> rule1 -> "DELETE, READ" -> "Alert and Audit" -> "SYSLOG"
policy1 -> rule1 -> "WRITE" -> "Alert and Audit" -> "MAIL"
Adding another action using commandGroupId, assuming commandGroupId=20000 exists, and it has "DELETE, WRITE"

add_action_to_fam_rule policyName=policy1 ruleName=rule1 command="READ" commandGroupId=20000 actionName="Ignore"
notificationType=""

policy1 -> rule1 -> "READ, DELETE, WRITE" -> "Ignore"
```

## Create a FAM policy and its rules from scratch for Windows and UNIX servers

Set up file activity monitoring by defining and managing policies and rules in the Policy Builder for Files window.

### About this task

Once you open the Policy Builder for Files and additional views within the policy builder, you can toggle between the various views by clicking Policy Builder for Files, New Policy and Create New Rule at the bottom of the page.

You can also create policies and rules using the API.

### Procedure

1. On a standalone or MU, access the FAM policy builder. Go to Protect > Security Policies > Policy Builder for Files.
2. Click to open the New Policy page.
3. In the Type field, select Windows, Linux, and Unix systems.
4. In the Policy Name field, type a name for the policy. (You can save the policy once a rule is defined.)
5. To add existing rules to the policy.
  - a. Click Show Templates. The Rule Templates table opens.
  - b. Optionally filter the list with the filter function.
  - c. Select one or more rules and click the right arrow
6. To create a new rule.
  - a. Click to open the Create New Rule page.
  - b. In the Rule name section, type the name.
  - c. In the Choose datasources section, specify a datasource manually, by selecting from a list of datasources, or by selecting a group of datasources. See [Datasource](#) and [Groups](#).
  - d. In the Define rule criteria to include or exclude file paths, optionally to monitor the subdirectories in the file path or to monitor removable media. See [Rule criteria](#).
  - e. In the Define rule action section, define the rule action. See [Rule Action](#).
7. Click Save.
8. To modify an existing rule and add it to the policy.
  - a. In the New Policy page, click Show Templates.
  - b. Under Rule Templates, select the rule and click .
  - c. Under Rule, select the rule and click , change the name, modify the other attributes as relevant, and click Save.
9. Change the order of the rules using the and .
10. Delete a rule by selecting it and clicking .
11. Click Save to save the policy, or Save and Install to install the policy immediately. (See [Using the Policy Installation tool](#)).

## Creating a FAM policy rule from the Investigative Dashboard Entitlements tab

You can use the monitored data, such as datasource names, user names, actions, and file paths, in the Investigation Dashboard Results Table to create policy rules.

### Before you begin

---

- The FAM bundle must be installed and configured
- Discovery and classification must be enabled
- Investigation Dashboard must be enabled, see [Enabling and disabling the Investigation Dashboard](#)

### Procedure

---

1. Choose File from the dropdown list in the product banner and click the search icon to open the Investigation Dashboard for file data.
2. Open the Results Table Entitlements tab. Click Details to see individual entries.
3. Choose one or more entries in the results that you want to use to populate a rule. You can use the Select all check box to include all the entries that are currently displayed (not all the entries in the database).
4. Right-click and choose Add Policy Rule.  
The Build Rule dialog opens with values from the entries that you selected. If you selected multiple entries, a group is created that contains the values from those entries. You can create a rule that is to be added to an existing policy, or create a new policy that includes your new rule.  
Note: A overly broad rule (a rule that monitors too many files) can overload the system and increase processing and response time.  
Note: A FAM rule can have more than one pattern in it. To protect both a directory and its contents, define a rule with two patterns /FAMtest/\* and /FAMtest.  
Note: When using FAM policy, setting a group to define monitored file paths requires either consideration of case sensitivity. Otherwise the group cannot be created successfully. The workaround is to create two different FAM policy rules. Clarification - If strings defined as members of group are different without considering case sensitive, the group can be created successfully. For example: 1. C:\ABC 2. C:\abcdef. If strings defined as members of group are same without considering case sensitive, the group can NOT be created. For example: 1. C:\ABC 2. C:\abc So it is not required to input members with all upper case characters or all lower case characters. Group builder is not case sensitive. However, in UNIX, which is case sensitive, the path /IBM/Guardium is different from the path /ibm/guardium. If the user wants to monitor both of these paths, the current Group builder has a limitation and will not see it as the same path.
5. Choose datasources, actions, and criteria. Overwrite any values that you want to change. Click Edit to modify each field.
6. To create a new policy and install it, click Create and Install. To create the policy but not install it, click OK.

## File activity policies for network-attached storage (NAS) and SharePoint

---

Set up file activity monitoring for NAS devices and SharePoint by defining policies and rules in the Policy Builder for Files.

- [Creating file activity policies for network-attached storage \(NAS\) devices](#)  
Use the Policy Builder for Files to set up file activity monitoring for NAS devices. You can configure multiple monitored hosts on the same server. Each monitored host can have its own policy configuration by using a distinct datasource.
- [Creating file activity policies for SharePoint](#)  
Use the Policy Builder for Files to set up file activity monitoring for SharePoint.
- [Creating a DAM access policy to monitor files on NAS and SharePoint](#)  
Use the comprehensive criteria and rule actions of Data Activity monitoring (DAM) access policy to monitor FAM for NAS and SP in deeper granularity. Set up alerts on a subset of users, audit all or a set of users, and optionally ignore a set of users or operations.

## Creating file activity policies for network-attached storage (NAS) devices

---

Use the Policy Builder for Files to set up file activity monitoring for NAS devices. You can configure multiple monitored hosts on the same server. Each monitored host can have its own policy configuration by using a distinct datasource.

### About this task

---

After you establish a connection between your monitoring agent and the Guardium system, you can configure FAM for NAS by using the Policy Builder for Files.  
Note: You can no longer configure FAM for NAS using the configuration app. Any manual change to the configuration file triggers an alert.

### Procedure

---

1. Go to Protect > Security Policies > Policy Builder for Files.
2. Click to create a new policy.
3. To enter the type of policy, click the drop-down box and select Network Attached Storage.
4. Enter a name for the new policy. The policy can be saved after a rule is defined.
5. To add existing rules to the policy:
  - a. Click Show Templates. The Rule Templates table opens.
  - b. Optionally filter the list with the filter function.
  - c. Select one or more rules and click

6. To create a new rule:
    - a. Click  to open the Create New Rule window.
    - b. Name the rule, and click Next.
    - c. Specify a datasource manually, by selecting from a list of datasources, or by selecting a group of datasources and click Next.
  7. Define rule criteria by including or excluding file paths, excluding accounts, or file extensions.
  8. Select the Specify action for specific operation or group checkbox to specify the operations that require monitoring, and the appropriate rule action. If the check box is not selected, all operations are monitored by default.  
Note: The operations that are selected override the settings on the configuration app of the monitoring agent.
  9. To configure an existing rule:
    - a. Click  to change the name, modify the other attributes as relevant, and click Save.
    - b. Delete a rule by selecting it and clicking .
10. Click Save to save the policy, or Save and Install to install the policy immediately. For more information, see [Using the Policy Installation tool](#).
- Attention:  
In Guardium® v11.2 and later, NAS datasources appear in the following format: <The name of the server where the agent is installed>:<the monitored host>\_<type of NAS device>:FAM-NAS.
- When FAM for NAS is upgraded to v11.2 or later, the existing policies that are installed on v11.0 or v11.1 do not work due to the change in the datasource format. To resolve this issue, update the name of the NAS datasource, save, and reinstall the policy.

## Creating file activity policies for SharePoint

Use the Policy Builder for Files to set up file activity monitoring for SharePoint.

### About this task

After you establish a connection between your monitoring agent and the Guardium system, you can configure FAM for SharePoint by creating and installing a policy.  
Note: You can no longer configure FAM for SharePoint using the configuration app. Any manual change to the configuration file triggers an alert.

### Procedure

1. Go to Protect->Security Policies->Policy Builder for Files.
  2. Click  to create a new policy.
  3. To enter the type of policy, click the drop down box and select SharePoint.
  4. Enter a name for the new policy. The policy can be saved after a rule is defined.
  5. To add existing rules to the policy:
    - a. Click Show Templates. The Rule Templates table opens.
    - b. Optionally filter the list with the filter function.
    - c. Select one or more rules and click .
  6. To create a new rule:
    - a. Click  to open the Create New Rule window.
    - b. Name the rule, and click Next.
    - c. Specify a datasource manually, by selecting from a list of datasources, or by selecting a group of datasources and click Next.  
SharePoint datasources appear in the following format: <The name of the server where the agent is installed>:FAM-SP.
  7. Define rule criteria by entering the site URL. Exclude accounts, if appropriate..
  8. Select the Specify action for specific operation or group check box to specify the operations that require monitoring, and the appropriate rule action. If the check box is not selected, all operations are monitored by default.  
Note: The operations that are selected override the settings on the configuration app of the monitoring agent.
  9. To configure an existing rule:
    - a. Click  to change the name, modify the other attributes as relevant, and click Save.
    - b. Delete a rule by selecting it and clicking .
10. Click Save to save the policy, or Save and Install to install the policy immediately. For more information, see [Using the Policy Installation tool](#).

## Creating a DAM access policy to monitor files on NAS and SharePoint

Use the comprehensive criteria and rule actions of Data Activity monitoring (DAM) access policy to monitor FAM for NAS and SP in deeper granularity. Set up alerts on a subset of users, audit all or a set of users, and optionally ignore a set of users or operations.

### Before you begin

Create and install a FAM policy to filter FAM traffic that you want to monitor. For more information, see [Creating file activity policies for network-attached storage \(NAS\) devices](#) and [Creating file activity policies for SharePoint](#).

Note: Set the FAM policy action to Audit Only.

### About this task

Apply Data Activity Monitoring (DAM) access policy to NAS and SharePoint to achieve granular policy filtering.

## Procedure

---

1. Go to Protect > Security Policies > Policy Builder for Data.
2. Create a policy by clicking the  icon.
3. From the Name and properties pane of the Create New Policy window, set the policy type to Data security policy and define a policy name.
4. Click the Rules pane to begin working with policy rules. Create a rule by clicking the  icon.
  - a. From the Rule definition pane of the Create New Rule window, define a Rule name. Set the Rule type to Access.
  - b. Click the Rule criteria pane. Use the menus to select individual parameters, define selection operators, and then specify values or groups to match.  
For FAM for NAS and SharePoint, use the following criteria:
    - Session level criteria
      - Operating system user: The username of NAS or SharePoint. The database username is also the same.
      - Client IP address: The IP address that is used to connect to NAS or SharePoint.
      - Server IP address: The IP address where the NAS or SharePoint server is hosted.
      - Server host name: The hostname of the NAS or SharePoint host
      - Service name: To process FAM for NAS traffic, use NASFAM. For SharePoint, use SPFAM.
    - SQL criteria
      - i. Command  
Note: Commands are case-sensitive.  
For NAS, use the following commands:
        - Rename
        - Update
        - Create
        - Read
        - Delete
        - Access Rights ChangeFor SharePoint, use the following commands:
        - CheckOut
        - CheckIn
        - View
        - Delete
        - Update
        - ProfileChange
        - ChildDelete
      - ii. Object
        - For NAS, provide the absolute path of the file name or directory name.
        - For SharePoint, provide the full URL to the SharePoint object.

Attention:

When both DAM and FAM for NAS and SP policies are installed to monitor NAS and SharePoint traffic, FAM rules are evaluated and triggered last, regardless of the order of the policies.

Enable Continue to next rule for all DAM policy rules to ensure that the FAM rules are triggered.

- c. Click the Rule action pane to begin working with rule actions, then create a new rule action by clicking the  icon.  
For FAM for NAS and SharePoint, use the following actions:
  - ALERT PER MATCH
  - ALERT DAILY
  - ALERT ONLY
  - ALERT PER TIME GRANULARITY
  - LOG MASKED DETAILS
  - LOG FULL DETAILS
  - LOG FULL DETAILS WITH REPLACED VALUES
  - SKIP LOGGING
  - LOG ONLY
- Note: FAM for NAS and SharePoint does not support actions that are tracked per session or require S-TAP.
- d. After the rule is defined, click OK to return to the Rules pane.  
Continue working with rules as needed.

5. After the policy and its rules are defined, click OK to save the policy and return to the Security Policies table.

---

## Configuring consolidation of FAM MS Office events

Use the FAM monitor Office event consolidation feature to filter out the extraneous, irrelevant MS Word, Excel, and PowerPoint file activities.

When FAM monitors MS Office products MS Word, Excel, and PowerPoint, it generates a lot of extraneous and confusing file events that make it difficult to determine what actually happened in the system. You can use the Office event consolidation feature to filter out the extraneous, irrelevant file activities so that only a clear concise stream of useful events is presented to the collector. The filter eliminates a very high percentage of extraneous events out of the data stream, although occasionally an extraneous file event could be reported. For instance, Windows and Office open files multiple times to read file attributes without ever actually loading the file into memory. For Office this occurs when a user opens a file. Office initially opens and closes the file to read its attributes (which generates a READ event) before actually reading the file into memory (which generates another READ event). Unfortunately it is impossible to distinguish opening a file to read its attributes, from Office opening and reading the actual file into memory.

The FAM monitor office filter software filters out all activity done to temporary files, all activity done to the office journaling files, and the majority of other events that don't represent what the end user actually did. It also eliminates a lot of the ambiguity as to what happened on the system by providing a much finer granularity of file events. For instance, instead of FILEOP events, it reports the actual underlying events that make up the FILEOP, namely RENAME FILE, SET FILE PERMISSIONS, and SET FILE PROPERTIES. There are also separate events for activity that occurs to folders. This includes CREATE FOLDER, OPEN FOLDER, CLOSE FOLDER, RENAME FOLDER, READ

FOLDER, WRITE FOLDER, EXECUTE FOLDER, DELETE FOLDER, SET FOLDER PERMISSIONS, and SET FOLDER PROPERTIES. These are the same events that are generated for files – the only difference is that they apply to folders instead.

The OPEN FILE, CLOSE FILE, OPEN FOLDER, and CLOSE FOLDER events are processed locally by the FAM monitor but are **not** delivered to the collector. The reason that they are not delivered to the collector is that the Windows file explorer program is constantly opening and closing files in the background and these events are rarely useful or desirable to have. Reporting all of them to the collector would essentially provide useless information to the end user and would flood the collector and the network with useless traffic.

The Office event consolidation is configured with these parameters, in the guard\_tap.ini file. The parameters apply only to FAM monitoring; they are ignored by the S-TAP.

To modify the guard\_tap.ini file:

1. Log on to the database server system using the root account.
2. Stop the S-TAP.
3. Make a backup copy of the configuration file: guard\_tap.ini. The default file locations is \Program Files\IBM\Windows S-TAP\Bin\
4. Open the configuration file in a text editor.
5. Edit the file as necessary. These parameters must be in the [Tap] section of the file.
6. Save the file.
7. Restart the S-TAP.

| Parameter Name        | Possible Values                                                               | Default Value                                      | Description                                                                                                                                                                                                                                                                                                                          |
|-----------------------|-------------------------------------------------------------------------------|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENABLE_OFFICE_FILTERS | 0, 1                                                                          | 1                                                  | Enables or disables the office filter component of the FAM monitor software. When disabled, all files events are reported to the collector including those for temporary files, journaling files, etc. When enabled, only useful files events related to the actual operation the end user performed are delivered to the collector. |
| WORD_EXTENSIONS       | List of file extensions<br>.docx .doc<br>.docm .dotm<br>.dotx .dot .odt       | .docx .doc<br>.docm .dotm<br>.dotx .dot .odt       | The file extensions that identify a file as a Microsoft Office Word source file. The FAM monitor software uses the office filter component on the event streams generated for these files.                                                                                                                                           |
| EXCEL_EXTENSIONS      | List of file extensions<br>.xlsx .xls .xlsm<br>.xlsl .xltx .xltm<br>.xlt .ods | .xlsx .xls .xlsm<br>.xlsl .xltx .xltm<br>.xlt .ods | The file extensions that identify a file as a Microsoft Office Excel source file. The FAM monitor software uses the office filter component on the event streams generated for these files.                                                                                                                                          |
| POWERPOINT_EXTENSIONS | List of file extensions<br>.pptx .pptm .ppt<br>.potx .potm .pot<br>.odp       | .pptx .pptm .ppt<br>.potx .potm .pot<br>.odp       | The file extensions that identify a file as a Microsoft Office PowerPoint source file. The FAM monitor software uses the office filter component on the event streams generated for these files.                                                                                                                                     |
| FSM_LOG_EVENTS        | 0, 1                                                                          | 0                                                  | Enables or disables the logging of file events to the FAM monitor text log file. When enabled, all events like CREATE FILE, READ FILE, etc. that are sent to the appliance are also logged to the application's circular text log file in the STAP ..\logs folder.                                                                   |

## Investigation Dashboard for data

The investigation dashboard is a preset group of charts and a table that help you understand what is happening in your system at any given time, and upon which you can build your own customized dashboards.

There are four default views for data activity monitoring, each with different charts and tables. Select the view from the dashboard menu . The default views cannot be modified.

The default dashboards contain data for the last hour presented in one or more of:

- Trimetric charts (3-axis data graphs). The default view is a color map. Additional views are bar graph, bubble graph, line graph, pie graph, step graph, and area graph.
- Results table: provides the search results and investigation features of the original quick search. The Results Table is always at the bottom of the dashboard. It can be added to any dashboard. Tabs are:
  - Activity: Summary and Details tabs. Each row in the Summary tab gives the number of instances of recorded activities per server-DB pair and the number of DB types. The Detailed Summary adds the count of Source Programs, DB users, OS users, Client hostname, Client IP, and date. Each row in the Details tab gives full details on one activity.
  - Outliers Summary and Details tabs: see [Interpreting data outliers in the investigation dashboard](#).
  - Errors Summary and Details tabs: Summary and Details tabs. Each row in the Summary tab gives the number of instances of reported errors per server and the number of DB types and DB users. The Detailed Summary adds the number of Client IPs, error types and dates. Each row in the Details tab gives full details on one error.
  - Violations Summary and Details tabs. Each row in the Summary tab gives the number of instances of recorded violations per server-DB pair and the number of DB types. The Detailed Summary adds the count of Source Programs, DB users, OS users, Client hostname, Client IP, severity, violation, and date. Each row in the Details tab gives full details on one violation.
  - Vulnerability Assessments Summary and Details tabs. These tabs show the last results per VA test. For example, a test that runs daily has daily updated results. The data is kept for 90 days. If a test wasn't executed during the last 90 days, the results are purged.

You can export the data in individual tabs to CSV and PDF. A comma in the data results corrupts the export to CSV, and data results can shift by one column.

Additional views that you can add or open, all from the Add Chart drop-down except the topology view:

- Topology view  : see [Using the topology view](#)
- Animated bubble chart: an animated visualization of data changes over the last 48 hours. The chart depicts the behavior of objects over a period of 24 hours. Each object is depicted as a circle, and its area and position (x and y axis) represent three user-selected variables. The animation represents the object's behavior over the 24 hours. Access from the Add Chart drop-down.
- Sankey chart: This chart presents four dimensions (and their relationships) in one view, giving a more complete and fluid view on the data. It is an extremely useful graph for investigating filtered data of a specific Alert, Outlier, Report, and Threat. See [Using the Sankey chart](#)
- Activity chart: a line chart that displays the volume of activity and outliers, located above the Results table. Access from the Add Chart drop-down.
- Data in-sight: 3D visualization of data activity, see [Using Data In-Sight](#).

Controls and options on this page:

- A categorized facet list of Where, Who, What, Exception, and When, from the search results, appears on the left side of every dashboard and cannot be removed. Filter the entire dashboard by the specific facets, by expanding the list and clicking individual facets.
- The Active Filters row at the top of the window shows the current filters. Delete filters by clicking the .
- Big Data Intelligence only: Select Guardium System or GBDI - Guardium Big Data Intelligence.
- Search field: free text search that filters the results in all fields simultaneously, irrespective of facet and no case-sensitivity. Exceptions:
  - Anomaly score does not support < or >
  - Searching in a specific field is case-sensitive. For example, when searching "Source Program=nnnnn" nnnn must match a value in the facets.
  - Escaping backslash (\) characters: To correctly escape a backslash character for use in a query condition, use two backslash characters. For example, to specify domain\user you need to enter domain\\user.
  - The summary tabs do not support free search.
-  Distributed search: see [Local and distributed search](#)
- Time period for which data is presented: modify by clicking the drop-down in the upper right corner. Options are last 1 hour, last 3 hours, last 1 day, last 3 days, any time period you specify. Default is one hour. If you select GBDI - Guardium Big Data Intelligence, the time period options are last 1 day, last 3 days, last 1 week, last 3 weeks, any time period you specify. The time period includes a time zone setting, by default the current Guardium system's time zone. Data is reported according to this time zone.
- Filters drop-down: see [Filtering data and saving filters in the investigation dashboard](#)
-  : see [Creating, saving, and exporting investigation dashboards](#)

## Filtering data and saving filters in the investigation dashboard

### About this task

You can filter data in the entire investigation dashboard, and in an individual chart. You can drill down from the Results Table into related information.

You can save filters for your future use. When you save a filter set, you choose if you want to share it, and choose the roles that you share it with.

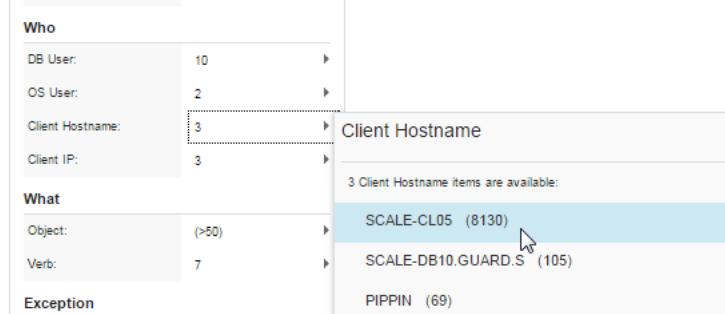

### Procedure

1. Use the rules and syntax to filter data. All of these are relevant for both the Details and Summary tab, except where noted.
  - To match an exact phrase, use double quotation marks around the search terms. For example, "**Profiling Alert List**" returns entries for Connection Profiling Alert List but not for Profiling List Alert.
  - To match all specified search terms, separate the terms with a space. For example, **Hadoop getlisting** returns any entries that contain both Hadoop and getlisting in any location or sequence.
  - To match any specified search terms, separate the terms with OR or a vertical bar (|). For example, **Hadoop OR getlisting** returns any entries that contain either Hadoop or getlisting in any location.
  - To exclude a specified search term, use NOT or a period (.). For example, **NOT Hadoop** does not return any entries that contain Hadoop in any location.
  - Wildcards are supported by using asterisks (\*) at the beginning or ending of a string. For example, **10.10.70.\*** returns any entries with the string 10.10.70. followed by any additional characters.
  - Search rules can be used in combination. For example, **2016-5-08 (19.\*|20.\*)** returns results in the time range of May 8 between the hours of 19:00:00 – 20:59:59.
  - To match an exact phrase in a specific column, enter "**field name=value**", for example "**DB USER=user123**". This search syntax is the only case-sensitive syntax. In the Details tab, you can also use this search for columns with numeric values with search values of < >. For example, "**Total Instances>1**". This is particularly useful when there results on multiple pages and you cannot see the full list of possible values.

Adding filters changes each view based on the *RefFilter* specified for the view. Current filters appear in the menu bar. Each one can be cleared by clicking its X.

2. Refine search results with any of the following methods:

- Select specific filters based on the facets list:

- Click the x or y-axis headers of a chart.
- Click an individual search result in the Results Table:

| Source Program     | DB User  | OS User | Client Hostname |
|--------------------|----------|---------|-----------------|
| DB2JCC_APPLICATION | DB2INST1 |         | PIPPIN          |
| DB2JCC_APPLICATION | DB2INST1 |         | PIPPIN          |
| DB2JCC_APPLICATION | DB2INST1 |         | PIPPIN          |

Note: You can select one or more rows and right-click one of the server/DB user/Client IP cells to add them to an existing group, or to create a new group.

3. Drill down by individual results by right-clicking on specific search results and exploring related outliers, errors, or violations, or viewing one of several available drill-down reports.

| Source Program     | DB User  | OS User | Client H |
|--------------------|----------|---------|----------|
| DB2JCC_APPLICATION | DB2INST1 | PIPPIN  |          |
| DB2JCC_APPLICATION | DB2INST1 |         |          |
| DB2JCC_APPLICATION | DB2INST1 |         |          |
| DB2JCC_APPLICATION | DB2INST1 |         |          |

4. To save a filter set, click **Filters > Save**. Provide a name for the filter and mark it as Private or click Share with to share the filter with specific roles. To save as your default filter set (dashboard always opens with these filters), select Set as default filter. When you are finished, click OK to save the filter.

## Monitor and audit

After you identify your sensitive data and take steps to protect it, you must monitor activities that access this data. In many cases you can use the data that is generated by monitoring to comply with audit requirements, either regulatory or internal.

- **[Enabling and disabling the Investigation Dashboard](#)**

This topic describes how to enable and disable the Investigation Dashboard.

- **[Basic data security monitoring policy](#)**

Use the basic data security monitoring policy to get started with Guardium SQL traffic monitoring.

- **[Smart assistant for compliance monitoring](#)**

The compliance monitoring smart assistant helps you quickly configure monitoring for GDPR, PCI, SOX, and other security standards and regulations.

- **[Investigation Dashboard](#)**

The Investigation Dashboard provides powerful tools for identifying and assessing problems that might exist in your Guardium® environment. It uses either local or system-wide unfiltered data, and provides numerous filter options to query data across an entire Guardium environment, potentially from any Guardium collector within that environment.

- **[Threat Detection Analytics](#)**

Guardium includes specialized threat detection analytics that scan and analyze audited data to detect symptoms that may indicate different types of database attacks.

- **[Data Protection Dashboard](#)**

The Guardium data protection dashboard provides a summary view of risk and compliance data intended for senior-level security officers.

- **[Building audit processes](#)**

Use the Audit Process Builder to streamline your compliance workflow process by consolidating, in one spot, database activity monitoring tasks such as: asset discovery; vulnerability assessment and hardening; database activity monitoring and audit reporting; report distribution; sign off by key stakeholders; and escalations.

- **[Audit and Report](#)**

Guardium organizes the data it collects into a set of domains. Each domain contains a different type of information relating to a specific area of concern: data access, exceptions, policy violations, and so forth.

- **[External data correlation](#)**

This topic describes creating and managing custom tables and custom domains, for importing enterprise information to use with existing Guardium internal data.

- **[Privacy sets](#)**

A privacy set is a collection of elements that can be used to do special monitoring.

- **[Custom Alerting](#)**

Alert messages can be distributed via e-mail, SNMP, syslog, or user-written Java™ classes. The last option is referred to as custom alerting.

- **[Flat Log Process](#)**

The Flat Log option is a process to allow the Guardium appliance to log information without immediately parsing it in real time.

- **[Running database entitlement reports](#)**

Database entitlement reports provide up-to-date snapshots of database users and their required access privileges. Learn how to prepare and run these reports to validate and ensure that users have only the privileges that are needed to perform their duties.

- **[User Identification](#)**

Guardium provides several methods to identify application users, when the actual database user is not apparent from the database traffic.

- **[Value Change Auditing](#)**

The Value Change Auditing feature tracks changes to values in database tables.

- **[Creating an Audit Database](#)**

Create an audit database and perform value-change monitoring activities.

- **[Monitored Table Access](#)**

This feature adds a "Last Assessed" field to relevant tables, for interaction with Optim Designer data lifecycle products.

- **[Installing and activating the FamMonitor on Windows servers](#)**

The FamMonitor enables monitoring and collection of audit information and policy rules, and real time alerts or blocking of suspicious users or connections on your Windows servers. You can install it by command line, the wizard, or GIM.

- **[File Activity Monitor for NAS and SharePoint](#)**

The Guardium File Activity Monitor (FAM) monitors activity across files and directories residing on NAS devices and SharePoint servers in the Windows environment.

- **[How to use PCI/DSS Accelerator to implement PCI compliance](#)**

Configure IBM® Guardium's PCI/DSS Accelerator and create a series of policies and reports, in order to meet PCI/DSS requirements.

- [Workflow Builder](#)

Use the Workflow Builder to define customized workflows (steps, transitions, and actions) that you can use with audit processes.

## Enabling and disabling the Investigation Dashboard

This topic describes how to enable and disable the Investigation Dashboard.

### Before you begin

The Investigation Dashboard has following minimum hardware requirements:

- 64-bit architecture
- 24 GB RAM
- 4-core CPU
- Investigation Dashboard functionality opens ports 8983 and 9983 on both central managers and collectors. The ports are opened when the Investigation Dashboard is enabled and closed when it is disabled. To use the Investigation Dashboard, ensure that bidirectional communication between Central managers and collectors on ports 8983 and 9983 is not blocked by any firewall.
- Central managers and managed units must be able to reach each other via host name and IP address: ensure that DNS is configured to resolve IP addresses and host names in both forward and reverse lookup. If DNS cannot be used, use the **support store hosts** command to manually add IP-host name combinations. For more information, see [support store hosts](#).

Restriction: The Investigation Dashboard and Data Level Security cannot be enabled concurrently.

### Procedure

1. Log in to the Guardium® system as a user or administrator with the CLI role.
2. Enable the Investigation Dashboard with the GuardAPI command:

```
grdapi enable_quick_search schedule_interval=2 schedule_units=MINUTE
```

To enable the Investigation Dashboard on all managed units of an environment, use the all=true parameter:

```
grdapi enable_quick_search schedule_interval=2 schedule_units=MINUTE all=true
```

Note: This GuardAPI executes many configuration scripts and, depending on the current unit status, can take a few minutes. By default, violations are not included in search results. To include violations, set the includeViolations parameter to **true**:

```
grdapi enable_quick_search schedule_interval=2 schedule_units=MINUTE includeViolations=true
```

To enable outlier detection, see [Outliers detection](#).

Additional parameters may be specified, such as the search index update interval. For more information, see [Investigation Dashboard APIs](#).

3. Use the following GuardAPI command to disable the Investigation Dashboard function at any time:

```
grdapi disable_quick_search
```

### Results

After you have enabled the Investigation Dashboard, see [Accessing the investigation dashboard](#) to learn more and begin using the investigation dashboard.

Attention: Indexed search data is retained for 3 days. Use the purge object Guardium CLI command to change the retention period. For example, the following command changes the retention period to 5 days: **store purge object age 36 5**. Note that 36 is the default object identification number associated with the search index. For additional information, see [Configuration and Control CLI Commands](#) reference information.

## Basic data security monitoring policy

Use the basic data security monitoring policy to get started with Guardium SQL traffic monitoring.

Guardium ships with a pre-defined policy installed by default: Default - Ignore Data Activity for Unknown Connections [template]. This default captures session-level information such as client and server IP addresses, database type, operating system user, source program, and database session start and end times, but it does not capture actual SQL activity.

Compared to the default policy, the basic data security monitoring policy allows you to starting monitoring SQL traffic right out of box. Using predefined groups of privileged users, privileged commands, and error codes for some of the most common use cases, the basic monitoring policy provides rules that address common data

access and attack patterns. Although it is not a comprehensive auditing policy, the basic monitoring policy offers a secure foundation while you develop database activity monitoring policies specific to your environment and needs.

#### 1. Prerequisites for the basic data security monitoring policy

Take simple steps to verify that you are ready to begin using the basic data security monitoring policy.

#### 2. Install the basic data security monitoring policy

#### 3. Create reports for basic data security monitoring

Create reports for monitoring administrative user activity and command execution.

#### 4. Next steps for data security monitoring

After installing the basic data security monitoring policy and creating reports, begin tuning the policies and using advanced analytics.

---

## Prerequisites for the basic data security monitoring policy

Take simple steps to verify that you are ready to begin using the basic data security monitoring policy.

## Procedure

---

### 1. Install S-TAP monitoring agents on your database servers and confirm that the S-TAP inspection engines are correctly configured.

For information about installing S-TAPs using the Guardium Installation Manager (GIM), see [Deploy monitoring agents](#). View or modify inspection engines on collectors by navigating to [Manage > Activity Monitoring > S-TAP Control](#).

### 2. Verify that S-TAPs are not configured to ignore database responses.

The db\_ignore\_response configuration parameter in the S-TAP configuration file guard\_tap.ini should be set to none (the default value). If you are managing the S-TAP using GIM, the equivalent GIM parameter is STAP\_DB\_IGNORE\_RESPONSE for Linux and UNIX systems or WINSTAP\_DB\_IGNORE\_RESPONSE for Windows systems.

### 3. Verify that the Log Records Affected setting is enabled for the inspection engines.

On each collector in a standalone environment (no central manager), navigate to [Manage > Activity Monitoring > Inspection Engines](#), select the Log Records Affected check box, and click Apply. Alternatively, log in to the each collector via SSH as the cli user and run the following command: `grdapapi update_engine_config logRecords=true`

In a managed environment, log in to the central manager via SSH as the cli user and run the following command once for each managed collector host name: `grdapapi update_engine_config logRecords=true api_target_host=<managed collector host name>"`

### 4. Upload the latest Guardium Database Protection Subscription Service (DPS) update to each collector in a standalone environment or to the central manager in a managed environment.

The latest DPS update is available on IBM Fix Central.

- Navigate to [Harden > Vulnerability Assessment > Customer Uploads](#).
- In the DPS Upload section, click Browse and choose the latest DPS update file, then click Upload.
- In the Import DPS section, click on the  icon to import the DPS update.

The import may take a while to finish. You can monitor the status of the import by connecting to the Guardium system via SSH as the cli user and running the following command: `show dps`

---

## What to do next

You are ready to install the basic data security monitoring policy.

Next topic: [Install the basic data security monitoring policy](#).

---

## Install the basic data security monitoring policy

## Before you begin

---

In a standalone environment (no central manager), follow this procedure on each collector. In a managed environment, follow this procedure on the central manager. For a rule-by-rule description of the basic data security monitoring policy, see [Understand the basic data security monitoring policy rules](#).

## Procedure

---

### 1. Navigate to [Protect > Security Policies > Policy Builder for Data](#).

### 2. Select the Basic Data Security Policy [template] and click [Install > Install](#).

### 3. Policy templates are cloned before installation: use the Clone policy template dialog to provide a unique name for the cloned policy and click OK.

### 4. After successful installation, click OK on the confirmation dialog.

### 5. Take the following actions on the Install policy dialog:

- Use the Installation action menu and select Install and override.  
Attention: The Install and override action replaces any currently-installed policies. Select a different installation action if you need to preserve installed policies.
- Accept the default setting to install and override All policies.
- Optional: If working from a central manager, select the managed units where the policy will be installed.
- Click OK.

---

## What to do next

Create reports based on SQL traffic collected by the basic monitoring policy.

## Understand the basic data security monitoring policy rules

Review a rule-by-rule description of the basic data security monitoring policy.

To see the rules included with the basic data security monitoring policy:

1. Go to Protect > Security Policies > Policy Builder for Data.
2. Select the Basic Data Security Policy [template] and click .
3. In the View Policy dialog, click the Rules section. The policy rules and criteria are listed in the table.

### Rule 1: XSS

This rule uses regular expression to detect well-known XSS (cross-site scripting) attack patterns in the SQL. Such code, if stored in the database, can be used to attack the WEB-UI. The rule action generates a high severity policy violation.

### Rule 2: SQL injection - tautology

This rule uses regular expression to detect a common pattern of SQL injection attack. Expressions such as `1=1` can be used by an attacker to add arbitrary SQL code at the end of improperly formed statements. The rule action generates a high severity policy violation.

### Rule 3: SQL injection - denial of service (DoS)

This rule uses regular expression to detect a common pattern of SQL injection attack. Commands such as `benchmark` can be used by an attacker to overload the database. The rule action generates a high severity policy violation.

### Rule 4: SQL injection - side channel

This rule uses regular expression to detect a common pattern of SQL injection attack. The `sleep` command, when embedded in SQL, can create performance and timeout issues and fail applications. The rule action generates a high severity policy violation.

### Rule 5: OS command injection

This rule uses regular expression to detect OS commands and executable code in SQL. Such code, if stored in the database, can be used to attack back-end or front-end systems. The action generates a high severity policy violation.

Rules 1-5 should be tuned to meet the specific needs of a specific environment to reduce false positives. Occurrences of each of these patterns might be an indication of an attack but they can also be legitimate actions on some environments. For example, rule 1 may generate false positives if it is applied to an application where logic intentionally uses many HTML tags in SQL statements. The rule conditions can be tuned to limit the rule to applications where many HTML tags in SQL statements are not expected, therefore SQL statements with HTML tags might indicate an XSS attack. Likewise, `1=1` and similar logic expressions (even `1=0`) are widely used in legitimate software. When these rules fire on legitimate operations they can be tuned by adding more criteria in the rules themselves, or in the policy, to distinguish between legitimate and illegitimate operations.

Note: The violations generated by rules 1 - 5 are also used by *Active Threat Analytics* if the feature is enabled.

### Rule 6: Monitor all database activity for admin users

This rule relies on the pre-defined Guardium group *Admin Users* to identify and comprehensively log all activities that are performed by those users. The rule uses the `LOG FULL DETAILS` action, and the group is per-populated with the default admin and certain non-admin users for most supported database types. The group does not contain any custom users with admin privileges that typically exist in production environments. To view admin users activity logged in Guardium, go to Reports > My Custom Reports > Admin Users Activity.

For more information, see [Create an Admin Users Activity report](#).

### Rule 7: Monitor all administrative commands

This rule relies on the pre-defined Guardium group *Administrative Commands* to identify and comprehensively log all activities that contain administrative commands that are listed in the group. The rule uses the `LOG FULL DETAILS` action, and the group is per-populated with the default administrative commands for most supported database types. To view administrative commands logged in Guardium, go to Reports > My Custom Reports > Administrative Commands Execution. For more information, see [Create an Administration Commands Execution report](#).

### Rule 8: Log a policy violation for repeated failed login attempts

This rule logs a policy violation if five or more failed login attempts are made within a 1-minute time interval. The rule uses the `LOG ONLY` action. Attempts by a malicious user to repeatedly guess the database password by trial and error might be captured by this rule. To view policy violations logged in Guardium, go to Comply > Reports > Incident Management to view the *Policy Violations / Incident Management* report. The Access Rule Description field indicates which policy rule triggered the violation.

### Rule 9: Log a policy violation if risk-indicative errors are generated

This rule relies on the predefined Guardium group *Risk-indicative error messages*. This group contains errors typically associated with malicious or unauthorized activities. The rule logs a policy violation when an error in that group occurs. The rule uses the `LOG ONLY` action. To view policy violations logged in Guardium, go to Comply > Reports > Incident Management to view the *Policy Violations / Incident Management* report. The Access Rule Description field indicates which policy rule triggered the violation.

### Rule 10: Log a policy violation on potential data exfiltration attempts

This rule inspects the number of rows that are returned by the database in response to queries per database session to identify potential *data exfiltration* attempts. Data exfiltration refers to attempts to move large amounts of data. If the total number of rows that are returned by database for a session reaches or exceeds 1000 within a 1-minute time interval, a policy violation is logged with the `LOG ONLY` action. To view policy violations logged in Guardium, go to Comply > Reports > Incident Management to view the *Policy Violations / Incident Management* report. The Access Rule Description field indicates which policy rule triggered the violation.

### Rule 11: Ignore heavy traffic load sessions (typically batch jobs)

This rule is designed to filter out traffic from potentially heavy batch jobs to avoid overwhelming the Guardium collector. This rule counts the number of SQL statements that are executed within a session. If the number reaches or exceeds 500 within a 1-minute time interval, the remainder of the session is ignored by using the `IGNORE S-TAP SESSION` action. The first 500 SQL statements for that session are logged for audit purposes.

## Create reports for basic data security monitoring

Create reports for monitoring administrative user activity and command execution.

## Procedure

---

1. On each collector in a standalone environment or on the central manager in a managed environment, navigate to [Investigate > Query-Report Builder](#).
2. [Create an Admin Users Activity report](#).
3. [Create an Administration Commands Execution report](#).

Previous topic: [Install the basic data security monitoring policy](#)  
Next topic: [Next steps for data security monitoring](#)

---

## Create an Admin Users Activity report

### Procedure

---

1. In the Queries-Reports pane, use the menu to select the Access domain.
2. Click  to open the New Query builder.
3. In the Query Name section, in the Query Name field, type `Admin Users Activity`.
4. Use the Select main entity menu to select FULL SQL.
5. Click Next.
6. In the Selected Columns section, select the following *Entity: Attribute* pairs then click  to add them to the report.
  - Client/Server: Analyzed Client IP
  - Client/Server: DB User Name
  - Client/Server: Server IP
  - Client/Server: Source Program
  - Client/Server: Service Name
  - FULL SQL: Full Sql
  - FULL SQL: Timestamp
7. Click Next.
8. In the Sort Order section, accept the default Sort results by column setting and click Next.
9. In the Conditions section, click  to add the following condition: Client/Server: DB User Name with the operator IN GROUP and group Admin Users.
10. Click Save.
11. Click Add to My Custom Reports to add the report to the [Reports > My Custom Reports](#) navigation item.

## Create an Administration Commands Execution report

### Procedure

---

1. In the Queries-Reports pane, use the menu to select the Access domain.
2. Click  to open the New Query builder.
3. In the Query Name section, in the Query Name field, type `Administration Commands Execution`.
4. Use the Select main entity menu to select FULL SQL.
5. Click Next.
6. In the Selected Columns section, select the following *Entity: Attribute* pairs then click  to add them to the report.
  - Client/Server: Analyzed Client IP
  - Client/Server: DB User Name
  - Client/Server: Server IP
  - Client/Server: Source Program
  - Client/Server: Service Name
  - FULL SQL: Full Sql
  - FULL SQL: Timestamp
7. Click Next.
8. In the Sort Order section, accept the default Sort results by column setting and click Next.
9. In the Conditions section, click  to add the following condition: Command: SQL Verb with the operator IN GROUP and group Administrative Commands.
10. Click Save.
11. Click Add to My Custom Reports to add the report to the [Reports > My Custom Reports](#) navigation item.

## Next steps for data security monitoring

After installing the basic data security monitoring policy and creating reports, begin tuning the policies and using advanced analytics.

### Procedure

---

1. Using the `Admin Users Activity` and `Administrative Commands Execution` reports, examine the traffic to identify and ignore trusted sessions. For more information, see the following videos:
  - [Guardium Policies: Part 1: Logging behavior and introduction to constructs](#)
  - [Guardium Policies: Part 2: Using policies to change logging behavior - Log full details](#)
  - [Guardium Policies: Part 3: Using policies to change logging behavior - Ignore Sessions](#)

- [Guardium Policies: Part 4: Using policies to change logging behavior - Alerting rules](#)
2. Run advanced analytics on the data logged by the *basic data security monitoring policy*.  
To learn more about enabling and using advanced analytics, see the following information:
  - [Active Threat Analytics](#)
  - [Outliers detection](#)
  - [Risk Spotter](#)
3. Continuously monitor and tune policies to keep up with the changes in the database and application landscape.  
The *basic data security monitoring policy* provides a starting point for monitoring and analyzing traffic, but your organization needs to maintain and tune policies according to the observed traffic and organizational requirements.

Previous topic: [Create reports for basic data security monitoring](#)

---

## Smart assistant for compliance monitoring

The compliance monitoring smart assistant helps you quickly configure monitoring for GDPR, PCI, SOX, and other security standards and regulations.

To get started, navigate to [Setup > Smart Assistant > Compliance Monitoring](#) and click the Set up compliance monitoring tile to begin. For more information about using the smart assistant, see [Set up compliance monitoring or application data monitoring](#).

Templates are provided to support the following standards and regulations:

- Basel Committee on Banking Supervision (BASEL II)
- California Consumer Privacy Act (CCPA)
- General Data Protection Regulation (GDPR)
- General Data Protection Regulation for Db2 for z/OS (GDPR for Db2 for z/OS)
- Health Insurance Portability and Accountability Act (HIPAA)
- Payment Card Industry Security Standard (PCI)
- Personally Identifiable Information (PII)
- Sarbanes-Oxley Compliance (SOX)
- **Databases**  
Use the database tab of the compliance monitoring smart assistant to identify databases for monitoring and manage database credentials needed for discovering sensitive data.
- **Applications**  
The applications tab of the compliance monitoring smart assistant provides a tree-based view of all applications and their assigned databases.
- **Compliance summary**  
The compliance summary provides an at-a-glance view of compliance monitoring configuration and immediate access to related policies, groups, and reports.
- **Application summary**  
The application summary provides an immediate view of database monitoring, group population, and policies associated with an application, including key security metrics for the associated databases.
- **Set up compliance monitoring or application data monitoring**  
The compliance and application data monitoring wizard is provided to automate many of the actions involved with policy configuration and deployment.

- 

## Databases

Use the database tab of the compliance monitoring smart assistant to identify databases for monitoring and manage database credentials needed for discovering sensitive data.

Identifying databases in your environment that require data protection is an important part of configuring compliance monitoring. The databases tab of the compliance monitoring smart assistant displays an inventory of known databases and a summary of their configuration status. Use this inventory to track compliance monitoring configuration status, add databases for monitoring, and manage the database credentials used for discovering sensitive data.

The database inventory supports the following database types:

- Db2
- Db2 z/OS
- Informix
- MongoDB
- MS SQL Server
- MS SQL SERVER (DataDirect)
- MS SQL SERVER (DataDirect - Dynamic Port)
- MySQL
- Netezza
- Oracle
- Oracle (DataDirect - Service Name)

- Oracle (DataDirect - SID)
- PostgreSQL
- SAP HANA
- Sybase
- Sybase IQ
- Teradata

Note: The inventory of known databases is established by any of the following:

- Observed traffic on collectors
- Existing datasources on a central manager
- Databases added using the compliance monitoring or database inventory tools, for example Import from CSV and Reconcile assets.

Known databases are refreshed hourly and the data is retained for 30 days by default.

It is possible to have more datasources defined than databases in the inventory. This happens when the same database is used in multiple datasource definitions or when a database that is not supported by the inventory is used in a datasource definition.

Get started by adding databases to the inventory. From the Databases tab, click the  icon to add an individual database or click the Import from CSV button to import multiple databases.

- [Add an individual database](#)  
Add an individual database to the inventory by manually providing information such as database type, host name, and service name.
- [Import multiple databases](#)  
Import multiple databases to the inventory from a spreadsheet containing information such as database type, host name, and service name.
- [Reconciling database inventory](#)  
Asset reconciliation compares a user-provided list of databases with the databases that are known to Guardium. This feature offers a quick way to identify old or unknown databases and to verify that Guardium provides the coverage that you want.

## Add an individual database

Add an individual database to the inventory by manually providing information such as database type, host name, and service name.

### Procedure

1. Click the  icon to open the Add database dialog.
2. Use the Database type menu to select the type of database to add.
3. The fields for defining a database vary depending on the database type. Complete all required fields.
4. Click OK to add the database.

### Results

An individual database is imported to the compliance monitoring database inventory. If you specified database credentials, the credentials are saved and a datasource is created for discovering sensitive data, running vulnerability assessments, and use with other Guardium processes. Configure advanced datasource features such as connection properties using the Setup > Tools and Views > Datasource definitions tool.

## Import multiple databases

Import multiple databases to the inventory from a spreadsheet containing information such as database type, host name, and service name.

### Before you begin

Importing databases is a quick and convenient way to populate the compliance monitoring smart assistant with databases for monitoring. Before you begin, prepare a comma-separated values (CSV) file with the database information to import. The file needs to meet the following requirements:

- The first row defines column names.
- Each row is complete, meaning that empty fields are accounted for with a delimiter (for example, a comma).
- Database type is defined using any of the following case-insensitive strings:
  - Db2
  - Db2 z/OS
  - Informix
  - MongoDB
  - MS SQL Server
  - MS SQL SERVER (DataDirect)
  - MS SQL SERVER (DataDirect - Dynamic Port)
  - MySQL
  - Netezza
  - Oracle
  - Oracle (DataDirect - Service Name)
  - Oracle (DataDirect - SID)
  - PostgreSQL
  - SAP HANA
  - Sybase
  - Sybase IQ

- Teradata
- MS SQL Server can be used for both MS SQL SERVER (DataDirect) and MS SQL SERVER (DataDirect - Dynamic Port) databases. Oracle can be used for both Oracle (DataDirect - SID) and Oracle (DataDirect - Service Name) databases.
- All database types require values for the Host name/IP address and Port number fields. In addition, specific databases require additional fields:
    - Db2, Db2 z/OS, Netezza, and PostgreSQL require Database name.
    - Informix requires Informix server.
    - MS SQL SERVER (DataDirect - Dynamic Port) requires Instance name. Note: port number is not required for MS SQL SERVER (DataDirect - Dynamic Port).
    - Oracle (DataDirect - Service Name) and Oracle (DataDirect - SID) require Service name.

Attention: Microsoft Excel format (XLS) is not supported. When exporting CSV from Excel, verify that the CSV file is created with complete rows and is not missing delimiters for empty fields.

## Procedure

---

1. Click the Import from CSV button to open the Import from CSV dialog.
2. Click the Browse button and select a CSV file to upload.
3. Use the Field delimiter field to define the delimiter used in the CSV file.  
In most instances, the default value (a comma) is appropriate.
4. Click the Load button to continue.
5. Use the drop-down menus to map columns from the CSV file to specific database information.  
For example, to import host information, use the Host name/IP menu to select the column name containing the host names or IP address of your databases.  
Note: Columns containing Instance name, Server name, and Service name information are automatically assigned based on the associated database type. For example, in a CSV file containing Db2 instance names and Oracle service names in a single column, mapping that column to either Instance name or Service name fields assigns the value to the correct field for the database type.
6. Click OK to import database information from the CSV file.  
If needed, a warning message displays any rows that are skipped due to incomplete or invalid data.

## Results

---

Multiple databases are imported to the compliance monitoring database inventory. If you imported database credentials, the credentials are saved and datasources are created for discovering sensitive data, running vulnerability assessments, and use with other Guardium processes. Configure advanced datasource features such as connection properties using the Setup > Tools and Views > Datasource definitions tool.

## Reconciling database inventory

---

Asset reconciliation compares a user-provided list of databases with the databases that are known to Guardium. This feature offers a quick way to identify old or unknown databases and to verify that Guardium provides the coverage that you want.

### Before you begin

---

Asset reconciliation supports the following databases:

- Db2
- Db2 z/OS
- Informix
- MongoDB
- MS SQL Server
- MS SQL SERVER (DataDirect)
- MS SQL SERVER (DataDirect - Dynamic Port)
- MySQL
- Netezza
- Oracle
- Oracle (DataDirect - Service Name)
- Oracle (DataDirect - SID)
- PostgreSQL
- SAP HANA
- Sybase
- Sybase IQ
- Teradata

Unsupported databases cannot be reconciled and are ignored with an error message.

Attention: Microsoft Excel format (XLS) is not supported. When exporting CSV from Excel, verify that the CSV file is created with complete rows and is not missing delimiters for empty fields.

## About this task

---

Reconciling database inventory (asset reconciliation) compares databases that are known to Guardium with an external, user-provided list of databases. Asset reconciliation accepts CSV or CMDB inputs and categorizes databases as existing only in Guardium, only in the external list, or as existing in both Guardium and the external list. For databases that are known to Guardium, the reconciliation process shows information about where the database is used, for example, in a datasource definition or with compliance monitoring. Asset reconciliation also supports an allowlist of databases that are not known to Guardium that can be ignored in the future.

## Procedure

---

1. Browse to Setup > Smart Assistant > Compliance Monitoring.
2. Select the Databases tab and click Reconcile assets to open the Reconcile database inventory dialog.
3. Select the list of databases to compare with databases that are known to Guardium.
  - To use a CSV file, select Compare to CSV file.
    - a. Click Browse and select a CSV file that contains the list of databases to compare.
    - b. Click Load to begin working with the CSV file.
    - c. Use the drop-down menus to map columns from the CSV file to specific database information.  
For example, to map host information, use the Host name/IP menu to select the column name that contains the hostnames or IP address of your databases.

Note:

    - Database type is a required field and must match one of the supported databases. For example, the strings Db2 LUW or Db2 v11 do not match the expected value, Db2.
    - Columns containing Instance name, Server name, and Service name information are automatically assigned based on the associated database type.  
For example, in a CSV file that contains Db2 instance names and Oracle service names in a single column, mapping that column to either Instance name or Service name fields assigns the value to the correct field for the database type.
  - d. Click OK.
  - To use CMDB, select Compare to CMDB.
    - a. Select an existing CMDB URL or click to add a new one.  
To add a new URL, define the Type (for example, Service Now), URL from the CMDB provider, and account credentials.
    - b. Select a Table to reconcile.
    - c. Click Load to begin working with the CMDB records.
    - d. Use the drop-down menus to map fields from the CMDB records to specific database information.  
For example, to map host information, use the Host name/IP menu to select the column name that contains the hostnames or IP address of your databases.

Note: Columns that contain Instance name, Server name, and Service name information are automatically assigned based on the associated database type.  
For example, in the CMDB table that contains Db2 instance names and Oracle service names in a single column, mapping that column to either Instance name or Service name fields assigns the value to the correct field for the database type.
  - e. Click Run Now or Schedule.
4. Begin working with the Asset reconciliation results dialog.

#### Databases not in Guardium

This table shows databases that are listed in the input (either CSV or CMDB) that are not known to Guardium.

- Select databases and click Add to allowlist to prevent them from appearing in this table during future reconciliations. You are asked to provide a brief justification for adding the databases to the allowlist.
- Select databases and click Add to Guardium inventory to add them to Guardium's list of known databases. After the databases are added to the inventory, they are available for use with compliance monitoring and other features.

#### Databases only in Guardium

This table shows databases that are known to Guardium but not listed in the input. In addition, the table indicates whether Guardium has observed traffic on the databases and how the databases are used in Guardium (for example in datasource definitions or compliance monitoring).

- Select databases and click to remove them from the Guardium list of known databases.

#### Matched databases

This table shows databases that are listed in the input and that are also known to Guardium. In addition, the table indicates whether Guardium has observed traffic on the databases and how the databases are used in Guardium (for example, in datasource definitions or compliance monitoring).

#### Rows rejected

This table lists rows from the input that identify an unsupported database type or do not contain enough information to uniquely identify a database. Each entry contains a brief description of the problem with the input.

#### Allowlist databases

This table lists databases in the input that can be ignored during the reconciliation process.

## Related information

## Applications

The applications tab of the compliance monitoring smart assistant provides a tree-based view of all applications and their assigned databases.

Use the applications tab to create, update, and delete applications. It is also possible to import a list of applications from CSV.

- [Add an individual application](#)  
Add an individual application for compliance monitoring and assign databases to the application.
- [Import multiple applications](#)  
Import multiple applications and industries from a spreadsheet.

## Add an individual application

Add an individual application for compliance monitoring and assign databases to the application.

## Procedure

1. Navigate to Setup > Smart Assistant > Compliance Monitoring and select the Applications tab.
2. Click the icon to open the New application dialog.
3. Optional: Use the Industry menu to select a predefined industry. Otherwise, type to define a new industry name.  
Selecting a predefined industry filters the Application menu.

Use the Industry field to define a meaningful hierarchy of applications in your environment. For example, create industries to group applications by geographical region such as Customer Relationship Management (North America) and Customer Relationship Management (Europe) or to separate Production and Test applications.

4. Use the Application menu to select an existing application. Otherwise, type to define a new application name.
5. Use the check boxes to select databases and the  and  icons to assign databases to the application.  
Databases added to the table using the  icon are assigned to the application.
6. Click Save to add the application and its assigned databases to the table.

## Results

---

An application is added to the table. If specified, the industry name is displayed in parentheses after the application name. View the databases assigned to an application by clicking the  icon next to the application name.

## What to do next

---

Edit existing applications using the  icon. Remove applications using the  icon.

Applications that have not been configured for compliance monitoring display an  icon in the Unconfigured column. To set up compliance monitoring for an application, use the Application summary tab and click the  icon for Set up application data monitoring.

---

## Import multiple applications

Import multiple applications and industries from a spreadsheet.

## Before you begin

---

Importing applications and industries is a quick and convenient way to populate the compliance monitoring smart assistant with applications for monitoring. Before you begin, prepare a comma-separated values (CSV) file with the information to import. The file needs to meet the following requirements:

- The first row defines column names.
- Each row is complete, meaning that empty fields are accounted for with a delimiter (for example, a comma).

Attention: Microsoft Excel format (XLS) is not supported. When exporting CSV from Excel, verify that the CSV file is created with complete rows and is not missing delimiters for empty fields.

## Procedure

---

1. Navigate to Setup > Smart Assistant > Compliance Monitoring and select the Applications tab.
2. Click the Import from CSV button to open the Import from CSV dialog.
3. Click the Browse button and select a CSV file to upload.
4. Use the Field delimiter field to define the delimiter used in the CSV file.  
In most instances, the default value (a comma) is appropriate.
5. Click the Load button to continue.
6. Use the drop-down menus for Application name and Industry name to map columns from the CSV file to application and industry names.  
Use the Industry field to define a meaningful hierarchy of applications in your environment. For example, create industries to group applications by geographical region such as Customer Relationship Management (North America) and Customer Relationship Management (Europe) or to separate Production and Test applications.
7. Click OK to import application information from the CSV file.  
If needed, a warning message displays any rows that are skipped due to incomplete or invalid data.

## Results

---

Multiple applications are imported to the table. If specified, industry names are displayed in parentheses after the application names.

## Compliance summary

---

The compliance summary provides an at-a-glance view of compliance monitoring configuration and immediate access to related policies, groups, and reports.

Open the summary by navigating to Setup > Smart Assistant > Compliance Monitoring and clicking the Compliance summary tab.

To configure a new compliance monitoring type, click the  icon on the Set up compliance monitoring tile. For more information about using the compliance monitoring wizard, see [Set up compliance monitoring or application data monitoring](#).

Several actions are available for configured compliance types:

- Click the View details link to open a panel showing associated groups, databases, policies, and reports. Tabs on the details panel provide convenient links for populating groups, opening tools like the Policy builder for data, or viewing reports.
- Click the  icon to open the compliance monitoring wizard and make changes to an existing configuration.

## Application summary

The application summary provides an immediate view of database monitoring, group population, and policies associated with an application, including key security metrics for the associated databases.

Open the summary by navigating to [Setup > Smart Assistant > Compliance Monitoring](#) and clicking the Application summary tab.

To configure a new application for data monitoring, click the  icon on the Set up application data monitoring tile. For more information about using the compliance monitoring wizard, see [Set up compliance monitoring or application data monitoring](#).

Several actions are available for configured applications:

- Click the View details link to open a panel showing associated groups, databases, policies, and reports. Tabs on the details panel provide convenient links for populating groups, opening tools like the Policy builder for data, or viewing reports.
- Click the  icon to open the compliance monitoring wizard and make changes to an existing application.

## Set up compliance monitoring or application data monitoring

The compliance and application data monitoring wizard is provided to automate many of the actions involved with policy configuration and deployment.

The wizard automates the following actions:

- A security policy is created and installed for the selected compliance type.
- A policy installation schedule is defined for 10:30 AM daily.
- A server IP group is populated with the server IP addresses of the selected databases.
- The current user is assigned to the selected compliance-type role, enabling access to the related reports and accelerators.
- Optionally create a discovery scenario for identifying and classifying sensitive data.
- Provide a summary of actions taken and next steps to finish configuring compliance monitoring.

Open the compliance and application data monitoring wizard by navigating to [Setup > Smart Assistant > Compliance monitoring](#) and selecting either the Compliance summary tab or the Application summary tab. Click the  icon to configure a new compliance type or the  icon to edit an existing configuration.

Note: Complete the compliance and application data monitoring wizard for each compliance type you want to configure. For example, to configure both GDPR and PCI, complete the wizard once for GDPR and then again for PCI.

### 1. Prerequisites for the compliance and application data monitoring smart assistant

The compliance and application data monitoring wizard has two optional prerequisites: deploying monitoring agents (S-TAPs) to database servers and gathering database credentials to allow Guardium to scan for tables containing sensitive data. Either of these steps can be completed later.

### 2. Select compliance type

Select one of the supported compliance types to configure, for example GDPR, PCI, or SOX, or configure monitoring using a custom policy.

### 3. Select databases or applications to monitor

Select known databases and applications for monitoring, or add information about new databases and applications.

### 4. Search for sensitive data

Identify database tables that contain sensitive data and add those tables to groups for monitoring.

### 5. Summary

See an overview of compliance and application data monitoring wizard actions and actions that you must take to complete the configuration. The summary is based on your progress through the wizard and configuration you may have completed elsewhere in Guardium.

## Prerequisites for the compliance and application data monitoring smart assistant

The compliance and application data monitoring wizard has two optional prerequisites: deploying monitoring agents (S-TAPs) to database servers and gathering database credentials to allow Guardium to scan for tables containing sensitive data. Either of these steps can be completed later.

## Before you begin

Open the compliance and application data monitoring wizard by navigating to [Setup > Smart Assistant > Compliance monitoring](#) and selecting either the Compliance summary tab or the Application summary tab. Click the  icon to configure a new compliance type or the  icon to edit an existing configuration.

## Procedure

### 1. From the Before you begin section, review the notes and prerequisites.

- Monitoring agents (S-TAPs) must be installed on database servers in order to monitor data. The agents do not need to be installed before completing the compliance monitoring configuration, but monitoring will not actually begin until the agents are installed.
- Use [Setup > Tools and Views > Configure Universal Connector](#) to establish monitoring with universal connectors. Universal connectors appear in Compliance Monitoring only after they have active traffic.
- Guardium needs appropriate database credentials to scan for and discover database tables containing sensitive data. If you want to configure discovery at this time, you will need to have the database credentials ready. Otherwise, credentials can be supplied later.

### 2. Click the Next button to continue.

**Next topic:** [Select compliance type](#)

## Select compliance type

Select one of the supported compliance types to configure, for example GDPR, PCI, or SOX, or configure monitoring using a custom policy.

### Procedure

- From the Select compliance type section, use the Which compliance type do you want to configure? control to select either Out of the box policies or Custom policies.  
Out of the box policies are predefined policies that support established data-security standards. For example, to configure the payment card industry standard, select Payment Card Industry Data Security Standard (PCI). Custom policies are policies you have created or modified outside the compliance and application data monitoring wizard, for example using the Policy Builder for Data.
- Click Next to continue through the wizard or click any of the enabled sections to edit its configuration.

**Previous topic:** [Prerequisites for the compliance and application data monitoring smart assistant](#)

**Next topic:** [Select databases or applications to monitor](#)

## Select databases or applications to monitor

Select known databases and applications for monitoring, or add information about new databases and applications.

### Procedure

- From the Select databases to monitor section:
  - Click the Databases tab and use the check boxes to select one or more databases for monitoring.  
If you have not previously added databases to the inventory, add individual databases by clicking the icon or import information about multiple databases by clicking the Import from CSV button. For more information, see:
    - [Add an individual database](#)
    - [Import multiple databases](#)
  - Click the Applications tab and use the check boxes to select one or more applications for monitoring.  
If you have not previously added applications, add an application by clicking the icon or import information about multiple applications by clicking the Import from CSV button. For more information, see:
    - [Add an individual application](#)
    - [Import multiple applications](#)

It is possible to select both databases and applications for monitoring.

- Click Next to continue through the wizard or click any of the enabled sections to edit its configuration.

**Previous topic:** [Select compliance type](#)

**Next topic:** [Search for sensitive data](#)

## Search for sensitive data

Identify database tables that contain sensitive data and add those tables to groups for monitoring.

### Procedure

- From the Search for sensitive data section, choose one option for identifying sensitive data.
  - The Scan for tables option uses the Guardium classifier to discover tables containing sensitive objects in your databases. The classifier requires credentials with adequate database privileges to perform the scan.
    - Use check boxes to select databases. Databases that are ready for scanning show a icon in the Ready for classification column. If needed, use the Add credentials link to specify login credentials for scanning a selected database.
    - Click Test connection to verify that the supplied credentials are valid for the databases being tested. The connection test does not verify that the supplied credentials have adequate database privileges to perform the classification scan.
  - If you already know where the sensitive data is located in your databases, select Manually define table names to manually define the table names or import a CSV file containing a list of table names that contain sensitive data.
    - Click the Browse button and identify a comma separated value (CSV) file containing sensitive objects.
    - Set the Field delimiter value to the separator used in the CSV file. The default value is a comma (,).
    - The Column to import menu displays columns from the selected CSV file. Use the menu to select the column containing sensitive object.
    - Click the Load button to add the sensitive objects to the Member table. Repeat the previous steps to import multiple columns or multiple CSV files.
    - In the Member table, add items by clicking the icon or remove items by selecting items and clicking the icon.
  - The Skip for now option allows you to identify the sensitive data in your databases at a later time. However, compliance monitoring policies depend on knowing where to look for sensitive objects, and your compliance monitoring strategy will not be complete until you complete this step. Return to the Search for sensitive data section at any time to complete this configuration.

Attention: When working with custom policies, Skip for now is the only available option. Use the Discover Sensitive Data tool to search for sensitive data on systems monitored with custom policies.

- Click Next to continue through the wizard or click any of the enabled sections to edit its configuration.

**Previous topic:** [Select databases or applications to monitor](#)

**Next topic:** [Summary](#)

## Summary

See an overview of compliance and application data monitoring wizard actions and actions that you must take to complete the configuration. The summary is based on your progress through the wizard and configuration you may have completed elsewhere in Guardium.

## Procedure

1. From the Summary section, review actions listed under Clicking Run setup takes the following actions.  
In particular, note the following:
  - Install compliance monitoring policy: click the View details link to view the policy and its rules.
  - Schedule policy re-installation: click the Edit link to view and edit the policy installation schedule. Regularly reinstalling policies is important if your groups are likely to change, for example when updating users or sensitive objects.
2. Review actions listed under You must complete the following actions.  
These actions are required to ensure effective compliance monitoring of your databases. In particular, note the following:
  - Populate groups: click the View details link to review and add members to groups. To add members, click the  icon next to the group to open the Edit group dialog. For more information, see [Using the group builder](#).
  - Install monitoring agents (S-TAPs) for databases: click the Install monitoring agents link to open the Smart assistant for deploying monitoring agents and begin installing S-TAPs on your database servers. For more information, see [Deploy monitoring agents](#).  
Attention: Monitoring agents are not required to complete the compliance and application data monitoring configuration, but they are required to allow monitoring data. Guardium will automatically begin monitoring data once the agents are installed.
3. Click Run setup to take the actions described in the Summary section.

Previous topic: [Search for sensitive data](#)

## Investigation Dashboard

The Investigation Dashboard provides powerful tools for identifying and assessing problems that might exist in your Guardium® environment. It uses either local or system-wide unfiltered data, and provides numerous filter options to query data across an entire Guardium environment, potentially from any Guardium collector within that environment.

The Investigation Dashboard's inter-related charts help reveal patterns, anomalies, and relationships across your data. You don't need detailed knowledge of topology, aggregation, or load balancing schemes. The Investigation Dashboard contains the original quick search for enterprise functions, and additional tools for visualizing and analyzing data.

Note: It is recommended to view the Investigation Dashboard in full screen mode.

Restriction: The Investigation Dashboard and the Data Level Security cannot be enabled concurrently.

## Operating Modes

The Investigation Dashboard supports three operating modes:

Central Manager only

Queries are submitted on a Central Manager return enterprise-wide results from all Guardium collectors with search enabled. Queries that are submitted on managed units return local results.

Central Manager only is the default operating mode.

All machines

Enterprise-wide search queries are submitted from any machine in the Guardium environment with search enabled. This mode can result in slower search results and requires connectivity between all managed units in the environment.

Local only

This mode limits search queries to the local collector where the search is submitted: no data is retrieved from other collectors in the Guardium environment. On a CM on local only mode, there is no data displayed.

See [Investigation Dashboard APIs](#) for information about setting the search mode.

- [Enabling File Activity in the investigation dashboard](#)
- [Accessing the investigation dashboard](#)
- [Using the Sankey chart](#)

The Sankey chart is an extremely useful method of investigating filtered data, for example, of a specific alert, outlier, report, or threat. Use the Sankey chart to reveal unsuspected relationships or oddities.

- [Using Data In-Sight](#)

The Data In-Sight visualization enables the user to profoundly examine a sequence of events that are captured by the Guardium system. It provides a comprehensive picture of activity in a specific time window, and helps to detect unusual behaviors.

- [Investigation Dashboard for files](#)

The investigation dashboard is a preset group of charts and a table that help you understand what is happening in your system at any given time, and upon which you can build your own customized dashboards.

- [Filtering data and saving filters in the investigation dashboard](#)

- [Filtering an individual chart](#)

You can filter an individual chart. The  icon becomes red when specific filters are set for a chart that are different than the general dashboard filters. Hover over the icon to see which filters are used in that chart.

- [Creating, saving, and exporting investigation dashboards](#)

- [Using the topology view](#)

The topology view is visualization of the Guardium appliances in the search results.

- [Local and distributed search](#)
- [Monitoring and automatic recovery for the Investigation Dashboard](#)  
Use Monitoring and automatic recovery to identify and recover issues in the investigation dashboard.

# Enabling File Activity in the investigation dashboard

## Before you begin

---

- UNIX-Linux: S-TAP for FAM and the FAM bundle must be installed and configured.
- Windows: The FAM discovery agent and the FamMonitor must be installed and configured.
- The Investigation Dashboard must be enabled.

## About this task

---

Note: The FAM queries the server for the server IP addresses and takes the first one it finds. There is no way to select "the appropriate" IP address from a host name when the host has multiple IP addresses. Specify the IP address explicitly if you want to see that IP address in the reports.

## Procedure

---

1. On the collector, at the CLI prompt, run the GuardAPI command:

```
grdapicl enable_fam_crawler [extraction_start] [schedule_start] [activity_schedule_interval] [activity_schedule_units]
[entitlement_schedule_interval] [entitlement_schedule_units]
```

Example: The following command sends updated discovery and classification results to enterprise search for classification data every 2 minutes and for entitlement information every day.

```
grdapicl enable_fam_crawler activity_schedule_interval=2 activity_schedule_units=MINUTE entitlement_schedule_interval=1
entitlement_schedule_units=DAY
```

By default, the extraction starts when you enter the command, extracting data from the moment (time) you entered the command.

2. Repeat on each collector.

# Accessing the investigation dashboard

## Procedure

---

1. Click Investigate > Search for Data Activity or Investigate > Search for File Activity.
2. Alternatively, toggle the search to User Interface and search for investigation dashboard. Then, select either Search for Data Activity or Search for File Activity.

## Results

---

The default investigation dashboard for data or files opens. By default, the only filter that is applied to the entire dashboard is to show the last hour of data.

## Using the Sankey chart

The Sankey chart is an extremely useful method of investigating filtered data, for example, of a specific alert, outlier, report, or threat. Use the Sankey chart to reveal unsuspected relationships or oddities.

### About this task

The Sankey chart simplifies answering questions such as:

- Is a specific database getting accessed by DB users with unique IPs?
- Are all the users accessing the database with the same source programs? How many of the users exhibit unusual (exceptional) behavior?
- What is the relationship between client IP, client host name, and DB user in the specific data environment?

Advantages of the Sankey chart include:

- Presents four dimensions (and their relationships) in one view, giving a more complete and fluid view of the data that otherwise requires multiple charts.
- Provides immediate and fluent focusing and scanning by hovering over different elements (for example, DB users) and viewing all the relevant activity. The width of the related links update proportionately to the hovered link width, representing the activity flow and quantity.
- Uses line widths to intuitively reflect volumes of activity.
- Reflects, at a glance, the relationships between the selected dimensions.
- Supports the central manager level (all collectors/aggregators within one central manager).
- All fields are configurable.

### Procedure

1. In the Investigation Dashboard window, click Add Chart Data in-Sight chart. The Sankey Settings window opens.
2. Select a category, one of: Activities, Errors, Outlier details, Outlier summary, Violations. The four axis fields update accordingly.
3. Select a value for each axis field.
4. Optional: Update the MaxRows. This limits the number of objects that can be included in each axis. (Default=20.)
5. Click Save.
6. View entities by:
  - Hover over different elements (for example, DB users) to view all the relevant activity.
  - Hover over a node to get the activity flow.
  - Click a node to filter (rerender) the chart.
  - Apply filters from the facet list for deeper investigations.
7. To modify chart settings, click .

## Using Data In-Sight

The Data In-Sight visualization enables the user to profoundly examine a sequence of events that are captured by the Guardium system. It provides a comprehensive picture of activity in a specific time window, and helps to detect unusual behaviors.

### About this task

Data in-sight introduces a revolutionary paradigm that uses human visual capabilities to gain an overall view on data transactions and identify unexpected behaviors. Guardium already provides robust machine learning and data-analysis features to assist audits and detect attacks. Algorithms, data analysis, and charts are designed based on accumulated experience and knowledge. Data in-sight uses the flexibility of human vision perception to spot associations and movements in the raw data that does not fit a pattern of known attacks that would otherwise be unnoticed. The tool presents various aspects of the data in a complex visual scenario, and provides the observer with tools to directly explore large amounts of complex data.

Data in-sight converts audited data to a 3-D chronological visualization of data flow, from sources to destinations, showing data transactions unfold exactly as they occurred.

The visualization space contains two planes, each represents entities of the audit domain of a specific type. Every entry in the audit data is represented as a moving 'flash line' from an object of the upper plane (for example, client IPs) to an object of the lower plane (for example, databases). The flash line between the source and the destination leaves a trail (a dotted line) indicating the presence of interaction between the specific source and destination, which gradually fades into the background. The trails form an overview of the interaction between sources and destinations in the selected time period. The size of each source and destination is relative to their level of activity. The sources are located near their destinations, and near other similar sources. The display can be modified in various ways, giving additional information or aspects on the data. You can view data in-sight with vr headsets.

Data in-sight is an answer to this constantly changing paradigm. It adds the flexibility of human visual perception to spot associations and movements in the raw data, irrespective of known attack types, that would otherwise be unnoticed.

Data in-sight converts audited data to a 3-D chronological visualization of data sources and destinations, showing data transactions unfold exactly as they occurred. The visualization space contains two planes, each represents entities of the audit domain of a one type. Each entry in the audit data is represented as a moving 'flash line' from an object of the upper plane (client IP, OS user, DB user, or source program) to an object of the lower plane (database, object, or server). The flash line between the source and the destination leaves a trail (a dotted line) indicating the presence of interaction between the specific source and destination, which gradually fades into the background. The flash line has the same color as the destination database. The trails form an overview of the interaction between sources and destinations in the selected time period. The sources are located near their destinations, and near other similar sources. The size of the destination entity is proportional to the volume of transactions relative to the other destination entities. There are many ways of modifying the display, including: color-code the top entity (color changes as data source details change), filter from the data in-sight chart, and the investigation dashboard facets. You can also view data in-sight with vr headsets.

## Procedure

- In the Investigation Dashboard window, click Add Chart > Data In-Sight chart. The Chart Settings window opens.
- In the Chart Settings pane, modify the object types that are represented in both planes, the type of data flow between them. You can optionally color-sort the entities in the top plane by a secondary criteria, providing another level of analysis. For example, if the objects of the top plane represent client IPs and you select color-sorting for source program, you can see the usage of different source programs by a specific IP client, and the usage of a common source program by different client IPs. An object whose color changes repeatedly indicates a frequent change of source program usage in a single client IP. Click Apply.

Table 1. Data In-Sight Chart Settings

| Field                         | Description and Values                                                                                       |
|-------------------------------|--------------------------------------------------------------------------------------------------------------|
| Data flow domain              | The type of data flow displayed. One of: Activities, Errors, Violations, Outliers.                           |
| Top plane entities            | The entity that is represented in the top plane. One of: Client IP, DB User, OS User, Source Program.        |
| Bottom plane entities         | The entity that is represented in the bottom plane. One of: Database, Object, Server.                        |
| Color sort top entities by    | Extra (optional) color classification of top entities by: None, Client IP, DB User, OS User, Source Program. |
| Show top plane label          | yes, no                                                                                                      |
| Show bottom plane label       | yes, no                                                                                                      |
| Max. entities in top plane    | Maximum number of entities that are shown in the top plane.                                                  |
| Max. entities in bottom plane | Maximum number of entities that are shown in the bottom plane.                                               |
| Top entities color            | Opens color palette to select color for top plane entities. Disabled if top entities are color sorted.       |
| Background color              | Opens a color palette to select color for background.                                                        |
| Planes color                  | Opens a color palette to select color for planes (one color for both planes).                                |

- Modify the display by:
  - Click the magnifier icon to enter full screen mode for more details
  - Rotate the view by holding down the left mouse button and dragging
  - Pan by holding down the right mouse button and dragging
  - Zoom in and out with the mouse wheel
- View entities by:
  - Hover over an entity to show its details in the legend
  - Click an entity to show only its data flows (other entities fade out). Click the background to exit.
  - Double-click an entity to use it as the active filter (over the entire dashboard)

5. The information pane, which is located in the upper right corner, shows the time stamp of the current displayed actions, the number of actions shown so far, and an indication of the rate of events per second. You can modify the display by:

|  |                                                 |
|--|-------------------------------------------------|
|  | Pause/restart data flow                         |
|  | Restart data flow from beginning of time period |
|  | Increase speed of data flow                     |
|  | Decrease speed of data flow                     |
|  | View from top (bird's eye)                      |
|  | View from side (default)                        |

- Use these buttons above the Control Panel as relevant:

|  |                                                        |
|--|--------------------------------------------------------|
|  | Activates full-screen mode for the Data In-Sight chart |
|  | Opens the Chart Settings                               |
|  | Closes the Data In-Sight chart                         |
|  | Opens a pop-up help                                    |

## Investigation Dashboard for files

The investigation dashboard is a preset group of charts and a table that help you understand what is happening in your system at any given time, and upon which you can build your own customized dashboards.

There are two default FAM views, each with different charts and tables. Select the view from the dashboard menu . The default views cannot be modified.

Note: The Server IP and Client IP are always the same in the dashboard, except for the case of connecting through remote desktop on Windows. Client IP is only supported when connecting through a remote desktop session.

Note: The FAM queries the server for the server IP addresses and takes the first one it finds. There is no way to select "the appropriate" IP address from a host name when the host has multiple IP addresses. Specify explicitly the IP address you want to see in the reports.

The default dashboards contain data for the last hour presented in one or more of:

- Trimetric charts (3-axis data graphs). The default view is a color map. Additional views are bar graph, bubble graph, line graph, pie graph, step graph, and area graph.
- Results table: provides the search results and investigation features of the original quick search. The Results Table is always at the bottom of the dashboard. It can be added to any dashboard. Tabs are:
  - Activity: Summary and Details tabs showing monitored data, based on the file server policy rules. Each row in the Summary tab gives the number of instances of recorded access activities per server and OS user. The Details tab adds the Server Hostname, Server, Client Hostname, Client IP, OS user, File Full Name, Command, Date and Time. Each row in the Details tab gives full details on one activity. Data in the Activity tab is consistent with the date and time of the collector.
  - Outliers: see [Interpreting file activity outliers in the investigation dashboard](#)
  - Errors: Summary and Details tabs. Each row in the Summary tab gives the number of instances of reported errors per server and client IP, and the date. The Detailed Summary adds the error details, and the time. Each row in the Details tab gives full details on one error.
  - Violations: Summary and Details tabs. Each row in the Summary tab gives the number of instances of recorded violations per server, source program and OS user combination. The Detailed Summary adds the Client IP, severity, violation and violation details, date, and time. Each row in the Details tab gives full

- details on one violation. Data in the Violations tab is consistent with the data and time of the file server.
- Entitlement: Summary and Details tabs. For file servers, this tab presents sensitive data based on the current FAM decision plans. Each row in the Summary tab gives the number of instances of recorded access activities per server and owner. The Details tab adds the Server Hostname, full path, Type, , Size, Classification Entities (the decision plan that caused this file to be identified as sensitive), Owner, Client Hostname, Client IP, OS user, File Full Name, users and groups with write, read, execute, and delete permissions, last modification, Version (Sharepoint only), creation time, Date, and Time. Each row in the Details tab gives full details on one activity. You can use the data in this table to create policy rules and groups for file servers, see [Creating a FAM policy rule from the Investigative Dashboard Entitlements tab](#).

Additional views that you can add or open are:

- Topology view  : see [Using the topology view](#)
- Animated bubble chart: an animated visualization of data changes over the last 48 hours. The chart depicts the behavior of objects over a period of 24 hours. Each object is depicted as a circle, and its area and position (x and y axis) represent three user-selected variables. The animation represents the object's behavior over the 24 hours. Access from the Add Chart drop-down.
- Activity chart: a line chart that displays the volume of activity and outliers, located above the Results table. Access from the Add Chart drop-down.

Controls and options on this page:

- A categorized facet list of Where, Who, What, Exception, and When, from the search results appears on the left side of every dashboard and cannot be removed. Filter the entire dashboard by the specific facets, by expanding the list and clicking on individual facets.
- The Active Filters row at the top of the window shows the current filters. Delete filters by clicking the .
- Search field: free text search that filters the results in all fields simultaneously, irrespective of facet and no case-sensitivity. Exceptions:
  - anomaly score does not support < or >
  - Searching in a specific field is case-sensitive. For example, when searching "Source Program=nnnnn" nnnn must match a value in the facets.
- Distributed search: see [Local and distributed search](#)
- Time period for which data is presented: modify by clicking the drop-down in the upper right corner. Options are last 1 hour, last 3 hours, last 1 day, last 3 days, any time period you specify. Default is one hour.
- Filters drop-down: see [Filtering data and saving filters in the investigation dashboard](#)
-  : see [Creating, saving, and exporting investigation dashboards](#)

# Filtering data and saving filters in the investigation dashboard

## About this task

You can filter data in the entire investigation dashboard, and in an individual chart. You can drill down from the Results Table into related information.

You can save filters for your future use. When you save a filter set, you choose if you want to share it, and choose the roles that you share it with.

## Procedure

- Use the rules and syntax to filter data. All of these are relevant for both the Details and Summary tab, except where noted.
  - To match an exact phrase, use double quotation marks around the search terms. For example, "**Profiling Alert List**" returns entries for Connection Profiling Alert List but not for Profiling List Alert.
  - To match all specified search terms, separate the terms with a space. For example, **Hadoop getlisting** returns any entries that contain both Hadoop and getlisting in any location or sequence.
  - To match any specified search terms, separate the terms with OR or a vertical bar (|). For example, **Hadoop OR getlisting** returns any entries that contain either Hadoop or getlisting in any location.
  - To exclude a specified search term, use NOT or a period (.). For example, **NOT Hadoop** does not return any entries that contain Hadoop in any location.
  - Wildcards are supported by using asterisks (\*) at the beginning or ending of a string. For example, **10.10.70.\*** returns any entries with the string 10.10.70. followed by any additional characters.
  - Search rules can be used in combination. For example, **2016-5-08 (19.\*|20.\*)** returns results in the time range of May 8 between the hours of 19:00:00 – 20:59:59.
  - To match an exact phrase in a specific column, enter "**field name=value**", for example "**DB USER=user123**". This search syntax is the only case-sensitive syntax. In the Details tab, you can also use this search for columns with numeric values with search values of < >. For example, "**Total Instances>1**". This is particularly useful when there results on multiple pages and you cannot see the full list of possible values.

Adding filters changes each view based on the *RefFilter* specified for the view. Current filters appear in the menu bar. Each one can be cleared by clicking its X.

- Refine search results with any of the following methods:
  - Select specific filters based on the facets list:

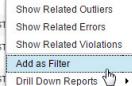

- Click the x or y-axis headers of a chart.
- Click an individual search result in the Results Table:

| Source Program   | DB User  | OS User | Client Hostname |
|------------------|----------|---------|-----------------|
| DB2JCC_APPLICATI | DB2INST1 |         | PIPPIN          |
| DB2JCC_APPLICATI | DB2INST1 |         | PIPPIN          |
| DB2JCC_APPLICATI | DB2INST1 |         | PIPPIN          |

Note: You can select one or more rows and right-click one of the server/DB user/Client IP cells to add them to an existing group, or to create a new group.

3. Drill down by individual results by right-clicking on specific search results and exploring related outliers, errors, or violations, or viewing one of several available drill-down reports.

| Source Program   | DB User  | OS User | Client H |
|------------------|----------|---------|----------|
| DB2JCC_APPLICATI | DB2INST1 |         | PIPPIN   |

4. To save a filter set, click Filters > Save. Provide a name for the filter and mark it as Private or click Share with to share the filter with specific roles. To save as your default filter set (dashboard always opens with these filters), select Set as default filter. When you are finished, click OK to save the filter.

## Filtering an individual chart

You can filter an individual chart. The  icon becomes red when specific filters are set for a chart that are different than the general dashboard filters. Hover over the icon to see which filters are used in that chart.

### About this task

A chart can have filters set as inactive, which means the chart data is not filtered by that field. This enables Guardium® to display other items, in addition to the ones related to the case, that may be similar or in some way provide additional insight into the investigation.

Example: While investigating activity on a server, you want to compare one of the charts with data from other servers. This is possible by deactivating the Server filter for just that one chart. To do this, you would click the  icon and select the Inactive radio button for the Server row.

### Procedure

1. Click the  icon.  
The Chart Filter Settings opens.
2. Click or clear the radio buttons as relevant, and click Apply.

## Creating, saving, and exporting investigation dashboards

### About this task

There are many ways of filtering the data in the dashboard. Filter sets can be private or shared. For example, a person who is knowledgeable about the environment can set up relevant filters. This person can create the filters for a specific investigator and then share the filter with that role. You cannot change and save the predefined system dashboards under their original names.

Important: All investigation dashboards are public. When a dashboard is saved, all users who have access to dashboards also have access to the saved dashboard through the dashboard menu. In addition, if you save a dashboard as the default dashboard, all users see that default.

You can use the same dashboards with different filter sets, depending on what data you want to see.

Example: Your dashboard includes an activity chart that shows the activities of database users with a breakdown by client IP. You want to view the same data filtered by different databases, such as HR versus Financial. You might want to add different command types for each database as well.

- Filter 1: by database HR, by verb SELECT
- Filter 2: by database FINANCIAL, by verb UPDATE

You can open the same dashboard and toggle through the different filter sets associated with that chart by using the and icons above the Active filters list. Any investigation dashboards, including threat diagnostics, can be encrypted and exported for sharing. Only the dashboard definitions are exported, not the filters.

If you have a dashboard that is configured with a good set of charts for investigating particular incident types, you can share this knowledge with other Guardium users without including actual attack data or revealing the filters.

## Procedure

1. To save the current display, click the icon.
2. To save a dashboard with a different name for modification and subsequent use, click the icon, and save it with a descriptive name and optionally a category.  
You can also define a category when you save the dashboard. The name and category can include spaces. To retrieve the dashboard later, click the icon to open the dashboard menu.
3. To export investigation dashboards, go to [Manage > Data Management > Definitions Export](#). From the Type menu, select Investigation Dashboard and select the dashboard definitions to export. Then, click Export.

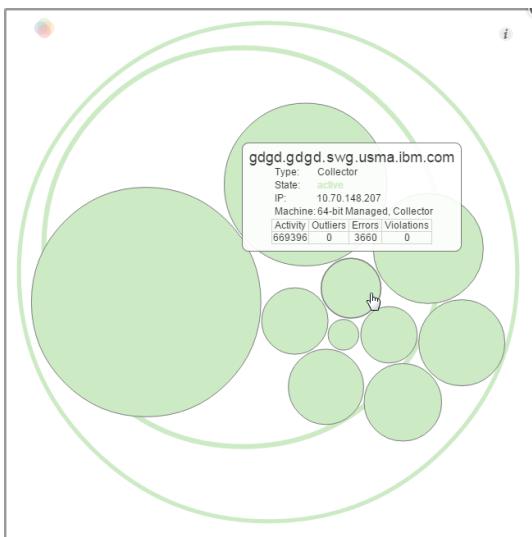

## Using the topology view

The topology view is visualization of the Guardium® appliances in the search results.

### About this task

You can view details about each server, select filter criteria, narrow search results to specific segments of the overall Guardium environment. Solid circles represent collectors and aggregators. Outlined circles represent Central Managers. The color of the circle indicates the status of the server. The outline color of the Central Manager indicates its status. The size of the circle indicates the relative volume of the collected data.

The topology view is not supported on stand-alone machines.

## Procedure

1. To open the topology view, click the Search server status view icon in the toolbar of the investigation dashboard.
2. Hover the mouse over an object to display detailed information about that object.

3. Select an object to narrow the search results to only that object and its children if any exist. Use Ctrl + click to select or deselect multiple objects in the topology view.
4. Close the topology view by clicking the close icon or clicking outside the topology browser. The search results update automatically to reflect the available data based on the scope selected in the topology view.

# Local and distributed search

## About this task

The Investigative Dashboards can run in either local or distributed modes. In local mode, searches are limited to the data available under the local machine (the machine from which the search is run). For example, a local search that is run from an individual collector returns results from data sources under that collector but not from any data sources under other collectors in the environment. In distributed mode, searches return data from across the entire Guardium® environment and results are not limited by the specific machine on which the search is run. A topology tool is provided to conveniently narrow search results to specific segments of the overall Guardium environment.

Investigative Dashboards default to local search mode.

## Procedure

1. To toggle between local or distributed search, click the Enable / Disable search all appliances icon  in the search window toolbar.  
Search results automatically update to reflect the available data based on the selection of local or distributed search.
2. See [Using the topology view](#) for information about filtering global search results by a specific segment of the Guardium environment.

# Monitoring and automatic recovery for the Investigation Dashboard

Use Monitoring and automatic recovery to identify and recover issues in the investigation dashboard.

Monitoring and automatic recovery is a process that monitors the engine behind the investigation dashboard. When Monitoring and automatic recovery detects issues, it displays them in the deployment health, lists their status, and runs the necessary steps to recover issues that can be recovered automatically.

If Monitoring and automatic recovery cannot recover an issue automatically, it displays the issue in the report under a different status. You can then troubleshoot those issues further.

Monitoring and automatic recovery is enabled by default and runs every 20 minutes on the central manager. It displays the issues that it finds in deployment health and in predefined admin reports. In those reports, the issues are further broken down per status (Open, In recovery, and All issues).

- [Viewing the Investigation Dashboard's status in deployment health views](#)  
View and monitor the Investigation Dashboard's status from deployment health views.
- [Viewing Investigation Dashboard issues in reports](#)  
You can see issues for the Investigation dashboard in various reports.
- [Viewing the Investigation Dashboard Issues alert for the Investigation dashboard](#)  
Receive alerts for new Investigation Dashboard issues that cannot be resolved automatically.
- [Addressing Investigation Dashboard issues](#)  
Learn about the different Investigation Dashboard issues and what you can do about them.
- [Running manual intervention for Investigation Dashboard issues](#)  
Understand when you need to run manual intervention for Investigation Dashboard issues, and which intervention steps to take.

## Viewing the Investigation Dashboard's status in deployment health views

View and monitor the Investigation Dashboard's status from deployment health views.

Status for Investigation Dashboard issues can be viewed from the deployment health table, deployment health topology, and deployment health dashboard. Issues are designated the status of No issues (green), Medium (orange), and Status unavailable (blue).

For example, the Investigation Dashboard column in the health deployment table displays a green, orange, or blue circle for each issue to indicate its status. The Details column of the same table provides more details as needed.

- A green circle without details in the Details column means that there are no issues on this unit at this moment.
- A green circle together with details in the Details column means that an issue is in recovery.
- An orange circle indicates that an open issue is detected and cannot be repaired automatically. A manual fix is required.
- A blue circle means that a unit is down or something is unavailable.

For more information, see [Deployment health topology and table views](#).

## Viewing Investigation Dashboard issues in reports

You can see issues for the Investigation dashboard in various reports.

Investigation dashboard issues can be viewed in the following reports:

- Investigation dashboard open issues. This report displays issues that the Monitoring and automatic recovery was not able to fix and require manual intervention to be resolved. Follow the manual fix recommendations or contact IBM Support.
- Investigation dashboard issues in recovery. This report displays issues that Monitoring and automatic recovery is trying to fix.
- Investigation dashboard issues. This report includes all issues, including issues that are open, in progress, and fixed.

For more information, see [Predefined admin reports](#)

# Viewing the Investigation Dashboard Issues alert for the Investigation dashboard

Receive alerts for new Investigation Dashboard issues that cannot be resolved automatically.

Alerts for the Investigation dashboard are designed to notify you of every new issue that cannot be resolved automatically.

For more information, see [Predefined alerts](#).

## Addressing Investigation Dashboard issues

Learn about the different Investigation Dashboard issues and what you can do about them.

Various Investigation Dashboard issues can appear in several reports, alerts, and deployment health views. To see what the various issues mean and what actions you can take regarding each one, see the following table.

| Issue                                                     | Description                                                                                                                                                                                                                                       |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The core is down.                                         | The Investigation dashboard isn't able to show data indexed in this core type from this collector. (For example, if ERROR_5 core is down, the Errors tab shows no data from this collector).                                                      |
| The node is missing.                                      | The Investigation dashboard isn't able to show data indexed in this missing node type from this collector. (For example, if ERROR_5 node is missing, the Errors tab shows no data from this collector).                                           |
| The core has a redundant replica and the replica is down. | The redundant replica is not needed. Since it is down, it is better to remove it. The user is not impacted.                                                                                                                                       |
| The core has a redundant replica. All replicas are down.  | The Investigation dashboard is not able to show data that is indexed in this core type where all its replicas are down from this collector. (For example, if ERROR_5 core's replicas are down, the Errors tab shows no data from this collector). |
| The collection configuration is incorrect.                | The Investigation dashboard isn't able to show data indexed in this collection type from all appliances. (For example, if the ERROR_5 configuration is wrong, the Errors tab shows no data from all appliances).                                  |
| The cores are down for the specified collection.          | The Investigation dashboard isn't able to show data indexed in this core type from this collector. (For example, if ERROR_5 cores are down, the Errors tab shows no data from this collector).                                                    |
| The unit is not listed in the cluster.                    | The Investigation dashboard isn't able to show data indexed on this collector.                                                                                                                                                                    |
| Incorrect hostname                                        | The Investigation dashboard isn't able to show data indexed in this core type from this collector. (For example, if ERROR_5 core is down, the Errors tab shows no data from this collector).                                                      |
| Data is not being indexed.                                | The Investigation dashboard isn't able to show data indexed in this data mart type from this collector. (For example, if Lucene Exception data mart is not running, the Errors tab shows no data from this collector).                            |
| Data indexing failed                                      | The Investigation dashboard isn't able to show data indexed in this data mart type from this collector. (For example, if Lucene Exception data mart fails, the Errors tab shows no data from this collector).                                     |

## Running manual intervention for Investigation Dashboard issues

Understand when you need to run manual intervention for Investigation Dashboard issues, and which intervention steps to take.

Monitoring and automatic recovery attempts to fix the issues it finds by running several recovery actions. If these attempts fail, you need to intervene manually.

To figure out when to intervene and how, first go to the Investigation dashboard open issues report. In the report, check the most recent automatic repair action that displays next to each open issue. Then, refer to the manual intervention recommendation for that repair action in the following table. In cases where your intervention still does not resolve the issue, contact IBM Guardium support.

| Last automated repair action                                                                                 | Recommendation                                                                                                                                                                                                                                                                                                                                               |

## Threat Detection Analytics

Guardium includes specialized threat detection analytics that scan and analyze audited data to detect symptoms that may indicate different types of database attacks.

Threat detection analytics scans and analyzes audited data to detect symptoms that may indicate SQL injection or Stored Procedure database attacks. Guardium does not rely on a comparison against an ever-changing dictionary of attack signatures. Instead, Guardium analyzes audit data activity, exceptions, and outlier data ([Outliers detection](#)) over extended periods of time looking for patterns that indicate an attack. By tracking the suspicious events over time and correlating them, Guardium creates a comprehensive picture of potential risks. This approach is more flexible and comprehensive, and does not require continual signature updates.

Threat detection analytics is supported on MSSQL, MySQL, Oracle, and Db2.

- [Characteristics of an SQL injection attack](#)

SQL injection attacks attempt to exploit web application vulnerabilities by concatenating user input with SQL queries. If successful, these attacks can execute malicious SQL commands by using the legitimate web application connection. SQL injection attacks can be difficult to identify because the individual steps of an attack, analyzed independently of the other steps, might be considered legitimate.

- [Characteristics of a stored procedure attack](#)

A malicious stored procedure is a block of code that is designed to evade detection, and to perform complex attacks over a period of time. The exact attack can be repeated, or it can change its characteristics over time.

- [Enabling and disabling threat detection analytics](#)

Understand the prerequisites and procedures for enabling threat detection analytics.

- [Viewing case reports](#)

View case reports in threat analytics.

- [Activating the audit process workflow for threat analytics](#)

This procedure describes how to schedule the audit processes and distribute the threat analytics results for Suspected Malicious Stored Procedures and Suspected SQL Injection cases.

- [Working with threat diagnostic dashboards](#)

A dashboard that is invoked from a specific threat case in either the Suspected malicious STP Cases (stored procedures) or Suspicion SQL Injection Attacks report is

called a threat diagnostic dashboard.

## Characteristics of an SQL injection attack

SQL injection attacks attempt to exploit web application vulnerabilities by concatenating user input with SQL queries. If successful, these attacks can execute malicious SQL commands by using the legitimate web application connection. SQL injection attacks can be difficult to identify because the individual steps of an attack, analyzed independently of the other steps, might be considered legitimate.

Using threat detection analytics, Guardium identifies potential SQL injection attacks by capturing the individual steps and analyzing them as part of a single complex attack.

Typical symptoms of SQL injection attacks that Guardium identifies include:

- An attacker that is trying to identify the structure of a dynamic SQL query, for example the number of columns queried.
- An unusually large quantity of new queries, specifically queries that are uniquely or unusually structured.
- Access to tables that contain information about the database structure.

## Characteristics of a stored procedure attack

A malicious stored procedure is a block of code that is designed to evade detection, and to perform complex attacks over a period of time. The exact attack can be repeated, or it can change its characteristics over time.

The stored procedure can be dormant for an extended period of time, making it harder to identify as suspicious. Even if unusual activity was noticed in a previous audit, by the time the next audit occurs the previous activity is forgotten. A malicious stored procedure can be used to disguise a drop of an important table, or to extract the contents of a table.

Examples of suspicious activity are:

- Creating a stored procedure with a DROP statement with sensitive objects.
- A DROP verb.
- SQL exceptions that are caused by missing objects.
- A procedure that is modified after it was dormant for an extended period of time.

Guardium tracks the activity around individual stored procedures, and together with Outlier mining data correlates the various symptoms and users. Guardium can detect these typical symptoms of this malicious stored procedure use case (presented in the order they typically occur):

1. A database administrator creates a malicious Procedure A, which deletes data from the customer table.
2. A month later the database administrator changes a commonly used Procedure B to call Procedure A.
3. A different user calls the modified Procedure B, such that the customer table data is deleted by that innocent user.

## Enabling and disabling threat detection analytics

Understand the prerequisites and procedures for enabling threat detection analytics.

Threat detection analytics is enabled, by default, on Guardium versions 10.1.4 and higher.

To enable threat detection analytics:

- Ensure that you meet the minimum required memory and storage requirements for search (4 CPU and 24 GB RAM).
- Verify that your system has logged application data. Specifically, SQLI requires application data because the injection initiates from the application. If the system "trusts" the application and does not monitor it in Guardium, the injection cannot be identified.
- Outlier detection is not required for SQL injection threat detection but it is required to fully support malicious stored procedure detection. For more information, see [Enabling and disabling outliers detection](#).
- Enable threat detection scanning on each collector or on multiple managed units from the central manager by using the Guardium API command: `grdapic enable_advanced_threat_scanning`. See [Threat detection analytics APIs](#) for more information about parameters available for the `enable_advanced_threat_scanning` command.
- Set up the audit process to send case reports to the relevant investigators. This is optional but recommended. See [Activating the audit process workflow for threat analytics](#) for more information.

Important: Threat detection relies on analysis and correlation of logged data. Thus, any rules that filter out traffic before logging are not considered for threat detection. Examine your use of IGNORE S-TAP SESSION rules carefully to determine the risk of not logging these sessions versus optimizing the capacity of the collector.

To disable threat detection analytics, use the Guard API command: `disable_advanced_threat_scanning`, either on individual collectors, or from the central manager.

## Prerequisites for malicious stored procedures analytics

- The analytics algorithm depends in part on sensitive objects groups. By default, the algorithm uses members in the system-defined sensitive objects group (group ID 5). If you already specified other sensitive object groups for outlier detection, threat detection uses the same groups. Even if outlier detection is not enabled, you can set your own sensitive object groups by using the same GuardAPI command:

```
set_outliers_detection_parameter parameter_name="sensitiveObjectGroupIds" parameter_value=<group ID>,<group ID>,...
```

- Policy rules must be installed to collect the necessary traffic for malicious stored procedure analysis.

Recommendation: Create the following rules in your policy in the suggested order. It is important to check the Continue to next rule checkbox for all these rules.

1. Access rule: Log Full Details where Command group filter is PROCEDURE DDL.

2. Access rule: Log Full Details where the Command group filter is EXECUTE Commands. If your database is Oracle, include the command BEGIN in the rule.

3. Exception rule: Log Only where the error type filter is SQL\_ERROR.

## Viewing case reports

---

View case reports in threat analytics.

Guardium analyzes the symptoms over time, correlates them, and assigns a score per identified possible attack. If the score indicates a likely attack, the set of events becomes a case whose ID is unique per collector. Cases are externalized in case reports, one per each suspected attack. Access case reports in one of the following ways:

- Set up an audit process to receive notifications in your To-Do list on the Central Manager, and open the report directly on the relevant associated collector. The To-Do list is updated once an hour.
- Access the reports in the UI by going to [Investigate](#) > [Exceptions](#).

In the case reports window, a case report presents, by default, up to 3 incidents (one per line). Each case includes a risk score from 1 to 3, with 3 being the most severe. In this window, you can:

- Hover on the case ID to view a summary of the attack (only stored procedure cases).
- Hover on the case ID and click [Link to Symptoms](#) to access the detailed symptoms report.
- Click the ID to open the case-specific threat diagnostic dashboard. See [Working with threat diagnostic dashboards](#).

Restriction: Case reports have the following restrictions:

- Data Level Security is not available.
- These reports cannot be cloned.
- You can create a distributed report for these case reports. However, the central manager does not provide direct links from the case report to the threat diagnostic dashboard. Additional hover help and links to symptoms are not available.

## Activating the audit process workflow for threat analytics

---

This procedure describes how to schedule the audit processes and distribute the threat analytics results for Suspected Malicious Stored Procedures and Suspected SQL Injection cases.

## About this task

---

Two preconfigured audit processes control the distribution of threat analytics reports to the appropriate reviewers:

- Suspected malicious STP Cases
- Suspected SQL Injection Cases

Each process pulls out the suspected cases on one attack type. You can customize these processes, or copy and create your own.

## Procedure

---

1. Go to [Comply](#) > [Tools and Views](#) > [Audit Process Builder](#). Optionally filter the available audit processes by clicking the [Inactive only](#) radio button or typing [Suspected](#) in the Filter box.  
The default task for this process is the corresponding report (Suspected malicious STP Cases or Suspected SQL Injection Cases). Do not modify the runtime parameters of these reports. However, you can add more tasks to this same audit process. For example, you can add both the threat reports into a single audit process.  
If you are defining these audit processes from a central manager, define a task for each collector for which you want to see threat data and use the [Remote Data Source](#) option.
2. Click [Send results](#) to define the audit process receivers who receive reports on suspected malicious stored procedures.
3. Select the default receiver (user) and then click the icon to define the appropriate receiver or receivers for your organization. When you are finished, click [OK](#).
4. Click [Schedule audit process](#) and review the schedule for the audit process.  
The recommendation is to run the process every day, every hour at 12:30 AM or later (after both outliers and threat detection usually run). Note that the checkbox [Auto run dependent jobs](#) has no effect for this task.

Important: Make sure that the [Activate schedule](#) checkbox is checked.

5. Click [Next](#) and then click [Save](#) to finish working with the audit process.

## Working with threat diagnostic dashboards

---

A dashboard that is invoked from a specific threat case in either the Suspected malicious STP Cases (stored procedures) or Suspicion SQL Injection Attacks report is called a threat diagnostic dashboard.

A threat diagnostic dashboard performs much like other investigation dashboards, except that the dashboard for that case is populated with the data from the suspicious events (db user, server, objects, etc.) and uses different charts to provide different views of the event and surrounding events that may be helpful in investigating the

possible attack. The relevant search and outlier data is also available on the same dashboard page as the charts.

In many cases, you will not need to change any of the preexisting filters for the predefined threat diagnostic dashboards. However, if you want to do some of your own comparative analysis, you can modify the preexisting filters.

See [Investigation Dashboard](#) for more information on working with dashboard and chart filters.

**Tip:** The threat diagnostic dashboard can only be opened by clicking on the case number in the relevant threat report. You cannot save changes to this dashboard or any other predefined dashboard. If you make changes and want to keep the dashboard for further investigation, you must copy it and save it under a new name. You must also save the filters by clicking the Filters menu and selecting Save.

Reference data is a set of predefined, chart-specific filters, for Threat Detection Analytics only, that show data similar to the case you're investigating but not included in the general dashboard filter. Reference data cannot be changed by users. Hover over the filter icon in each chart to see the Reference Data.

In a typical suspected malicious stored procedure attack, the threat diagnostic dashboard is filtered for this attack and includes the following general dashboard filters:

- Server: 8.34.223.145
- DB user: USER1
- Database: 8.4.134.213:31.5.12
- DB type: MYSQL
- Object: stp1\_name

The chart for DB user can include reference data for similar DB users, such as USER2, USER3 and USER4. This enables you to compare the activities of the suspected user with similar users, even though those additional users are not included on the general dashboard filters.

Not all fields include associated reference data. Any field for which there is no predefined reference filter is filtered as on the dashboard.

In some charts, filters can be inactivated so that you can compare data regardless of the filters chosen for the entire dashboard. This gives a wider picture of the activity.

Click the filter icon to open the Chart Filter Settings, and make modifications.

- [Investigating SQL injection threats](#)
- [Investigating stored procedure threats](#)

## Investigating SQL injection threats

### About this task

This procedure describes investigating a suspected SQL injection attack, using the threat diagnostic dashboard.

### Procedure

1. From the To Do list, or from [Investigate > Exceptions](#), open the Suspected SQL injection Cases dashboard. Each line is a case, with a Confidence (%) rating of certainty of an attack, and a risk level of the attack.
2. Click View to evaluate for false positives. Hover over the selected case id and click Symptoms to open the SQL Injection Case Symptoms page. Every suspicious action is described, and the SQL string displayed. You can see the exact modifications the user made to strings. By progressing from string to string, you can observe how the attacker methodically gained more data using errors returned from previous queries.
3. Click the id number to open the default diagnostic dashboard for SQL injection attacks, which is filtered by the incident's date and suspected web-application connection details. This helps narrow the investigation to database traffic that occurred during the attack. You can change or drop the filter to broaden the scope of investigation. Use the bottom grid to get more detailed information on the chart's data. Note that if you move to a standard dashboard, all filters specific for the suspected SQL injection attack are canceled.
4. Use these guidelines while investigating the charts:
  - Change the timescale to look for peaks at time of the attack
  - Look for violation of any security policy, and see if any violations correlate to other activity at the time of the attack
5. Drill-down by changing filters, timeframe, etc. to see if there are differences across the system.
6. Evaluate the charts in the dashboard:

#### Activities count per time and object

This chart contains the most used database objects in the time of the attack. By expanding the time frame of the dashboard you can compare the difference in activity before and after the attack. Click a cell if you want to filter for a particular object. The color indicates different object names.

#### Error count per time and error

This chart indicates how many SQL errors were generated by the web application. A high rate of SQL errors can indicate that some sort of SQL injection attack is taking place. The color indicates different error types.

#### Outlier count per time and outlier reason

An SQL injection attack involves a large number of new queries with a different structure than usual queries. Those queries generate outliers. Use this chart to see the volume and score of outliers generated by the offended web application.

#### Violations count per time and violation

During an SQL Injection attack the attacker is likely to violate security policies that log access to unauthorized objects. Compare the volume and types of violations to understand the risk of the attack.

#### Suspicious error types

Use this chart to explore specific SQL errors that are used in SQL injection attacks in order to exploit the vulnerability. Click a cell to filter the search and look at the SQL statement that generated this error. You may notice an injected SQL code.

#### Suspicious object names

Use this chart to view the suspicious objects that are used during SQL injection attacks. Expand the time frame of the search to see if those objects were used before the attack started. Compare the volume of the usage of those objects.

## Investigating stored procedure threats

## About this task

---

Investigate a suspected stored procedure attack by using the threat diagnostic dashboard.

## Procedure

---

1. From the To Do list, or from [Investigate > Exceptions](#), open the Suspected malicious STP Cases dashboard. Each line is a case. Each case shows a Confidence rating of certainty of an attack and a risk level of the attack.
2. Click View to evaluate for false positives.
3. Hover over the selected case ID to view the case details.
4. Click symptoms to open the Malicious STP Case Symptoms page.
5. Click the ID number to open the default diagnostic dashboard for SQL injection attacks, which filters according to the incident's date and suspected web-application connection details. This filtering helps to narrow the investigation to database traffic that occurred during the attack. You can change or drop the filter to broaden the scope of investigation. Use the grid on the page to get more detailed information on the chart's data.
6. Use these guidelines while you investigate the charts:
  - Change the timescale to look for peaks at the time of the attack.
  - Look for violations of any security policy, and see whether any violations correlate to other activity at the time of the attack.
7. Drill-down by changing filters, time frame, and more to see whether differences exist across the system.
8. Evaluate the charts in the dashboard:
  - Compare errors on different servers  
Use this chart to understand whether this server and DB user have exceptionally more errors than other servers and DB users.
  - Compare errors from different database users with similar behavior  
Use this chart to compare the error types and their volume on this DB user compared to similar DB users. The similar DB users are all users that created stored procedures.
  - Similar activities on stored procedures by this database user  
Use this chart to see stored procedures that the user created or modified at the specific period. The chart filters by verb. Use this chart also to drill down and see what the user did on the different stored procedures.
  - Compare violations from database users with similar behavior  
Compare the volume and type of violation (policy) on DB users that create stored procedures.
  - Compare outliers from database users with similar behavior  
Use this chart to compare the volume and type of outliers on this DB user with other DB users that create stored procedures.
  - Outliers by data on this database user  
Use this chart to see the volume and score of outliers on the specific DB user.

---

## Data Protection Dashboard

The Guardium® data protection dashboard provides a summary view of risk and compliance data intended for senior-level security officers.

The data protection dashboard contains several charts and graphs in addition to compliance and risk statistics designed for continuous display on a large monitor. To open the dashboard, navigate to [Investigate > Guardium Data Protection Dashboard](#).

View this dashboard on your central manager.

**CAUTION:**

The session does not expire and you are not automatically logged out while viewing the data protection dashboard. Use care when leaving the dashboard open for long periods of time.

Information:

- The dashboard automatically refreshes every 20 minutes.
- The default search settings are for distributed search with data collected from the previous one day.

---

## Charts and graphs

Several line charts allow you to quickly compare different types of data. For example, a chart can display the volume of activities, errors, and violations over time.

An Anomalous activities chart displays a summary of outliers in relation to overall activity. On this chart, an outliers summary dot represents an unexpected volume of outliers.

Information: The y-axis of these charts is a log axis and may distort the chart proportions, and the values or counts are not logged.

---

## Risk and compliance statistics

The Risk statistic shows the number of tests that failed with critical severity and the number of datasources where those failure occurred. Each datasource can have multiple failed tests.

Monitored datasources shows the number of datasources for which the system is logging activities. This statistic is calculated by looking at the available access domain data.

Compliance to-do list tasks shows the following summary of audit processes: the number of processes that were closed today, the number of processes that have been open for less than three days, and the number of processes that have been open for more than three days.

Information:

- Statistics are not affected by facet and text search filters, but statistics are affected by the search mode. To change the search mode, use the ▾ control to expand the top pane, then click the  icon to toggle between distributed and local search.
- The statistics components are recalculated once every hour.

## Building audit processes

Use the Audit Process Builder to streamline your compliance workflow process by consolidating, in one spot, database activity monitoring tasks such as: asset discovery; vulnerability assessment and hardening; database activity monitoring and audit reporting; report distribution; sign off by key stakeholders; and escalations.

Guardium audit processes provide the following capabilities:

- Audit processes support company privacy and governance requirements, such as PCI-DSS, SOX, Data Privacy, and HIPAA.
- The audit process can export audit results to external repositories for additional forensic analysis such as Syslog, CSV or CEF files, or external feed.
- Generate an Audit Process Log report that shows a detailed activity log for all tasks, including start and end times.
- The results of each audit process, including the review, sign-off trails, and comments, can be archived and later restored and reviewed through the Investigation Center (if enabled). For more information, see [Restoring and viewing audit results in the investigation center](#).

Elements of the compliance workflow automation process can include,

- A process definition
- A set of tasks
- A distribution plan that defines the following elements:
  - Receivers - Individual users, user groups, roles, email, or ticket.  
Note: To configure tickets, you need to set up external ticket service for alerts. For more information, see [Configuring an external ticketing system](#).
  - The review and signing responsibility for each receiver.
  - The distribution sequence by setting the Continuous flag.
- A schedule - The audit process can be run immediately, or you can run the process regularly on a defined schedule.

## Creating an audit process

To start building an audit process, go to Comply > Tools and Views > Audit Process Builder.

1. From the Audit Process Builder page, click the  icon to open the Create New Audit Process page.
2. Click Name and archive to enter a name for your audit process.
3. Click Show advanced options to manage the following optional information.
  - Archive - Store a copy of audit process output after the retention period has expired. If needed, you can restore archived results.
  - Allow results to be purged prior to review - Deletes the results of an ad hoc process before all workflow activities have finished, such as reviews and sign-offs. This feature allows you to delete results in a specified period (such as 1 day) even if the results have not been reviewed.
  - Keep for a minimum of x days or y runs - Determine how long to keep the archived files. You can select either the number of days or then number of runs to archive. When a new archive file is stored, Guardium deletes the oldest file.
  - CSV/CEF file name - Provide a label for CSV or CEF files that are generated by audit processes.
  - Zip CSV for email - When emailing the file, select whether to compress the file before it is sent.  
Note: Guardium cannot export CSV files larger than 10 GB. Guardium recommends that you select Zip CSV for mail.
  - Email subject - The subject line for all emails for all receivers for that audit process. The subject can include one (or more) of the following variables. The variable is replaced with the following information:
    - %%ProcessName - The audit process description.
    - %%ExecutionStart - The start date and time of the first task.
    - %%ExecutionEnd - The end date and time of the last task.
  - 12.1 and later Custom email template- Use an existing custom email template or create a new template. To create a new template:
    - Click the New icon to open the New Template window.
    - Provide a unique name for the template.
    - Create the message that you want to include in the email. The message can include basic HTML options as well as the following messages:
      - %%ExecutionEnd - Process execution end timestamp.
      - %%ExecutionStart - Process execution start timestamp.
      - %%ProcessName - The name of the audit process.
      - %%UserAction - Required user action, which can be review or sign.
    - Click OK to save your new template.

The email template that you saved is available from the Global profile Named Template Finder window. For more information, see [Global profile](#).

Note: You can also create a custom email template from Named Template on the Global Profile page. For more information, see [Creating or updating named messages](#).

4. Export results - Specify whether to export results when an audit process runs, based on how export results are configured on the Results Export (Files) page. For more information, see [Exporting \(files\) results](#).

Note: If you do not configure the export results, these settings are ignored (and audit process results are not exported).

Specify when to export the results,

- Select Disabled to export results based on the configuration that you set in Results Export (Files).
- Select At the end of the process to export the results after the audit process successfully completes.
- Select At the end of each task to export the result after each task within the audit process completes.

5. Roles - By default, an audit process is assigned to a user with *audit process* privileges. Select Roles to open the role window and select other roles that can access this audit process.

6. Click Next to open Add tasks. Click the  icon to begin adding a task. You must define at least one audit task before you can save the process. Each type of task requires different information. For more information about creating and configuring tasks, see [Audit process task types](#)

Attention: For most task types, you need to define other steps first (such as creating a security assessment or privacy set). Guardium suggests that you make sure that you create the required scenarios before you start building the audit process.

7. After you name the audit process and add one task, click Save to save your work. If needed, add more tasks.

8. Click Send results to add or change who receives the audit process results. From the Receiver table, click the New icon to begin adding a receiver. Each receiver type provides different options. For more information about receivers and receiver types, see [Audit process receivers](#).

9. Click Schedule audit process to configure a schedule for running the audit process. For more information, see [Scheduling](#).

Note: Scheduling applies only to the Guardium unit on which you are defining this audit process. To manage an audit process from a central manager, you can create a distribution profile. For more information, see [Working with configuration profiles](#).

10. To test the audit process, select Run audit process and then click Run once now.

Users with the audit-delete role can delete audit process results. If you have audit-delete privileges, Delete Results displays in the Run audit process ribbon. Audit activity is tracked in the User Activity Audit Trail report.

Note: Audit process results from remote sources are limited to 100,000 results. To change that limit, use the **store save\_result\_fetch\_size** CLI command.

9. Click Save to save your changes or Reset to clear all of the changes you made since the last time you saved your work.

To add comments for the audit process, click the audit process name and then Show advanced options, and in the Comments window, click the New icon.

## Stopping an audit process

---

You can stop audit processes that are currently running or that have not run yet. Stopping an audit process does not deliver partial results; the audit process stops and returns a stopped error message. However, if tasks are complete, the results are still sent.

To stop an audit process from the Audit Process Log (Comply > Tools and Views > Audit Process Log), run the [stop\\_audit\\_process](#) GuardAPI by taking one of the following steps,

- Click the Actions menu, and select **stop\_audit\_process**.
- Place your cursor on any line, right-click to open the pop-up menu. Select Invoke and then select **stop\_audit\_process**.

For any user, stopping an audit process displays only the line that belongs to that user (just the tasks, not all the details). An admin user can see all the details and can stop anyone's audit processes. A user can stop only their own audit processes.

To stop an audit process on a remote source, select **stop\_audit\_process** from a line (not the Action menu) and specify the Target Host , which can be a group of managed units or the IP address of a managed unit.

Note: You cannot stop running audit processes for Privacy Sets Audit Tasks or External Feed Audit Tasks. If the Privacy Set or External Feed tasks are running, they finish even if the process is stopped.

## Adding workflow events

---

Define a formal sequence of event types for certain tasks.

1. From the Audit Process Builder, create an audit task.
2. Depending on the task, Events and Additional Columns displays on the Edit task window.  
For example, the Events and Additional Columns is displayed on the Edit task window for the *Report* Task type and the *Admin Users Login* report.
3. Click Events and Additional Columns to display the Event & Sign-off window. The workflow that you created appears as a selection in Event and Sign-off.
4. Highlight this choice and click Apply to save your selection.
5. If you need to add additional information (such as company codes, or business unit labels) as part of the workflow report, add this information under Define Additional Columns then click Add. To select a predefined or created groups column, change the Type column to Group.
6. When you are done, click Close this window.
7. Click OK to save the task and then Save to save the entire audit process definition.

Notes:

- Under the Report choices are two procedural reports that are available to admin users (and users with the admin role), Outstanding Events and Event Status Transition. Add these two reports to two new audit tasks to show details of all workflow events and transitions. These reports are not filtered (observed data level security filtering is not applied).
- Additional Columns is unavailable for some tasks.
- When you clone a process, the task that is associated with the process is added to the cloned process. But, if you make changes to this task, the workflow that is associated with the original task is not cloned.
- You can delete an event status only if the status is not in the first status of any events, and if it is not used by any action. The validation provides a list of events or actions that prevent the status from being deleted.
- The owner or creator of a workflow event can always see all statuses of this event, regardless of what roles are assigned to these statuses.

For more information about the Workflow builder, see [Workflow Builder](#).

## Audit processing notes

---

- On a central manager, reports can reference data from remote datasources (managed units). Audit processes that use these reports are accessible from the central manager only, and cannot be seen from managed units.
- Use the [store max\\_audit\\_reporting](#) CLI command to configure the audit report threshold.  
When you define reports, make sure that the number of days (defined by the FROM-TO fields) does not exceed a certain threshold. The default threshold is one month. If this threshold is exceeded, a runtime error results when the audit task runs on the aggregator.

No warning message displays when you create a report with an invalid FROM-TO range. Instead, an error displays in the Task Parameters window in the Audit Process setup page.

- You can create an audit task with a FROM-TO range that is wider than the value of the [store max\\_audit\\_reporting](#) CLI command. Audit processes defined on the aggregator can be run on managed collectors (when this aggregator is a manager). Audit tasks that are run on collector unit do not have a max\_audit\_reporting limitation.
- You can use audit processing for the aggregator server to create ad hoc databases for each aggregator task and specify only the relevant days for that task. You can keep the ad hoc databases for the aggregation server in the system for up to 14 days (depending on the value of the [store aggregator drop ad\\_hoc\\_audit\\_db](#) CLI command). If needed, use these databases for post-run analysis by Guardium support services.
- All audit processes are stopped when a patch installation runs.
- **Audit process task types**  
When you create an audit process with the Audit Process Builder, you need to select the database activity monitoring tasks to include in your audit process. Create the monitoring activities that you want to include before you start building the audit process.
- **Audit process receivers**  
Use the audit process builder to send audit process output to many different people or groups (receivers). These process receivers can view and manage audit process output.
- **Exporting audit results**  
Reports that contain information that can be used by other applications, or reports that contain large amounts of data, can be exported to other file formats.

- [How to distribute workflow through Guardium groups](#)

Using the receiver group option, define a single Compliance Workflow audit process that will send different results to different Guardium users based on a pre-defined, custom mapping.

- [Audit Process To-Do List](#)

Use the Audit Process To-Do List to track tasks that are assigned to you or other users.

- [Comparing discovery and classification results](#)

Compare results from different runs of the same discovery and classification process.

- [Using the host references report](#)

The Host references report provides an easy way to identify where a server is used in Guardium and simplifies the process of decommissioning that server or updating its host name or IP address.

---

## Audit process task types

When you create an audit process with the Audit Process Builder, you need to select the database activity monitoring tasks to include in your audit process. Create the monitoring activities that you want to include before you start building the audit process.

### Process task types

---

An audit process can contain any number of audit tasks. Select the type of task from the New task window.

- Report - Produces a report, which can be either custom or a Guardium® predefined report. The report type must be Tabular.
- Security assessment - The security database assessment scans the database infrastructure for vulnerabilities, and provides an evaluation of database and data security health, with both real-time and historical measurements. The report compares the current environment against preconfigured vulnerability tests based on known flaws and vulnerabilities. The tests are grouped by using common database security best practices (like STIG and CIG1), as well as incorporating custom tests. The application generates a Security Health Report Card, with weighted metrics (based on best practices) and recommends action plans to help strengthen database security.
- Entity audit trail - Produces a detailed report of activity that relates to a specific entity is produced (for example, a client IP address or a group of addresses).
- Privacy set - Produces a report that details access to a group of object-field pairs (a Social Security number and a date of birth, for example) during a specified time period.
- Discover sensitive data - Scans the existing database metadata and data, reporting on information that might be sensitive, such as Social Security numbers or credit card numbers.
- External feed - Exports data to an external specialized application for further forensic analysis.

Note: The External Data Feed is an optional component that is enabled by a product key. This feature displays only if it is enabled.

Note: If data level security at the observed data level is enabled, then audit process output is filtered so that users see only the information of their databases.

### Defining a report task

---

Before you begin, you need a report. For more information about creating reports, see [Using the Query-Report Builder](#).

1. Select Report as the task type.
2. Enter a name for this task and select an existing report (which can be either a Guardium pre-defined or a user-defined report).
3. Select the format that you want for exporting: CSV, CEF, PDF, Write to Syslog, and Compress. For more information, see [Exporting audit results](#).
4. PDF options apply to both PDF attachments and PDF export files. If you select PDF, then you can further select from:
  - Report - The current results
  - Diff - The differences between a new report and the previous report (only available if a previous report exists)
  - Reports and Diff - Both the current and diff reports

Note: The maximum number of rows that can be compared at one time is 5000. If the number of result rows exceeds the maximum, an error message displays.

5. Enter all of the remaining information in the New task window. The information varies depending on the report that you select.

Note: When setting time periods, you can select Sync QUERY\_FROM\_DATE to the previous execution date to prevent missing or duplicate data in scheduled audit processes. If you select this option, be aware that:

- The audit process must run at least once before the setting takes effect.
- If an audit process has not run recently, consider disabling the setting to avoid an excessive amount of data in the report.

6. Click OK.

### Defining a security assessment task

---

Before you begin, you need a security assessment. For more information, see [Creating an assessment](#).

1. Select Security Assessment as the task type.
2. Enter a name for this task and select an existing security assessment.
3. Optionally, select whether to export the output in AXIS (Apache EXtensible Interaction System, used by QRadar) or SCAP (Security Content Automation Protocol) format.  
AXIS or SCAP saves the audit process results in XML format and transfers the file to the destination defined in Results Export. For more information, see [Exporting \(files\) results](#).
4. Select whether to create a PDF report that contains,
  - Report - The current results
  - Diff - The differences between a new report and the previous report (only available if a previous report exists)
  - Report and Diff - Both the current and diff reports

5. Click OK.

Note: If a security assessment task is empty (for example, a security assessment with a set of no roles), the empty security assessment does not display in the drop-down list in Audit Builder.

### Defining an entity audit trail task

---

1. Select Entity Audit Trail as the task type.
2. Enter a name for this task and then select the type of entity to audit. Depending on the entity that you select, supply the following information:
  - Object - Enter an object name.
  - Object Group - Select an object group from the list.
  - Client IP - Enter a client IP address.
  - Client Group IP - Select a client IP group.
  - Server IP - Enter a server IP address.
  - Application User Name - Enter an application user name.
3. Select whether to export the audit trail as a CSV file, and optionally, supply a label. For more information, see [Exporting output to CSV, CEF or PDF format](#).
4. Select whether to compress the audit trail.
5. In the Task Parameters section, supply runtime parameter values (Enter Period From and To are required).
6. Click OK.

## Defining a privacy set task

---

Before you begin, you need to create a privacy set. For more information, see [Privacy sets](#).

1. Select Privacy set as the task type.
2. Enter a name for this task and then select a privacy set from the Privacy Set list.
3. Select either Report by Access Details or Report by Application User to indicate how you want to sort and display the results.
4. Select whether to export the privacy set as a CSV file, and optionally, supply a label. For more information, see [Exporting output to CSV, CEF or PDF format](#).
5. Select whether to compress the privacy set.
6. Click OK.

## Defining a discover sensitive data task

---

Before you begin, you need to create a sensitive data scenario. For more information, see [Discover sensitive data](#).

1. Select Discover sensitive data as the task type.
2. Enter a name for this task and then select an existing sensitive data scenario from the Discover Sensitive Data list.
3. Click OK.

## External feed task

---

This type of task feeds data that is collected by Guardium to an external application, mapping the data to a format recognized by that application. External feed is an extra-cost feature, which is enabled by a patch.

If you use external feeds in a central manager environment, you must install the external feed patch on the central manager, and on all managed units on which the task runs. For more information, see [Working with external feeds](#). For more information about how the data is mapped from Guardium to an external application, see the documentation for the purchased option.

1. Select External Feed as the task type.
2. Enter an name for this task and then enter the following options:
  - Select a feed type from the Feed Type list
  - Select an External Feed event
  - Select a report from the Report list. Depending on the report selected, additional parameters display.
  - Under Extract Lag, enter the number of hours by which the feed is to lag, or select Continuous to include data up to the time that the audit task runs.
  - Select one or more datasources for the external feed. If needed, click the  icon to create a new datasource.
3. Click OK.

## Using APIs to automate audit process runs

---

By default, some reports are linked to API functions. You can use these API calls to run for every record within a task of type report in an audit process. You can also add API mapping to a report by right-clicking in the report row, select Add API mapping, and selecting the API function in the Add API Mapping window. To configure an API for automatic execution for a report task:

1. From the Report task, select a report for which API for automatic execution displays, such as the Guardium Group Details, Job Dependencies, or Restored Data reports.
2. From API for automatic execution select an API from the list.
3. Click Event and Additional Columns. The Event, Sign-off & Additional Column window opens.
4. Under Define Additional Columns, in the Column Name, type API\_RESULT\_TEXT.
5. In the Type column, select Text.
6. Click Add.
7. Run the audit process and click View Results. The API\_RESULT\_TEXT column has the returned text, and the BY column has the name of the API ran, and the date and time when it was run.

## Audit process receivers

---

Use the audit process builder to send audit process output to many different people or groups (receivers). These process receivers can view and manage audit process output.

Audit process receivers are notified via email or their To-Do list of pending audit process results. You can designate any receiver as a signer for a process. In this case, the results can be held at that point on the distribution list until that receiver electronically signs the results or releases them.

You can define any number of receivers for a workflow automation process, and you control the order in which they receive results. In addition, receivers can notify other receivers, using the Escalate function. It is also possible to run an audit process with no defined receivers. For example, you can create an audit process with no receivers

that writes to syslog and has no need to review (or sign) the results.

## Adding receivers

---

From the Audit Process Builder,

1. Open the Send results ribbon and then click  to open the New Receiver window.
2. From the New Receiver window, select a Receiver type, which can be one of the following:
  - Role - Select a role from the Role list. Guardium sends results to all users with the specified role.
  - Email - Specify an address in Email address. Guardium sends results to the specified email address. In addition, you can select the following options:
    - Email format - Choose whether to send results as a PDF or in CSV format.
    - Approve if empty - Automatically approve this report if no results are returned.
    - Do not include online links to reports in email - Remove links to online reports from the notification email. Select this option if the receiver might not have access to Guardium system.
  - User Group - Select or create a new user group in the Group list. Guardium sends results to all users that are members of the group.
  - User - Select a user from the User list or click Search Users to find a user to add. Guardium sends results to the specified user.
3. Ticket- Click  to begin searching for either a user or group to whom to assign this ticket.
  - From the Search Users or Search Groups window, enter the name of the user or group.
  - Click Search.
  - Select a user or group, then click Add.

Guardium assigns the ticket to the specified user or group.

3. For Role, User Group, and User receivers, you can set the following options:

- Action - Select any of the following actions:
    - Review - The receiver does not need to sign the results.
    - Sign off - The receiver must sign the results (electronically, by clicking Sign Results when viewing the results online). For user groups, if Sign off is selected, all members of the group must sign.
    - Approve if empty - Automatically approve this report if no results are returned.
    - Add to to-do list - Send a notice of to the user's audit process to-do list. For more information, see [Audit Process To-Do List](#).
  - Email format - Select an email format:
    - None - Do not send email to the receiver.
    - Links only - Include hypertext links to the results (on the Guardium system).
    - Full results - Include a copy of the results in PDF or CSV format.
- Note: Results from Security Assessment or Discover Sensitive Data tasks might return sensitive information.
3. Distribution sequence - Select whether audit process results are sent to all receivers at the same time (Simultaneous) or only after the previous receiver reviews or signs off on the results (Sequential).

## Receiver details

---

When you select Role or User Group as a receiver, all users that belong to the group or having that role receive the results.

If you select a group receiver, and any workflow automation task uses the special runtime parameter `./LoggedUser` in a query condition, then the query executes separately for each user in the group, and each user receives only their results.

For example, assume that your company has three DBAs, and each DBA is in charge of a different set of servers. You use the Custom Data Upload facility to upload the areas of responsibilities of each DBA (with server IPs) to the Guardium® system. You can correlate that to the database activity domain, and then use a report in this custom domain as an audit task. If a user group that contains the three DBAs is designated as the receiver, each DBA receives the report relevant only for their collection of servers.

If you specify a group receiver and require sign-off, each member of the group must sign the results separately (as explained earlier, each member of the group may be looking at a different set of results).

If you select Email as the receiver, the results are sent to the specified email address. When you specify an email address, that address that is used to filter the data. The email address must belong to a user who is logged in or is under the user in the data hierarchy.

If you specify a role receiver, only one user with that role needs to sign the results. The other users with that role are notified when the results are signed.

Note: Be sure to configure audit processes so that all roles that act on an event associated with an audit process are receivers of that audit process. When you create a workflow event, you can assign a role to every status that is used by that event (that is, users with that role can only see events when the event is in the specified status). When you assign an event to an audit process, it is important that every role that is assigned to a status of this event have a receiver on this audit process. Otherwise, an audit result row can end up with a status where none of its receivers are able to see this row or change its status.

If this situation occurs, the admin user (who can see all events, regardless of their roles) can see the row and change its status. However, if data level security is on, the admin user might not be able to see this row. In this case, the admin user must either turn off data level security (from Global Profile) or have the dataset\_exempt role.

## Hypertext links to process results

---

In email messages, there are conditions where links to process results on the Guardium system will not work. For example:

- If you access email from a location where you cannot normally access the Guardium system, the links do not work. For example, if you are on your personal computer, you might have access to your email over the Internet, but not to your company's private network or LAN, where the system is installed.
- If you have not accessed your email for a longer period of time than the report results are kept, those results are not available when you click the link. For example, if results are kept for seven days, and you take a two week vacation, your email may contain links to results older than seven days, and those links will not work.

## Modifying the receivers list after an audit process runs

---

After an audit process runs, any user can add, edit, delete, and rearrange receivers on the receivers list. From the Audit Process Builder, select an active audit process and open its Send results ribbon:

- Click , , or to add, edit, or delete receivers.
- Click to enable the reorder controls and change the position of receivers in the list.

Changes to the receivers list are tracked in the User Activity Audit Trail report. From the report, right-click an UPDATE activity type, select Detailed Guardium user activity, and look for Audit process entries under the Modified entity column.

Note:

If you delete the Guardium user account for a receiver on the list, Guardium substitutes the admin user account (which is never deleted) for that receiver. In this case, the admin user receives any email notifications that are sent to a deleted receiver, and the admin user must act upon any results released to that receiver.

## How results are released to receivers

---

Results are released to the Guardium users listed on the receivers list, subject to the Continuous check box, as follows:

- If the Continuous check box is marked, distribution continues to the next receiver on the list without interruption.
- If the Continuous check box is cleared, distribution to the next receiver is held until the current receiver performs the required action (review or sign).

For example, assume you want to define a workflow process for DBAs:

- All DBAs should receive their results at the same time, with each DBA receiving a different result set based on the server IPs with which they are associated.
- Only when ALL DBAs have signed, the DBA Manager should see the results.
- Only when DBA Manager releases the report, the Auditors should see the results.
- All Auditors should receive the reports at the same time, but only one of them (any of them) needs to sign each result. The others will be updated when a result was signed.
- An auditor can escalate a result to the Audit Manager.

To define this flow:

- The DBAs group would be named as the first receiver.
- The DBA Manager would be next on the list.
- The Auditors role (not group) would be next on the list. Any Auditor could sign and others will be notified. Also, any auditor can escalate a results set to the Audit Manager.

Note: The results will only distribute to the next receiver when the current receiver has marked the Continuous button. This is completely separate from the review/sign functionality and does not depend on the review/sign functionality all.

Note: Process results that are exported to CSV or CEF files are sent to another network location by the Guardium archiving and exporting mechanism. These results are not subject to the receivers list or to any signing actions. They are subject to the Guardium CSV/CEF export schedule (if any is defined), and they are subject to the access permissions that have been granted for the directory in which they are ultimately stored.

## View or sign results

---

- Open the Compliance Workflow Automation results.
- If signing is required, click the Sign Results button.
- Optional. To forward these results to another user, click Escalate, and see Forward Results to Additional Receivers (in Escalation section).
- Click Close this window link.

Note: If there are outstanding events, then the results cannot be signed either from the audit viewer or from the To-do list. If there are outstanding events and an attempt is made to sign the results, the following message appears:

**Audit process cannot be signed - has pending events.**

**Please update all outstanding events prior to signing this result.**

Note: When viewing audit process results, if a result has events associated with it, the Sign Results button is not available on this result until all events are in a Final state or cannot be seen by this user (due to data-level security).

Note: This report also contains a date or Last Action Time, located in a column between Receiver and Status. This report shows that the result was signed by user AAA, but also when this user AAA signed this result.

## Release results without signing or viewing

---

- Open your To-Do List panel.
- Click the Continue button for the results you want to release to the next receiver on the distribution list.
- Click Close this window link.

## View Results Distribution

---

- Open the compliance workflow automation results.
- Expand the Distribution Status panel by clicking the (Show Details) button.
- Click Close this window link.

## View receiver comments added to results

---

- Open the compliance workflow automation results.
  - Expand the Comments panel by clicking the Show Details button.
- Note: These are the comments that were attached to the results when the report page was retrieved from the Guardium system. If you add comments of your own, or if other receivers are adding comments simultaneously, you will not see those comments until you refresh your page (using your browser Refresh function).

- Click Close this window link.

## Escalate process results

---

A receiver of process results can forward the results notification for review and/or sign-off to additional receivers. If you escalate the results to a receiver outside of the original audit and sign-off trail, and the results include a CSV file, that file will not be included with the notification.

Regardless of who is a receiver of an audit result, an escalation can involve any user on the system, provided the Escalate result to all users box is checked in the Setup > Tools and Views > Global Profile menu. A check mark in this box escalates audit process results to all users, even if data level security at the observed data level is enabled. The default setting is enabled. If the check box is disabled (no check mark in the check box), then audit process escalation will only be allowed to users at a higher level in the user hierarchy. If the check box is disabled, and there is no user hierarchy, then no escalation is permitted.

Also, depending on event permissions, if for example, the infosec user can only see events in status1 and dba user can only see events in status2, the dba user will receive a different result than the result the infosec user saw when the infosec user clicked Escalate. It is possible that infosec will escalate to dba, and dba will receive an audit result with 0 rows in it.

1. If the compliance workflow automation results you want to forward are not open, open them now.
2. Click Escalate.
3. Select the receiver from the Receiver list.
4. In the Action Required column, select Review (the default) or Review and Sign.
5. Click the Escalation button to complete the operation.

Note: Audit process results cannot be escalated to a group of users, only to users or roles.

When escalating to a user who already has the result in the user's to-do list, a popup message will appear, asking if an additional email should be sent. If yes, an additional email will be sent to the user, but the to-do list will not be incremented.

## Exporting audit results

Reports that contain information that can be used by other applications, or reports that contain large amounts of data, can be exported to other file formats.

### Exporting output to CSV, CEF or PDF format

You can export report, entity audit trail, and privacy task output to CSV files, and export database activity reports to a CEF file. When exporting to CEF or CSV files, keep in mind the following details,

- Each record in the CSV or CEF file represents a row on the report.
- CEF and CSV file output can be written to syslog. If the remote syslog capability is used, this results in the immediate forwarding of the output CEF or CSV file to the remote syslog locations. You can use the remote syslog function to direct messages from each facility and severity combination to a specific remote system. For more information, see [Facility and priority of syslog messages](#). For more information about the remotelog (syslog) CLI command, see [store remotelog](#)
- Guardium creates the file to export in addition to the standard task output, but does not replace it. Exporting the files can be useful for the following tasks,
  - Integrating with an existing SIEM (Security Incident and Event Manager) in your infrastructure (such as QRadar, ArcSight, Network Intelligence, LogLogic, or TSIEM).
  - Reviewing and analyzing very large compliance task results sets. Results sets exported to PDF are limited to 5,000 rows of output. There is no limit to the number of rows that can be written to an exported CSV or CEF file when using an audit process.
- Exported CSV and CEF files are stored on the Guardium® system, and are named in the format:

`process_task_YYYY_MM_DD-HHMMSS.<csv | cef>`

Where `process` is the process name and `task` is the task name that you defined for this audit process. The date-time stamp is generated when the task runs.

- You cannot access the exported CSV or CEF files directly on the Guardium system. Your Guardium administrator must use the CSV/CEF Export function to move these files from the Guardium system to another location on the network. To access those files, check with your Guardium administrator to determine their location. The fact that exported files are sent outside of the Guardium system has two important implications:
  - The release of these files is not connected to the results distribution plan defined for the audit process. These files are exported on a schedule defined by the Guardium administrator.
  - Once the CSV/CEF Export function runs, all exported files will be available to anybody (Guardium user or not) who can access the destination directory defined for the CSV/CEF Export operation. For this reason, your Guardium administrator may want to schedule additional jobs (outside of the Guardium system) to copy sets of exported files from the Guardium CSV/CEF Export destination directory, to directories with appropriate access permissions.

- CSV/CEF Export activity is available in the Aggregation/Archive Activity report.

Note: If observed data level security is enabled, then audit process output (including files) is filtered so users will see only the information for their assigned databases. Files sent to an email receiver as an attachment will be filtered. However, files downloaded locally on the machine and then moved elsewhere using the Results Export function are not subject to data level security filtering.

The following table summarizes what happens when an audit process file is exported to CSV, CEF, or PDF.

Table 1. Exporting Audit Task Output to CSV, CEF or PDF Files

| Function                                | Level         | CSV                                                                                   | CEF                                                                                   | PDF                                                                                   |
|-----------------------------------------|---------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------|
| Attach to email                         | Receiver      | Full Details radio --> PDF check box                                                  | N/A                                                                                   | Full Details radio --> PDF check box<br>The radio buttons are only for receiver PDF   |
| Export file                             | Task          | Export CSV file check box                                                             | Export CSV file check box                                                             | Export CSV file check box                                                             |
| Report empty and Approve if Empty = yes | Receiver      | Export not affected (empty files will be exported)<br>Attachment, no email attachment | Export not affected (empty files will be exported)<br>Attachment, no email attachment | Export not affected (empty files will be exported)<br>Attachment, no email attachment |
| Zip attachment                          | Audit Process | If no file generated, nothing to zip<br>Merge all CSVs into one ZIP file              | N/A                                                                                   | If no file generated, nothing to zip<br>PDF is not zipped                             |
| Compress (export)                       | Task          | Compressed, separate file for each CSV file                                           | Compressed, separate file for each CSV file                                           | PDF is not compressed                                                                 |

## How zip for email and compress work for audit task output

---

Zip for email is the highest level of control for Audit Task Export. Zip for email produces a set of CSV or CEF files. PDFs are never zipped or compressed.

Compress works on individual files.

Note: For CSV attachments, when Zip for Email is cleared, Compress can still be applied. And Compress can be per task. Thus one Audit Task may send a .csv file while another may send a .csv.gz file, in the same email.

The interaction of Zip for Email and Compress is as follows:

- Zip for email checked (regardless of whether Compress is also checked), the attachment is one zip file of CSV files.
- Zip for email not checked, and Compress checked, the attachment is a set of csv.gz files.
- Zip for email not checked, and Compress not checked, the attachment is a set of CSV files.
- Compress checked, Download All will be csv.gz.
- Compress cleared, Download All will be csv.
- Compress checked or cleared, download displayed will still be CSV.
- Compress checked, export of CSV/CEF files will be gzipped.
- Compress cleared, export of CSV/CEF files will not be gzipped.

---

## How to distribute workflow through Guardium groups

Using the receiver group option, define a single Compliance Workflow audit process that will send different results to different Guardium users based on a pre-defined, custom mapping.

Value-added: Setup a single audit process and distribute the appropriate results to the appropriate manager. This saves having to create separate audit processes for separate receivers.

IBM® Guardium®'s Compliance Workflow Automation automatically delivers reports, classification results, and security assessment results to Guardium users on a scheduled basis. Result receivers can be defined as Guardium users, Guardium roles or user groups.

For example, consider a large organization that has fifteen DBA managers that need to review the activities for the DBAs they manage without viewing the activities of the other manager's DBAs. One solution would be to setup fifteen separate audit processes; one for each manager. This would take a lot of time to configure and it is difficult to manage: Each audit process needs to be scheduled separately and any global change would need to be made individually for all fifteen audit processes.

The user group distribution method, on the other hand, permits the setup of a single audit process and distributes the appropriate results to each manager based on a manager/DBA mapping. This process requires more upfront configuration but reduces to maintenance time. Only one audit process needs to be scheduled and changes only need to be applied in one location.

## User mapping

---

The first step in the process is to map the users to the data elements within Guardium that will be the basis for report distribution. The example that will be used in this document will be based on objects, but you can apply these concepts with any data element within Guardium.

Example: Three users have responsibility over three different sets of tables, based on audit requirements (PCI, HIPPA, and CCI) within a database server, as follows:

Table 1. User with Table/Object

| User   | Table/Object         |
|--------|----------------------|
| User01 | db2inst1.cc_numbers  |
| User01 | db2inst1.ccn         |
| User02 | db2inst1.ADDRESSES   |
| User02 | db2inst1.SSN_NUMBERS |
| User02 | db2inst1.G_CUSTOMERS |
| User02 | db2inst1.G_EMPLOYEES |
| User02 | db2inst1.G_FUNDS     |
| User03 | db2inst1.doctor      |
| User03 | db2inst1.medicare    |
| User03 | db2inst1.med_history |

This table must be added as a custom table within Guardium, either manually or through a data upload. The following steps demonstrate how to create a custom table manually. The screenshots are from the "admin" user interface, but they can also be accessed from within the "user" user interface.

1. Navigate to Reports > Report Configuration Tools > Custom Table Builder and press the **Manually Define** button.

2. At the **Custom Table Builder** screen, define the table layout. Make sure that **Group Type** matches the correct data element in Guardium. Press **Apply** and **Back** when complete.

3. Press **Edit Data** to manually add the records. Note, if you have a large amount of data, choose **Upload Data** to import from an external data source.

4. Press **Insert**.

5. Enter each combination of values and press **Insert** until you have added all of the required records.

Custom Table Builder

**Custom Data - Insert Record**

Table: ObjectUserMapping Entity: ObjectUserMapping

- Leave a field blank to not specify a value for the column.  
 - Use 'guardium://empty' to specify an empty value.  
 - Use 'guardium://null' to specify the value NULL.

|                        |                     |
|------------------------|---------------------|
| User - Text(255)       | User01              |
| SensObject - Text(255) | db2inst1.cc_numbers |

Cancel **Insert**

6. When complete, press the **Query** button to review the data.

Custom Table Builder

**Custom Data Editor**

Table: ObjectUserMapping Entity: ObjectUserMapping

There are currently 10 row(s) in this table. **Insert...**

Query rows to view, update, or delete:

| Column     | Type | Size | Filter (optional) |
|------------|------|------|-------------------|
| User       | Text | 255  |                   |
| SensObject | Text | 255  |                   |

- Leave Filter blank to omit criteria for a column  
 - Use 'guardium://empty' to specify an empty value.  
 - Use 'guardium://null' to specify the value NULL.  
 - All other comparisons use LIKE and accept the '%' wildcard

**Query** **Back**

7. Press return when complete.

Custom Table Builder

## Custom Domains

Next, join this custom table to the Guardium table structure using Custom Domains.

1. Navigate to Reports > Report Configuration Tools > Custom Domain Builder. Highlight *[Custom]* Access and press **Clone**.

The screenshot shows the IBM Guardium Data Protection interface. The top navigation bar includes 'System View', 'Administration Console', 'Tools' (with a dropdown arrow), 'Daily Monitor', 'Guardium Monitor', 'Tap Monitor', 'Incident Management', and 'Reports'. Under 'Tools', 'Custom Domain Builder' is selected. On the left, a sidebar lists various tracking categories like 'Access Tracking', 'Report Building', and 'Custom Domain Builder'. The main panel is titled 'Domain Finder' and contains a list of domain entities such as 'S-TAP Info', 'STAP Association History', 'SYBASE: Accnts With Sys Or Sec Admin Roles', etc. A red box highlights the 'Custom Domain Builder' option in the sidebar and the 'Object' entity in the list.

2. In the Custom Domain Builder:

- Highlight the new table created under **Available entities**.
- Highlight the table under **Domain entities** to which you would like to join the custom table.
- Under **Join condition** choose the fields on each table on which to create the join and press **Add Pair**.

This screenshot shows the 'Custom Domain Builder' dialog. The 'Custom Tables Domain' section has a 'Domain name' of '-ObjectUserMapping01'. The 'Available entities' pane on the left lists various MySQL and Netezza privilege tables. The 'Domain entities' pane on the right lists domain entities like 'Access Period', 'Session', 'Client/Server', 'SQL', 'Command', and 'Object'. The 'Object' entity is highlighted with a red box. The 'Join condition' section at the bottom shows a pair 'SensObject' = 'Object Name' selected with a red box. Buttons for 'Delete All Pairs', 'Add Pair', 'Apply', and 'Back' are visible.

3. Press the arrows (>>) button to move the custom table from **Available entities** to **Domain entities**.

This screenshot shows the 'Custom Domain Builder' dialog after pressing the '>>' button. The 'Available entities' pane now shows the '-ObjectUserMapping' table moved to the 'Domain entities' pane. The 'Domain entities' pane still contains the 'Object' entity. The 'Join condition' section remains the same as in the previous screenshot.

4. Press the **Detail** button to review the joins.

## Custom Report

Next, create a report to distribute to the users.

1. Navigate to Reports > Report Configuration Tools > Report Builder and select the new domain from the Domain drop-down menu.

The screenshot shows the 'Custom Query Builder' interface with the 'Domain Finder' search results. The search term '-ObjectUserMapping01' is entered in the search bar, and the results list various database objects and privileges. A red box highlights the 'Search' button at the bottom right of the search results panel.

2. Press **New...**

The screenshot shows the 'Query Finder' section of the 'Custom Query Builder'. It includes fields for 'Query Name', 'Report Title', and 'Main Entity', each with dropdown menus. A red box highlights the 'New...' button at the bottom right.

3. Enter a **Query Name** and **Main Entity** and press **Next**.

The screenshot shows the 'New Query - Overall Details' step. The 'Query Name' field is set to '-ObjectUserMapping01' and the 'Main Entity' field is set to 'Object'. A red box highlights the 'Next' button at the bottom right.

4. Create a new report with a run-time parameter for the user field created in the custom table.

The screenshot shows the 'ObjectUserMapping01' query configuration screen. The 'Query Fields' table has the following data:

| Seq. | Entity        | Attribute    | Field Mode | Order by | Sort Rank | Descend |
|------|---------------|--------------|------------|----------|-----------|---------|
| 1    | Client/Server | Server IP    | Value      |          |           |         |
| 2    | Client/Server | Client IP    | Value      |          |           |         |
| 3    | Client/Server | DB User Name | Value      |          |           |         |
| 4    | Command       | SQL Verb     | Value      |          |           |         |
| 5    | Object        | Object Name  | Value      |          |           |         |

The 'Query Conditions' section contains the following WHERE clause:

```

WHERE ObjectUserMapping = User = (Parameter) LoggedUser

```

The 'Runtime Params.' dropdown is set to 'LoggedUser'. A red box highlights the 'Generate Tabular' button at the bottom left.

## User Group

Create a new group of “Guardium Users” based on the custom table.

1. Navigate to Setup>Tools and Views>Group Builder and create a new group with **Guardium Users** as the **Group Type**.

The screenshot shows the 'Group Builder' tool within a larger application interface. The top navigation bar includes 'System View', 'Administration Console', 'Tools' (with a gear icon), 'Daily Monitor', 'Guardium Monitor', 'Tap Monitor', 'Incident Management', and 'Reports'. The left sidebar lists various builders: Access Map Builder/Viewer, Alert Builder, Alias Builder, Audit Process Builder, Audit Process To-do List, Auto-discovery Configuration, Baseline Builder, CAS Host Config, CAS Template Set Config, Classification Policy Builder, Classification Process Builder, Datasource Definitions, Group Builder (which is selected and highlighted with a red box), Policy Builder, Portlet Editor, Privacy Set Builder, Replay Builder, Security Assessment Builder, Time Period Builder, Value Change Audit DB Creation, Value Change Audit DB Update & Upload, Value Change Auditing Builder, and Workflow Builder.

The main panel displays the 'Group Builder' interface. It includes a 'Modify Existing Groups' section with a list of items such as 'App Users', 'Application Servers', 'Customer Tables', 'Allowed Connections', 'appservers', 'DBAs', 'IBM Citrix IPs', 'IBM DBAs', and 'Non-system tables'. Below this are buttons for 'Auto Generated Calling Prox', 'Populate from Query', 'LDAP', 'Group Filter', 'Roles...', 'Clone', 'Modify', and 'Delete'. A section titled 'Flatten All Hierarchical Groups Scheduling' indicates that flattening is not scheduled, with buttons for 'Modify Schedule...' and 'Run Once Now'.

The 'Create New Group' section is highlighted with a red box. It contains fields for 'Application Type' (set to 'Public'), 'Group Description' (set to '-ObjectUser'), 'Group Type Description' (set to 'Guardium Users'), 'Group Sub Type Description' (with 'Category' and 'Classification' fields), and a 'Hierarchical' checkbox. A large 'Add' button is located at the bottom right of this section.

2. Add all of the users from the custom table.

This screenshot shows the 'Manage Members for Selected Group' dialog box. At the top, it displays the 'Group Name' as '-ObjectUser' and the 'Group Type' as 'Guardium Users'. It includes buttons for 'Modify Group Type' and 'Modify Category'. The main area is titled 'Group Members' and features a 'Filter' input field and a list of members: 'user01', 'user02', 'user03', and 'user04'. These four entries are highlighted with a red box. Below the list, there are three sections: 'Create & add a new Member named' with a text input 'user05' and an 'Add' button; 'Rename selected Member to' with a text input and an 'Update' button; and 'Delete selected Member' with a 'Delete' button. At the bottom are buttons for 'Add Comments', 'Aliases...', 'LDAP', and 'Back'.

## Audit Process

1. Create a new Audit Process.
2. Choose the group created in User Group as the **Receiver**
3. Choose the custom report created in step 4 as the task.
4. In the run-time parameter, enter the special tag "./LoggedUser". This will cause the results to be distributed based on the custom mapping.
5. Press **Run Once Now** to run the Audit Process

When the audit process completes, each receiver should a different result set based the mapping:

## Users

User01

| Report details: |               |              |             |                                                                |                                                       |                                   |

## Audit Process To-Do List

Use the Audit Process To-Do List to track tasks that are assigned to you or other users.

As an administrator, you can perform any actions on any to-do list entry. Any actions that you take are logged, indicating that the action was taken by the administrator on behalf of the user. You can manage audit processes one at a time or in bulk. For more information, see Step 3.

- Open the Audit Process To-Do List by one of:

- Click the icon in the page banner.
- Browse to Comply > Tools and Views > Audit Process To-Do List.
- If you receive an email notification, click the To-Do List link to open your To-Do List. Alternatively, click the report link to open the results. In either case, you must have access to your email from a location that also has access to Guardium®.

- Take one of the following steps to filter the list:

- Select the user whose To-Do list you want to open, either from View To-Do List of, or click Search Users and select a Role or User from the Search Users dialog.
- Type in part or all of a Process name and click Search.
- Select either an Execution start date, an Execution end date, or both.

- Within the processes list, you can mark multiple processes as viewed or signed. To work with multiple processes:

- Select one or more processes from the list and click Mark selected as viewed to change each process to viewed. When prompted, add a comment and then click Add comment. The comment is the same for all selected processes.

- If you have signing authority, you can then click Mark selected as signed to mark each selected process as signed. When prompted, add a comment and then click Add comment.

If you select Apply to all processes with selected name, and then click Mark selected as viewed or Mark selected as signed, Guardium performs the requested action on all processes with the selected name.

For example, say the **Process1** process runs every 10 minutes. You usually turn it off at night, but you forgot and when you come in the next morning, multiple pages of **Process1** audit processes are waiting in your To-Do list. Rather than opening each **Process1** process, you can take the following steps:

- a. Select **Process1** from the list and select Apply to all processes with selected name. All processes named **Process1** are selected, even if they are not on the visible page.
- b. Click Mark selected as viewed.
- c. Enter a comment and click Add comment.
- d. All of the **Process1** processes in your list are now marked as viewed. If you have signing authority, then Sign viewed results displays for each process.
- e. If you have signing authority, you can now select a process again, and select Apply to all processes with selected name.
- f. Then, click Mark selected as signed, enter a comment, and click Add comment.

Note: When you select Apply to all processes with selected name, the action applies to all of the processes with the same name, even if they are not on the same page. That is, if you have 80 processes that are named **Process1**, but only 20 are visible, Guardium marks all 80 processes as either read or signed.

4. Click Search. The page refreshes with the search results.

5. The options for viewing the To Do items are as follows:

- View: Click to open a dialog to view details about the process, including distribution status and comments. In this dialog, you can
  - Sign Results: The receiver must have Sign Off enabled to be allowed to sign off.
  - Escalate: Add a Receiver to Review or Review and Sign.
  - Comment: View and add comments.
  - Download PDF: downloads a PDF of the process to your local drive.
  - PDF options: Recreate PDF, and Report (the current results), Diff (difference between one earlier report and a new report), or Reports and Diff (both). Note: The selection of PDF Content applies to both PDF attachments and PDF export files. Diff is available only after the first time this task runs since Diff requires a previous result. The maximum number of rows that can be compared at one time is 5000. If the number of result rows exceeds the maximum, the message compare first 5000 rows only shows up in the diff result.
  - Other results for this process list: Click to view the timestamps of additional results for this process. Click  to open another report in a new window.
  - Compare with other results: compare results from different runs of the same process.
- Download as PDF: downloads a PDF of the process to your local drive.

6. Click Refresh to refresh the display.

Note: To send files to an external server without sending email and without adding results to the to-do list, define an audit process without receivers. In the Send results section, create a receiver, clear Add to to-do list in the New Receiver page and then delete all receivers (including the one you created). The results of the audit process are now available in the audit process builder and a user that has access to the audit process builder and the audit process can view the results in Guardium.

## To-Do Lists and Data Level Security

---

Use the View To-Do List of menu to see the to-do lists of other users. Unlike the menu of users with admin role, the menu for other users includes only those users who are under the current user in the Data Level Security (DLS) hierarchy. If you have the admin or exempt role, then all users are shown in the menu.

If you access another user's results, the data that is presented in the report is filtered according to the Data Level Security and the role of the selected user. For example, for a custom workflow, the data is filtered according to the role of the selected user and the status that is defined for their role.

If you have an admin role, you can view the results of a user in your hierarchy based on the Data Level Security and the role of the selected user. If you access the result for a user who is not under the hierarchy, then it shows the result by using the Data Level Security of the administrator and shows for all roles.

When a result is added to a user's to-do list because of a change in an event status, if the result is not already in the to-do list, then Guardium sends an email to the user. The email does not contain a PDF, just a notification and link.

If a user goes to some other user's to-do list, a message indicates which user is determining the DLS filtering.

## Comparing discovery and classification results

---

Compare results from different runs of the same discovery and classification process.

### Procedure

---

1. Open the audit process to-do list and click View to open the results of a classification process.  
For more information, see [Audit Process To-Do List](#).
2. From the results window, click Compare with other results to open the results-comparison dialog.
3. From the results-comparison dialog, select the timestamp of another set of results from the same process and click Go to open the Classification run results compare view window.
4. Work with the information presented in the results-comparison view:
  - a. Use the Compare results menu to change the timestamp of the process results being compared.  
The results selected here are compared to the results of the process selected in step 1.  
Note: The results being compared are listed by timestamps in the Later results and Earlier results fields of the results-comparison view.
  - b. Use the View menu to define what is shown in the comparison view.  
The View menu includes the following options:
    - Rows unique to the later results displays only rows unique to the newer results.
    - Rows unique to the earlier results displays only rows unique to the earlier results.
    - Unchanged rows displays only rows that are unchanged between both sets of results.

Each option indicates the number of included rows, for example Rows unique to the later results (27) indicates that there are 27 rows unique to the later results.

# Using the host references report

The Host references report provides an easy way to identify where a server is used in Guardium and simplifies the process of decommissioning that server or updating its host name or IP address.

## About this task

---

The report returns all instances of a host name or IP address from the following Guardium locations:

- Custom tables
- Datasources
- Datasource groups
- Discover sensitive data scenarios (classification processes)
- Groups
- Policy rules
- Queries
- Security assessments

Note: Querying a host name returns instances of that host name or its associated IP address. Querying an IP address returns instances of that IP address or its associated host name.

Run the report from any Guardium system by using the Audit Process Builder. In a centrally managed environment, running the report on the central manager provides the best performance.

The following procedure describes running the report on an ad hoc basis by generating a one-time report of where an IP address is used. For more information about building and scheduling audit process, see [Building audit processes](#).

## Procedure

---

1. Go to Comply > Tools and Views > Audit Process Builder.
2. Create an audit process by clicking the  icon.
3. In the Name and archive panel, use the Name field to name the audit process. Click Next to continue.
4. In the Add tasks panel of the audit process builder, click the  icon to create a new task.  
Complete the following steps by using the New Task dialog.
  - a. Set the Task type to Report.
  - b. Use the Name field to name the task.
  - c. Set the Report field to Host references.
  - d. In the Task parameters section, use the Host name or IP address field to specify the host name or IP address of a server in your Guardium environment.
  - e. Click OK to close the dialog and save the task.
5. To immediately run the report and see the results, open the Run audit process panel and click Run Once Now.  
For information about defining a complete audit process with receivers and a schedule, see [Building audit processes](#).
6. View the results by clicking View Results.

# Audit and Report

Guardium organizes the data it collects into a set of domains. Each domain contains a different type of information relating to a specific area of concern: data access, exceptions, policy violations, and so forth.

All domains and their entities are described in [Domains, Entities, and Attributes](#).

Access to each domain within the Query-Report Builder is controlled by security roles. For detailed instructions on how to build queries, see [Using the Query-Report Builder](#).

In addition to the standard set of domains, users can define custom domains to contain information that is uploaded to the Guardium appliance. For example, your company might have a table relating generic database user names (hr23455 or qa4872, for example) to real persons (Paula Smith, John Doe). Once that table has been uploaded, the real names can be displayed on Guardium reports, from the custom domain. For more detailed information on how to define and use custom domains, see [External data correlation](#).

# External data correlation

This topic describes creating and managing custom tables and custom domains, for importing enterprise information to use with existing Guardium internal data.

You might have valuable information in various databases in your environment. It can be useful for an audit report to correlate relevant information from your databases with the data that is collected by Guardium. You can create custom tables on Guardium that combine enterprise information with existing Guardium internal data. You can then create queries for this information as if it were predefined data.

For example, you have a table that contains all employees, their database usernames, and the department to which they belong (such as, Development, Financial, Marketing, or HR). You can upload this table and all its data, and cross-reference this table with Guardium's internal tables. You can then see, for example, which employees from Marketing are accessing the financial database (which might constitute a suspicious activity).

For more information about data marts, see [Data Mart](#).

## Custom tables

Browse to the Custom Table Builder by using one of the following paths:

- Comply > Custom Reporting > Custom Table Builder
- Reports > Report Configuration Tools > Custom Table Builder

A custom table contains one or more attributes that you want to have available on the appliance. By uploading data for that table from an existing table, you can relate the encoded and real names.

Before you define a custom table, verify that the data you need from the existing database is a supported data type. A data type is supported if it is taken as one of the following SQL type by the underlying JDBC driver: INTEGER, BIGINT, SMALLINT, TINYINT, BIT, BOOLEAN, DECIMAL, DOUBLE, FLOAT, NUMERIC, REAL, CHAR, VARCHAR, DATE, TIME, TIMESTAMP. The following table summarizes some of the supported and unsupported data types for uploading to a custom table.

**Enterprise reports with custom tables:** If for any reason, the central manager did not receive data from a managed unit for the custom table in an enterprise report in the last 24 hours, the Guardium® UI banner displays the message:

Central manager experienced failure getting data from collector. Central manager experienced error in the last 24 hours uploading data.

Click the report name to open the Scheduled Jobs Exceptions report and view details of the managed units that had exceptions.

## Supported and unsupported data types for custom tables

Use this table to see the supported and unsupported data types for certain databases.

Table 1. Supported and Unsupported Data Types for Custom Tables

| Databases | Supported Data Types                                                                                                                             | Unsupported Data Types                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Oracle    | float number char varchar2 date nchar nvarchar2                                                                                                  | long clob raw nclob longraw bfile rowid urowid blob                             |
| DB2®      | char varchar bigint integer smallint real double decimal date time timestamp                                                                     | blob blob longvarchar datalink                                                  |
| Sybase    | char nchar varchar nvarchar int smallint tinyint datetime smalldatetime                                                                          | text binary varbinary image timestamp                                           |
| MS SQL    | bigint bit char datetime decimal float int money nchar numeric nvarchar real smalldatetime smallint tinyint smallmoney varchar unique identifier | text                                                                            |
| Informix® | char nchar integer smallint decimal smallfloat float serial date money varchar nvarchar datetime                                                 | text                                                                            |
| MySQL     | bigint decimal int mediumint smallint tinyint double float date datetime timestamp time year<br>char binary enum set                             | longtext tinyblob tinytext blob text mediumblob<br>mediumtext longblob longtext |

Note: Blob value (even a value of 1 K) in dynamic SQL can be captured, but same size blob value in static SQL cannot be captured.

## Archiving and restoring custom tables

From the Custom Table Builder, select a table to manage and then select Purge/Archive to open the Custom Table Data Purge page.

Click Archive to include the data in the custom table in the normal data archive. The selected custom table data is archived according to the date in SQLGUARD\_TIMESTAMP column of the custom table.

You can archive data from either a collector or an aggregator.

When you prepare archived data to restore, keep in mind the following points:

- You can restore data to any collector or aggregator that is managed by the same central manager as the source collector. The metadata must be available or the custom table data cannot be restored.
- Data that is archived from an aggregator can be restored to any aggregator managed by the same central manager as the source aggregator.
- If the custom table structure changes between the archive time and the restore time in a way that results in an SQL error (for example, columns are removed or the type changes), then a warning message appears on the aggregation/archive activity report and the data is not restored.
- If a custom table is included in the default purge, then the restored data is kept for the number of days that are specified on the restore screen.
- If the custom table is set to overwrite data when it uploads, then restored data is deleted when the upload occurs.

## Custom domains

A custom domain contains one or more custom tables. If it contains multiple tables, you define the relationships between tables when you define the custom domain.

## Custom queries

A custom query accesses data from a custom domain. Use the Custom Query Builder to create queries against custom domains. Custom queries can then be used like any other query to generate reports or audit tasks, populate groups, or to define aliases.

## Database entitlement reports

DB Entitlement Reports use the Custom Domain feature to create links between the external data on the selected database with the internal data of the predefined entitlement reports. See topic, [Link External Data to Internal Data](#), on this subject. For more information about using predefined database entitlement reports, see [Running database entitlement reports](#). To see entitlement reports, log on to the user portal, and go to the DB Entitlements tab.

## LDAP import into custom tables

Enrich Guardium tables with LDAP data by using an LDAP server as a datasource. Retrieve and configure LDAP attributes that can be used to customize reports.

1. Open the Custom Table Builder.
2. To create a new table definition, click Manually Define and define the entity. For more information, see [Manually defining a table definition](#).
3. From the Custom Table Builder screen, select your custom table definition and click LDAP Import.
4. Click  to create a new LDAP datasource.
  - From the Configuration tab, specify the LDAP connection information and define the Base DN. The Base distinguished name (DN) specifies the starting point of the search in the LDAP tree. Optionally include a search filter in LDAP search syntax. For example, `objectClass=person`.
  - Click the Mapping tab to map the columns of the custom table to the LDAP fields.
  - Click the Schedule tab and add a schedule to import the LDAP data.
  - Click Save to save the configuration.
5. To import data, select the LDAP Host from the LDAP configurations screen and click Run Once Now or wait for the schedule that you defined.  
Tip: To view the imported LDAP data, click the LDAP datasource from the Custom Tables list, and click Edit Data.

The custom table now has LDAP data that can be used to create custom reports.

You can configure custom tables for LDAP in the Guardium CLI by using the following GuardAPI commands:

- [Create custom table for LDAP import](#)
- [Update custom table for LDAP import](#)
- [Delete custom table for LDAP import](#)
- [List custom table for LDAP import](#)
- [Run custom table for LDAP import](#)

To import an existing table structure, see [Uploading a table definition](#).

## Uploading a table definition

Create a custom table by the uploading a table definition. You can access the table's metadata from the database server on which the metadata is defined.

Note: Custom Tables uploaded to Guardium are optional components enabled by product key. If these components are not enabled, the Custom Tables choices listed do not display in the Custom Table Builder selection.

1. From the Custom Table Builder, click Upload Definition to open the Import Table Structure page. It is not necessary to select an item.
2. Enter a description for the table in the Entity desc field. This is the name you use to reference the table when you create a custom query.
3. Enter the database table name for the table in the Table Name field. This is the name you use to create the table in the local database.
4. Enter a valid SQL statement for the table in the SQL Statement field. The result set returned by the SQL statement must have the same structure as the custom table that you define. For example, if the custom table contains all columns from the table named `my_table`, enter `select * from my_table`.  
Note: Do not include any newline characters in the SQL statement. All columns must be explicitly named; if needed, use a column alias.
5. Click Add Datasource to open the Select datasource window. From Select datasource, you can define where the external database is located, and the credentials that are needed to retrieve the table definition and content later in the process.
6. Use Select datasource to identify the database from where you will upload the table definition.
7. Click Retrieve to upload the table definition. The SQL statement runs and retrieves the table structure. The SQL request is sent to the external database from the Guardium system. Remember that only the definition is being uploaded. You can upload data later.

## Manually defining a table definition

1. From the Custom Table Builder, click Manually Define to open the Define Entity panel.
2. Enter a description for the table in the Entity desc field. This is the name you will use to reference the table when creating a custom query. Use of the special characters `\$|&;`"` are not allowed in the entity description.
3. Enter the database table name for the table in the Table Name field. This is the name you will use to create the table in the local database.
4. For each column in the table to be defined:
  - Enter a name in the Column Name box. This will be the name of the column in the database table.
  - Enter a name in the Display Name box. This is the name you will use to reference the attribute in the Custom Domain Builder and the Custom Query Builder.
  - Select a data type (Text, Date, Integer, Float, or TimeStamp).
  - For a Text attribute, enter the maximum number of characters in the Size box. (The Size box is not available for other data types.)
  - If uniqueness is to be enforced on the column, check the Unique box.
  - If the attribute being defined corresponds to a group type, select that group type from the Group Type list.
  - Click Add to add the column.
5. Use the Entity Key drop-down list to identify which column will be used as the entity key. The Entity Key is used in the query builder when selecting count.
6. If additional changes are made after the Add button, such as deletion of a column, or changing an attribute, Click Apply to save any changes.
7. Click Done when you have added all columns for the table.

## Modifying a table definition

If you modify the definition of a custom table, you may invalidate existing reports based on queries using that table. For example, an existing query might reference an attribute that has been deleted, or whose data type has been changed. When applying changes to a custom table, if any queries have been built using attributes from that table, the Queries are displayed in the Query List panel. Note: You can also use the Modify to view and validate the table structures that were imported.

1. From the Custom Table Builder, select the custom table to modify.
2. Click Modify to open the Modify Entity page.
3. For information about modifying a table definition, see [Manually defining a table definition](#).

4. After you apply changes to a custom table, if any queries might be invalid due to changes to attributes from that table, the queries are displayed in the Query List page. Use Query List to choose and change queries. You do not have to make all changes immediately as you can always come back and use the Check for Invalid Queries option.

## Invalid queries

---

If you modify the definition of a custom table, you may invalidate existing reports based on queries using that table. For example, an existing query might reference an attribute that has been deleted, or whose data type has been changed. It is a good idea to check for invalid queries after the table modification process.

1. From the Custom Table Builder, click Invalid Queries.
2. The queries are displayed in the Query List panel. Use Query List to choose and change queries.

## Purging data from a custom table

---

Data can be purged from custom tables on the Guardium server on demand, or on a scheduled basis.

1. From the Custom Table Builder, select a custom table to purge.
2. Click Purge to open the Custom Table Data Purge panel.
3. Click Purge All to purge now.

Note: Run once now purge will look at the RESTORED\_DATA table for retention. Purge ALL will purge all records that are deleted without checking the retention.

4. In the Configuration panel, enter the age of the data to be purged, as a number of days, weeks or months prior to the purge operation date.
5. Click Run Once Now to run a schedule purge operation once.
6. Click Modify Schedule to open the standard Schedule Definition panel and schedule a purge operation.
7. Click Done to close the panel.

## Uploading data to a custom table

---

1. From the Custom Table Builder, click on the name of the table whose data you want to upload.
2. Click Upload Data to open the Upload Data page.
3. In the SQL statement box, enter a valid SQL statement for the table. The result set returned by the SQL statement must have the same structure as the custom table defined. For example, if the custom table contains all columns from the table named my\_table, enter `select * from my_table`.

Important: Different SQL databases have unique syntax requirements. For example, compare the following SQL statements for uploading from an Oracle database and uploading from a Microsoft SQL Server database:

```
Oracle example
select * from xxx WHERE coll > TO_DATE('^FromDate^', 'YYYY/MM/DD HH24:MI:SS');

#Microsoft SQL Server example
select * from xxx WHERE coll > CONVERT(DATETIME, '^FromDate^');
```

To create a functional SQL statement for uploading data, test the statement outside of Guardium with the SQL interface of the specific database being used.

Do not include any newline characters in the SQL statement.

The following fields, which are internal to Guardium, are available for use within SQL statements:

- `^FromDate^` and `^ToDate^` where the value is equal to the previous upload date and the current upload date, respectively.
- `^fromID^` where the value is equal to the maximum value of the ID column from the previous upload.

Important:

- When you use `^FromDate^` or `^ToDate^` do not specify an Id column name.
- When you use `^fromID^`, specify an Id Column name and Id column type.

4. If using `^fromID^` specify the ID column name and Id column type for the table defined within the datasource. The specified column name is used for tracking by ID.
5. In the DML command after upload box, enter a DML command (an update or delete SQL statement) with no semicolon, to be executed after uploading the data.

Note: Do not include any newline characters in the SQL statement.

6. To configure Overwrite Default Purge, select Per upload to purge data in the custom table before the upload. Select Per datasource to purge data for that datasource before the upload.

7. Check Default Purge (in the Upload Custom Data screen) to be part of the Default Custom Table Purge Job purge object which has an initial default age of 60 days.

To add a purge schedule for this table, go to initial Custom Table Builder page, select a custom table and click Purge to open a Custom Table Data Purge configuration screen.

8. Check the Use default schedule box only if uploading tables from previous versions of Guardium. This check box only appears in a central manager view and only for the following predefined custom tables: CM Buffer Usage Monitor, Enterprise No Traffic, S-TAP Changes, and S-TAP Info.

9. Click Add Datasource to open the Select Datasource page. From Select Datasource you can identify one or more databases from which to upload the table data. You can add multiple datasources to upload from multiple sources.

Notes:

- For a central manager, on the Import Data page, you can select Include default source. If this box is checked, upload data iterates through all online registered managed units.
- When adding a datasource, the application cannot be scheduled to run without specifying the user name and password of the selected datasource.

10. You can click Check/Repair to compare the schema of the custom table to the schema of the meta-data. In a central management environment, the custom table definition resides on the central manager, and the custom table may not exist on the local (managed unit) database. Click the Check/Repair button to check if the custom table exists locally, and create one if it does not.

11. Click Verify Datasources to test the external database connection. An acknowledgment screen will appear.

12. Click Apply.

13. To upload data to this custom table, do one of the following:

- Click Run Once Now to upload data manually.
- Check Modify schedule to configure the schedule.

## Maintaining custom tables

---

When following the procedure for creating a Custom Table (detailed previously) and selecting a predefined custom table, click Maintenance to manage the table engine type and table index. The table engine types for custom tables/entitlements (InnoDB and MyISAM) will appear for all predefined custom databases as the data stored on the Guardium internal database is MySQL-based. The two major types of table storage engines for MySQL databases are InnoDB and MyISAM. Major differences between these MySQL table engine types:

- InnoDB is more complex while MyISAM is simpler.
- InnoDB is more strict in data integrity while MyISAM is looser.
- InnoDB implements row-level lock for inserting and updating while MyISAM implements table-level lock.
- InnoDB has transactions while MyISAM does not.
- InnoDB has foreign keys and relationship constraints while MyISAM does not.

Note:

- Changing the engine type is disallowed (and the selection grayed out) if the row number in the table is greater than 1M.
- The Length for Text Columns field does not apply to and is not saved for integer-only columns.

The other selection in the Maintain Custom Table menu is Manage Table Index. Click Insert to open Table Index Definition. The pop-up screen suggests columns in the table to add to indexes based on columns used on custom domains as Join conditions. Select the columns and save. Indexes will be created (or re-created).

To maintain performance, MySQL allows a maximum length for indexes:

- MyISAM : 1000 bytes = 333 characters
- InnoDB: 3072 bytes = 1024 characters

The utf8mb3 character set uses 3 bytes per character. If columns with more characters than the limit are required, use a subset of the column length.

For example, instead of :

```
create index a1 on CUSTOM.aaa (id, `System` (255), aaa(255), qqq(255));
```

Use:

```
create index a1 on CUSTOM.aaa (id, `System` (100), aaa(100), qqq(100));
```

## Scheduling custom data uploads

Once a custom table definition is in place, data can be uploaded to custom tables on the Guardium appliance on a scheduled basis.

Note: New installations do not automatically start Enterprise reports. There is one upload schedule for each custom table. The total amount of disk space reserved on the Guardium appliance for custom tables is 4GB.

1. Open the Custom Table Builder.
2. Choose a custom table by clicking on the entity label and highlighting it.
3. Click Upload Data to open the Import Data panel.
4. Mark the Use Default Schedule check box to upload this table using the default schedule. Otherwise, this custom table uses its own upload data schedule.
5. Click Modify Schedule to open the standard Schedule Definition panel and modify the schedule.
6. Click Done when you are finished.

The Enterprise reports custom upload are like other jobs. There are two ways to enable them:

- In the Custom Table Upload GUI. (requires license for custom upload)
- Use GuardAPI from the CLI:

```
grdapapi add_schedule jobName=CustomTablePurgeJob_CM_SNIFTER_BUFFER_USAGE obGroup=customTableJobGroup Enterprise S-TAPS
Changed: grdapapi add_schedule jobName=customTableDataUpload_106 jobGroup=customTableJobGroup CM Buffer Usage Monitor:
grdapapi add_schedule jobName=customTableDataUpload_104 jobGroup=customTableJobGroup S-TAP Info: grdapapi add_schedule
jobName=customTableDataUpload_80 jobGroup=customTableJobGroup
```

Attention: When scheduling custom table jobs, the Start Time defines the time at which the schedule begins each day. For example, setting Start Time to 4 p.m. means the schedule will run from 4 PM until midnight each day. To create schedules that run continuously throughout the day, set Start Time to 12 a.m. (Midnight).

## Creating a custom domain

After defining one or more custom tables, define a custom domain so that you can perform query and reporting tasks using the custom data. The information collected is organized into domains, each of which contains a different type of information relating to a specific area of concern: data access, exceptions, policy violations, etc. There is a separate query builder tool for each domain. Custom domains allow for user-defined domains and can define any tables of data uploaded to the Guardium appliance. See [Custom Domains](#). The usage for these custom entitlement (privileges) domains are for entitlement reports which are found if logged in as a user. To see these reports, go to the user tab, DB Entitlements.

Note: DB Entitlements Domains are optional components enabled by product key. If these components have not been enabled, the choices listed in the Custom Domains help topic will not appear in the Custom Domain Builder selection.

1. Open the Custom Domain Builder by navigating to one of the following:
  - Comply > Custom Reporting > Custom Domain Builder
  - Reports > Report Configuration Tools > Custom Domain Builder
  - Comply > Custom Reporting > Custom Domain Builder
2. Click Domains to open the Domain Finder panel.
3. Click New to open the Custom Tables Domain panel.
4. Enter a Domain Name. Typically, you will be including a single custom table in the domain, so you may want to use the same name for the domain.
5. The Available Entities box lists all custom tables that have been defined (and to which you have access). Select an entity. Optionally, click the (Filter) tool to open the Entity Filter and enter a Like value to select only the entities you want listed, and click Accept. This closes the filter window and returns you to the Custom Tables Domain panel, with only those entities matching the Like value listed in the Available Entities box. Select the entity you want to include.
6. Click the >> arrow button to move the entity selected in the Available Entities list to the Domain Entities list.
7. To add an entity to a domain that already has one or more tables, follow these steps. You will need to use the Join Condition to define the relationship between the entities. For each additional entity:

- Note: When data level security is on, internal entities added to the custom domain cannot belong to different domains with filtering policies.
- a. From the Domain Entities box, select an entity. All of the attributes of that entity will become available in the field drop-down list of the Domain Entities box. Select the attribute from that list that will be used in the join operation.
  - b. From the Available Entities list, select the entity you want to add. All of the attributes of that entity will become available in the field dropdown list of the Available Entities box. Select the attribute from that list that will be used in the join operation.
  - c. Select = (the equality operator) if you want the join condition to be equal (e.g., domainA.attributeB = domainC.attributeD). Select outer join if you want the join condition to be an outer join using the selected attributes.
- Note: Known limitation: After an entity is added, the Detail window in the GUI always displays it as an inner join. However, the correct join condition is saved in the table.
- d. Click Add Field Pair. Add Field Pair can be used to add more attributes pairs of these two entities to the join condition.
  - e. Repeat the steps for any additional join operations.
8. Select the Timestamp attribute for the custom domain entity.
- Note: At least one entity with a timestamp must be used, since a timestamp is required to save a custom domain.
9. Click Apply.

## Modifying a custom domain

---

The goal is to create a linkage between external data and the internal data.

1. Open the Custom Domain Builder.
2. Choose the Custom Domain that you wish to clone.
3. Click Modify to open the Custom Tables Domain panel.
4. See Open Custom Domain Builder and Linking External Data to Internal Data for assistance.
5. Click Apply to save the changes.

## Removing a custom domain

---

1. Open the Custom Domain Builder.
2. Choose the Custom Domain that you wish to clone.
3. Click Domains to open the Domain Finder panel.
4. Click Delete to remove the custom domain.

## Cloning a custom domain

---

1. Open the Custom Domain Builder.
2. Choose the Custom Table that is in the domain you wish to clone.
3. Click Domains to open the Domain Finder panel.
4. Click Clone to open the Custom Tables Domain panel.
5. Change the Domain Name to reflect the new domain.
6. See Open Custom Domain Builder and Linking External Data to Internal Data for assistance.
7. Click Apply to save the changes.

## Linking external data to internal data

---

The goal is to create a linkage between external data and the internal data.

1. Open the Custom Domain Builder.
2. Choose the Custom Table that has your external data.
3. Click Domains to open the Domain Finder panel.
4. Click Modify to open the Custom Tables Domain panel.
5. Click the Filter icon next to the Available Entities.
6. Un-check the Custom box for the filter and optionally fill in a Like condition to filter entity names and click Accept.
7. Select an entity from the Available Entities that you would like to link with your external data.
8. Select the field that will be used to join data with your external data.
9. Highlight the table from the Domain Entities that contains your external data
10. Select the field that will be used to join data with the internal data.
11. Click the Add Field Pair to add the relationship.
12. Click the double arrow >> to add the internal table to the Domain Entities list.
13. Click Apply to save the changes.

## Working with custom queries

---

This section describes how to open the Custom Query-Report Builder. For more information about defining a query, see [Using the Query-Report Builder](#). Use the Custom Query Builder to build queries against data from custom domains, which contain one or more custom tables.

1. From the Custom Query Builder, select a custom domain from the list. The list of queries/reports under this domain opens.
2. To view, modify or clone an existing query, select it from the Query Name list.

## Bidirectional interface to and from InfoSphere Discovery

---

Both IBM® Guardium and InfoSphere® Discovery can identify and classify sensitive data, such as social security numbers or credit card numbers.

A Guardium customer can use a bidirectional interface to transfer identified sensitive data information from one product to another. Those customers who have already invested the time in one InfoSphere product can transfer the information to the other InfoSphere product.

Note: In Guardium, the Classification process is an ongoing process that runs periodically. In InfoSphere Discovery, Classification is part of the Discovery process that usually runs once.

The data is transferred via CSV files.

The summary of Export/Import procedures is as follows:

- Export from Guardium - Run the predefined report (Export Sensitive Data to Discovery) and export as CSV file.
- Import to Guardium - Load to a custom table against CSV datasource; define default report against this datasource.

Follow these steps:

- Export from Guardium
  - Export Classification Data from Guardium to InfoSphere Discovery
1. As an admin user in the Guardium application, go to Tools > Report Building > Classifier Results Tracking > Select a Report > Export Sensitive Data to Discovery.  
Note: Add this report to the UI pane (it is not by default).
  2. Click the Customize icon on the Report Result screen and specify the search criteria to filter the classification results data to transfer to Discovery.
  3. Run the report and click Download All Records.
  4. Save as CSV and import this file to Discovery according to the InfoSphere Discovery instructions.

Import to Guardium

Import Classification Data from InfoSphere Discovery to IBM Guardium

1. Export the classification data as CSV from InfoSphere Discovery based on InfoSphere Discovery instructions.
2. Open the Custom Table Builder by navigating to either of the following:
  - Comply > Custom Reporting > Custom Table Builder
  - Reports > Report Configuration Tools > Custom Table Builder
3. Select ClassificationDataImport and click Upload Data.
4. In Upload Data screen, click Add Datasource, click New, define the CSV file imported from Discovery as new datasource (Database Type = Text).  
Note: Alternatively you can load the data directly from Discovery database if you know how to access the Discovery database and Classification results data.
5. After defining the CSV as Datasource, click Add in Datasource list screen.
6. In Upload data screen click Verify Datasource and then Apply.
7. Click Run Once Now to load the data from the CSV.
8. Go to Report Builder, select the Classification Data Import report, Click Add to Pane to add it to your Portal and then navigate to the report.
9. Access the Report, click Customize to set the From/To dates and execute the report.

The report result has the classification data imported from InfoSphere Discovery. Double-click to invoke APIs assigned to this report. The data imported from Discovery can be used for the following:

- Add new Datasource based on the result set.
- Add/Update Sensitive Data Group.
- Add policy rules based on datasource and sensitive data details.
- Add Privacy Set.

## CSV interface signature

The following table provides examples of CSV interface signatures used in the bidirectional transfer between Guardium and InfoSphere Discovery.

Table 2. CSV Interface signature

| Interface signature                                        | Example                                              |
|------------------------------------------------------------|------------------------------------------------------|
| Type                                                       | Db2                                                  |
| Host                                                       | 9.148.99.99                                          |
| Port                                                       | 50001                                                |
| dbName (Schema name for Db2 or Oracle, db name for others) | cis_schema                                           |
| Datasource URL                                             |                                                      |
| TableName                                                  | MK_SCHED                                             |
| ColumnName                                                 | ID_PIN                                               |
| ClassificationName                                         | SSN                                                  |
| RuleDescription                                            | Out-of-box algorithm of InfoSphere Discovery         |
| HitRate                                                    | 70% - not available for export in Guardium Vers. 8.2 |
| ThresholdUsed                                              | 60% - not available for export in Guardium Vers. 8.2 |

## Privacy sets

A privacy set is a collection of elements that can be used to do special monitoring.

A privacy set consists of one or more object-field pairs - for example, the salary field of the employee table, or all fields of the salary history table. All access to these elements within a given time frame can be reported.

Select any of the topics to work with privacy sets.

## Open the privacy set builder

To access a privacy set definition, your Guardium® user account must be assigned a security role that is also assigned to that privacy set definition. Privacy sets that you cannot access will not display in a list of privacy sets.

To open the Identify Privacy Set page, browse to one of the following locations:

- Comply > Tools and Views > Privacy Set Builder
- Discover > Database Discovery > Privacy Set Builder

From the Identify Privacy Set you can create a new privacy set, modify an existing privacy set, or run a privacy set report.

## Creating a privacy set

---

1. Click the  icon to open the Privacy Set Definition page.
2. In the Privacy Set Description box, enter a unique name for the privacy set. Do not include apostrophe characters in the name. This is the name that will display in the Identify Privacy Set panel.
3. From the Security Classification drop-down list, optionally select a security classification for this privacy set.
4. In the Elements in this Privacy Set pane, for each element pair to include:
  - Enter an object name in the Object box.
  - Enter a field name in the Field box, or mark the Any Field in this Object box to include all fields contained in the specified object.
  - Click Add this new Object – Field Pair.
5. When all elements have been added, click Save.
6. Optionally, click the Roles button to add Roles.
7. Optionally, click the Comments button to add comments.

## Modifying a privacy set

---

1. Select the privacy set you want to modify and click Modify.
2. Make the changes you want to the privacy set definition.
3. Click Save.
4. Click Done when you are finished.

## Cloning a privacy set

---

1. Select the privacy set you want to clone and click Clone.
2. The cloned privacy set is named COPY OF selected privacy set. Guardium suggests that you change this name to something more meaningful.
3. Make any additional changes to the privacy set definition, as necessary. F
4. Click Save.
5. Click Done when you are finished.

## Deleting a privacy set

---

If an auditing process is running, you cannot remove a privacy set. Stop the auditing process, then follow the steps to remove the privacy set.

1. Select the privacy set you want to delete.
2. Click Delete and confirm the action.
3. Click Done.

## Running a privacy set report

---

This procedure describes how to run a privacy set report on demand. To schedule a privacy set report, include it in a compliance workflow (see Compliance Workflow Automation).

1. Select a privacy set from the privacy set list and click Run.
2. In the Task Parameters, enter the starting and ending times for the task.
3. Specify how to display the results:
  - Report by Access Details - Default. Displays the access count for each combination of client IP, server IP, server (name), server type, database protocol, source program name, and database user name
  - Report by Application User - Displays a separate column with that name (following DB User Name) and the output is additionally qualified by the application user.
4. Click Run Once Now. After the report has been executed, it will be displayed in a separate window.
5. Click Done.

---

## Custom Alerting

Alert messages can be distributed via e-mail, SNMP, syslog, or user-written Java™ classes. The last option is referred to as custom alerting.

When an alert is triggered, a custom alerting class can take any action appropriate for the situation; for example, it might update a Web page or send a text message to a telephone number.

To create a custom alerting class, first contact Technical Support to obtain the necessary interface file. The following topic describes how to implement the interface. See Use the Custom Alerting Interface, and also the following topic which contains an example: Sample Custom Alerting Class.

Once the class has been compiled, it must be uploaded to the Guardium® appliance. See Manage Custom Classes.

For guidelines on testing a custom alerting class, see the Test a Custom Alerting Class section later in this topic.

Note: Do not take or run custom code from untrusted data sources to order to reduce the risk of security vulnerabilities.

Note: Do not take or run custom code from untrusted sources.

Note: Do not write a custom class that gets data from an untrusted source.

---

## Use the Custom Alerting Interface

The custom alerting class must be in the com.guardium.custom package and must implement the com.guardium.custom.alerts.CustomerDefinedAlertingIfc interface:

```
package com.guardium.custom
public class YourClassNameHere implements CustomerDefinedAlertingIfc {
```

The interface contains the five methods described.

Table 1. processAlert Method

| Method 1    |                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------|
| Description | Process a single alert message.                                                                                         |
| Syntax      | public void processAlert (String message, Date timeStamp)                                                               |
| Parameters  | A String containing the message generated by the alert.<br>A java.util.Date for the time the alert message was created. |

Table 2. getMessage Method

| Method 2    |                                        |
|-------------|----------------------------------------|
| Description | Return the alert message               |
| Syntax      | public String getMessage ()            |
| Parameters  | A String containing the alert message. |

Table 3. getTimeStamp Method

| Method 3    |                                                              |
|-------------|--------------------------------------------------------------|
| Description | Return the timestamp associated with the alert message.      |
| Syntax      | public Date getTimeStamp ()                                  |
| Parameters  | A java.util.Date for the time the alert message was created. |

Table 4. setMessage Method

| Method 4    |                                           |
|-------------|-------------------------------------------|
| Description | Set the alert message.                    |
| Syntax      | public void setMessage (String inMessage) |
| Parameters  | A String containing the alert message.    |

Table 5. setTimeStamp Method

| Method 5    |                                                              |
|-------------|--------------------------------------------------------------|
| Description | Set the timestamp associated with the alert message.         |
| Syntax      | public void setTimeStamp (Date inDate)                       |
| Parameters  | A java.util.Date for the time the alert message was created. |

## Sample Custom Alerting Class

The following sample program implements the five methods described in the previous section. For the processAlert method, this program simply writes the alert message and timestamp to the system console.

```
/*
 * Sample Custom Alerting Class
 *
 */
package com.guardium.custom;
import java.text.DateFormat;
import java.util.Date;
public class HandleAlerts implements CustomerDefinedAlertingIfc {
private String message = "";
private Date timeStamp = null;
public void processAlert(String message, Date timeStamp) {
setMessage(message);
setTimeStamp(timeStamp);
System.out.println(getMessage() + " on " +
DateFormat.getDateInstance().format(getTimeStamp()));
}
public void setMessage(String inMessage) {
message = inMessage;
}
public String getMessage(){
return message;
}
public void setTimeStamp(Date inDate){
timeStamp = inDate;
}
public Date getTimeStamp(){
return timeStamp;
}
}
```

## Test a Custom Alerting Class

After compiling a custom alerting class, follow the procedure to test it.

1. Upload the custom class to the appliance. This is an administration function that is performed from the Administrator Console. See Manage Custom Classes.
2. Define a correlation or real-time alert to use the custom alerting class. Regardless of which alert type generates the alert, testing is easier if you assign a second notification type (email, for example) against which you can compare the custom alerting results.
3. Check the environment by doing one of the following:
  - For a correlation alert:

- Check that the Anomaly Detection polling interval is suitable for testing purposes and that Anomaly Detection has been started. If the polling interval is too long (it may be 30 minutes or more), you may have a long wait before the query runs.
  - Check that the Alerter polling interval is suitable for testing purposes and that the Alerter has been started.
  - Check that the alert to be tested has been marked Active.
  - For a real-time alert:
    - Check that policy containing the rule with the custom alert action is the installed policy.
    - Verify that the inspection engine was restarted after the updated policy was installed.
    - Check that the Alerter polling interval is suitable for testing purposes and that it has been started.
4. Take whatever action is necessary to trigger the alert (generate a number of login failures, for example).
- 

## Flat Log Process

The Flat Log option is a process to allow the Guardium® appliance to log information without immediately parsing it in real time.

This saves processing resources, so that a heavier traffic volume can be handled. The parsing and amalgamation of that data to Guardium's internal database can be done later, either on a collector or an aggregator unit.

There are two Guardium features involving the Flat Log Process.

- Flat Log by throttling mechanism. This feature is implemented by running the CLI command, **store alp\_throttle 1**. The same policy that is applicable to real-time S-TAP traffic is used to process traffic that was logged by the flat log process. For Flat Log by throttling mechanism, do not select the Flat Log checkbox in the Policy Builder.
- Flat Log by policy definition. Selection of this feature involves **Setup > Tools and Views > Policy Installation and Manage > Activity Monitoring > Flat Log Process**.

Note: Rules on flat does not work with policy rules involving a field, an object, SQL verb (command), Object/Command Group, and Object/Field Group. In the Flat Log process, "flat" means that a syntax tree is not built. If there is no syntax tree, then the fields, objects and SQL verbs cannot be determined.

The following actions do not work with rules on flat policies: LOG FULL DETAILS; LOG FULL DETAILS PER SESSION; LOG FULL DETAILS VALUES; LOG FULL DETAILS VALUES PER SESSION; LOG MASKED DETAILS.

When the Log Flat (Flat Log) checkbox option listed in the Create New Policy pane of the Policy Builder is checked,

- Data is not parsed in real time.
  - The flat logs can be seen on a designated Flat Log List report.
1. Navigate to **Manage > Activity Monitoring > Flat Log Process**.
  2. Select the activity to perform:
    - Process - Merge the flat log information to the internal database.
    - Archive/Aggregation/Purge - Archive or aggregate, and optionally purge, the flat log.
    - Purge Only - Purge the flat log data.
  3. Click **Apply** to save the configuration.
  4. For a Process activity, do one of the following:
    - Click **Run Once Now** to merge the flat log information to the internal database immediately.
    - Click **Modify Schedule** to define a schedule for this activity. You can select the start time, restart frequency, and repeat frequency. For the **Schedule by..** field, you must select either Day/Week or Month. See [Scheduling](#) for more information about scheduling.

## Running database entitlement reports

Database entitlement reports provide up-to-date snapshots of database users and their required access privileges. Learn how to prepare and run these reports to validate and ensure that users have only the privileges that are needed to perform their duties.

### Before you begin

This task requires downloading scripts from a Guardium system and running those scripts on a database server. You need to identify the IP address of the machine that is used to access the Guardium system for downloading scripts. The address can be either an individual workstation where you download the scripts before you transfer them to a database server, or the database server itself. If the relevant scripts for Vulnerability Assessment are already download and run, you can start at step [5](#).

### About this task

Along with authenticating users and restricting role-based access privileges to data, even for the most privileged database users, periodically perform entitlement reviews: validate and ensure that users have only the privileges that are required to perform their duties. This process is known as database user rights attestation reporting.

You can use the Guardium predefined database entitlement (privilege) reports to see who has system privileges and who granted these privileges to other users and roles. Database entitlement reports are important for auditors who are tracking changes to database access, and to ensure that security holes do not exist from lingering accounts or ill-granted privileges.

DB entitlement reports use the Custom Domain feature of Guardium® to create links between the external data on the selected database with the internal data of the predefined entitlement reports. Predefined entitlement reports are available for many data sources, including: Oracle; MySQL; DB2®; Sybase; Sybase IQ; Informix®; MS SQL 2000/2005/2008; Netezza®; Teradata; and PostgreSQL; Db2 on z/OS. For MS SQL Server and Oracle databases you can also use [Entitlement Optimization](#) to access this information. For a full description of the domains in the DB entitlement reports, see [Database Entitlement Reports](#). (For more information about the Custom Domain Builder, Custom Query Builder, or Custom Table Builder, see [External data correlation](#).)

DB Entitlement Reports require access to the database and specific database privileges, similar to Vulnerability Assessments (VA). Both are enabled by scripts that are run in the database itself. (The scripts are used for both VA and entitlement reporting.) Use these database-specific SQL scripts as guidance to define database user roles that connect to the database. Once created, these groups or roles can be assigned to any database user who needs to run an assessment. The available scripts are:

- gdmonitor-db2.sql (for Db2)
- create\_CKADBVA\_schema\_tables\_zOS.sql (for Db2 on zOS)
- gdmonitor-db2-zOS.sql (for Db2 on zOS)
- gdmonitor-mss.sql (for MS-SQL 2005 and up)
- gdmonitor-mss.sql (for MS-SQL 2005 and up)
- gdmonitor-mss-SA.sql (for MS-SQL)
- gdmonitor-mys.sql (for MySQL)
- gdmonitor-netezza.sql (for Netezza)
- gdmonitor-ora.sql (for Oracle)
- gdmonitor-ora-container.sql (for Oracle Container DB)
- gdmonitor-postgres.sql (for PostgreSQL)
- gdmonitor-syb.sql (for Sybase)
- gdmonitor-teradata.sql (for Teradata)
- gdmonitor-sybaseIQ.sql (for SybaseIQ)
- Jconnect\_SybaseIQ\_requirement.txt (for SybaseIQ)
- gdmonitor-db2-IBMi.sql (for Db2 on iSeries)
- gdmonitor-Aster.sql (for Aster)
- gdmonitor-mongodb24.sql (for MongoDB 2.4)
- gdmonitor-mongodb26andAbove.sql (for MongoDB 2.6 and above)
- gdmonitor-hive-Cloudera.sql (for Hive on Cloudera Hadoop distribution)
- gdmonitor-Cloudera-Manager.sql (for Cloudera Manager)
- gdmonitor-DSE-Cassandra.sql (for DataStax Cassandra)
- gdmonitor-SAP-Hana.sql (For SAP Hana)
- gdmonitor-Apache-Cassandra.sql (For Apache Cassandra)
- gdmonitor-azure.sql (For SQL DB Azure)
- gdmonitor-Couchbase.sql (For Couchbase)
- gdmonitor-ifx.sql (For Informix)
- gdmonitor-mariaDB.sql (For MariaDB)
- gdmonitor-mongodb26-To-34.sql (For MongoDB version 2.6 to 3.4)
- gdmonitor-mongodb36andAbove.sql (For MongoDB version 3.6 and up)
- gdmonitor-mss2000-only.sql (For MS SQL Server 2000)
- gdmonitor-Neo4j.sql (For Neo4j)
- gdmonitor-ora-autonomous.sql (For Oracle autonomous)
- gdmonitor-ora-RDS.sql (For Oracle RDS)
- gdmonitor-PerconaMySQL.sql (For Percona MySQL)
- gdmonitor-postgres.sql (For PostgreSQL)
- gdmonitor-Redshift.sql (For Redshift)
- gdmonitor-Snowflake.sql (For Snowflake)
- gdmonitor-syb.sql (For Sybase)
- gdmonitor-sybaseIQ.sql (For SybaseIQ)
- gdmonitor-teradata.sql (For Teradata)

Important: Before you run any scripts, be sure to read the instructions in the script headers and review the database actions that the script takes.

## Procedure

---

1. On a Guardium system, enable the file server by using the **fileserver** CLI command.

For example, to enable the file server for 1 hour and download the scripts to a system with IP address **10.0.0.1**, use the following command:

```
fileserver 10.0.0.1 3600
```

When successfully initiated, the output is similar to:

```
Starting the file server...
The file server is ready at https://guardium.host.com:8445
The timeout has been set to 3600 seconds and it may timeout during the uploading.

The upload will only be accessible from the IP you are logged in from: 10.0.0.1

Press ENTER to stop the file server.
```

2. On the machine where you download the scripts, use a web browser to access the file server.

For example, to access the scripts on a Guardium system that runs at **https://guardium.host.com:8445**, enter the following URL:

```
https://guardium.host.com:8445/log/debug-logs/gdmonitor_scripts/
```

3. Download the required scripts using the web browser's Right-click->Save link as... action or a similar function.

Review the README.txt files to identify the correct scripts to use for specific database types.

4. Follow the instructions in the file header.

5. Add data sources or databases to the appliance.

6. Assign data sources to entitlements (browse to Comply->Custom Reporting->Custom Table Builder. Select the custom table listing of your entitlement. Click Upload Data. Assign data sources to the entitlement report at the Import Data menu screen. When you are done, click Run Once Now.

7. To see entitlement reports, type the report name in the Quick Search.
- 

## User Identification

Guardium® provides several methods to identify application users, when the actual database user is not apparent from the database traffic.

Some database applications are designed to use or share a small number of database user accounts. These applications manage their users independently of the database management system, which means that when observing database traffic from outside of the application, it can be difficult to determine the application user who is controlling a database connection at any given point in time. However, when questionable database activities occur, you need to relate specific actions to specific individuals, rather than to an account shared by groups of individuals. In other words, you must know the application user, not just the database user.

Guardium provides several methods to identify application users, when the actual database user is not apparent from the database traffic:

- Identify Users via Application User Translation - For some of the most popular commercial applications (Oracle EBS, PeopleSoft, SAP, etc.), Guardium can identify users automatically.
- Identify Users via API - The Application Events API allows you to signal Guardium when an application user takes or relinquishes control of a connection, or when any other event of interest occurs. (This can be used for more than just identifying users.)
- Identify Users via Stored Procedures - Many applications use database stored procedures to identify the application user. In these cases, user information can usually be extracted from the stored procedure parameters.

Within the enterprise, it may be necessary to employ several methods to identify users, depending on the applications used.

- **[Identify Users using the Application User Translation](#)**

Some applications manage a pool of database connections. In such three-tier architectures the pooled connections all log in to a database by using a single functional ID, and then manage all application users internally. When a user session needs access to the database, it acquires a connection from the pool, uses it and then releases it back to the pool. Guardium sees how the application interacts with the database, but it cannot attribute specific database actions to specific application users. For some widely used applications, Guardium has built-in support for identifying the end-user information from the application, and can relate database activity to the application end users.

- **[Identify Users with API](#)**

Some applications that manage users internally, cannot identify application user from the traffic. You can use the Application Events API to signal Guardium when a user acquires or releases a connection, or when any other event of interest occurs. The Application Events API provides simple calls that can be issued from within the application for this purpose.

- **[Identify Users via Stored Procedures](#)**

In many existing applications, all of the information needed to identify an application user can be obtained from existing database traffic, from stored procedure calls. Once Guardium knows what calls to watch for, and which parameters contain the user name or other information of interest, users can be identified automatically.

---

## Identify Users using the Application User Translation

Some applications manage a pool of database connections. In such three-tier architectures the pooled connections all log in to a database by using a single functional ID, and then manage all application users internally. When a user session needs access to the database, it acquires a connection from the pool, uses it and then releases it back to the pool. Guardium® sees how the application interacts with the database, but it cannot attribute specific database actions to specific application users. For some widely used applications, Guardium has built-in support for identifying the end-user information from the application, and can relate database activity to the application end users.

To use this function, follow these procedures:

1. Define an Application User Translation configuration for the application. See [Configure Application User Detection](#).
2. Populate any pre-defined groups that are required for that application. See [Populate Pre-defined Application Groups](#).
3. Create a report that includes the Application User Translation, using the APP\_USER\_NAME attribute in the App User Name Entity of the Access domain. Add the report(s) to your dashboard. There are predefined reports for EBS (EBS Application Access) and Peoplesoft (PSFT Application Access) that include this attribute. You can use these reports, or copy and modify them. See [Using the Query-Report Builder](#).

---

## Selective Audit Trail and Application User Translation

If the installed data access policy uses the selective audit trail feature to limit the amount of data logged, take note of these important considerations that apply to application user translation:

- The policy ignores all of the traffic that does not fit the application user translation rule (for example, not from the application server).
- Only the SQL that matches the pattern for that security policy is available for the special application user translation reports.

---

## Application user aliases

Each alias is a colon-separated string in the format **AppUserName :**

**Responsibility.** Responsibility can be empty. For example, the alias for APPLICATION USER is created by querying the Oracle Database server to get the App User Name. The Oracle Database server is defined in the GUI as either SERVER IP or Connect to Server IP if it is not empty. The Responsibility is based on the ID of the Value column (the DB\_VALUE of the ALIAS table in the format APPS\_CODE : ID).

---

## Oracle EBS with multiple interfaces

Guardium does not have specific pre-defined reports for Oracle EBS Application User Translation. Use the APP\_USER\_NAME in the Access domain to create your own reports.

When you add a new interface for an Oracle EBS server that is already defined, add another Data Source using the Connect to Server IP field. See step [13](#).

---

## Configure Application User Detection

1. Go to Protect > Database Intrusion Detection > Application User Translation. Details for existing application user translation configurations are displayed at the top of the page.

2. Type a unique code in the Application Code box.

Note: Under Central Management, you must use different application codes on different managed machines. This prevents aliases generated for the users from conflicting with each other. (Under Central Management, there is one set of aliases that is shared by all managed units.)

3. From the Application Type list, select the application type:
  - BO-WI - Business Objects / Web Intelligence
  - EBS - Oracle E-Business Suite
  - PeopleSoft
  - SAP Observed
  - SAP DB
  - SIEBEL Observed
  - SIEBEL DB
4. In the Application Version box, enter the application version number (11, for example).
5. From the Database Type list, select the database type. Only the types that are available for the selected Application Type and Version are displayed.  
Note: When the Application Type is set to EBS, SIEBEL DB, or SAP DB, you have the option of selecting from preexisting datasources by clicking Add Datasource. The datasource must match one of the supported database types for the application type being configured.
6. In the Server IP box, type the IP address the application uses to connect to the database.
7. In the Port box, type the port number the application uses to connect to the database.
8. In the Instance Name box, type the instance name the application uses to connect to the database.
9. In the DB Name box, type the database name for the application. (Required for some applications, not used for others.)
10. Check the Active box to enable user translation. Nothing is translated until after the first import of user definitions.
11. Enter a User Name for Guardium to use when accessing the database. Enter a password for Guardium to use when accessing the database.
12. Select the Responsibility box if you want to associate responsibilities (Administration, for example) with user names. Or clear the Responsibility box to just record user names. When the box is cleared, all activities performed by a user are grouped together, regardless of the responsibility at the time the activity occurred.
13. If the Application Type is EBS (Database Type is Oracle), two additional choices appear: Connect to Server IP and Connect to User Name. If populated, the system connects using that IP and username in order to retrieve the Responsibility and User Names. To support an Oracle Cluster Database that has multiple private/virtual interfaces for EBS connections and one public interface for the Guradium connection, create multiple "Application User Translation" configurations. For each configuration, enter one of the Virtual/Private interface IP addresses in the Server IP field and enter the public connected interface IP address to the Connect to Server IP field. Make sure this IP is connectable with Guardium and is able to retrieve the Responsibility and Application User Name.
14. Click Add to save the Application User Translation definition.
15. Continue to the procedure [Populate Pre-defined Application Groups](#)
16. Go to Manage > Activity Monitoring > Inspection Engines and click Restart Inspection Engines in the Inspection Engine Configuration panel.
17. Return to the Application User Translation page, click Run Once Now to import the user definitions for this application (and any others defined).
18. The data import of Application User Translation can be confirmed by looking at predefined reports, for example SAP Application Access. Go to Reports > Report Configuration Tools > Query-Report Builder and choose the report SAP Application Access. Regenerate this report and add to a pane, then set the date range to rather large (for example, go back a year for data).
19. In the Application User Translation page, click Modify Schedule to define an import operation to run on a regular basis. You should schedule the importing of user definition data at whatever interval is suitable for your environment. The maximum time that a new application user name is not available is the time between executions of the import operation. For instructions on how to use the scheduler, see [Scheduling](#)

Note: The first time Run Once Now is clicked after installing the Application User Translation setting(s), it retrieves the last update-date for the tables it looks at.

## Populate Pre-defined Application Groups

When Application User Translation has been configured, you must populate at least two pre-defined groups with information that is specific to your environment. This table identifies the groups that must be populated for each application type. For instructions on how to populate a group, see [Groups overview](#).

| Application | Pre-Defined Group  | Group Type |
|-------------|--------------------|------------|
| EBS         | EBS App Servers    | Client IP  |
|             | EBS DB Servers     | Server IP  |
| PeopleSoft  | PSFT App Servers   | Client IP  |
|             | PSFT DB Servers    | Server IP  |
|             | PeopleSoft Objects | Objects    |
| Siebel      | SIEBEL App Servers | Client IP  |
|             | SIEBEL DB Servers  | Server IP  |
| SAP         | SAP App Servers    | Client IP  |
|             | SAP DB Servers     | Server IP  |
|             | SAP - PCI          | Objects    |

## Unwilling to give DB\_USER PASSWORD for EBS application

In some cases you won't want to use the Oracle EBS DB\_USER for translating EBS traffic. In this scenario, when setting up Oracle EBS and wanting to translate traffic with Application User Translation, there are two choices to make it work:

- Supply the username and password that EBS uses to talk to Oracle (often APPS/\$passwd).
- If you don't want to provide the password the DB\_USER EBS uses to access Oracle, it is still possible to use Application User Translation, however the process is more complicated.

1. Make/choose a login for Oracle that permits access to the database for gathering aliases/users/responsibilities. That user needs access to the table [APPLSYS.FND\_USER and the view FND\_RESPONSIBILITY\_VL which combines two tables: APPLSYS.FND\_RESPONSIBILITY and APPLSYS.FND\_RESPONSIBILITY\_TL.

```
(CREATE VIEW FND_RESPONSIBILITY_VL AS SELECT /* $HEADER$ */ B.ROWID ROW_ID , B.WEB_HOST_NAME ,
B.WEB_AGENT_NAME , B.APPLICATION_ID , B.RESPONSIBILITY_ID ,
B.RESPONSIBILITY_KEY , B.LAST_UPDATE_DATE , B.LAST_UPDATED_BY ,
B.CREATION_DATE , B.CREATED_BY , B.LAST_UPDATE_LOGIN ,
B.DATA_GROUP_APPLICATION_ID , B.DATA_GROUP_ID , B.MENU_ID ,
B.START_DATE , B.END_DATE , B.GROUP_APPLICATION_ID ,
B.REQUEST_GROUP_ID , B.VERSION , T.RESPONSIBILITY_NAME ,
T.DESCRIPTION FROM FND_RESPONSIBILITY_TL T , FND_RESPONSIBILITY B
```

```
WHERE B.RESPONSIBILITY_ID = T.RESPONSIBILITY_ID
AND B.APPLICATION_ID = T.APPLICATION_ID
AND T.LANGUAGE = USERENV('LANG'))
```

2. Run the following SQL statements directly from the Oracle EBS system:  
`select RESPONSIBILITY_ID, RESPONSIBILITY_NAME from FND_RESPONSIBILITY_VL order by RESPONSIBILITY_ID; and select USER_ID, USER_NAME from FND_USER order by USER_ID;`

Once the user is set up so that those two statements successfully run, two different Application User Translation entries are needed. Both need to have the same server IP, port, and instance name, (and of course EBS and Oracle chosen for APP type and APP server type).

It does not matter if the Application Code is identical or not. One entry needs the username that EBS uses to connect to the database (usually APPS), but you can put in an incorrect (dummy) password. The second entry needs the username and password that has been created to access those tables.

3. Once both are entered with Active and Responsibility selected, click Run Once Now, and start or restart EBS (assuming that there is an Inspection Engine (S-TAP or net) looking at the traffic). The collection of data and the assignment of APPS user names to that data for the EBS traffic now takes place.

## Oracle privileges needed for the Oracle EBS App User

Translation:

1. Grant select on the following tables to Custom DB User:
  - APPLSYS.FND\_USER
  - APPLSYS.FND\_RESPONSIBILITY
  - APPLSYS.FND\_RESPONSIBILITY\_TL
2. Create a private synonym FND\_USER on APPLSYS.FND\_USER for Custom DB User.
3. Create a view called FND\_RESPONSIBILITY\_VL for Custom DB User. You can find this view under the APPS user to use as your template.

## How to Validate SAP Stack for Application User Translation

When supporting IBM® Guardium SAP Application User Translation, there is a difference between the ABAP Stack and Java™ Stack.

Note:

ABAP Stack and Java Stack have different kernel specifications.

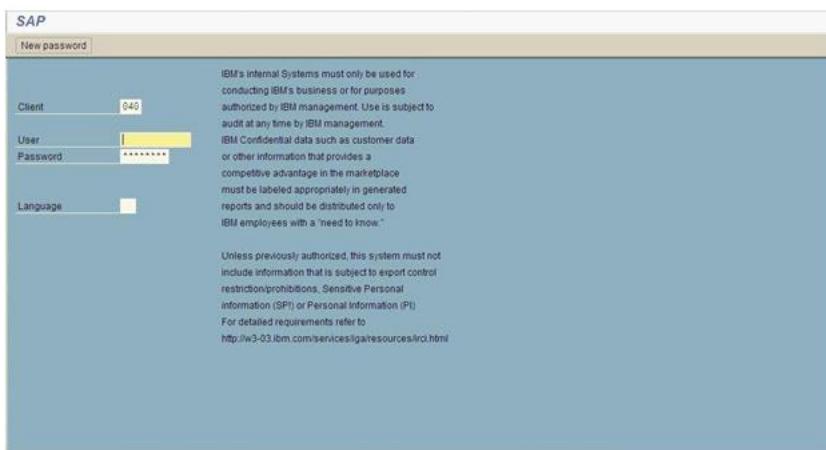

ABAP Stack and Java Stack systems have different tables.

ABAP Stack

Traditional ECC (Enterprise Core Components) SAP systems are written in ABAP code and are predominantly accessed via the SAP GUI, although web access is possible.

SAP ABAP systems have direct (read/write/update) access to traditional SAP databases. The databases are very large and contain all the sensitive data. This is where IBM Guardium is best utilized.

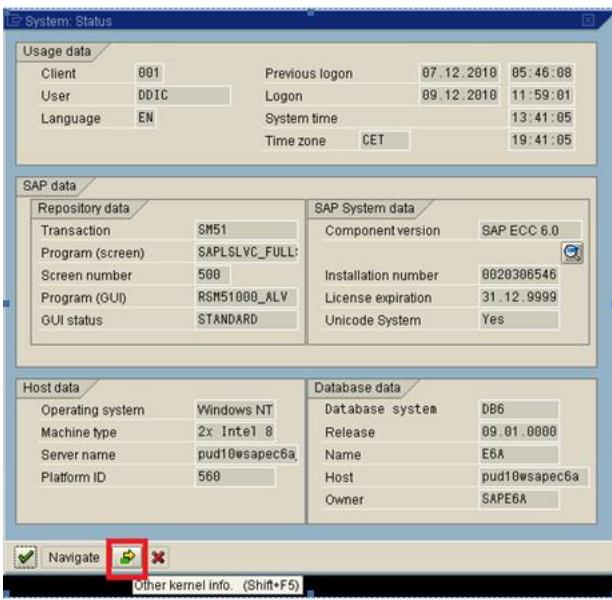

The following screen appears when you enter the SAP GUI (ABAP Stack):

1-SAP GUI (ABAP Stack)

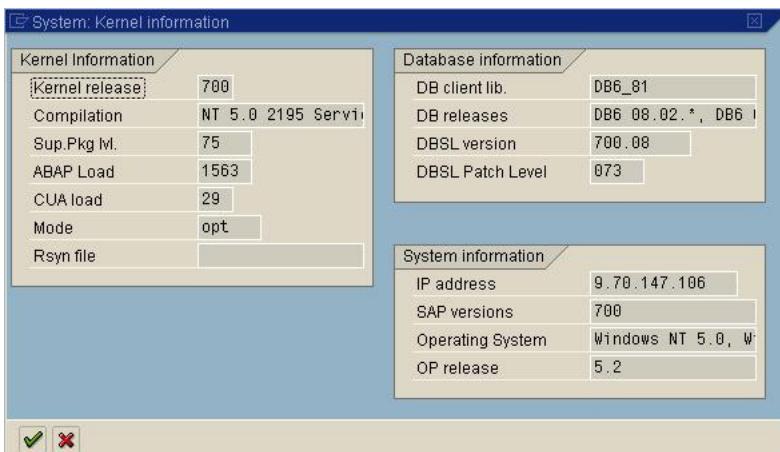

To validate the ABAP Stack SAP Kernel module for Application User Translation, follow these steps:

1. Log in to SAP.
2. Go to System > Status

2-System Status (ABAP Stack)

3. Click Other Kernel Info on the System Status screen.

3-System Kernel Information (ABAP Stack)

In this example, the kernel is 700.

SAP with a DB2® backend is also available for SAP kernel 640, but the user needs to set DB6\_DBDSL\_ACCOUNTING=1 (in kernel 700 and up, this DB6\_DBDSL\_ACCOUNTING value is 1 by default). SAP for Oracle backend requires a kernel of 710 or higher.

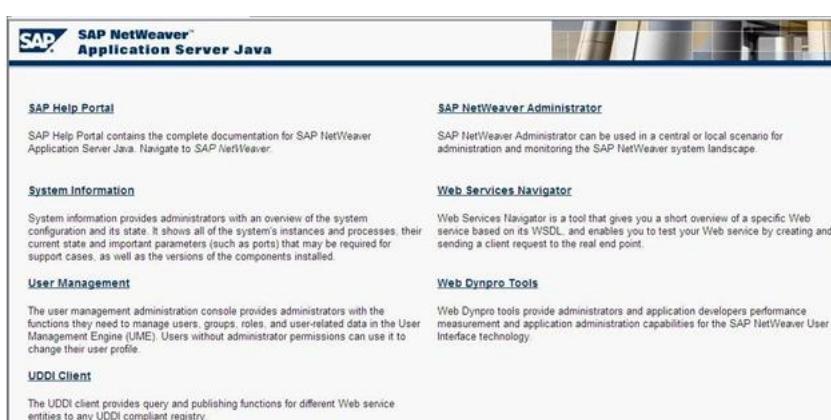

Data gets put into the app user field and the app event string.

Java Stack

SAP Portal systems are written in Java code and are the front end web applications utilizing pre-canned queries to display SAP related web pages.

Portal systems can only be accessed via a web browser. Portal system databases are much smaller with only a few tablespaces.

The following screen appears when you enter SAP Portal System (Java Stack).

#### 4-SAP Portal System (Java Stack)

To validate the Java Stack SAP Kernel module for Application User Translation, follow these steps: 1. Click on System Information.

The screenshot shows the SAP System Information interface with the 'System TCJ' tab selected. It displays detailed information about the system components:

- Message Server:** Host: magn13, Port: 2901, Type: DB2/AIX64 (SQL,09056).
- Enqueue Server:** Host: magn13, Port: 2021.
- Database:** Name: TCJ, Host: magn13, Type: DB2/AIX64 (SQL,09056).
- Software Components:** Name: sap.com/SAP-JECCOR, Version: 7.00 SP22 (1000.7.00.22.6.2010114162028), Applied: 2010523001119, License Number: 0020278108, System Number: 000000000310632781.
- Instance JC00:** Host: magn13, OS: AIX (ppc64) 5.3.
- dispatcher:** PID: 1002719, Node ID: 2919900, Name: IBM 39 VM, Vendor: IBM Corporation, Version: 2.3, JMI Parameters: Telnet Port: 50008.
- server01:** VM, system properties, Cluster, Node ID: 2919950, Kernel Version: 7.00 PatchLevel 97159.450.
- SDM:** VM, PID: 868526, SDM Port: 50018.

#### 5-System TCJ (Java Stack)

In this example, the SAP Kernel version is 7.00.

SAP for either Db2 or Oracle requires a kernel of 7.02 or higher.

SAP sets similar client properties in the Java stack as it did for ABAP Stack.

## Identify Users with API

Some applications that manage users internally, cannot identify application user from the traffic. You can use the Application Events API to signal Guardium® when a user acquires or releases a connection, or when any other event of interest occurs. The Application Events API provides simple calls that can be issued from within the application for this purpose.

Note: If your Guardium security policy has Selective Audit Trail enabled, the Application Events API commands that are used to set and clear the application user and/or application events are ignored by default, and the application user names and/or application events are not logged. To log these items so that they are available for reports or exceptions, include a policy rule to identify the appropriate commands, specifying the Audit Only rule action.

## GuardAppUser - Identify Users by API

Use two pre-defined triggers to set both Application User names and Application Event data.

- GuardAppEvent
- GuardAppUser

These each have start and stop triggers, and the Event has sub-triggers to set Type, Username, StrValue, NumValue, and Date.

The Guardium system is able to read special Select statements for the AppUserName and the AppEvent details.

The form is:

```
Select "action" [additional parameters] FROM [location]
```

Table 1. Action options

| Syntax                  | Action                                                         |
|-------------------------|----------------------------------------------------------------|
| GuardAppUser:<username> | Set GDM_CONSTRUCT_INSTANCE.APP_USER_NAME to <username>         |
| GuardAppUserReleased    | Clear APP_USER_NAME for subsequent queries                     |
| GuardAppEvent:Start     | Start a GuardAppEvent (and it looks for additional parameters) |
| GuardAppEvent:Released  | End a GuardAppEvent (clears info for subsequent queries)       |

Table 2. Additional parameters (which set the values in GDM\_APP\_EVENT)

| Parameters                             | Syntax                                           |
|----------------------------------------|--------------------------------------------------|
| GuardAppEventType: <event type string> | Set APP_EVENT_TYPE to <event type string>        |
| GuardAppEventUserName:<evntursname>    | Set GDM_APP_EVENT.APP_USER_NAME to <evntursname> |
| GuardAppEventStrValue:<strvalue>       | Set EVENT_VALUE_STR to <strvalue>                |
| GuardAppEventNumValue:<num>            | Set EVENT_VALUE_NUM to <num>                     |
| GuardAppEventDateValue:<date>          | Set EVENT_DATE to <date>                         |

Some examples of select statements follow:

Select guardappuser:tiberius from dual

Select guardappuserreleased from dual

Select GuardAppEvent:Start, GuardAppEventType:Event1, GuardAppEventUserName:Tiberius, GuardAppEventStrValue:abc, GuardAppEventNumValue:123, GuardAppEventDateValue:2016-01-26 15:55:28 from dual

Select GuardAppEvent:Released from dual

The FROM portion of the statement varies by database type.

Oracle: from DUAL  
Db2 from SYSIBM.SYSDUMMY1  
Informix from SYSTABLES  
MS-SQL <blank>  
Sybase <blank>  
MySQL either <blank> or from DUAL

## Guardium Identify App User name and Named Templates

---

There are several way to capture App User Name through Guardium. Guardium has two Turbine tables where APP\_USER\_NAME field values are stored, based on the way the data was received:

GDM\_CONSTRUCT\_INSTANCE  
GDM\_APP\_EVENT

The Named template %%AppUserName parameter in Guardium (see Global Profile menu) is mapped to the Turbine table, GDM\_CONSTRUCT\_INSTANCE. In order to use it in the Named Template, Guardium needs the APP\_USER\_NAME in the GDM\_CONSTRUCT\_INSTANCE table to be populated with the App User value.

Change the syntax of SQL command in the application to the following:

```
SELECT 'GuardAppUser:<value>'
```

This will put the values into the right table and this will replace the %%AppUserName parameter in the Named template with the right value.

Example

.....

```
select 'GuardAppUser:DB2_User' FROM SYSIBM.SYSDUMMY1 ;
select * from AppUser_DB2;
select 'GuardAppUserReleased' FROM SYSIBM.SYSDUMMY1 ;
select * from NoMoreUser_DB2;
```

.....

Look for the results in /var/log/messages file:

```
Jan 24 12:49:41 vx64 guard_sender[28274]: LEEF:1.0|IBM|Guardium|10.0|Alert per match|ruleID=20003|ruleDesc=Alert per match|severity=INFO|devTime=2016-01-24
11:50:39|serverType=DB2|classification=|category=|dbProtocolVersion=3.0|usrName=Db2_User|sourceProgram=DB2JCC_APPLICATION|start=1448383760000|dbUse=r=DB2INST1|dst=9.70.144.126|dstPort=50000|src=9.70.144.126|srcPort=58781|protocol=TCP|type=SQL_LANG|violationID=20|sql=select * from AppUser_DB2 FOR
READ ONLY|error=
```

## Set the Application User via GuardAppUser

---

Use this call to indicate that a new application user has taken control of the connection. The supplied application user name will be available in the Application User attribute of the Access Period entity. For this session, from this point on, Guardium will attribute all activity on the connection to this application user, until Guardium receives either another GuardAppUser call or a GuardAppUserReleased call, which clears the application user name.

To signal when other events occur (you can define event types as needed), use the GuardAppEvent call, described in the following section.

Syntax: `SELECT 'GuardAppUser:user_name' FROM location`

`user_name` is a string containing the application user name. This string will be available as the Application User attribute value in the Access Period entity.

`FROM location` is used only for Oracle, DB2®, or Informix®. (Omit for other database types.) It must be entered exactly as follows:

- Oracle: `FROM DUAL`
- Db2: `FROM SYSIBM.SYSDUMMY1`
- Informix: `FROM SYSTABLES`

Note: For Db2 for z/OS traffic, add a slash star comment enclosing 'GuardAppUser:user\_name' inside the SQL query. For example:

```
select /* 'GuardAppUser:user_name' */ col from tbl
```

## Clear the Application User via GuardAppUserReleased

---

Use the GuardAppUserReleased call to signal that the current user has relinquished control of the connection. Guardium will clear the application user name, which will remain empty for the connection until it receives another GuardAppUser call.

Syntax: `SELECT 'GuardAppUserReleased' FROM location`

`FROM location` is used only for Oracle, Db2, or Informix. (Omit for other database types.) It must be entered exactly as follows:

- Oracle: `FROM DUAL`
- Db2: `FROM SYSIBM.SYSDUMMY1`
- Informix: `FROM SYSTABLES`

## Set an Application Event via GuardAppEvent

---

This call provides a more generic method of signaling the occurrence of application events. You can define your own event types and provide text, numeric, or date values to be stored with the event, both when the event starts and when it ends. You can use this call together with the GuardAppUser call. Guardium will attribute all activity on the connection to this application event, until it receives either another GuardAppEvent:Start command or a GuardAppEvent:Released command.

Syntax:

```
SELECT 'GuardAppEvent:Start|Released',
'GuardAppEventType:type',
'GuardAppEventUserName:name',
'GuardAppEventStrValue:string',
'GuardAppEventNumValue:number',
'GuardAppEventDateValue:date' FROM location
```

Start | Released - Use the keyword Start to indicate that the event is taking control of the connection or Released to indicate that the event has relinquished control of the connection.

type identifies the event type. It can be any string value, for example: Login, Logout, Credit, Debit, etc. In the Application Events entity, this value is stored in the Event Type attribute for a Start call, or the Event Release Type attribute for a Released call.

name is a user name value to be set for this event. In the Application Events entity, this value is stored in the Event User Name attribute for a Start call, or the Event Release User Name attribute for a Released call.

string is any string value to be set for this event. For example, for a Login event you might provide an account name. In the Application Events entity, this value is stored in the Event Value Str attribute for a Start call, or the Event Release Value Str attribute for a Released call.

number is any numeric value to be set for this event. For example, for a Credit event you might supply the transaction amount. In the Application Events entity, this value is stored in the Event Value Num attribute for a Start call, or the Event Release Value Num attribute for a Released call.

date is a user-supplied date and optional time for this event. It must be in the format: yyyy-mm-dd hh:mm:ss, where the time portion (hh:mm:ss) is optional. It may be the current date and time or it may be taken from a transaction being tracked. In the Application Events entity, this value is stored in the Event Date attribute for a Start call, or the Event Release Date attribute for a Released call.

FROM location is used only for Oracle, Db2, or Informix. (Omit for other database types.) See the following example. However, any dummy table name is acceptable for the dummy SQL.

- Oracle: FROM DUAL
- Db2: FROM SYSIBM.SYSDUMMY1
- Informix: FROM SYSTABLES

The GuardAppEvent call populates an Application Events entity (see Application Events Entity in the Entities and Attributes section of the Appendices). When creating Guardium queries and reports, you can access the Application Events entity from either the Access Tracking domain or the Policy Violations domain.

If any Application Events entity attributes have not been set using the GuardAppEvent call, those values will be empty.

Regarding the two date attributes:

- Event Date is set using the GuardAppEvent call, or from a custom identification procedure as described in the following section.
- Timestamp is the time that Guardium stores the instance of the Application Event entity.

---

## Identify Users via Stored Procedures

In many existing applications, all of the information needed to identify an application user can be obtained from existing database traffic, from stored procedure calls. Once Guardium® knows what calls to watch for, and which parameters contain the user name or other information of interest, users can be identified automatically.

In the simplest case, an application might have a single stored procedure that sets a number of property values, one of which is the user name. A call to set the user name might look like this:

```
set_application_property('user_name', 'JohnDoe');
```

In a custom procedure mapping (described later), you can tell Guardium to:

- Watch for a stored procedure named set\_application\_property, with a first parameter value of user\_name.
- Set the application user to the value of the second parameter in the call (JohnDoe, in the example).

There may be multiple stored procedures for an application: one to start an application user session, one to end a session, and others to signal key events particular to that application. Guardium's custom identification procedure mechanism can be used to track any application events you want to monitor.

Since each of your applications may have a different way of identifying users, you may have to define separate custom identification procedure mappings for each application. To do that, follow the procedure outlined.

---

## Define a Custom Identification Procedure Mapping

1. Navigate to Protect > Database Intrusion Detection > Custom ID Procedures.
2. To view an existing mapping, hold the mouse pointer over the More Info column icon for the row containing the map you want to view.
3. To add a mapping, click Add.

4. In the Custom Map Name box, enter the name to be used for this mapping.
5. In the Procedure Name box, enter the name of the database procedure that will supply information.
6. Select Set or Clear from the Action list to indicate whether the procedure call will set or clear application values.
7. If application information can be obtained from an existing stored procedure call, but only under one or two conditions:
  - Use a Condition Location box to specify which stored procedure call parameter is to be tested
  - Use the corresponding Condition Value box to specify the value that must be matched to set application information from one or more of the other parameters.
  - For example, assume that a stored procedure named set\_context is used by an application to set a number of values, one of which is the user name. The procedure is passed three parameters: an application name, a property name, and a value. Three typical calls are illustrated:
    - set\_context('publishing\_application', 'role\_name', 'manager');
    - set\_context('publishing\_application', 'user\_name', 'jsmith');
    - set\_context('publishing\_application', 'company', 'guardium');
  - In the examples, the second statement illustrates the format of the call we are interested in. The second parameter (the property name) is the parameter that needs to be tested, so 2 would be entered in the Condition1 Location box, and user\_name in the Condition1 Value box.
  - If a second format of the call also sets the user name, then the Condition2 Location and Value boxes can be used. For example, assume that the following format of the procedure call is sometimes used to set a user name:
    - set\_context('admin\_application', 'admin\_name', 'wjones');
  - To use this procedure, to set the application user name, enter 2 in the Condition2 Location box, and admin\_name in the Condition2 Value box.

Note: If two conditions are used, the user name or any other information being extracted must be in the same parameter position for both types of calls.
8. For a Clear action:
  - To clear the application user only, set Application Username Position to 1 and all other positions to zero.
  - All other clear actions will clear the application event and the application user.
9. For a Set action, use the Parameter Position pane to indicate which stored procedure parameters map to which Guardium application event attributes. The first procedure parameter is numbered 1. Use 0 (zero – the default) for all attributes that are not set by the call. Application Username Position – Enter the parameter position of the application user name you want associated with database activity from this point forward (until reset, as described previously). Event String Value Position – Enter the parameter position of a string value for the event (for a login, this might be a user or account name). Event Number Value Position – Enter the parameter position of a numeric value for the event (for a transaction, this might be a dollar amount). Event Type Position – Enter the parameter position of a name for the event type (Login, Logout, Credit Request, etc.). Event Date Position – Enter the parameter position of a date/time value for the event. The format must be yyyy-mm-dd hh:mm:ss. The time portion (hh:mm:ss) is optional, and if omitted will be set to 00:00:00.

Note: If the Application Username Position is the only field configured and there is no current application event associated with this session, no new event will be created. Instead, the application user will be available in the Access Period Application User. If there is a current application event associated with this session, the application user will be updated in the Access Period Application User, and in a new application event.

10. In the Server Information pane: Select the database server type from the Server Type list. Enter the database user name in the DB Username box. Optional: Enter a database name in the Database Name box. If omitted, all databases will be monitored. Optional: Identify one or more servers. If no server is specified, all servers will be monitored. To select a specific server only, enter the server IP address and network mask in the Server IP and Server Net Mask boxes; or, to select a group of servers, select a server group from the Server IP Group list or click the Groups button to define a new group of servers.
11. When you are done, click the Add button to add the mapping to the list.
12. Reinstall the policy on the Guardium collector where you defined the custom ID procedure. The stored procedures will not be analyzed and processed by Guardium until the policy is reinstalled.

## Value Change Auditing

The Value Change Auditing feature tracks changes to values in database tables.

The Value Change Auditing feature tracks changes to values in database tables. For each table in which changes are to be tracked, you select which SQL value-change commands to monitor (insert, update, delete). Each time a value-change command is run against a monitored table, before and after values are captured. On a scheduled basis, the change activity is uploaded to a Guardium® system, where all the reporting and alerting functions can be used. The basic steps to perform to use the Value Change Auditing feature are:

1. Create an audit database on the database server. This database is where value-change data is stored until it is uploaded to the Guardium system. See [Creating an Audit Database](#).
2. Identify the tables to be monitored, and for each table select the value-change commands (insert, delete, update) for which changes will be recorded. To record the changes, a trigger is created for each table to be monitored, and that trigger writes the value-change data to the audit database. To allow updates to the audit database (by the trigger), all users with update privileges for the monitored table are given appropriate privileges for the audit database. This has implications for users who are given update privileges for that table later (see step 4). For detailed instructions on how to define the monitoring activities, see Define Monitoring Activities.
3. Schedule uploads to transfer value-change data from the database server to the Guardium system. See Schedule Value-Change Uploads.
4. Maintain audit database access privileges. After a trigger has been created, a new user may be given access to the table on which the trigger is based. If that user issues a monitored value-change command, it will fail because that user will not have appropriate privileges to update the audit database. See Maintain Privileged Users Lists.
5. Monitor change activity from the administrator console, or use the Value Change Tracking query domain to create custom reports on the Guardium appliance. See Value-Change Reporting.

## Define Monitoring Activities

After you define an audit database, use the Value Change Auditing Builder to identify the tables to be monitored, and to select the types of changes (inserts, updates, deletes) to be recorded.

1. Open the Value Change Auditing Builder by navigating to Harden > Configure Change Control (CAS Application) > Value Change Auditing Builder.
2. Click Add Datasource to open the Select datasource window.
3. Select a datasource on which an audit database is defined, or click  to define a new audit database. For information about defining an audit database, see [Creating an Audit Database](#).
4. Click Save to close the Select datasource window and add the selected datasource to the Value Change Audit page.
5. Optionally enter a Schema Owner and/or Object Name to limit the number of tables that are displayed when choosing the tables to be monitored. You can use the % (percent) wildcard character. For example, to limit the display to all tables that begin with the letter a, enter a% in the Object Name box.
6. Click Choose Tables To Monitor to open the Define Data Audit panel.

7. Mark the Select box for each table to be monitored.

Attention: For Microsoft SQL Server, Sybase, and Sybase IQ, the Guardium system does not receive audit updates to any column that is a primary key or part of a composite key.

Note: You cannot define a trigger for a table that contains one or more user-defined data types.

The Trigger Defined column indicates if a trigger is already defined for the table. The Audit Insert, Audit Delete, and Audit Update check boxes indicate if the trigger will record changes for that command.

If the Trigger Defined column is not marked, marking the Select checkbox for a table automatically marks all three the Audit checkboxes (Audit Insert, Audit Delete, and Audit Update). If you do not want to monitor one or two of those commands, clear the appropriate checkbox.

8. Click Add Selections to define triggers for the selected tables. You will be informed of the action taken.

9. Click OK to close the message box and re-display the Define Data Audit panel. The selected tables remain selected, and the Trigger Defined column is now marked for those tables. Note: The instant a trigger is defined for a table, it is active and recording changes for the selected commands in the audit database. The configuration of triggers is done entirely on the database server, which is unlike most other Guardium configurations, which are defined on the Guardium database, and then activated or deactivated as a separate task.

10. To define additional actions, repeat these steps, or remove triggers by marking the appropriate Select check boxes and clicking Remove Selections.

11. Click Done after you complete all changes.

Note: The Cancel button does not back out any changes that you have made to triggers using the Add or Remove Selections buttons.

## After Defining Monitoring Activities

---

If you have added value-change monitoring activities to a datasource for the first time, you should schedule uploads for this datasource, because the audit database will be emptied only after the data recorded there has been uploaded to the Guardium system. See the next section.

## Schedule Value-Change Uploads

---

1. Open the Value Change Auditing Builder by navigating to Harden > Configure Change Control (CAS Application) > Value Change Auditing Builder.

2. Select the audit datasource for which you want to schedule uploads, and click Schedule Upload to open the general-purpose task scheduler. If you need help defining a schedule, see Scheduling in the Common Tools book.

## Maintain Privileged Users Lists

---

When the value-change feature adds a trigger for a database table, all current users with permission to update that table are granted permission to update the audit database table. This is required because the trigger updates the audit database with new and/or old values. If a new user is granted update permission for a monitored table, when that user attempts an update, the update is not allowed because that user does not also have permission to update the audit database. When this happens, you must update the audit database privileged users list by using the Value Change Auditing Builder.

To update the audit database privileged users list, the database user ID that is used to log in to the monitored database must be the creator of any role to which new users have been added. Otherwise, the members of that role will not be available.

1. Open the Value Change Auditing Builder by navigating to Harden > Configure Change Control (CAS Application) > Value Change Auditing Builder.

2. Click Add Datasource to open the Select datasource window. Select the appropriate datasource from the list, and click Save.

3. Click Update Audit Tables Privileged Users. The permissions for all users who can run triggers to update the audit database tables are updated, and you are informed when the operation completes.

4. Click OK to close the message box.

## Value-Change Reporting

---

You can view value-change data from the default Values Changed report, or you can create custom reports using the Value Change Tracking domain. By default, the Value Change Tracking domain is restricted to users having the admin role.

## Values Changed Default Report

---

There is one default values-changed report available by navigating to Reports > Real-Time Guardium Operational Reports > Values Changed.

The main entity for the Values Changed report is the Changed Columns entity. In most cases, there is a separate row of the report for every column change that is detected for every audit action (Insert, Update, Delete). However, for MS SQL Server and Sybase, if the monitored table does not have a primary key, there are two rows per change, with the old and new values displayed on separate rows.

## Creating an Audit Database

---

Create an audit database and perform value-change monitoring activities.

To create an audit database and perform value-change monitoring activities, you must have a user account with appropriate permissions to:

- Create a database on the server
- Create a database user account on the server

Log in to each database to be monitored Create tables and triggers on each database to be monitored

## Before Defining an Audit Database under Informix or Sybase

---

For Informix® and Sybase (except for Sybase IQ, which does not support triggers) and depending on the operating system for the database server, you must perform one of the following procedures before defining the audit database.

## Informix Setup - Locate or Create a New Database Space

---

This topic applies for Informix (9.4 or later). Under Informix, we strongly recommend that you avoid using the default root database space, root\_dbs. You cannot drop this space or reduce its size.

You should use any other database space that has been defined, or to create a new database space, perform one of the following procedures (depending on the operating system).

## Informix - Create an Informix Database Space on a Windows Server

---

This procedure is performed outside of the Guardium® GUI, and applies for Informix version 9.4 or later.

1. Verify that the database server is online and listening.
2. Create a zero-byte file named guardium\_dbs\_dat.000 in the C:\IFMXDATA\server-name directory (server-name is the name of the Informix server or the service name). You can do this by saving an empty text file, and then renaming the file, replacing the txt suffix with 000.
3. Make the following directory the working directory:  
C:\Program Files\Informix\bin
4. Execute following command:

```
C:\Program Files\Informix\bin>onspaces -c -d guardium_dbs -p C:\IFMXDATA\server-name\guardium_dbs_dat.000 -o 0 -s 150000
```

If the file is created successfully, you see the following messages:

```
Verifying physical disk space, please wait ...
Space successfully added.
** WARNING ** A level 0 archive of Root DBSpace will need to be done.
```

5. Restart the Informix server, and use a suitable tool (Aqua Data Studio remote client, for example) to connect and verify that the space named guardium\_dbs has been created. Your first connection attempt may fail with a message about the server running in Quiescent Mode. If this happens, attempt to re-connect at least two more times, and it should work.
6. To verify that the guardium\_dbs database space has been created, use Aqua Data Studio, and look under Storage.

## Informix - Create an Informix Database Space on a Unix Server

---

This procedure is performed outside of the Guardium GUI, and applies for Informix version 9.4 or later.

1. From a command-line window, enter the following commands:

```
su - informix
cd demo/server
vi guardium_dbs
```

2. Without adding any text, save the empty guardium\_dbs file.
3. Enter the following commands:

```
chmod 660 guardium_dbs
cd ../../bin
onspaces -c -d guardium_dbs -p /home/informix10/demo/server/guardium_dbs -o 0 -s 100000
```

## Sybase Setup - Initialize Disks

---

This topic applies for Sybase servers only (except for Sybase IQ, which does not support triggers). Depending on the operating system of the database server, perform one of the following procedures to initialize disks.

## Sybase - Initialize Disks on a Windows Sybase Server

---

1. Connect to the server on which you want to create the Guardium audit database: guardium\_audit.
2. Create a folder named guardium\_audit, under the c: drive.
3. Connect to the database.
4. Execute the following commands:

```
use master
go
disk init name="guardium_auditdev", size=8192
go
disk init name="guardium_auditlog",
physname="c:/guardium_audit/guardium_auditlog", size=8192
go
```

## Sybase - Initialize Disks on a Unix Sybase Server

---

1. Connect to the database.
2. Execute the following statements:

```
use master
go
disk init name = 'guardium_auditdev', physname
=''/home/sybase/data/guardium_auditdev' , size = 8192
go
disk init name = 'guardium_auditlog', physname
=''/home/sybase/data/guardium_auditlog' , size = 8192
go
```

## Create the database

---

For an Informix or Sybase database, be sure to perform the preliminary tasks before performing this procedure.

1. Open the Value Change Database Builder by navigating to Harden > Configuration Change Control (CAS Application) > Value Change Audit Database Creation.

2. Click Add Datasource to open the Select datasource window.

Datasources that are defined from the Value Change Auditing application are labeled Monitor Values. Datasources that are defined for other applications have different labels (such as Listener, or DBAnalyzer). The other datasources may not have the appropriate set of database access permissions for that Value Change

Auditing application, which requires a user account with database administrator authority. If a suitable datasource is not available, click to define a database to monitor. For information about defining datasources, see [Creating a datasource definition](#).

Note: If a GUARDIUM\_AUDIT database already exists on this dbserver, you cannot create another one. You must drop the GUARDIUM\_AUDIT database/user before you create a new one.

3. Select a datasource that uses an administrator account, and click Save to add it to the Datasources window on the Create Value Change Audit Database page.
4. Enter an Audit Datasource Name. This is the name that identifies the datasource later, to define monitoring tasks and to upload data. Do not confuse this name with the name of the Datasource from the Datasources panel.
5. Optionally select Share Datasource to share this datasource with other applications (Classification, for example). The default is not to share the datasource. This type of datasource requires administrator privileges, so you may not want to share this datasource with other applications.

Note: To share a datasource with other users, assign security roles to that datasource.

6. For any database type other than DB2®, there are additional fields in the Audit Configuration pane. All fields are required. Referring to the following table, enter the appropriate values.

Table 1. Additional Audit Configuration Fields Table

| Database Type | Field: Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Informix      | <b>Database Space:</b> Enter the name of an existing database space to use, or enter the name of the database space you created for the audit database (guardium_dbs in the example shown previously). If you leave this blank, the default root_dbs space will be used, which we do not recommend.                                                                                                                                                                                                                                                                                                                                                                                  |
| MS SQL Server | <b>Audit User Name:</b> Enter a new database user name to use when accessing the audit database. This user will be given the sysadmin role.<br><br><b>Audit Password:</b> Enter a password.<br><br>An additional choice appears in Value change Audit Database Creation menu screen when then the datasource is MSSQL server. This additional choice appears only when the datasource is MSSQL Server.<br><br>Compatibility Mode: Choices are Default or MSSQL 2000. The processor is told what compatibility mode to use when monitoring a table.<br><br>Use the GuardAPI command, <code>grdapli list_compatibility_modes</code> to show the compatibility modes for MS SQL Server. |
| Oracle        | <b>Audit Password:</b> Enter the password for the system user, which will be the database account used to access the audit database.<br><br><b>Default Tablespace:</b> Enter a name for the default tablespace.<br><br><b>Temp Tablespace:</b> Enter a name for the temporary tablespace.                                                                                                                                                                                                                                                                                                                                                                                            |
| Sybase        | <b>Audit User Name:</b> Enter a new database user name to use when accessing the audit database. This user will be granted the sa_role.<br><br><b>Audit Password:</b> Enter a password.<br><br><b>Data Device Name:</b> Enter the same data device name used when initializing the disk for the audit database (guardium_auditdev in the disk initialization procedure described earlier).<br><br><b>Log Device Name:</b> Enter the same log device name used when initializing the disk for the audit database (guardium_auditlog in the disk initialization procedure described earlier).                                                                                          |

7. Click Create Audit Database to create the audit database.

8. Use the selection Value Change Audit Database Update and Upload on the Config and Control tab to select the actions in this table.

Restriction: For Microsoft SQL Server, Sybase, and Sybase IQ, the Guardium system does not receive updates to any column that is a primary key or part of a composite key.

| Action          | Description                                                                  |
|-----------------|------------------------------------------------------------------------------|
| Delete          | Click to remove the datasource from the Datasources pane.                    |
| Modify          | Click to edit this datasource definition in the Datasource Definition panel. |
| Schedule Upload | Click to schedule the upload of this audit datasource.                       |

## What to do next

---

After you create an audit database on a database server, it is available for use by the Value Change Auditing Builder for building triggers. For more information, see [Value Change Auditing](#).

## Monitored Table Access

---

This feature adds a “Last Assessed” field to relevant tables, for interaction with Optim Designer data lifecycle products.

This feature is also called “Table Last Referenced”.

This feature uses Guardium’s External Feed that is preconfigured with the data (a predefined External Feed map), and an audit process to run it.

## Follow these Steps

---

1. Create the target (Optim) tables on any Informix® database. Use the script.

2. Open the Audit Process Builder by navigating to Comply-> Tools and Views-> Audit Process Builder, then edit the process named Table Last Referenced. Add a datasource to the External Feed task (the Informix datasource that contains the tables) and setup the run-time parameter for servers group. All the rest is predefined and there is no need to change it.
3. Run (or schedule to run periodically) the audit process.

Note: The resulting table will show only the last run. The receiver count is the count of the receivers, and not the count of run results since the last run only. IBM® Guardium® can detect external references to database objects, specifically tables. This capability, in conjunction with Optim Designer, can be used to manage the retirement of inactive tables or archiving with certain retention policies.

Guardium collects and maintains a list of tables with the date of last reference. The list is built using policies in Guardium that dictate the interval of last reference and the frequency to be used for updating the list content. The information captured by Guardium is referred to as the "last reference" list and supplies the following information: What tables are no longer referenced? What table access trends exist for retirement candidates?

Having the ability to accurately plan for the retirement of applications will help to:

- Plan for hardware retirement or redeployment
- Reduce cost of ownership by moving or retiring those resources supporting the applications (for example, hardware, DBA(s), Application owners, IT operations such as backups).
- Know what tables are rarely or never accessed

This functionality of IBM Guardium has been added directly to the Optim Designer user interface.

The information supplied by Guardium to Optim consists of the following attributes per table entry:

**Table 1. Monitored Table Access List Entry**

| List Entry     | Description                                          |
|----------------|------------------------------------------------------|
| Field          | Comment                                              |
| DataSourceDesc | Description                                          |
| Server IP      |                                                      |
| Host Name      |                                                      |
| DB Vendor      | for example, Oracle, DB2®                            |
| User Name      | for example, for Oracle it mostly defines the schema |
| Database Name  |                                                      |
| Schema         |                                                      |
| Table          |                                                      |
| Date           | Date of last access                                  |

## Script to create Informix tables in the Optim product

---

```
Last_referenced_datasource
create table last_referenced_datasource (
 id serial(1) not null,
 datasource_desc varchar(100),
 server_ip char(39),
 host_name varchar(200),
 db_vendor char(40),
 primary key (id) constraint last_referenced_datasource_pk
);

Last_referenced_table
create table last_referenced_table (
 id serial(1) not null,
 datasource_id int not null,
 user_name char(32),
 db_name char(128) not null,
 schema_name char(128) not null,
 table_name char(128) not null,
 last_reference datetime year to second not null,
 primary key (id) constraint last_referenced_table_pk,
 foreign key (datasource_id) references last_referenced_datasource(id) constraint last_referenced_table_fk
);
```

---

## Installing and activating the FamMonitor on Windows servers

The FamMonitor enables monitoring and collection of audit information and policy rules, and real time alerts or blocking of suspicious users or connections on your Windows servers. You can install it by command line, the wizard, or GIM.

- [Install the FamMonitor installation package with the wizard](#)  
Use the wizard to install the FamMonitor installation package on your Windows database.
- [Install the FamMonitor bundle with GIM](#)  
Install the GIM client on the Windows server, then use it to install the FamMonitor.
- [FamMonitor GIM installation parameters](#)  
Understand the parameters that you can use in your GIM installation of the FamMonitor bundle.
- [Install and uninstall the FamMonitor installation package with command line](#)  
Use the command line installation to install the FamMonitor installation package on your Windows database.
- [FamMonitor command line installation parameters](#)  
Understand the parameters that you can use in your script installation of the FamMonitor installation package.

## Install the FamMonitor installation package with the wizard

Use the wizard to install the FamMonitor installation package on your Windows database.

### Before you begin

---

- The FamMonitor installation package must be accessible. Download from [Fix Central](#) or obtain from your Guardium representative.
- If S-TAP is installed, it is V11.0 and higher.

### Procedure

---

1. Log on to the database server using a system administrator account.
2. Unload and unzip the FamMonitor installation package on the database.
3. Double-click Setup.exe to open the wizard.
4. Accept the licensing agreement and click Next.
5. Follow the prompts. Most customers prefer Setup type as Typical. The custom setup gives a custom install directory.  
Use the Appliance Address(es) field to type in additional Guardium® hostnames or IP addresses. If there is a failover, the FAM agent attempts to connect to the next appliance on the list.
6. When the installation is complete, click Finish to close the installer.
7. On the Guardium system, in the Windows Services, verify that IBM Security Guardium FAM for Windows is Running.
8. On the Guardium GUI , in the S-TAP Control page, verify that the FAM Status is active.

### Results

---

Monitoring and collection of audit information and policy rules starts, enabling real time alerts or blocking of suspicious users or connections.

## Install the FamMonitor bundle with GIM

Install the GIM client on the Windows server, then use it to install the FamMonitor.

### Before you begin

---

- FamMonitor bundle is uploaded on the GIM server. The FamMonitor bundle name starts with: FAMMONITOR
- The GIM client is installed on the file server.
- If S-TAP is installed, it is V11.0 and higher.

### About this task

---

All GIM parameters for FamMonitor start with FAMMONITOR\_.

### Procedure

---

- Verify that the GIM client is installed on the database server. See [Installing the GIM client on a Windows server](#).
  - Upload the FAM bundle to the GIM server.
    - Go to Manage > Module Installation > Upload Modules.
    - Click Choose File and select the FAM bundle that you want to install.
    - Click Upload to upload the module to the appliance.

The module appears in the Import Uploaded Modules table.

    - In the Import Uploaded Modules table, click the check box next to the FamMonitor bundle you want to install.

The bundle imports and becomes available for installation. The Upload Modules page resets and the Import Uploaded Modules table is now empty.
  - Navigate to Manage > Module Installation > Set up by Client.
  - In the Choose clients section, select the database servers where you want to install the FamMonitor. Select individual clients using check boxes in the table, or use the Select client group menu to select a group of clients. Click Next to continue.
  - In the Choose bundle section, use the Select a bundle menu to select the FamMonitor bundle.
- After selecting a software bundle, the Selected bundle action column indicates Install, the action that will be performed for each client:
- Attention:
- By default, the Select a bundle menu shows only the latest uploaded bundle version regardless of platform or compatibility with selected clients. To install a different bundle version for a specific platform or client, clear the Show only latest versions check box and select the required bundle.
  - If you upload and import new bundles while using the Set up by Client tool, refresh the browser to see the new bundles.
  - If you already have a bundle scheduled for installation, installing a new bundle removes the existing schedule.
- Click Next to continue.
6. In the Choose parameters section, specify values for required and optional parameters. Use the or to add or remove optional parameters. Use the to search for parameters by name or description.
- Important: Unless identified as a client-specific parameter, values provided in the Choose parameters section are applied to all client installations. For client-specific parameters, the value field is disabled and values are defined per-client in the Configure clients section.
- Click Next to continue.
7. In the Configure clients section, use the table to review and edit parameter values for each client.
- Editable parameters show a icon next to the parameter value. Click the icon to edit the value.
- When installing on a Central Manager, you must provide a value for FAMMONITOR\_SQLGUARD\_IP
  - When installing on a Collector: GIM, by default, takes the GIM client values for FAMMONITOR\_TAP\_IP and FAMMONITOR\_SQLGUARD\_IP. You do not need to assign any other parameter values. The GIM client values are GIM\_CLIENT\_IP and GIM\_URL, respectively.
- Configure additional parameters as relevant. See full parameter list in [FamMonitor GIM installation parameters](#).
- Note: You can also configure GIM parameters using the grdapi command: `gim_update_client_params`.
8. Click Install to begin the software installation. Use the icon to schedule the installation, then click OK to continue.

## Results

Monitoring and collection of audit information and policy rules, enabling real time alerts or blocking of suspicious users or connections.

## FamMonitor GIM installation parameters

Understand the parameters that you can use in your GIM installation of the FamMonitor bundle.

Table 1. FamMonitor GIM installation parameters

| GIM parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FAMMONITOR_SQLGUARD_IP             | The Guardium IP.                                                                                                                                                                                                                                                                                                                                                                |
| FAMMONITOR_ADDITIONAL_SQLGUARD_IPS | Additional Guardium® hostnames or IP addresses. If there is a failover, the FAM agent attempts to connect to the next appliance on the list.                                                                                                                                                                                                                                    |
| FAMMONITOR_ENABLED                 | <ul style="list-style-type: none"> <li>0: FamMonitor is stopped after installation.</li> <li>1: FamMonitor is started after installation.</li> </ul>                                                                                                                                                                                                                            |
| FAMMONITOR_FAM_NORDP               | Determines whether Guardium records the remote client IP address or the server IP address as the client IP address in its file events, for users connected by remote desktop. <ul style="list-style-type: none"> <li>0: Guardium records the remote client IP address.</li> <li>1: Guardium records the server IP address as the client IP address.</li> </ul> <p>Default=0</p> |
| FAMMONITOR_INSTALL_DIR             | Required. This is the install directory. The default install path is program files\ibm\fammonitor                                                                                                                                                                                                                                                                               |
| FAMMONITOR_INSTALLER_LOG_DIR       | Specifies the location for storing the FamMonitor installer log files. Use this parameter if you want don't want to use the default location (C:\Program Files\IBM\Windows Fam Monitor).                                                                                                                                                                                        |

| GIM parameter       | Description                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| FAMMONITOR_TAP_IP   | The local/client IP. Required for unattended installation.                                                                   |
| FAMMONITOR QUIET    | Install silently. (Does not require a value.)                                                                                |
| FAMMONITOR_CMD_LINE | Adds key and value to Famonitor config file. Format: key1=value1 key2=value2, separated by space between pairs of key-value. |

## Install and uninstall the FamMonitor installation package with command line

Use the command line installation to install the FamMonitor installation package on your Windows database.

### Before you begin

- The FamMonitor installation package must be accessible. Required for file monitoring. Download from [Fix Central](#) or obtain from your Guardium representative.

### Procedure

- Log on to the database server using a system administrator account.
- Copy the installation package to your database, and using the Windows Command Prompt, navigate to the Windows FAM installer directory.  
For example,

```
cd c:\Windows-FamMonitor-V11.0.0.nn
```

You should find a **setup.exe** executable in the installation package directory.

- Install FamMonitor using the **setup.exe** executable with the appropriate parameters.

The required parameters are:

- TAPHOST
- APPLIANCE
- UNATTENDED

All parameters except INSTALLPATH can be updated after the installation. A typical install command is:

```
setup.exe -UNATTENDED -APPLIANCE 10.0.147.234 -TAPHOST 10.0.145.41
```

where:

- UNATTENDED (required) invokes the command-line installer.
- APPLIANCE specifies the IP address of the Guardium® system that will control the FamMonitor.
- TAPHOST (required) specifies the client IP address where the FamMonitor is being installed.

Optional parameters:

- INSTALLPATH
- CUSTOMER
- COMPANY
- SERVICEUSER
- SERVICEPASSWORD
- START: 0 means the FAM monitor service is stopped after install

Mandatory parameter for **uninstall**:

- UNINSTALL

For a complete description of the parameters, see [FamMonitor command line installation parameters](#).

### Results

Monitoring and collection of audit information and policy rules starts, enabling real time alerts or blocking of suspicious users or connections.

## FamMonitor command line installation parameters

Understand the parameters that you can use in your script installation of the FamMonitor installation package.

Install the FamMonitor installation package using the **setup.exe** executable with the relevant parameters, in this format:

**Setup.exe -PARAMETER value**

Do not use "=" sign to assign values to the parameters.

Table 1. FamMonitor command line installation parameters

| Command line parameter | Description                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| APPLIANCE              | Required. The Guardium IP. You can set up multiple appliances by specifying this parameter multiple times, each with a unique value.                                                     |
| COMPANY                | Specify to change the company name.                                                                                                                                                      |
| CUSTOMER               | Specify to change the customer name.                                                                                                                                                     |
| INSTALLERLOGPATH       | Specifies the location for storing the FamMonitor installer log files. Use this parameter if you want don't want to use the default location (C:\Program Files\IBM\Windows Fam Monitor). |
| INSTALLPATH            | This is the install directory. The default install path is program files/ibm/fammonitor.                                                                                                 |

| Command line parameter | Description                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NORDP                  | Determines whether Guardium records the remote client IP address or the server IP address as the client IP address in its file events, for users connected by remote desktop. <ul style="list-style-type: none"> <li>• 0: Guardium records the remote client IP address.</li> <li>• 1: Guardium records the server IP address as the client IP address.</li> </ul> Default=0 |
| SERVICEUSER            | Specifies the service user account.                                                                                                                                                                                                                                                                                                                                          |
| SERVICEPASSWORD        | The password for the user.                                                                                                                                                                                                                                                                                                                                                   |
| START                  | <ul style="list-style-type: none"> <li>• 0: FamMonitor is stopped after installation</li> <li>• 1: FamMonitor is started after installation.</li> </ul>                                                                                                                                                                                                                      |
| TAPHOST                | Required for unattended installation. The local/client IP.                                                                                                                                                                                                                                                                                                                   |
| UNATTENDED             | Required. Install silently. (Does not require value.)                                                                                                                                                                                                                                                                                                                        |
| UNINSTALL              | Uninstalls the FamMonitor. A value is not required.                                                                                                                                                                                                                                                                                                                          |

## File Activity Monitor for NAS and SharePoint

The Guardium File Activity Monitor (FAM) monitors activity across files and directories residing on NAS devices and SharePoint servers in the Windows environment.

NAS or network-attached storage is a file-level storage system based on networked appliances containing multiple storage devices. SharePoint is a web-based collaborating platform and a document management & storage system.

FAM's ability to monitor these environments enables users to identify threats and streamline operations.

Use the following work flow to enable File Activity Monitoring across your NAS devices or SharePoint environment.

- [Supported platforms for file activity monitoring](#)
- [Monitoring Permissions](#)  
Enable these permissions to allow file activity monitoring on your NAS or SharePoint environments.
- [Installation](#)  
Use these instructions to install the File Activity Monitor (FAM) on your NAS or SharePoint environment.
- [Configuration](#)  
After installing, configure the File Activity Monitor (FAM) to begin monitoring your NAS or SharePoint environment.
- [Viewing Results](#)  
To view file activity on your NAS device, use the NAS File Activities report. For SharePoint, use the SharePoint File Activities report.
- [Uninstallation](#)  
Uninstall the File Activity Monitor (FAM) for network-attached storage (NAS) devices or SharePoint by using the Windows Control Panel.

## Supported platforms for file activity monitoring

For the list of supported platforms for files, see [Guardium Supported Platforms for Files](#).

## Monitoring Permissions

Enable these permissions to allow file activity monitoring on your NAS or SharePoint environments.

### NAS Permissions

#### NetApp Data ONTAP Cluster-Mode Permissions

The policy name and credentials are case-sensitive when targeting a NetApp Data ONTAP Cluster-Mode device. The policy name must be `StealthAUDIT` and the engine name must be `StealthAUDITEngine`. A tailored FPolicy is recommended as it decreases the impact on the NetApp device.

The credential that is associated with the FPolicy used to monitor activity must be provisioned with at least the following CLI commands:

| CLI command | Access   |
|-------------|----------|
| version     | Readonly |
| volume      | Readonly |
| vserver     | Readonly |

For more options to enable and configure the FPolicy, use the following CLI commands:

#### Employing the “Enable and connect FPolicy” Option.

The File Activity Monitor can be configured to ensure that everything is actively monitored with periodic checks on the FPolicy. If the “Enable and connect FPolicy” option is enabled, then the credential requires the following permissions to enable the FPolicy, connect to the FPolicy, and collect events:

| CLI Command | Access   |
|-------------|----------|
| version     | Readonly |
| volume      | Readonly |

| CLI Command                    | Access   |
|--------------------------------|----------|
| vserver                        | Readonly |
| vserver fpolicy disable        | All      |
| vserver fpolicy enable         | All      |
| vserver fpolicy engine-connect | All      |

#### Employing the “Configure FPolicy” Option

The File Activity Monitor can automatically configure FPolicy. If the “Configure FPolicy” option is enabled, then the credential requires the following permissions to enable the FPolicy, connect to the FPolicy and collect events:

| CLI command                                                           | Access   |
|-----------------------------------------------------------------------|----------|
| version                                                               | Readonly |
| volume                                                                | Readonly |
| vserver                                                               | Readonly |
| server fpolicy                                                        | All      |
| security certificate install (only needed for FPolicy TLS connection) | All      |

#### NetApp Data ONTAP 7-Mode Permissions

It is necessary to enable the “file and printer sharing” where FAM is installed.

An FPolicy must be configured on the target device for file activity monitoring. A tailored FPolicy is recommended as it decreases the impact on the NetApp device. The credential associated with the FPolicy used to monitor activity must be provisioned with access to the following API calls:

- login-http-admin api-system-api-list
- api-system-get-version
- api-cifs-share-list-iter-\* api-volume-list-info-iter-\*

If the File Activity Monitor will be automatically configuring the FPolicy, then the following command is also needed:

- api-fpolicy\*

If the File Activity Monitor will be configured to use the “Enable and connect to the FPolicy” option, then the following command is also needed:

- cli-fpolicy\*

The credential must also have the following permissions on the target device:

- Group membership in both of the following groups:
- ONTAP Power Users
- ONTAP backup Operators

#### EMC Celeraic or Unity device

The EMC Common Event Enabler (CEE) should be installed on the Windows proxy server where FAM agent is deployed.

#### EMC Isilon device

The EMC Common Event Enabler (CEE) should be installed on the Windows proxy server where the File Activity Monitor agent is deployed.

#### Hitachi

A Hitachi device can host multiple Enterprise Virtual Servers (EVS). Each EVS has multiple file systems. Auditing is enabled and configured per file system. HNAS generates the audit log files in EVT format (a standard event log format in Windows XP/2003 and earlier). Hitachi stores the generated audit logs in a user specified location on the file system. FAM accesses this location to collect the log files as they are generated. The credential used to monitor activity must be provisioned with:

- Capability of enabling a File System Audit Policy on the Hitachi device
- Audit rights to the Hitachi log directory

## Firewall rules - Windows Proxy Server

#### NetApp Data ONTAP Cluster-Mode Firewall Rules

The following firewall settings are required for communication between FAM and the NetApp Data ONTAP Cluster-Mode device:

| Communication Direction | Protocol         | Ports | Description    |
|-------------------------|------------------|-------|----------------|
| FAM to NetApp           | HTTP (Optional)  | 80    | ONTAPI         |
| FAM to NetApp           | HTTPS (Optional) | 443   | ONTAPI         |
| NetApp to FAM           | TCP              | 9999  | FPolicy events |

#### NetApp Data ONTAP 7-Mode Firewall Rule

The following firewall settings are required for communication between FAM and the NetApp Data ONTAP 7-Mode device:

| Communication Direction | Protocol        | Ports                                   | Description |
|-------------------------|-----------------|-----------------------------------------|-------------|
| FAM to NetApp*          | HTTP (optional) | 80                                      | ONTAPI      |
| FAM to NetApp*          | HTTP (optional) | 443                                     | ONTAPI      |
| FAM to NetApp           | TCP             | 135, 139<br>Dynamic Range (49152-65535) | RPC         |
| FAM to NetApp           | TCP             | 445                                     | SMB         |
| FAM to NetApp           | UDP             | 137, 138                                | RPC         |
| NetApp to FAM           | TCP             | 135, 139<br>Dynamic Range (49152-65535) | RPC         |
| NetApp to FAM           | TCP             | 445                                     | SMB         |

| Communication Direction | Protocol | Ports    | Description |
|-------------------------|----------|----------|-------------|
| NetApp to FAM           | UDP      | 137, 138 | RPC         |

\*Only required if using the FPolicy Configuration and FPolicy Enable and Connect options within the File Activity Monitor.

#### EMC Firewall Rules

The following firewall settings are required for communication between FAM and the EMC Celerra, Dell EMC Unity, or EMC Isilon device:

| Communication Direction                      | Protocol | Ports             | Description       |
|----------------------------------------------|----------|-------------------|-------------------|
| EMC Isilon Device to CEE Server              | TCP      | TCP 12228         | CEE Communication |
| EMC Device (other than Isilon) to CEE Server | TCP      | RPC Dynamic Range | CEE Communication |

#### Hitachi Firewall Rules

The following firewall settings are required for communication between FAM and the Hitachi device:

| Communication Direction | Protocol | Ports | Description |
|-------------------------|----------|-------|-------------|
| Unidirectional          | TCP      | 445   | SMB         |

## SharePoint Permissions

- The provided domain user must be a local admin on the SharePoint application server.
- Auditing settings must be enabled on SharePoint.

## Installation

Use these instructions to install the File Activity Monitor (FAM) on your NAS or SharePoint environment.

### Before you begin

- Review the monitoring permissions: [Monitoring Permissions](#).
- For detailed platform prerequisites and support, see [Supported platforms for file activity monitoring](#).
- Prerequisite for EMC devices: To monitor an EMC device, the EMC Common Event Enabler (CEE) must be installed on the Windows proxy server where FAM is installed.

### Procedure

- To monitor a NAS device, install FAM on a Windows server that can access the NAS device through the network. To monitor SharePoint, install FAM directly on the SharePoint server or SharePoint server farm.  
Note: No other Guardium products must be installed on this server.
- Download the FAM for NAS or FAM for SharePoint package from [Fix Central](#) to the server and extract this file.
- From the FAM package installer directory and run the executable file **setup.exe** in the installer directory.
- Follow the prompts in the wizard to complete the installation.
  - In the Network Addresses screen, enter a list of Guardium hostnames or IP addresses. If there is a failover, the FAM agent connects to the next appliance on the list.  
Note:  
For NAS, the default installation directory is C:\Program Files\IBM\FAMforNAS  
For SharePoint, the default installation directory is C:\Program Files\IBM\FAMforSP

## Configuration

After installing, configure the File Activity Monitor (FAM) to begin monitoring your NAS or SharePoint environment.

Use the Policy builder for Files to configure monitoring for SharePoint and NAS devices. For more information, see [File activity policies for network-attached storage \(NAS\) and SharePoint](#)

FAM supports multiple services that are pointed to the same monitoring host. You can include multiple entries in the FAM configuration utility that point to different Guardium® appliances, have different local IP addresses, and include different policies. This feature provides the flexibility to create different rules for the same monitored host. You can monitor different parts of a share or site collection in the monitored host and report to different collectors.

## Viewing Results

To view file activity on your NAS device, use the NAS File Activities report. For SharePoint, use the SharePoint File Activities report.

### Procedure

- Click My Dashboards > Create New Dashboard to open a new dashboard.
- Click Add Report to display a list of available reports. The Add a Report dialog shows a list of all reports that meet your criteria. You can browse the list of reports or type a string in the Filter field. The list of reports is updated as you type.
- File activity on NAS devices can be viewed through the NAS File Activities report and file activity on SharePoint can be viewed through the SharePoint File Activities report. Click the report to add it to your dashboard.

## Results

In order to view results, create and install a custom policy. The default installed policy is "Ignore Data Activity for Unknown Connections [template]", which ignores all traffic. For more information on how to create a policy, see [Creating and installing a policy and policy rules](#).

## Uninstallation

Uninstall the File Activity Monitor (FAM) for network-attached storage (NAS) devices or SharePoint by using the Windows Control Panel.

Note: If cmd.exe is open during uninstallation and the FAM for SharePoint folder is the current directory, then the folder is not removed. Close cmd.exe and delete the FAM for SharePoint folder manually. The folder is deleted automatically when the system restarts.

## How to use PCI/DSS Accelerator to implement PCI compliance

Configure IBM® Guardium®'s PCI/DSS Accelerator and create a series of policies and reports, in order to meet PCI/DSS requirements.

PCI/DSS (Payment Card Industry/ Data Security Standard) is a set of technical and operational requirements designed to protect cardholder data.

Value-added: Give customers a whole view of PCI/DSS and provide predefined policies and reports to save configuration time.

Follow these steps:

1. Configure PCI role.
2. Configure reports and policies that follow the requirements.

### Configure PCI role

1. Login via the Guardium GUI page using the "accessmgr" user account. Select a user (in this case, user1), and click on Roles.

The screenshot shows a table titled 'User Browser' with columns: Username, First Name, Last Name, Email, and Actions. There are three rows: 'accessmgr' (First Name: accessmgr, Last Name: accessmgr, Email: user@pci.com, Actions: Edit, Roles, Change Layout), 'admin' (First Name: admin, Last Name: admin, Email: user@pci.com, Actions: Edit, Roles, Change Layout), and 'user1' (First Name: user, Last Name: pci, Email: user@pci.com, Actions: Edit, Roles, Change Layout, Delete). The 'Edit' and 'Roles' buttons are highlighted in red.

2. In the user role form, check PCI, and then save the assignment.

The screenshot shows the 'User Role Form' for user 'user1'. The title is 'Roles for user pci'. A table lists roles with checkboxes for assignment. The 'pci' role has a checked checkbox and is highlighted with a red border. Other roles listed include accessmgr, admin, appdev, audit, cas, cli, datasec-exempt, dba, diag, infosec, inv, netadm, optim-audit, review-only, and user. At the bottom are 'Save' and 'Back' buttons.

## Implement PCI accelerator

Log on using "user1" and click Accelerators.

## Overview

1. Click PCI Accelerator for Compliance.
2. Click PCI Data Security Standard.

### PCI Accelerator for Compliance

The PCI Data Security Standard consists of twelve basic requirements. Several of the requirements are focused on protecting physical infrastructure (for instance, Requirement 1: Install and maintain a firewall configuration to protect data) or implementing procedural best practices (for instance, Requirement 5: Use and regularly update anti-virus software). However, an additional, heavy emphasis is placed on real-time monitoring and tracking of access to cardholder data and continuous assessment of database security health status (for instance, Requirement 10: Track and monitor all access to network resources and cardholder data).

The PCI Accelerator simplifies organizational processes needed to support these monitoring and tracking mandates and to allow for cardholder data security. The Accelerator report templates can be customized to directly reflect specific organizational and regulatory requirements. You can access these templates using the tabs provided:

- PCI Data Security Standard overview
- Plan and Organize
- PCI Req. 10: Track and Monitor Access
- PCI Req. 11: Regularly Test and Validate
- PCI Policy Violations Monitoring

Other tools in the Guardium family of solutions available to assist in meeting regulations include the following:

- **Cardholder Database Access Map** - A graphical map of access between cardholder database access clients and servers. This map provides an at-a-glance view of activities by access type, content, and frequency. To open the Access Map builder and viewer, select View > Access Map > Access Map builder.
- **PCI Compliance Security Assessments** - A detailed view of database access security health used to automate the compliance processes with continuous real-time snapshots customized for user defined tests, weights, and assessments. The security assessment acts as a "report card" to help track progress on addressing database vulnerabilities. To create a security assessment, select Assess/Harden > Vulnerability Assessment > Assessment builder.
- **Full Audit Trail** - The non-intrusive generation of a full audit trail for data usage and modifications required by regulatory compliance. This capability is located under the Monitor/Audit tab.
- **Automated Scheduling** - Automated scheduling of PCI work flows, audit tasks, and distribution of information to responsible parties across the organization. This functionality is located under the Comply tab.

### PCI Data Security Standard

The Payment Card Industry (PCI) Data Security Standard offers a single approach to safeguarding sensitive data for all credit card brands. This standard is the result of collaboration between Visa and MasterCard, with the objective of creating common industry security requirements. Other card companies operating in the U.S. have also endorsed the PCI Data Security Standard within their respective programs.

The PCI Data Security Standard delivers a framework of tools and measurements needed to protect against cardholder data exposure and compromise across the entire payment industry. It applies to all members, merchants, and service providers that store, process, or transmit cardholder data utilizing any payment channels, including retail (brick-and-mortar), mail/telephone order, and e-commerce.

### PCI Compliance Validation

Separate and distinct from the mandate to comply with PCI requirements is the validation of compliance. The validation process is a fundamental and critical function that identifies and corrects vulnerabilities, and protects customers by ensuring that appropriate levels of cardholder information security are maintained. Card vendors have prioritized and defined levels of PCI compliance validation based on the volume of transactions, the potential risk, and exposure introduced into the systems by merchants and service providers. These include:

- Internal control
- Ongoing assessment (i.e., governance, measurement, and recordkeeping)
- Disclosure (i.e., investigation, reporting, and certification)

## Plan and Organize

### Plan and Organize

Click the Overview for an introduction of how the predefined reports follow the compliance.

1. Cardholder Server IPs List: Cardholder information database server list. According to the company's actual situation, set the PCI Authorized Server IPs group information, which specifies the database server that stores cardholder information.
2. Cardholders Databases: Cardholder information database. Set the PCI Cardholder DB: designated group information, which is stored in the database's cardholder information.
3. Cardholder Objects: Cardholder information object. This needs to set the PCI Cardholder Sensitive objects.
4. DB Clients to Servers Map: Client/server mapping and PCI Authorized Server IPs set group information, which specifies the database servers storing cardholder information. Query can be used to find client access to the cardholder database.
5. Active DB Users: Administrator in addition to categories of users, which visited the cardholder database. Set the "PCI Authorized Server IPs" and "PCI Admin Users".
6. Cardholder DB Administration: Cardholder database management operations. Set the PCI Authorized Server IPs and Admin Users.
7. Authorized Source Programs: Credit program access. Set the PCI Authorized Server IPs, PCI Authorized Source Programs. Procedure for recording Credit Cardholder database access.
8. Unauthorized Application Access: Non-credit program access. Set the PCI Authorized Server IPs, PCI Authorized Source Programs. Records of credit program for the cardholder database access.
9. 8.5.8 Shared Accounts: PCI eighth requirements to have each person having computer access to be assigned a unique ID. Set PCI Authorized Server IPs to count the number of times the same database username is trying to access from the cardholder database IP.

In the statements, click to view a report form, and then determine what specific group content needs to be filled in.

Here is the actual name of the group:

Navigate to Setup > Tools and Views > Group Builder, and in the Modify Existing Groups selection, select the group name.

Click Modify (the pencil icon) and go to Manage Members for Selected Group page. Add new members.

The group can also be filled through a customized query.

#### PCI Req. 10 Track & Monitor

Click the Overview for an introduction of how the Guardium monitor and predefined reports follow the compliance.

1. 10.2 and 10.3 Automation - Use the online help Protect help book and Comply Help book to automate this section.
2. 10.2.1 Data Access - PCI Access to cardholder data, Set the PCI Authorized Server IPs and PCI Admin Users.
3. 10.2.2 Admin Activity - PCI Activity by Admin. user. Set the PCI Authorized Server IPs and PCI Admin Users.
4. 10.2.3 Audit Trail Access - To follow this section completely, at least four kinds of reports must be defined: Logins to SQLGuard; User activity audit trails on Guardium server; Scheduled job exceptions; and, User to-to lists. Navigate to investigate > Query-Report Builder to create reports as you need.
5. 10.2.4 Invalid Access - PCI - Invalid Login Access Attempts: record the login failed try in the database. PCI - Unauthorized Application access: record the database access not defined in PCI Authorized Source Programs.
6. These three sections can also use the Monitor and Audit Help Book in the embedded online help - 10.2.6 Initialization Log, 10.5 Secure audit trails, and 10.6 Access Auditing.

#### PCI Req. 11 Ongoing Validation

Click Overview for a discussion on the importance of vulnerabilities assessment. Click Harden > Assessment Builder to build an assessment process.

#### PCI Policy Monitoring

Click Overview to introduce the Policy.

1. To show your current policy installations, navigate to Setup > Tools and Views > Policy Installation and choose a suitable policy for installation.

The screenshot displays two windows side-by-side. The left window is titled 'Policy Violation Count' and shows a large blue '0' indicating no violations. The right window is titled 'Currently Installed Policies' and lists one policy entry: 'Policy\_for\_uninstall\_Rule\_0002' with a date of '2016-07-15 07:15:07'.

2. Policy Violations - Records of violation operations.

## Workflow Builder

Use the Workflow Builder to define customized workflows (steps, transitions, and actions) that you can use with audit processes.

For additional information, see [Building audit processes](#). Follow these steps to:

- Define the workflow steps (Event Status)
- Define the flow of transit from one step to another (Actions)
- Define which actions require sign-off
- Assign roles to each status, to define the users permitted to view each status

Relevant Terms for this feature

Event Type - Custom workflow

Event Status - State/status of the workflow.

Event Action - Action/Transition

Note: Workflow Builder is an optional component enabled by product key.

## Create a Workflow Process

1. With an Admin account, open the Workflow Builder by navigating to Comply > Tools and Views > Workflow Builder. With a User account that has DataPrivacy privileges, open the Workflow Builder by navigating to Accelerators > Data Privacy > Track & Monitor > Audit Trail and Workflow Automation.
2. At the first screen (Event Type), click Event Status to go to the Event Status configuration.
3. Click Add Event Status to define a new Event Status. A multiple of Event Status are expected. Fill in the status description and place a check mark in the Is Final check box if the task is a final task in the workflow.
4. Click Event Type and then click Add on Add Event Type Definition to define a new Event Type.
5. Fill in the description and designate the first task in the workflow.
6. Then choose all the Allowed Status for the workflow from the Available Status list, by highlighting the Status item and clicking on the > button between the Available Status List and Allowed Status List.
7. When done, click the Save button. Note: the Save button (or Cancel button) only apply to changes made to name, default event or available events.
8. Go to the Defined Event Actions section of the Event Type menu screen. Defined Event Actions involves designating the separate Event Actions of the workflow.
9. Click the New button.
10. Fill in the Event Action Description and designate Prior status, Next status and if Sign-off of this event action is required. Click the Apply button.
11. Repeat Steps 9 and 10 until all event actions are described and designated.
12. Go to the Roles section of the Event Type menu screen. Roles involve defining who can see the event when it is in a particular Event Action. For example, who can see events that are "Under Review" and who can see events that are "Approved".
13. Select the Event Type Status and click the Roles button.
14. In the Assign Security Roles panel, mark all of the roles you want to assign (you will only see the roles that have been assigned to your account). Click Apply to save security role choices. Click the Back button.
15. Repeat steps 13 through 14 until all event type status have had roles defined.
16. The configuration effort from Workflow Builder is done.
17. Open the Audit Process Builder by navigating to Comply > Tools and Views > Audit Process Builder to schedule the workflow and build and show workflow reports. See the Audit Process Builder steps under Define a Report Task.

There is a usage scenario, Workflow Builder Workflow Example in the Appendices.

Note: If the task type in Audit Process Builder is Classification Process, then Workflow Builder can not create customized workflows.

Warning Note: When a workflow event is created, every status used by that event can be assigned a role (meaning that events can only be seen by this role when in this status). When an event is assigned to an audit process, it is important that every role that is assigned to a status of this event have a receiver on this audit process.

Otherwise, it is possible that an audit result row can be put into a status where none of its receivers are able to see this row or change its status.

If an audit row becomes inaccessible, the admin user (who is able to see all events, regardless of their roles) would be able to see the row and change its status. However, if data level security is on, the admin user may not be able to see this row. The admin user would need to either turn data level security off (from Global Profile) or have the dataset\_exempt role. It is important to configure the audit process so that all roles who must act on an event associated with this audit process are receivers of this audit process.

Note: Deletion of a event status is permitted only if the status is not in the first or final status of any events, and if it not used by any action. The validation will provide a list of events/actions that prevent the status from being deleted.

## Add Default Events only to limited number of records

---

When running an Audit Process report task, the results of this process task are saved in the table, REPORT\_RESULT\_DATA\_ROW. This table will have a row for every row of the report. If this report task also has a default event assigned to it, a row is added to the table, TASK\_RESULT\_ADDITIONAL\_INFO, for every row of the report. This may lead to a disk space issue only if default events are used for large results. Create events only on task results with a limited number of records, otherwise users will never be able to manage the large number of records. If default events are used in the intended limited manner, there will not be any disk space issues nor any usability issues, since it is not easy to close thousands of events.

## How to create Customized Workflows

Define customized workflows made up of specific customer steps, transitions and actions to be further used in an audit process.

### About this task

---

Define and manage workflow based on customer's specific practices.

See Workflow Builder for an overview of this component.

#### Prerequisites

- See How to create an Audit Workflow. For additional information, see Compliance Workflow Automation.
- After creating this customized workflow, See How to combine Customized Workflow with Audit Workflow.

### Procedure

---

1. Open the Workflow Builder by navigating to Comply > Tools and Views > Workflow Builder.
2. At the first screen (Event Type), click the Event Status button to go to the Event Status configuration.
3. Click on Add Event Status to define a new Event Status. A multiple of Event Status are expected. Fill in the status description and place a check mark in the Is Final check box if the task is a final task in the workflow. When done, go to the next step.

An example of a simple three-step workflow is: Open to Review state to Approve or Not Approved. Each step of the workflow is a separate Defined Task Event Status.

The workflow tasks of the example are: Open, Review state, Approve after review, or Not approved. Also, if the task is the final task in a workflow, place a check mark in the Is Final column. Examples of a final task in the example are Approved or Not Approved.

Description: My workflow

First Status: Open

**Allowed Status**

Available Status:

Allowed Status: Approve after review (Final), Not approved (Final), Open, Review State

**Defined Event Actions**

|                                                                                                                                                                                                                                                       | Event Action Description | Prior Status | Next Status          | Sign-off                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|--------------|----------------------|-------------------------------------|
|    | Under Review             | Open         | Review State         | <input type="checkbox"/>            |
|    | Approved                 | Review State | Approve after review | <input checked="" type="checkbox"/> |
|    | Not approved             | Review State | Not approved         | <input checked="" type="checkbox"/> |

**New...**

**Roles**

Roles have been assigned to this event type with status Approve after review

Roles have been assigned to this event type with status Not approved

Roles have been assigned to this event type with status Open

Roles have been assigned to this event type with status Review State

**Cancel** **Save**

**New Event Type** **Event Status**

4. Click on the Event Type button and then click on the Add button of Add Event Type Definition to define a new Event Type.
5. Fill in the description and designate the first task in the workflow.
6. Then choose all the Allowed Status for the workflow from the Available Status list, by highlighting the Status item and clicking on the > button between the Available Status List and Allowed Status List.
7. When done, click the Save button.
8. Go to the Defined Event Actions section of the Event Type menu screen. Defined Event Actions involves designating the separate Event Actions of the workflow.
9. Click the New button.
- From the simple three-step workflow example, an Event Action of Under Review has a prior status of Open and a next Status of Review State. The Event Action of Approved follows Under Review with a prior status of Review State and next status of Approve after review. Or the Event Action of Not approved has a prior status of Review State and a next status of Not Approved. There is also a signoff capability for designated reviewers per Event Action (continuous or sequential). See the previous screen shot.
10. Fill in the Event Action Description and designate Prior status, Next status and if Sign-off of this event action is required. Click the Apply button.
11. Repeat Steps 9 and 10 until all event actions are described and designated.
12. Go to the Roles section of the Event Type menu screen. Roles involve defining who can see the event when it is in a particular Event Action. For example, who can see events that are "Under Review" and who can see events that are "Approved".
13. Select the Event Type Status and click the Roles button.
14. In the Assign Security Roles panel, mark all of the roles you want to assign (you will only see the roles that have been assigned to your account). Click Apply to save security role choices. Click the Back button.
15. Repeat steps 13 through 14 until all event type status have had roles defined.
16. The configuration effort from Workflow Builder is done.
17. Open the Audit Process Builder by navigating to Comply>Tools and Views>Audit Process Builder to schedule the workflow and build and show workflow reports. See the Audit Process Builder steps under Define a Report Task.

## How to use Customized Workflows

Define an audit process that follows the customer's customized workflow practices. Bring the customer's specific auditing processes and practices into the Guardium® solution.

### About this task

## Customized Workflows within the Guardium Audit Workflow process

The formal sequence of event types created in Workflow Builder is managed by clicking on the Event and Additional Column button in the Audit Tasks window. This button will appear after an audit task has been created and saved. This additional button will not appear until the audit task is saved.

### Prerequisites

- See How to create Customized Workflows. For additional information, see Workflow Builder.
- See How to create an Audit Workflow. For additional information, see Compliance Workflow Automation.
- Define an audit process that follows the customer's customized workflow practices by following the additional steps.

## Procedure

1. Configure these workflow activities when Adding An Audit Task.
2. Create and save an Audit Task. After saving, an additional button, Events and Additional Columns, will appear.
3. Click this additional button.

| Column Name   | Mandatory                           | Type   | Size | Group |
|---------------|-------------------------------------|--------|------|-------|
| Company Code  | <input checked="" type="checkbox"/> | String | 50   |       |
| Business Unit | <input checked="" type="checkbox"/> | String | 50   |       |
|               | <input type="checkbox"/>            | String | 50   |       |

[Close this window](#)

4. At the next screen, place a checkmark in the box for Event & Sign-off. The workflow created in Workflow Builder will appear as a choice in Event & Sign-off.
5. Highlight this choice. Save your selection.
6. If additional information (such as company codes, business unit labels, etc.) is needed as part of the workflow report, add this information in the Additional Column section of the screen and then click Apply (save). When done, close this window.
7. Apply (save) your Audit Task. Apply (save) the entire Audit Process Definition. Click on the Run Once Now to create the report. Click on View to see the report.
8. Click on the Run Once Now to create the report. Click on View to see the report.

This Event and Additional Column button appears in all audit tasks.

Note: If data level security at the observed data level has been enabled (see Global Profile settings), then audit process output will be filtered so users will see only the information of their databases.

Under the Report choices within Add an Audit Task are two procedural reports, Outstanding Events and Event Status Transition. Add these two reports to two new audit tasks to show details of all workflow events and transitions. These two reports will not be filtered (observed data level security filtering will not be applied). These two reports are available by default in the list of reports only to admin user and users with the admin role.

# Opening Workflow Process Results

Use View to see the Workflow Process Results

Do one of the following:

- Open your Workflow Automation To-do List (see Audit Process To-Do List) and click View for the results set you want to view or sign.
- If you have received an e-mail notification containing hypertext links to your To-Do List or the results, click one of those links to open your To-Do List or the results directly from the e-mail. You must have access to the Guardium® system at the location from which you are accessing your e-mail (or these links will not work). If you are not logged in, you will be prompted to log in to the Guardium system.

Note: When you register a new managed unit to a central manager, you might be unable to view audit results. The application does not show results that have a timestamp before the managed unit was registered to the central manager. The timestamp of the registration uses the central manager time, and the timestamp of the audit result uses the managed node time. So, if the central manager time is ahead of the managed unit time, results generated on the managed unit are not visible until the managed unit time passes the time of registration. This should happen in no more than 24 hours, possibly less depending on the locations of the two machines. You should be able to view the results of audit processes on the managed unit within 24 hours of registration.

## Reports

Data protection requires monitoring of data and file activity. Guardium gathers a large amount of data about your database environment, and about your Guardium system. You can view this data in reports.

Guardium provides sophisticated reporting tools that includes many predefined reports. However, you may want to build your own custom report or to modify an existing report.

Each report presents information that is defined by the report's unique query. The query defines what information is gathered, and how it is displayed in the report. Queries are also used to gather information for other purposes. For example, a group can be populated from the results of a query.

You can use dashboards to group reports for display. You can add custom reports and predefined reports to a dashboard, and to My Custom Reports.

## Limitations

- PDFs generated manually or using an audit process are limited to 5,000 rows. Manually exported CSV files are limited to 30,000 rows (this default is configurable using the `store csv_max_size` CLI command). Any number of rows can be exported to CSV when using an audit process. For more information, see [Building audit processes](#) and [Exporting a report](#).
- Group builder and Alias builder. When importing group members from Members tab, Import From query using Run Once Now, the maximum number of imported members is 5,000 rows. This is not configurable. For more information, see [Populating groups](#) and [Define Aliases using a Query](#).
- Group builder and Alias builder. When importing group members from Members tab, Import From query using a schedule, the maximum number of imported members is 20,000 rows by default. You can configure this limit using the CLI command `show/store populate_from_query_maxrecs`. For more information, see [Populating groups](#) and [Define Aliases using a Query](#).
- **Predefined reports**  
Before creating custom reports from scratch, take advantage of the predefined Guardium reports.
- **Creating dashboards and adding reports**  
You can create one or more dashboards, add reports to them, and configure their appearance.
- **Opening the investigation dashboard, filtered for report entities**
- **Viewing reports**  
There are several ways to view a report, including your dashboard and UI search.
- **Using the Query-Report Builder**  
If the predefined reports do not meet your needs, create a query from scratch, or clone and modify an existing query.
- **Domains, Entities, and Attributes**  
Each domain contains a set of data stored in Guardium that relates to a specific purpose or function (data access, exceptions, policy violations, and so forth). The data is grouped by entities. An entity is a set of related attributes, and an attribute is basically a field value.
- **Custom Domains**  
Custom domains allow for user defined domains and can define any tables of data uploaded to your Guardium system.
- **Data Mart**  
Use data marts to extract data for subsequent use. Use datamarts for more efficient storage of frequently accessed data; for data that you want to preserve after its purge time; for exporting data from Guardium; and for creating distributed reports.
- **Distributed Report Builder**  
This central manager feature provides a way to automatically gather data from all or a subset of the Guardium managed units that are associated with this particular central manager. Distributed reports are designed to provide a high-level view, to correlate data from across data sources, and to summarize views of the data. Continue to use aggregators for the row level data gathering across collectors.
- **Working with API calls and reports**
- **Working with external feeds**  
Use external feeds to send Guardium report data directly to an external database. Sending reporting data to an external database is useful in several scenarios, for example when combining or correlating Guardium data with non-Guardium data, when using Guardium data with external tools, or when machine-parsing records in especially large reports.
- **Creating reports for z/OS**  
Learn how to create Guardium reports for z/OS data sources by customizing built-in reports and example queries.

## Predefined reports

Before creating custom reports from scratch, take advantage of the predefined Guardium reports.

Get the information that you seek faster, by accessing predefined reports available from the Guardium application. These predefined reports can be cloned and customized to the needs of the user.

Using the Guardium predefined reports is a best practice recommendation, enabling organizations to quickly and easily identify security risks, such as inappropriately exposed objects, users with excessive rights, and unauthorized administrative actions. Examples of the many predefined reports include: accounts with system privileges; all system and administrator privileges, which are shown by user and role; object privileges by user; and all objects with PUBLIC access.

The parameters (columns) display can be edited using Customize in any report screen.

Use the search function of help to go to the specific report directly. Use quotation marks around words or phrases to precisely define search terms.

## Use cases for predefined reports

---

Database administrator

- SQL Errors - An increase in SQL errors may indicate a SQL injection attack.
- DDL (verify schema changes) - This report displays the client IP from which the DDL was requested, the main SQL verb (a specific DDL command), and the total objects accessed for that record.
- Failed logins - This report indicates attempts to access the database with expired login credentials.

Information security officer

- Failed logins - People with proper credentials trying to access the database.
- Terminated users - Terminated users trying to access the database.
- Policy violations - Users and issues that violate security policies.

Auditors

- Compliance reports - PCI, SOX, Data Privacy
- Compliance workflow - Shows evidence of signoffs and procedures.

- **Predefined admin reports**

This section provides a short description of predefined reports for the admin user.

- **Predefined user reports**

This section provides a short description of all predefined reports for users with default user access.

- **Predefined common reports**

This section provides a short description of all predefined reports available for users with either default user access rights or default admin access rights.

---

## Predefined admin reports

This section provides a short description of predefined reports for the admin user.

Note: If data level security at the observed data level is enabled (see [Data level security filtering](#)), then the audit process output is filtered so users see only the information about their databases.

**Enterprise reports with custom tables:** If for any reason, the central manager did not receive data from a managed unit for the custom table in an enterprise report in the last 24 hours, the Guardium® UI banner displays the message:

Central manager experienced failure getting data from collector. Central manager experienced error in the last 24 hours uploading data.

Click the report name to open the Scheduled Jobs Exceptions report and view details of the managed units that had exceptions.

The predefined admin reports are listed in alphabetical order.

## Active Risk Spotter - Risky Users Scores

---

This report details the current risky users, including the server IP, the overall risk score, and scores for all of the risk indicators.

## Active S-TAPs changed

---

This alert only runs on Central Manager systems. S-TAP Host, S-TAP version, S-TAP changed, timestamp and count are shown.

| Domain                   | Based on Query        | Main Entity   |
|--------------------------|-----------------------|---------------|
| Internal - not available | Active S-TAPs changed | Not available |
| Run-Time Parameter       | Operator              | Default Value |
| Period From              | none                  | none          |

## Admin User Logins

---

Summary of logins to the database using a database user name defined in the Admin Users group. The report displays the client IP address from which the user with administrative privileges logged into the database, database user name, source program, session start date and time, and session total for that record.

| Domain             | Based on Query    | Main Entity   |
|--------------------|-------------------|---------------|
| Access             | Admin Users Login | Session       |
| Run-Time Parameter | Operator          | Default Value |
| Period From        | >=                | NOW -1 DAY    |
| Period To          | <=                | NOW           |

## Aggregation/Archive Log

This report lists Guardium aggregation activity by Activity Type. Each row of the report contains the Activity Type, Start Time, File Name, Status, Comment, Guardium Host Name, Records Purged, Period Start, Period End, and count of log records for the row. You can limit the output by setting the Guardium Host Name run-time parameter, which is set to % by default (to select all servers). The Records Purged column contains a count of records purged only when the activity type is Purge.

| Domain                    | Based on Query          | Main Entity     |
|---------------------------|-------------------------|-----------------|
| Aggregation/Export/Import | Aggregation/Archive Log | Agg/Archive Log |
| Run-Time Parameter        | Operator                | Default Value   |
| Period From               | >=                      | NOW -1 WEEK     |
| Period To                 | <=                      | NOW             |
| Guardium Host Name        | LIKE                    | %               |

## 12.1 and later Aggregator Global Collector ID

This report maps the collector ID and collector name to the aggregator.

| Domain                         | Based on Query                 | Main Entity                    |
|--------------------------------|--------------------------------|--------------------------------|
| Aggregator Global Collector ID | Aggregator Global Collector ID | Aggregator Global Collector ID |
| Run-Time Parameter             | Operator                       | Default Value                  |
| Period From                    | >=                             | NOW -3 HOUR                    |
| Period To                      | <=                             | NOW                            |
| Show Aliases                   | Radio buttons                  | Default                        |
| Remote Data Source             | Drop-down menu                 |                                |
| Refresh Rate                   | Drop-down menu                 | 0                              |

## All Guardium Applications - Roles

This menu pane displays two reports: All Roles - Application Access - and All Roles - User.

### All Roles - Application Access

For each role, this report lists the number of applications to which it is assigned. To list the applications to which a role is assigned, click on the role and drill down to the Record Details report.

| Domain                   | Based on Query                 | Main Entity    |
|--------------------------|--------------------------------|----------------|
| Internal - not available | All Roles - Application Access | Not available  |
| Run-Time Parameter       | Operator                       | Default Value  |
| Period From              | >=                             | NOW -100 MONTH |
| Period To                | <=                             | NOW            |

### All Roles - User

For each role, this report lists the number of users to which it is assigned. To list the users to which a role is assigned, click on the role and drill down to the Record Details report.

| Domain                   | Based on Query | Main Entity    |
|--------------------------|----------------|----------------|
| Internal - not available | Role - User    | Not available  |
| Run-Time Parameter       | Operator       | Default Value  |
| Period From              | >=             | NOW -100 MONTH |
| Period To                | <=             | NOW            |

## Analytic Outlier Details

| Domain                    | Based on Query            | Main Entity               |
|---------------------------|---------------------------|---------------------------|
| Analytic Outliers Details | Analytic Outliers Details | Analytic Outliers Details |
| Run-Time Parameter        | Operator                  | Default Value             |
| Period From               | >=                        | NOW -3 HOUR               |
| Period To                 | <=                        | NOW                       |
| DB User name              | LIKE                      | %                         |
| DB Name                   | LIKE                      | %                         |
| Source program            | LIKE                      | %                         |

| OS User                   | LIKE                      | %                         |

## Analytic Outlier Summary by Date - enhanced

| Domain                    | Based on Query            | Main Entity               |
|---------------------------|---------------------------|---------------------------|
| Analytic Outliers Details | Analytic Outliers Details | Analytic Outliers Details |
| Run-Time Parameter        | Operator                  | Default Value             |
| Period From               | >=                        | NOW -3 HOUR               |
| Period To                 | <=                        | NOW                       |
| Server IP                 | LIKE                      | %                         |
| DB User name              | LIKE                      | %                         |
| DB Name                   | LIKE                      | %                         |
| OS User                   | LIKE                      | %                         |

## Analytic Threat Case Details

This report presents details of an identified threat case. You need to enter the case ID and the datasource to view the report.

| Domain                  | Based on Query | Main Entity                      |
|-------------------------|----------------|----------------------------------|
| Eagle Eye               | Not available  | Symptom type                     |
| Run-Time Parameter      | Operator       | Default Value                    |
| Enter Value for Case Id |                | text field                       |
| Show Aliases            |                | Radio buttons (On, Off, Default) |
| Remote Data Source      |                | Drop-down menu                   |
| Refresh rate in seconds |                | 0                                |

## Appliance Settings

This report displays configuration settings from a Guardium system. Use the *appliance settings* report to quickly review and validate Guardium settings.

| Domain                   | Based on Query        | Main Entity                      |
|--------------------------|-----------------------|----------------------------------|
| Internal - not available | Active S-TAPs changed | Not available                    |
| Run-Time Parameter       | Operator              | Default Value                    |
| Show Aliases             |                       | Radio buttons (On, Off, Default) |
| Remote Data Source       |                       | Drop-down menu                   |

## Application Objects Summary

This report is a summary of every definition in the Guardium application. For instance, type Oracle in the ObjectNameLike space in the Run-Time Parameters page of Application Objects and find all the Object Types and Object Descriptions where Oracle is used.

Note: This report presents metadata and as such is not filtered through the Data Level Security mechanism. This metadata could include database related information such as Oracle SIDs.

| Domain              | Based on Query              | Main Entity         |
|---------------------|-----------------------------|---------------------|
| Application Objects | Application Objects Summary | Application Objects |
| Run-Time Parameter  | Operator                    | Default Value       |
| ObjectNameLike      | %                           | %                   |
| ObjectTypeLike      | %                           | %                   |

## Approved TAP clients

Only specific S-TAPs are permitted to connect to the Guardium application. This report shows which S-TAP is approved and the status of it.

| Domain                   | Based on Query       | Main Entity   |
|--------------------------|----------------------|---------------|
| Internal - not available | Approved TAP Clients | Not available |
| Run-Time Parameter       | Operator             | Default Value |
| Period From              | >=                   | NOW -1 DAY    |
| Period To                | <=                   | NOW           |

## Assessment Datasources

This report is a summary of datasources that are linked to a security assessment.

| Domain                   | Based on Query                                                               |               | Main Entity         |
|--------------------------|------------------------------------------------------------------------------|---------------|---------------------|
| Internal - not available | Assessment and the datasources (or datasource groups) used by the assessment |               | SECURITY_ASSESSMENT |
| Run-Time Parameter       | Operator                                                                     | Default Value |                     |
| Assessment               | LIKE                                                                         | %             |                     |
| Refresh rate in seconds  |                                                                              | 0             |                     |

## Assessment Roles Allowed

This report is a summary of the roles that are mapped to a security assessment.

| Domain                   | Based on Query                                     |               | Main Entity         |
|--------------------------|----------------------------------------------------|---------------|---------------------|
| Internal - not available | Assessment and the roles defined in the assessment |               | SECURITY_ASSESSMENT |
| Run-Time Parameter       | Operator                                           | Default Value |                     |
| Assessment               | LIKE                                               | %             |                     |
| Refresh rate in seconds  |                                                    | 0             |                     |

## Assessment Tests

This report lists the tests that are included in a security assessment.

| Domain                   | Based on Query                                                          |                                  | Main Entity         |
|--------------------------|-------------------------------------------------------------------------|----------------------------------|---------------------|
| Internal - not available | Assessment and the associated tests that are included in the assessment |                                  | SECURITY_ASSESSMENT |
| Run-Time Parameter       | Operator                                                                | Default Value                    |                     |
| Period From              | >=                                                                      | 2009-01-01 00:00:00              |                     |
| Period To                | <=                                                                      | NOW                              |                     |
| Assessment               | LIKE                                                                    | %                                |                     |
| Test Description         | LIKE                                                                    | %                                |                     |
| Assessment ID            | LIKE                                                                    | %                                |                     |
| Test ID                  | LIKE                                                                    | %                                |                     |
| Show Aliases             |                                                                         | Radio buttons (On, Off, Default) |                     |
| Remote Data Source       |                                                                         | Drop-down menu                   |                     |
| Refresh Rate (Seconds)   |                                                                         | 0                                |                     |

## Available VA Tests

Following reports are available as part of Available VA Tests

- Available VA Tests
- Available VA Tests - Detailed
- 12.1 and later Available VA Tests - CIS
- 12.1 and later Available VA Tests - STIG

The Available VA Tests report and Available VA Tests - Detailed report lists all the security assessment tests in the Guardium system where the reports are generated. The **Available VA Tests - Detailed** report is a more comprehensive version of the **Available VA Tests** report. The Available VA Tests - CIS and Available VA Tests - STIG reports provide ability to filter VA Available Tests report by CIS and STIG, respectively.

### Available VA Tests report

Use the following selections to configure the Available VA Tests report:

| Domain             | Based on Query     | Main Entity                      |
|--------------------|--------------------|----------------------------------|
| VA Tests           | Available VA tests | Assessment Tests                 |
| Run-Time Parameter | Operator           | Default Value                    |
| Test Type          | LIKE               | %                                |
| Category           | LIKE               | %                                |
| Datasource Type    | LIKE               | %                                |
| Severity           | LIKE               | %                                |
| Show Aliases       |                    | Radio buttons (On, Off, Default) |
| Remote Data Source |                    | Drop-down menu                   |

| Run-Time Parameter     | Operator | Default Value |
|------------------------|----------|---------------|
| Refresh Rate (Seconds) |          | 0             |

#### Available VA Tests - Detailed report

Use the following selections to configure the Available VA Tests - Detailed report:

| Domain                    | Based on Query           | Main Entity                      |
|---------------------------|--------------------------|----------------------------------|
| Internal - not available  | Internal - not available | Internal - not available         |
| Run-Time Parameter        | Operator                 | Default Value                    |
| Period From               | >=                       | 2009-01-01 00:00:00              |
| Period To                 | <=                       | NOW                              |
| Test ID                   | LIKE                     | %                                |
| Test Description          | LIKE                     | %                                |

## Audit Process Log

### Audit Process Log

This report shows a detailed activity log for all tasks including start and end times. This report is available for admin users. Audit tasks show start and end times, however the start and end of Security Assessments and Classifications (which go to a queue) is the same.

The Audit Process has been expanded to the signoff of specific rows beyond a user signing off on the entire audit process. Displays a list of what has been signed off and what is the status of specific rows.

Use this Audit Process Log to stop audit processes. Tasks can be stopped only if the tasks have not been run or are running. Any more tasks that have not started will not execute. Partial results will not be delivered. If tasks are complete, stopping the audit process will not stop the sending of the results. Stopping the audit process is done through a GrdAPI command, invoke api, from the Audit process Log report. For any user it only shows the line belonging to the user (but without all the details - just the tasks). Admin users get to see all the details and can stop anyone's runs. Users can only stop their own runs.

Stopping the audit process does not cancel queries running using a remote source. Neither will such online reports using a remote source.

Not supported for Privacy sets and External Feed. This means that if the Privacy set task was started or the External Feed has started - it will finish even if the process is stopped (as opposed to a query which will be killed).

## Available Patches

Displays a list of available patches. There are no run-time parameters. The reporting domain is system-only.

## Audit Job Task Security Assessment

Displays the definition of the audit process job and the task name that runs a security assessment.

| Domain                   | Based on Query           | Main Entity              |
|--------------------------|--------------------------|--------------------------|
| Internal - not available | Internal - not available | Internal - not available |
| Run-Time Parameter       | Operator                 | Default Value            |

## 12.1 and later Audit Process Task Details

Provides audit process information including the Audit process items, audit tasks and the record count for the audit tasks that belong to the audit process items. This report is useful for validating the data that is sent to SIEM and ensures the same number of records are sent in a file.

| Domain                   | Based on Query                 | Main Entity   |
|--------------------------|--------------------------------|---------------|
| Internal - not available | All Roles - Application Access | Not available |
| Run-Time Parameter       | Operator                       | Default Value |
| Period From              | >=                             | NOW - 3 HOURS |
| Period To                | <=                             | NOW           |
| Remote Data Source       | Drop-down menu                 | --            |
| Show Aliases             | Radio buttons                  | Default       |
| Refresh Rate (Seconds)   | Drop-down menu                 | 0             |

## Buffer Usage Monitor

Provides an extensive set of buffer usage statistics. For more information, see [BigData Intelligence Buff Usage Monitor domain](#).

| Domain             | Based on Query     | Main Entity                  |
|--------------------|--------------------|------------------------------|
| Buffer Usage       | Buff Usage Monitor | Sniffer Buffer Usage Monitor |
| Run-Time Parameter | Operator           | Default Value                |
| Period From        | >=                 | NOW -1 DAY                   |
| Period To          | <=                 | NOW                          |

## Cassandra DB Object privileges granted to grantee

Lists all the Cassandra DB Object privileges that are granted to users and roles.

| Domain                                            | Based on Query                                    | Main Entity                                       |
|---------------------------------------------------|---------------------------------------------------|---------------------------------------------------|
| Cassandra DB Object privileges granted to grantee | Cassandra DB Object privileges granted to grantee | Cassandra DB Object privileges granted to grantee |
| Run-Time Parameter                                | Operator                                          | Default Value                                     |
| Period From                                       | >=                                                | NOW -3 HOUR                                       |
| Period To                                         | <=                                                | NOW                                               |
| Enter Value for Role                              | LIKE                                              | %                                                 |
| Enter Value for Resource                          | LIKE                                              | %                                                 |
| Enter Value for Permission                        | LIKE                                              | %                                                 |
| Show Aliases                                      | Radio buttons                                     | Default                                           |

| Run-Time Parameter     | Operator       | Default Value |

## Cassandra Role granted to User Role

Lists all the Cassandra roles that are granted to a user.

| Domain                              |                | Based on Query                      | Main Entity                         |
|-------------------------------------|----------------|-------------------------------------|-------------------------------------|
| Cassandra Role granted to User Role |                | Cassandra Role granted to User Role | Cassandra Role granted to User Role |
| Run-Time Parameter                  | Operator       | Default Value                       |                                     |
| Period From                         | >=             | NOW -3 HOUR                         |                                     |
| Period To                           | <=             | NOW                                 |                                     |
| Enter Value for Role                | LIKE           | %                                   |                                     |
| Enter Value for Member              | LIKE           | %                                   |                                     |
| Show Aliases                        | Radio buttons  | Default                             |                                     |
| Remote Data Source                  | Drop-down menu |                                     |                                     |
| Refresh Rate (Seconds)              | Drop-down menu | 0                                   |                                     |

## Cassandra SuperUser Role

Lists all the Cassandra users with a SuperUser role.

| Domain                   |                | Based on Query           | Main Entity              |
|--------------------------|----------------|--------------------------|--------------------------|
| Cassandra SuperUser Role |                | Cassandra SuperUser Role | Cassandra SuperUser Role |
| Run-Time Parameter       | Operator       | Default Value            |                          |
| Period From              | >=             | NOW -3 HOUR              |                          |
| Period To                | <=             | NOW                      |                          |
| Enter Value for Role     | LIKE           | %                        |                          |
| Show Aliases             | Radio buttons  | Default                  |                          |
| Remote Data Source       | Drop-down menu |                          |                          |
| Refresh Rate (Seconds)   | Drop-down menu | 0                        |                          |

## CAS Deployment

This CAS reports details the Database type, OS name, Hostname and OS type.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| CAS                | CAS Deployment | Not available |
| Run-Time Parameter | Operator       | Default Value |
| DB Type            | Like           | %             |
| OS_Name            | Like           | %             |
| Hostname           | Like           | %             |
| OS_Type            | Like           | %             |

## Changes (CAS)

### CAS Change Details

For each monitored item, the changes are listed in order by owner.

| Domain             | Based on Query     | Main Entity        |
|--------------------|--------------------|--------------------|
| CAS Changes        | CAS Change Details | Host Configuration |
| Run-Time Parameter | Operator           | Default Value      |

| Run-Time Parameter | Operator | Default Value |
|--------------------|----------|---------------|
| DB_Type            | Like     | %             |
| Host_Name          | Like     | %             |
| Instance_Name      | Like     | %             |
| Monitored_Item     | Like     | %             |
| OS_Type            | Like     | %             |
| Type               | Like     | %             |

#### CAS Saved Data

This report lists the data saved for each change detected. This report is sorted by host name, and then by the most recent modification time.

| Domain                    | Based on Query | Main Entity |
|---------------------------|----------------|-------------|
| CAS Changes               | CAS Saved Data | Saved Data  |
| <b>Run-Time Parameter</b> |                |             |
| Host_Name                 | Like           | %           |
| Monitored_Item            | Like           | %           |
| Saved_Data_Id             | Like           | %           |

## Configuration (CAS)

---

#### CAS Instances

This report lists CAS instance definitions (a CAS instance applies a template set to a specific CAS host). The default sort order for this report is non-standard. The sort keys are, from major to minor: Host Name (ascending), Instance (ascending) and Last Status Change (descending).

| Domain                    | Based on Query | Main Entity            |
|---------------------------|----------------|------------------------|
| CAS Config                | CAS Instances  | Monitored Item Details |
| <b>Run-Time Parameter</b> |                |                        |
| Host_Name                 | Like           | %                      |
| OS_Type                   | Like           | %                      |
| DB_Type                   | Like           | %                      |
| Instance                  | Like           | %                      |

#### CAS Instance Config

This report lists CAS instance configuration changes. The default sort order for this report is non-standard. The sort keys are, from major to minor: Host Name (ascending), Instance (ascending) and Last Status Change (descending). You can limit the output by using any of the following runtime parameters, which select all values by default.

| Domain                    | Based on Query      | Main Entity            |
|---------------------------|---------------------|------------------------|
| CAS Config                | CAS Instance Config | Monitored Item Details |
| <b>Run-Time Parameter</b> |                     |                        |
| Host_Name                 | Like                | %                      |
| OS_Type                   | Like                | %                      |
| Template_Id               | Like                | %                      |

## Connection Profiling List

---

Connection Profiling List is a group of all allowed connections (the Connection Profiling List show all connection details).

| Domain                    | Based on Query            | Main Entity   |
|---------------------------|---------------------------|---------------|
| Internal - not available  | Connection Profiling List | Client Server |
| <b>Run-time parameter</b> |                           |               |
| Query From Date           | >=                        | NOW -1 DAY    |
| Query To Date             | <=                        | NOW           |

## Connections Quarantined

---

Guardium policies can be used to terminate or quarantine connections in real time. Use threshold alerts, based on queries. See Quarantine under the Policies topic for configuration instructions.

| Domain                    | Based on Query          | Main Entity           |
|---------------------------|-------------------------|-----------------------|
| Connection Quarantine     | Connections Quarantined | Connection Quarantine |
| Period From               | >=                      | NOW -1 DAY            |
| <b>Run-Time Parameter</b> |                         |                       |
| Server IP                 | LIKE                    | %                     |
| DB User                   | LIKE                    | %                     |
| Server Name               | LIKE                    | %                     |
| Period From               | >=                      | NOW -1 DAY            |
| Period To                 | <=                      | NOW                   |

## CPU Tracker

---

Lists the Software TAP Host and number of CPUs on machines running S-TAPs.

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| Internal - not available |                | Not available |
| Run-Time Parameter       | Operator       | Default Value |
| None                     |                |               |

## CPU Usage

By default, displays the CPU usage for the last two hours. This graphical report is intended to display recent activity only. If you alter the From and To run-time parameters to include a larger timeframe, you may receive a message indicating that there is too much data. Use a tabular report to display a larger time period.

| Domain             | Based on Query | Main Entity                  |
|--------------------|----------------|------------------------------|
| Sniffer Buffer     | CPU Usage      | Sniffer Buffer Usage Monitor |
| Run-Time Parameter | Operator       | Default Value                |
| Period From        | >=             | NOW -2 HOUR                  |
| Period To          | <=             | NOW                          |

## Databases by Type/ Number of DB per type

Server type and client sources for each database type monitored.

| Domain             | Based on Query        | Main Entity   |
|--------------------|-----------------------|---------------|
| Access             | Number of db per type | Client/Server |
| Run-Time Parameter | Operator              | Default Value |
| Period From        | >=                    | NOW -1 DAY    |
| Period To          | <=                    | NOW           |

## Databases Discovered

For the reporting period, for each Discovered Port entity where the DB Type attribute value is NOT LIKE Unknown, this report lists the Probe Timestamp, Server IP, Sever Host Name, DB Type, Port, Port Type, and count of Discovered Ports for the row.

| Domain             | Based on Query       | Main Entity       |
|--------------------|----------------------|-------------------|
| Auto-discovery     | Databases Discovered | Discovered Port   |
| Run-Time Parameter | Operator             | Default Value     |
| Period From        | >=                   | NOW -1 DAY        |
| Period To          | <=                   | NOW               |
| PortNotLike        | NOT LIKE             | No default value. |

## Datamart Extraction Log

The extraction log has data about both table and file extractions. It presents:Data Mart Name, Collector IP, Server IP, from-time, to-time, ID, run started, run ended, number of records, status, error code.

## Data Sources

Lists all datasources defined: Data -Source Type, Data-Source Name , Data-Source Description, Host, Port, Service Name, User Name, Database Name, Last Connect, Shared, and Connection Properties..

You can restrict the output of this report using the Data Source Name run time parameter, which by default is set to "%" to select all datasources.

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| Internal - not available | Data-Sources   | Not available |
| Run-Time Parameter       | Operator       | Default Value |
| Data Source Name         | LIKE           | %             |
| Period From              | >=             | NOW -1 DAY    |
| Period To                | <=             | NOW           |

## Days not exported or archived

This report lists the days whose data was not exported or archived, for a system that has a daily archive or export, and if Allow purge without exporting or archiving is not selected. For more details, see [Viewing days whose data was not archived or exported](#).

| Domain                  | Based on Query                   | Main Entity    |
|-------------------------|----------------------------------|----------------|
| Catalog                 | Days not exported or archived    | Entry          |
| Run-Time Parameter      | Operator                         | Default Value  |
| Period From             | >=                               | NOW -2 WEEK    |
| Period To               | <=                               | NOW            |
| Show Aliases            | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source      |                                  | Drop-down menu |
| Refresh rate in seconds |                                  | 0              |

## DB Users Mapping List

The mapping between database users (Invokers of SQL that caused a violation) and email addresses for real time alerts.

| Domain             | Based on Query        | Main Entity          |
|--------------------|-----------------------|----------------------|
| Auto-discovery     | DB Users Mapping List | Guardium Users Login |
| Run-Time Parameter | Operator              | Default Value        |
| Period From        | >=                    | NOW -1 DAY           |
| Period To          | <=                    | NOW                  |

## Default DB Users Enabled

This report details the default users found enabled after a database scan through the group of default users and list of servers supplied to the Non-credential Scan API. When an enabled user is found within a database, that occurrence of database/user is reported only once. Subsequent scans will update the timestamp and database version of the database. If a subsequent scan does not find a previously found user the timestamp remains unaffected so as to keep a history with the last time the user was found enabled on a database. Scans are run under the Classifier Listener and submitted jobs (with the non\_credential\_scan API) may be tracked using the Guardium Job Queue report.

| Domain                   | Based on Query           | Main Entity              |
|--------------------------|--------------------------|--------------------------|
| Default DB Users Enabled | Default DB Users Enabled | Default DB Users Enabled |
| Run-Time Parameter       | Operator                 | Default Value            |
| Period From              | >=                       | NOW -1 DAY               |
| Period To                | <=                       | NOW                      |

## Definitions Export/Import Log

This report lists Guardium export/import activity by Activity Type. Each row of the report contains the Activity Type, Start Time, File Name, Status, Comment, and count of log records for the row.

| Domain              | Based on Query                | Main Entity     |
|---------------------|-------------------------------|-----------------|
| Aggregation/Archive | Export-Import Definitions Log | Agg/Archive Log |
| Run-Time Parameter  | Operator                      | Default Value   |
| Period From         | >=                            | NOW -1 DAY      |
| Period To           | <=                            | NOW             |

## Discovered Instances

This S-TAP report details the following information:

Timestamp, Host, Protocol, Port Min, Port Max, KTAP DB Port, Instance Names, Client, Exclude Client, Proc Names, Named Pipe, DB Install Dir, Proc Name, DB2® Shared Mem Adjustment, DB2 Shared Mem Client Position, DB2 Shared Mem Size, Unix Socket, DB User, DB Version.

Columns are populated as relevant, according to the database type.

| Domain               | Based on Query       | Main Entity          |
|----------------------|----------------------|----------------------|
| Discovered Instances | Discovered Instances | Discovered Instances |
| Run-Time Parameter   | Operator             | Default Value        |
| Period From          | >=                   | NOW -1 DAY           |
| Period To            | <=                   | NOW                  |

## Discovered Instances Rules Add or Replace Log

This report details the following information: Timestamp, Host, Result, Report Only.

| Domain                               | Based on Query                                | Main Entity                        |
|--------------------------------------|-----------------------------------------------|------------------------------------|
| Discovered Instances                 | Discovered Instances Rules Add or Replace Log | Discovered Instances Rules Results |
| Run-Time Parameter                   | Operator                                      | Default Value                      |
| Period From                          | >=                                            | NOW -3 HOUR                        |
| Period To                            | <=                                            | NOW                                |
| Enter Value for Report Only (Yes/No) | Like                                          | %                                  |
| Show Aliases                         | Radio buttons (On, Off, Default)              | Default                            |
| Remote Data Source                   |                                               | Drop-down menu                     |
| Refresh rate in seconds              |                                               | 0                                  |

## Discovered Instances Rules Results

This report details the following information:

Timestamp, Host, Result Message, Result Type, Report Only, Identifier, Discovered, Protocol, Port Min, Port Max, Instance Name, Named Pipe, DB Install Dir, Proc Name, DB2 Shared Mem Adjustment , DB2 Shared Mem Client Position, DB2 Shared Mem Size, Unix Socket, DB User, DB Version.

| Domain               | Based on Query                     | Main Entity                        |
|----------------------|------------------------------------|------------------------------------|
| Discovered Instances | Discovered Instances Rules Results | Discovered Instances Rules Results |
| Run-Time Parameter   | Operator                           | Default Value                      |
| Period From          | >=                                 | NOW -3 HOUR                        |
| Period To            | <=                                 | NOW                                |

| Run-Time Parameter                   | Operator                         | Default Value  |
|--------------------------------------|----------------------------------|----------------|
| Period From                          | >=                               | NOW -3 HOUR    |
| Period To                            | <=                               | NOW            |
| Enter Value for Report Only (Yes/No) | Like                             | %              |
| Show Aliases                         | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source                   |                                  | Drop-down menu |
| Refresh rate in seconds              |                                  | 0              |

## Dropped Requests

Tracks requests dropped by an inspection engine (Exception Description = Dropped database request). Under extremely rare, high-volume situations some requests may be lost. When this happens, the sessions from which the requests were lost are listed in the Dropped Requests report.

| Domain             | Based on Query   | Main Entity   |
|--------------------|------------------|---------------|
| Exceptions         | Dropped Requests | Exception     |
| Run-Time Parameter | Operator         | Default Value |
| Period From        | >=               | NOW -1 DAY    |
| Period To          | <=               | NOW           |

## Enterprise S-TAP Association History

Enterprise S-TAP Association History reports on how long the S-TAP reported to the specific Guardium system in the Load balancer environment.

In order to see this report, you must schedule the CustomTableStapAssocicationJob. (It is not automatically scheduled by default.) For example, to schedule this job to run hourly, run the command: **grdapi schedule\_job cronString="0 0/1 \* 1,2,3,4,5,6,7" jobType="customTableStapAssocication"**

If you set the job to run hourly, you'll see S-TAP association changes with a one hour delay. If you need to see the changes sooner, you can schedule this job to run at more frequent intervals. However, there can be a tradeoff in central manager environments with a large number of S-TAPs, between frequency of reports and load on the system. If the S-TAPs move frequently, running this job every five minutes might burden the central manager. Set the frequency according to your needs, and your environment. To set the job to run every five minutes, run the command: **grdapi schedule\_job cronString="0 0/5 0/1 \* 1,2,3,4,5,6,7" jobType="customTableStapAssocication"**

## Enterprise Buffer Usage Monitor

This report shows the aggregate of sniffer buffer usage from all managed units. There is a need to set the schedule for the upload. See the description of the Sniffer Buffer Usage entity for a description of the fields listed on this report.

| Domain                  | Based on Query          | Main Entity          |
|-------------------------|-------------------------|----------------------|
| Enterprise Buffer Usage | Enterprise Buffer Usage | Sniffer Buffer Usage |
| Run-Time Parameter      | Operator                | Default Value        |
| Period From             | >=                      | NOW -1 DAY           |
| Period To               | <=                      | NOW                  |

## Enterprise S-TAP (Detailed) View

See [S-TAP Info \(Central Manager\)](#) for information on this report.

## Enterprise S-TAP View

See [S-TAP Info \(Central Manager\)](#) for information on this report.

## Exception Count

For the reporting period, the total number of exceptions logged.

| Domain             | Based on Query  | Main Entity   |
|--------------------|-----------------|---------------|
| Exceptions         | Exception Count | Exception     |
| Run-Time Parameter | Operator        | Default Value |
| Period From        | >=              | NOW -1 DAY    |
| Period To          | <=              | NOW           |

## Export Sensitive Data to Discovery

Guardium and InfoSphere® Discovery have mechanisms for the Classification of Sensitive Data.

A bidirectional interface is provided to transfer the identified sensitive data from Guardium to InfoSphere Discovery and from InfoSphere Discovery to Guardium.

This data will be transferred via CSV files. See [External data correlation](#) for further information.

| Domain                   | Based on Query                     | Main Entity                    |
|--------------------------|------------------------------------|--------------------------------|
| Internal - not available | Export Sensitive Data to Discovery | Classification Process Results |
| Run-Time Parameter       | Operator                           | Default Value                  |
| Period From              | >=                                 | NOW -3 HOURS                   |

| Run-Time Parameter | Operator | Default Value |
|--------------------|----------|---------------|
| Period To          | <=       | NOW           |
| Rule Description   | LIKE     |               |
| Schema             | LIKE     |               |

## External Tickets

---

Displays details of tickets that are created in Guardium and sent to external sources such as ServiceNow or Resilient.

| Domain                          | Based on Query  | Main Entity     |
|---------------------------------|-----------------|-----------------|
| Internal - not available        | External Ticket | External Ticket |
| Run-Time Parameter              | Operator        | Default Value   |
| Period From                     | >=              | NOW -3 HOUR     |
| Period To                       | <=              | NOW             |
| Enter Value for Guardium Source | LIKE            | %               |
| Enter Value for Ticket Number   | LIKE            | %               |
| Refresh rate in seconds         |                 | 0               |

## FAM Config Change

---

Displays details about the changes in the File Activity Monitor (FAM) configuration.

| Domain                  | Based on Query                   | Main Entity    |
|-------------------------|----------------------------------|----------------|
| Exceptions              | FAM Config Change                | Exception      |
| Run-Time Parameter      | Operator                         | Default Value  |
| Period From             | >=                               | NOW -3 HOUR    |
| Period To               | <=                               | NOW            |
| Show Aliases            | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source      |                                  | Drop-down menu |

## FAM Progress

---

Displays details about the progress of File Discovery, Entitlement and Classification (FDEC) scans for NAS and Sharepoint.

Note: FDEC does not provide live updates for removed objects. The numbers in the Removed Objects column always reflects the total number of removed objects.

| Domain                                | Based on Query | Main Entity   |
|---------------------------------------|----------------|---------------|

| Refresh Rate (seconds)          |                                        | 0              |

The job queue

Assessments and Classifications run in their own separate process called the job queue. Jobs are queued and have their status maintained while a listener periodically polls the queue looking for waiting jobs to run.

Stopping

Running jobs, when right-clicked for drill-down, there is an option to stop the running job and cancel it. The job can not be restarted at this point.

Halting

Running jobs are monitored to reduce the number of hung jobs that might cause the job queue to become overloaded. If a job is inactive for 30 minutes, the listener is terminated and restarted, effectively stopping the operation of a job. Before the listener is restarted, a process called the cleaner runs, the status is set from RUNNING to HALTED, and then the listener is restarted. A status of HALTED means the job was not able to run to completion.

Resubmitting

Sometimes the listener gets restarted for reasons other than a job hanging, for example rebooting the machine. When the cleaner halts the running jobs, it will see if the job has responded in the past 8 minutes. If it has, the job will be copied and that copy will be resubmitted onto the job queue. The original halted will still display on the queue, and still have the results it was able to process available.

Monitoring

The mechanism by which jobs maintain their active status is by touching the timestamp on the job queue record. It is important to note that the job queue record is used for the entire job. Each individual classifier rule or assessment test interacts with the timestamp for its parent process, and they do not have individual timestamps that are monitored.

The classifier will update its timestamp before every rule is tested and after every SQL operation. For example, if the classifier is scanning the data in a database that supports paging, it will touch the timestamp after each batch of data is brought back from the database. This is because, depending on the state of the target database, the classifier has the potential to invoke some long-running queries that will be limited to 30 minutes of execution.

Assessments touch the timestamp after each test in the assessment is evaluated. Most assessment tests run in a few seconds or less.

Observed Tests

The exception to the relatively quick-running assessment tests is the category of observed assessment tests. These tests are based on queries and reports that use the internal sniffing data on the Guardium appliance and can run for longer periods of time and are unable to update the timestamp while they are in process. Therefore, observed assessment tests have their timestamps set two hours into the future when they are started, essentially giving them two hours and thirty minutes to run to conclusion. This can be confusing when looking at the job queue and seeing the timestamp set to a time in the future. Just like any other assessment test, when the observed test ends, the timestamp will be touched. If the next test is an observed test, the timestamp will once again be set two hours into the future. Otherwise, the timestamp will be set to the current time.

## Guardium usage summary

Displays a list S-TAP hosts, number of processors per the Guardium License Metric Tool (ILMT), and the estimated number of processor value units (PVUs).

To calculate the accurate number of PVUs, see <https://www-112.ibm.com/software/howtobuy/passportadvantage/pvucalculator/pvucalc.wss>

| Domain                    | Based on Query                         | Main Entity    |

| Show Aliases              | Radio buttons (On, Off, Both, Default) | Default        |

| Run-Time Parameter     | Operator | Default Value |
|------------------------|----------|---------------|
| Refresh Rate (seconds) |          | 0             |

## GIM Clients Status

Displays a list of GIM clients, including the client name, OS, vendor, installation date, module name, module version, module state, module schedule, and the system the GIM module reports to.

| Domain             | Based on Query     | Main Entity   |
|--------------------|--------------------|---------------|
| GIM Clients Status | GIM Clients Status | GIM Clients   |
| Run-Time Parameter | Operator           | Default Value |
| Client Name        | %                  | Not available |
| Client OS          | %                  | Not available |

## GIM Events List

Displays a list of GIM Events.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| GIM Events         | GIM Events     | GIM Events    |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -1 DAY    |
| Period To          | <=             | NOW           |

## GIM Installed Modules

Displays a list of installed GIM Modules.

Note: This report shows the modules that have been associated with the host. If a module has been assigned to a host, the assigned version does appear in this report, even if the module has not yet been scheduled or installed. To check the currently installed module, review the GIM Client Status report.

| Domain             | Based on Query     | Main Entity    |
|--------------------|--------------------|----------------|
| GIM Installed Base | GIM Installed Base | GIM Installed  |
| Run-Time Parameter | Operator           | Default Value  |
| none               | not applicable     | not applicable |

## Group Usage Report

Displays the list of all defined groups and all the entities that rely on each group.

## Guardium API Exceptions

Displays a time stamp and description of all GuardAPI exceptions. These are jobs where the Exception Type ID is GUARD\_API\_EXCEPTION.

| Domain             | Based on Query          | Main Entity   |
|--------------------|-------------------------|---------------|
| Exception          | Guardium API Exceptions | Exception     |
| Run-Time Parameter | Operator                | Default Value |
| Period From        | >=                      | NOW -1 DAY    |
| Period To          | <=                      | NOW           |

## Guardium entitlement consolidation report (using ILMT)

This report provides details on active/inactive S-TAP installed on the data server. If the ILMT agent is installed, the report shows the processors value of the data server. If the ILMT agent is not installed, the processor value is blank. This report helps indicate the processor value of the server with an installed, and active S-TAP. The ILMT agent provides the processor value once an ILMT agent is installed; this report does not replace ILMT requirements in any sense (Follow ILMT compliance and audit requirements).

| Domain                 | Based on Query                            | Main Entity    |
|------------------------|-------------------------------------------|----------------|
| Internal-not available | Guardium entitlement consolidation report | Not available  |
| Run-Time Parameter     | Operator                                  | Default Value  |
| Period From            | >=                                        | NOW -3 HOUR    |
| Period To              | <=                                        | NOW            |
| Remote Data Source     |                                           | Drop-down menu |
| Show Aliases           | Radio buttons (On, Off, Both, Default)    | Default        |
| Refresh Rate (seconds) |                                           | 0              |

## Guardium Group Details

For the reporting period, each row of the report lists a group member. The columns contain the following information: Group Description, Group Type, Group Subtype, Timestamp (from the Group Member entity), Group Member, and count of Group Member entities for the row. The value of the timestamp is set to the current time whenever the record is updated.

You can restrict the output of this report using the run-time parameters, both of which are used with the LIKE operator and a default value of %, which selects all values.

| Domain             | Based on Query         | Main Entity    |
|--------------------|------------------------|----------------|
| Group              | Guardium Group Details | Group Member   |
| Run-Time Parameter | Operator               | Default Value  |
| Group Description  | LIKE                   | %              |
| Group Type         | LIKE                   | %              |
| Period From        | >=                     | NOW -100 MONTH |
| Period To          | <=                     | NOW            |

## Guardium Users

Lists each user, date of last activity, and number of roles assigned. For each user, you can drill down to the Record Details report to see the roles assigned to that user.

| Domain                   | Based on Query | Main Entity    |
|--------------------------|----------------|----------------|
| Internal - not available | User Role      | Not available  |
| Run-Time Parameter       | Operator       | Default Value  |
| Period From              | >=             | NOW -100 MONTH |
| Period To                | <=             | NOW            |

## Host History (CAS)

This report lists CAS host events. The default sort order for this report is non-standard. The sort keys are, from major to minor: Host Name (ascending), Instance and Event Time (descending).

| Domain             | Based on Query   | Main Entity   |
|--------------------|------------------|---------------|
| CAS Host History   | CAS Host History | Host Event    |
| Run-Time Parameter | Operator         | Default Value |
| Host_Name          | Like             | %             |
| OS_Type            | Like             | %             |
| Event_Type         | Like             | %             |

## Inactive Inspection Engines

Lists all inactive inspection engines

| Domain                   | Based on Query              | Main Entity               |
|--------------------------|-----------------------------|---------------------------|
| Internal - not available | Inactive Inspection Engines | S-TAP Verification Header |
| Run-Time Parameter       | Operator                    | Default Value             |
| Query from date          | >=                          | NOW -3 HOUR               |
| Query to date            | >=                          | NOW                       |

## Inactive S-TAPs Since

Lists all inactive S-TAPs defined on the system. It has a single run-time parameter: Period From, which is set to now -1 hour by default. Use this parameter to control how you want to define inactive. This report contains the same columns of data for the S-TAP Status report with the addition of a count for each row of the report.

| Domain                   | Based on Query        | Main Entity   |
|--------------------------|-----------------------|---------------|
| Internal - not available | Inactive S-TAPs Since | Not available |
| Run-Time Parameter       | Operator              | Default Value |
| Period From              | >=                    | NOW -1 HOUR   |

## Installed Patches

Displays the patches: Patch Number, Guardium Version, Patch Description, Patch Dependencies, Creation Date, Request Received, Installed By, Status, Status Description, Timestamp, Requested Schedule.

| Domain                  | Based on Query    | Main Entity     |
|-------------------------|-------------------|-----------------|
| Installed Patches       | Installed Patches | Installed Patch |
| Run-Time Parameter      | Operator          | Default Value   |
| Refresh rate in seconds |                   | 0               |

## Investigation dashboard issues

This report displays all Investigation dashboard issues that Monitoring and automatic recovery discovered, including those that are open, in progress, and fixed.

You can limit the output by setting the Guardium Host Name run-time parameter, which is set to % by default (to select all servers). This reduces the number of issues you see in the report.

| Domain                         | Based on Query                 | Main Entity                    |
|--------------------------------|--------------------------------|--------------------------------|
| Investigation dashboard issues | Investigation dashboard issues | Investigation dashboard issues |
| Run-Time Parameters            | Operator                       | Default Value                  |
| Period From                    | >=                             | NOW -3 HOUR                    |

|           |      |     |
|-----------|------|-----|
| Period To | <=   | NOW |
| Host Name | LIKE | %   |

## Investigation dashboard issues in recovery

This report displays the Investigation dashboard issues that Monitoring and automatic recovery is currently trying to fix.

Condition – Investigation Dashboard issue

Status = 'Recovery in progress'

You can limit the output by setting the Guardium Host Name run-time parameter, which is set to % by default (to select all servers). This reduces the number of issues you see in the report.

| Domain                         | Based on Query                             | Main Entity                    |
|--------------------------------|--------------------------------------------|--------------------------------|
| Investigation dashboard issues | Investigation dashboard issues in recovery | Investigation dashboard issues |
| Run-Time Parameters            | Operator                                   | Default Value                  |
| Period From                    | >=                                         | NOW -3 HOUR                    |
| Period To                      | <=                                         | NOW                            |
| Host Name                      | LIKE                                       | %                              |

## Investigation dashboard open issues

This report displays the Investigation dashboard issues that Monitoring and automatic recovery was not able to fix that require manual intervention to resolve

Condition – Investigation Dashboard

issue status = 'Error'

You can limit the output by setting the Guardium Host Name run-time parameter, which is set to % by default (to select all servers). This reduces the number of issues you see in the report.

| Domain                         | Based on Query                      | Main Entity                    |
|--------------------------------|-------------------------------------|--------------------------------|
| Investigation dashboard issues | Investigation dashboard open issues | Investigation dashboard issues |
| Run-Time Parameters            | Operator                            | Default Value                  |
| Period From                    | >=                                  | NOW -3 HOUR                    |
| Period To                      | <=                                  | NOW                            |
| Host Name                      | LIKE                                | %                              |

## Logged R/T Alerts

For the reporting period, the total number of logged real time alerts, listed by rule description.

| Domain             | Based on Query    | Main Entity           |
|--------------------|-------------------|-----------------------|
| Policy Violations  | Logged R/T Alerts | Policy Rule Violation |
| Run-Time Parameter | Operator          | Default Value         |
| Period From        | >=                | NOW -1 DAY            |
| Period To          | <=                | NOW                   |

## Logged Threshold Alerts

For the reporting period, the total number of threshold alerts logged.

| Domain             | Based on Query | Main Entity             |
|--------------------|----------------|-------------------------|
| Alert              | Logged Alerts  | Threshold Alert Details |
| Run-Time Parameter | Operator       | Default Value           |
| Period From        | >=             | NOW -1 DAY              |
| Period To          | <=             | NOW                     |

## Logging Collectors (valid only from aggregation unit)

The Logging Collectors report appears under the Daily Monitor Tab and it is valid only on an aggregator unit. This report shows the number of sessions per Server IP, per collector and per day. For example: on May 19, aggregator #1 collected 100 sessions for Server 192.168.x.x1, 50 sessions for Server 192.168.x.x2; aggregator #2 collected 30 sessions for Server 192.168.x.x3, 90 sessions for Server 192.168.x.x4; etc.

| Domain             | Based on Query     | Main Entity        |
|--------------------|--------------------|--------------------|
| Exceptions         | Logging Collectors | Logging Collectors |
| Run-Time Parameter | Operator           | Default Value      |
| Period From        | >=                 | NOW -1 DAY         |
| Period To          | <=                 | NOW                |

## Logins to Guardium

All values for this report are from the Guardium Logins entity. For the reporting period, each row of the report lists the User Name, Login Succeeded (1= Successful, 0=Failed, -1 =password expired, -2 = login from different IP), Login Date And Time, Logout Date And Time (which is blank if the user has not yet logged out), Host Name,

Remote Address (of the user) and count of logins for the row.

| Domain             | Based on Query  | Main Entity          |
|--------------------|-----------------|----------------------|
| Guardium Logins    | Guardium Logins | Guardium Users Login |
| Run-Time Parameter | Operator        | Default Value        |
| Host Name          | LIKE            | %                    |
| Period From        | >=              | NOW -1 DAY           |
| Period To          | <=              | NOW                  |

## Managed Units (Central Manager)

Enterprise report on a Central Manager that shows which managed units are up. Use this report in a Statistical Alert to send an email to an ADMIN anytime a managed unit is down.

| Domain                   | Based on Query | Main Entity                      |
|--------------------------|----------------|----------------------------------|
| Internal - not available | Managed Units  | Managed Units                    |
| Run-Time Parameter       | Operator       | Default Value                    |
| Host Name                | LIKE           | %                                |
| Remote Data Source       |                | Drop-down menu                   |
| Show Aliases             |                | Radio buttons (On, Off, Default) |

## NAS File Activities

Displays details about the file activity in Network-Attached Storage (NAS) devices.

| Domain                 | Based on Query                   | Main Entity    |
|------------------------|----------------------------------|----------------|
| Access                 | NAS File Activities              | Object/Command |
| Run-Time Parameter     | Operator                         | Default Value  |
| Period From            | >=                               | NOW -3 HOUR    |
| Show Aliases           | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source     |                                  | Drop-down menu |
| Refresh Rate (seconds) |                                  | 0              |

## Number of Active Audit Processes

Number of active Guardium audit processes. When central management is used, this report contains data only on the Central Manager, and is empty on all managed units (the standard message, No data found for requested query, displays). There are no run-time parameters for this report.

| Domain        | Based on Query             | Main Entity   |
|---------------|----------------------------|---------------|
| Audit Process | Number of Active Processes | Audit Process |

## Oracle Unified Audit Activity

This report presents the server, client, and database details for the logged Oracle traffic.

| Domain                 | Based on Query                | Main Entity            |
|------------------------|-------------------------------|------------------------|
| Access                 | Oracle Unified Audit Activity | STAP SQL Configuration |
| Run-Time Parameter     | Operator                      | Default Value          |
| Period From            | >=                            | NOW -3 HOUR            |
| Period To              | <=                            | NOW                    |
| Refresh Rate (seconds) |                               | 0                      |

## Oracle Unified Audit (S-TAP configuration) Activity

This report shows details of the S-TAP and host configurations for Oracle Unified Auditing, the data pull interval and number of rows, and the timeout.

| Domain                 | Based on Query                                      | Main Entity              |
|------------------------|-----------------------------------------------------|--------------------------|
| S-TAP Status           | Oracle Unified Audit (S-TAP Configuration) Activity | Client/Server by Session |
| Run-Time Parameter     | Operator                                            | Default Value            |
| Period From            | >=                                                  | NOW -3 HOUR              |
| Period To              | <=                                                  | NOW                      |
| Refresh Rate (seconds) |                                                     | 0                        |

## Outstanding Audit Process Reviews

Number of outstanding Guardium audit processes, listed by Guardium users.

Table 1. Outstanding Audit Process Reviews

| Domain        | Based on Query                    | Main Entity             |
|---------------|-----------------------------------|-------------------------|
| Audit Process | Outstanding Audit Process Reviews | Task Results To-Do List |

## Primary Guardium Host Change Log

Log of primary host changes for S-TAPs. The primary host is the Guardium unit to which the S-TAP sends data. Each line of the report lists the S-TAP Host, Guardium Host Name, Period Start and Period End.

| Domain                   | Based on Query                 | Main Entity   |
|--------------------------|--------------------------------|---------------|
| Internal - not available | Primary SGuard host change log | Not available |
| Run-Time Parameter       | Operator                       | Default Value |
| Period From              | >=                             | NOW -1 DAY    |
| Period To                | <=                             | NOW           |

## Query Entities and Attributes

This report lists all the entities and attributes in Guardium reports and was created to simplify the linkage between the Guardium attributes to the GuardAPI calls.

Use this report to also invoke create\_constant\_attribute, create\_api\_parameter\_mapping, delete\_api\_parameter\_mapping, or list\_param\_mapping\_for\_function.

| Domain                                                                                                                                                                                                                                    | Based on Query                               | Main Entity                             |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-----------------------------------------|
| Any of Guardium reporting domains                                                                                                                                                                                                         | Any of the entities for the reporting domain | Any of the attributes within the entity |
| Run-Time Parameter                                                                                                                                                                                                                        | Operator                                     | Default Value                           |
| Report Name Like<br>if <> '%' it will show only the domain/entity and attributes used by reports that match the new parameter.<br>IF '%' then all domains, queries and attributes are displayed (including those not used by any report). | not applicable                               | not applicable                          |

## Replay Statistics

This report shows Replay Statistics for Execution Start/End Date; Configuration Name; Schedule Setup Name; Job Status; Statistic Description; Session ID; Successful Queries; Failed Queries; Total Queries; Type; Active/Waiting/Completed Tasks.

| Domain                  | Based on Query    | Main Entity              |
|-------------------------|-------------------|--------------------------|
| Replay Results Tracking | Replay Statistics | Replay Result Statistics |
| Run-Time Parameter      | Operator          | Default Value            |
| Query from date         | >=                | NOW -1 DAY               |
| Query to date           | <=                | NOW                      |
| Session                 | >=                | Not available            |
| Session                 | <=                | Not available            |

## Replay Summary

For the reporting period, a measure of what query failed or succeeded. Checkmark required in Replay Configuration for Query Failed or Query Succeeded.

| Domain              | Based on Query | Main Entity    |
|---------------------|----------------|----------------|
| Replay Results      | Replay Summary | Replay Results |
| Run-Time Parameter  | Operator       | Default Value  |
| Query from date     | >=             | NOW -1 DAY     |
| Query to date       | <=             | NOW            |
| Results status      | %              | Not available  |
| Schedule setup name | %              | Not available  |

## Request Rate

By default, displays the request rate for the last two hours. This graphical report is intended to display recent activity only. If you alter the run-time parameters to include a larger timeframe, you may receive a message indicating that there is too much data. Use a tabular report to display a larger time period.

| Domain             | Based on Query | Main Entity                  |
|--------------------|----------------|------------------------------|
| Sniffer Buffer     | Request Rate   | Sniffer Buffer Usage Monitor |
| Run-Time Parameter | Operator       | Default Value                |
| Period From        | >=             | NOW -2 HOUR                  |
| Period To          | <=             | NOW                          |

## Restored Data

This report has two columns: RESTORED\_DAY and EXPIRATION\_DATE. When the user restores data from archive, this table is populated according to the data restored and the duration specified for keeping this data. The purge process looks at this table to determine what data can be purged and cleans up records that expired. RESTORED\_DAY is the date of the data that was restored and is in the past. EXPIRATION\_DATE is the date when this data will be purged and is a date in the future.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Restored Data      | Restored Data  | Restored Data |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -10 DAY   |

| Run-Time Parameter | Operator | Default Value |
|--------------------|----------|---------------|
| Period To          | <=       | NOW +10 DAY   |

## Risky Users - Connection Profiling List

This report is the Connection Profiling List, filtered for risky users.

| Domain                                       | Based on Query            | Main Entity                |
|----------------------------------------------|---------------------------|----------------------------|
| Access                                       | Connection Profiling List | Client Server              |
| Run-Time Parameter                           | Operator                  | Default Value              |
| Query from date                              | >=                        | NOW -1 DAY                 |
| Query to date                                | <=                        | NOW                        |
| Client IP/Src App/DB User/Server IP/Svc Name | not like group            | Connection Profiling List  |
| Client IP/Src App/DB User/Server IP/Svc Name | like group                | Risk Spotter - Risky Users |

## Risky Users - Policy Violation

This report is the Policy Violation, filtered for risky users.

| Domain                                       | Based on Query                 | Main Entity                |
|----------------------------------------------|--------------------------------|----------------------------|
| Policy Violations                            | Risky Users - Policy Violation | Policy Rule Violation      |
| Run-Time Parameter                           | Operator                       | Default Value              |
| Client IP/Src App/DB User/Server IP/Svc Name | like group                     | Risk Spotter - Risky Users |
| Policy Rule Violation:Severity               | >=                             | 1                          |

## Risky Users - SQL Errors

This report is the SQL Errors report, filtered for risky users.

| Domain                                       | Based on Query           | Main Entity                |
|----------------------------------------------|--------------------------|----------------------------|
| Exception                                    | Risky Users - SQL Errors | Exception                  |
| Run-Time Parameter                           | Operator                 | Default Value              |
| Exception Type:Exception Type Description    | like                     | Database%Server%           |
| Client IP/Src App/DB User/Server IP/Svc Name | like group               | Risk Spotter - Risky Users |

## Runtime Sensitive Object Identifier

Displays output from the Runtime Sensitive Object Identifier session level policy. For more information, see [Runtime sensitive-object identification](#).

| Domain                              | Based on Query                      | Main Entity                         |
|-------------------------------------|-------------------------------------|-------------------------------------|
| Runtime Sensitive Object Identifier | Runtime Sensitive Object Identifier | Runtime Sensitive Object Identifier |

## Scheduled Job Exceptions

Displays a timestamp and the description for each scheduled job exception (including assessment errors).. These are jobs where the Exception Type ID is one of the following: SCHED\_JOB\_EXCEPTION, ASSESSMENT\_EXCEPTION, or ASMT\_ERROR.

| Domain             | Based on Query | Main Entity          |
|--------------------|----------------|----------------------|
| Sniffer Buffer     | CPU Usage      | Sniffer Buffer Usage |
| Run-Time Parameter | Operator       | Default Value        |
| Period From        | >=             | NOW -2 HOUR          |
| Period To          | <=             | NOW                  |

## Scheduled Jobs

Displays the list of currently scheduled jobs.

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| Internal - not available | Scheduled Jobs | Not available |

## Session Count

For the reporting period, the total number of different sessions open.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Access             | Session Count  | Session       |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -1 DAY    |
| Period To          | <=             | NOW           |

## SharePoint File Activities

Displays details about the file activity in a SharePoint environment.

| Domain                 | Based on Query                   | Main Entity    |
|------------------------|----------------------------------|----------------|
| Access                 | SharePoint File Activities       | Object/Command |
| Run-Time Parameter     | Operator                         | Default Value  |
| Period From            | >=                               | NOW -3 HOUR    |
| Show Aliases           | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source     |                                  | Drop-down menu |
| Refresh Rate (seconds) |                                  | 0              |

## SQL Count

For the reporting period, the total number of different SQL commands issued.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Access             | SQL Count      | SQL           |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -1 DAY    |
| Period To          | <=             | NOW           |

## S-TAP Agent Upgrade Pre-Check

Before starting a GIM upgrade, you can check whether any of the database servers that host Linux-UNIX S-TAP agents need to be rebooted during the S-TAP upgrade. This check is for GIM upgrades only; it does not cover any other upgrade scenarios.

If the bundles were installed from the managed unit, run the report on the managed unit. If all clients are managed by the central manager (all GIM clients point to the central manager, which is best practice and the recommended setup), run the report from the central manager. The reboot status of GIM clients that point to a managed unit is not captured in a report that is run on the central manager. Verify that the GIM agent is installed on the database server before you run the report (relevant for upgrades from a non-GIM installation). (None of the other modules or bundles need to be installed). All database servers that are listed in the report will need reboot.

There are no run-time parameters. This reporting domain is system-only.

Columns: S-TAP Host, Installed by GIM, GIM Parameter Name, Live Update.

| Run-Time Parameter      | Operator | Default Value |
|-------------------------|----------|---------------|
| Refresh rate in seconds |          | 0             |

## S-TAP agent with WINSTAP\_CMD\_LINE parameter

Displays details of what values exist in the WINSTAP\_CMD\_LINE field for all Windows S-TAPs.

Windows only: This report is available only for Windows systems.

There are no run-time parameters.

Columns: S-TAP Host, WINSTAP\_CMD\_LINE Parameter Value.

| Domain                   | Based on Query           | Main Entity |
|--------------------------|--------------------------|-------------|
| Internal - not available | Internal - not available | GIM Clients |

## S-TAP Configuration Change History

This report is displayed only when an inspection engine is added or changed. It lists the S-TAP configuration changes; each inspection engine change appears on a separate row. Each row lists the S-TAP Host, DB Server Type, DB Port From, DB Port To, DB Client IP, DB Client Mask, and Timestamp for the change.

| Domain                   | Based on Query               | Main Entity   |
|--------------------------|------------------------------|---------------|
| Internal - not available | Configuration Change History | Not available |
| Run-Time Parameter       | Operator                     | Default Value |
| Period From              | >=                           | NOW -1 DAY    |
| Period To                | <=                           | NOW           |

## S-TAP Events

Use this report for information on the S-TAP (from SOFTWARE\_TAP\_EVENT table in internal database).

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| Internal - not available | S-TAP Events   | Not available |
| Run-Time Parameter       | Operator       | Default Value |
| event type               | LIKE           | %             |
| host type                | LIKE           | %             |
| Period From              | >=             | NOW -3 DAY    |
| Period To                | <=             | NOW           |

## S-TAP Info (Central Manager)

On a Central Manager, an additional report, S-TAP Info, is available. This report monitors S-TAPs of the entire environment. Upload this data using the Custom Table Builder.

S-TAP info is a predefined custom domain which contains the S-TAP Info entity and is not modifiable like the entitlement domain.

When defining a custom query, go to upload page and click Check/Repair to create the custom table in CUSTOM database, otherwise save query will not validate it. This table loads automatically from all remote sources. A user cannot select which remote sources are used - it pulls from all of them.

Based on this custom table and custom domain, there are two reports:

**Enterprise S-TAP View** shows, from the Central Manager, information on an active S-TAP on a collector and/or managed unit (If there are duplicates for the same S-TAP engine, one being active and one being inactive, then the report only uses the active).

**Detailed Enterprise S-TAP View** shows, from the Central Manager, information on all active and inactive S-TAPs on all collectors and/or managed units.

If the Enterprise S-TAP View and Detailed Enterprise S-TAP View look the same, it is because there only one S-TAP on one managed unit being displayed. The Detailed Enterprise S-TAP View would look different if there are more S-TAPs and more managed units involved.

There is an Alert: Inspection Engines and S-TAP that alerts once a day on any activity related to inspection engine and S-TAP configuration. See [Predefined Alerts](#).

## S-TAP Last Response

Pre-defined query and report are available, but not added to any panels.

The query/report displays All S-TAP Hosts and the last response (heartbeat) sent by each host.

The purpose of this query is to be able to define an alert that triggers when an S-TAP on a host did not respond for a given period of time.

The input parameters are: Last response From, and, Last Response To.

For example, when executed with Last response From = NOW -5 DAYS and Last Response To = NOW - 3 HOURS, it displays the host name and the last response time for those hosts that sent the last response in the last 5 days, but had no response in the last 3 hours.

## S-TAP Status

Displays status information about each inspection engine defined on each S-TAP Host. This report has no From and To date parameters, since it is reporting current status. Each row of the report lists all the Guardium Hosts, DB Exec File, DB Server Type, Status, Last Response, Primary Host Name, Yes/No indicators for the following attributes: KTAP Installed, Shared Memory Driver Installed, DB2 Shared Memory Driver Installed, Named Pipes Driver Installed, and App Server Installed. In addition, it lists the Hunter DBS.

Note: The DB2 shared memory driver has been superseded by the DB2 Tap feature.

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| Internal - not available | S-TAP Status   | Not available |

## S-TAP Status Monitor

For each S-TAP reporting to this Guardium appliance, this report identifies the S-TAP Host, S-TAP Version, DB Server Type, Status (active or inactive), Last Response Received (date and time), Primary Host Name, and true/false indicators for: KTAP, MS SQL Server Shared Memory, DB2 Shared Memory, Local TCP monitoring, Named Pipes Usage, and Encryption; and the Guardium Hosts column that lists all hosts.

This report has no run-time parameters, and is based on a system-only query that cannot be modified.

## S-TAP Uninstall Events

Uninstalling an S-TAP could be evidence of harmful activity. This report details S-TAP uninstall events.

| Domain                   | Based on Query                   | Main Entity    |
|--------------------------|----------------------------------|----------------|
| Internal - not available | Not available                    | Not available  |
| Run-Time Parameter       | Operator                         | Default Value  |
| Period From              | >=                               | NOW -3 HOUR    |
| Period To                | <=                               | NOW            |
| Show Aliases             | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source       |                                  | Drop-down menu |
| Refresh rate in seconds  |                                  | 0              |

## S-TAP Verification

List all results of S-TAP verifications, including: DB server type, Inspection engine identifier, Port range, Last response from S-TAP, Inspection engine status, Last verification time, Verification schedules, Next scheduled time, Datasource name, Datasource description, Verification type, Instance name, KTAP, MSS shm, WinDb2 shm, Win TCP, Pipes, Encrypted?, Firewall installed, DB install dir, Load balancing, Alternate IPs, TLS, DB Exec File.

| Domain                   | Based on Query     | Main Entity               |
|--------------------------|--------------------|---------------------------|
| Internal - not available | S-TAP Verification | S-TAP Verification Header |
| Run-Time Parameter       | Operator           | Default Value             |
| Query from date          | >=                 | NOW -3 HOUR               |
| Query to date            | >=                 | NOW                       |

## STAP/Z Files

STAP/Z provides files with raw data collected from DB2 (on z/OS®) containing DB2 events, SQL statements, etc. This report lists an Interface ID, UA file name (Un-normalized Audit Event), UT file name (Un-normalized Audit Event text), UH file name (Un-normalized Audit Event host variables), File Status, Total Number of Events Processed, Number of Events Failed, and Timestamp. The Run-time parameters are FileName Like % and FileStatus Like %.

This report has two run-time parameters, FileName Like % and FileStatus Like %. It is based on a system-only query that cannot be modified.

## Symptoms

| Domain                  | Based on Query                   | Main Entity    |
|-------------------------|----------------------------------|----------------|
| Eagle Eye               | Symptoms                         | Syptompe       |
| Run-Time Parameter      | Operator                         | Default Value  |
| Period From             | >=                               | NOW -3 HOUR    |
| Period To               | <=                               | NOW            |
| Enter Value for Case ID | Like                             | %              |
| Show Aliases            | Radio buttons (On, Off, Default) | Default        |
| Remote Data Source      |                                  | Drop-down menu |
| Refresh rate in seconds |                                  | 0              |

## TCP Exceptions

For the reporting period, for each exception where the Exception Description of the Exception Type entity is TCP/IP Protocol Exception, a row of this report lists the following attribute values from the Exception entity: Exception Timestamp, Exception Description, Source Address, Destination Address, Source Port, Destination Port, and count of Exceptions for that row.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Exceptions         | TCP Exceptions | Exception     |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -1 DAY    |
| Period To          | <=             | NOW           |

## Templates (CAS)

This report lists CAS templates. By default, all template items are listed.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| CAS Templates      | CAS Templates  | Template      |
| Run-Time Parameter | Operator       | Default Value |
| Access_Name        | Like           | %             |
| Template_Set_Name  | Like           | %             |
| Audit_Type         | Like           | %             |

## Test Detail Exception

This report lists all the test detail exceptions that are applied to a security assessment.

| Domain                   | Based on Query         | Main Entity   |
|--------------------------|------------------------|---------------|
| Internal - not available | Test Detail Exceptions | Not available |
| Run-Time Parameter       | Operator               | Default Value |
| Period From              | >=                     | NOW -3 HOUR   |
| Period To                | <=                     | NOW           |
| Approver                 | LIKE                   | %             |
| Exception Type           | LIKE                   | %             |
| Exception Detail         | LIKE                   | %             |
| Test Description         | LIKE                   | %             |
| Datasource Group         | LIKE                   | %             |
| Datasource Name          | LIKE                   | %             |
| Assessment               | LIKE                   | %             |
| Refresh Rate in seconds  |                        | 0             |

## Test Exceptions Original report and Test Exceptions report

Both reports indicate pairs of tests and datasources that are exempted temporarily. The Test Exceptions report is a more comprehensive version of the Test exceptions Original report.

### Test Exceptions Original report

Use the following selections to configure the Test Exceptions Original report:

| Domain                   | Based on Query  | Main Entity   |
|--------------------------|-----------------|---------------|
| Internal - not available | Test Exceptions | Not available |

| Run-Time Parameter | Operator | Default Value |
|--------------------|----------|---------------|
| Period From        | >=       | NOW -12 MONTH |
| Period To          | <=       | NOW           |

#### Test Exceptions report

Use the following selections to configure the Test Exceptions report:

| Domain                   | Based on Query  | Main Entity   |
|--------------------------|-----------------|---------------|
| Internal - not available | Test Exceptions | Not available |
| Run-Time Parameter       | Operator        | Default Value |
| Period From              | >=              | NOW -3 HOUR   |
| Period To                | <=              | NOW           |
| Approver                 | LIKE            | %             |
| Test Description         | LIKE            | %             |
| Datasource Group         | LIKE            | %             |
| Datasource Name          | LIKE            | %             |
| Assessment               | LIKE            | %             |
| Refresh Rate in seconds  |                 | 0             |

## Threat analytics case for analysis

When a case is assigned in the active threat analytics page, this report is sent to the assignee. It includes the case details and its observations.

| Domain                  | Based on Query                     | Main Entity               |
|-------------------------|------------------------------------|---------------------------|
| Active Threat Analytics | Threat analytics case for analysis | Analytic case observation |
| Run-Time Parameter      | Operator                           | Default Value             |
| Case number             | =                                  |                           |
| Period From             | >=                                 | NOW -3 HOURS              |
| Period To               | <=                                 | NOW                       |

## Threat Analytics Case Observations

This is a drill down report from the open cases and the closed cases reports. It shows the case's observations.

| Domain                  | Based on Query                     | Main Entity               |
|-------------------------|------------------------------------|---------------------------|
| Active Threat Analytics | Threat analytics case observations | Analytic case observation |
| Run-Time Parameter      | Operator                           | Default Value             |
| Case number             | =                                  |                           |
| Period From             | >=                                 | NOW -3 HOURS              |
| Period To               | <=                                 | NOW                       |

## Threat analytics closed cases

| Domain                  | Based on Query                | Main Entity   |
|-------------------------|-------------------------------|---------------|
| Active Threat Analytics | Threat analytics closed cases | Analytic case |
| Run-Time Parameter      | Operator                      | Default Value |
| Period From             | >=                            | NOW -3 HOURS  |
| Period To               | <=                            | NOW           |

## Threat analytics open cases

| Domain                  | Based on Query              | Main Entity   |
|-------------------------|-----------------------------|---------------|
| Active Threat Analytics | Threat analytics open cases | Analytic case |
| Run-Time Parameter      | Operator                    | Default Value |
| Period From             | >=                          | NOW -3 HOURS  |
| Period To               | <=                          | NOW           |

## Threat finder run log

This report gives results of the threat finder runs.

| Domain                   | Based on Query        | Main Entity                      |
|--------------------------|-----------------------|----------------------------------|
| Analytic Outliers Status | Threat Finder Run Log | Analytic status                  |
| Run-Time Parameter       | Operator              | Default Value                    |
| Period From              | >=                    | NOW -3 HOURS                     |
| Period To                | <=                    | NOW                              |
| Show Aliases             |                       | Radio buttons (On, Off, Default) |
| Remote Data Source       |                       | Drop-down menu                   |
| Refresh rate in seconds  |                       | 0                                |

## Throughput

For each Access Period in the reporting period, each row lists the Period Start time, the count of Server IP addresses, and the total number of accesses (Access Period entities).

You can restrict the output of this report using the Server IP run time parameter, which by default is set to % to select all IP addresses.

| Domain                   | Based on Query       | Main Entity   |
|--------------------------|----------------------|---------------|
| Internal - not available | DB Server Throughput | Not available |
| Run-Time Parameter       | Operator             | Default Value |
| Period From              | >=                   | NOW -1 DAY    |
| Period To                | <=                   | NOW           |
| Server IP                | LIKE                 | %             |

## Throughput (graphical)

This report is a Distributed Label Line chart version of the tabular Throughput report. It plots the total number of accesses over the reporting period, one data point per Period Start time.

You can restrict the output of this report using the Server IP run time parameter, which by default is set to % to select all IP addresses.

| Domain             | Based on Query               | Main Entity   |
|--------------------|------------------------------|---------------|
| Access             | DB Server Throughput - Chart | Access Period |
| Run-Time Parameter | Operator                     | Default Value |
| Period From        | >=                           | NOW -1 DAY    |
| Period To          | <=                           | NOW           |
| Server IP          | LIKE                         | %             |

## User Activity Audit Trail Reports

The User Activity Audit Trail menu selection displays two reports. In addition, from each of those reports, a third report can be produced. See:

- User Activity Audit Trail
- System/Security Activities
- Detailed Guardium User Activity (Drill-Down)

### User Activity Audit Trail

For the reporting period, for each User Name seen on a Guardium User Activity Audit entity, each row displays the Guardium User Name, an Activity Type Description (from the Guardium Activity Types entity), a Count of Modified Entity values, the Host Name, and the total number of Guardium Activity Audits entities for that row.

From any row of the this report, the Detailed Guardium User Activity report is available as a drill-down report.

| Domain             | Based on Query            | Main Entity                  |
|--------------------|---------------------------|------------------------------|
| Guardium Activity  | User Activity Audit Trail | Guardium User Activity Audit |
| Run-Time Parameter | Operator                  | Default Value                |
| Host Name          | LIKE                      | %                            |
| Period From        | >=                        | NOW -1 DAY                   |
| Period To          | <=                        | NOW                          |

### System/Security Activities

For the reporting period, for each User Name seen on a Guardium User Activity Audit entity, each row displays the Guardium User Name, an Activity Type Description (from the Guardium Activity Types entity), a Count of Modified Entity values, the Host Name, and the total number of Guardium Activity Audits entities for that row.

From any row of the this report, the Detailed Guardium User Activity report is available as a drill-down report.

| Domain             | Based on Query            | Main Entity                  |
|--------------------|---------------------------|------------------------------|
| Guardium Activity  | User Activity Audit Trail | Guardium User Activity Audit |
| Run-Time Parameter | Operator                  | Default Value                |
| Host Name          | LIKE                      | %                            |
| Period From        | >=                        | NOW -1 DAY                   |
| Period To          | <=                        | NOW                          |

### Detailed Guardium User Activity (Drill-Down)

This report is not available from the menu, but can be opened for any row of the User Activity Audit Trail report, or the System/Security Activities report. For the selected row of the report, based on the User Name and Activity Type Description, this report lists the following attribute values, all of which are from the Guardium User Activity Audit entity, except for the Activity Type Description, which is from the Guardium Activity Types entity: User Name, Timestamp, Modified Entity, Object Description, All Values, and a count of Guardium User Activity Audits entities for the row.

| Domain                    | Based on Query                  | Main Entity                  |
|---------------------------|---------------------------------|------------------------------|
| Guardium Activity         | Detailed Guardium User Activity | Guardium User Activity Audit |
| Run-Time Parameter        | Operator                        | Default Value                |
| Activity Type Description |                                 | value from calling report    |
| Period From               | >=                              | NOW -1 DAY                   |
| Period To                 | <=                              | NOW                          |
| User Name                 |                                 | value from calling report    |

Warning: Users should be aware that activities of the root user, and other sensitive system accounts, are logged. Drilling down into the activity of these users may show sensitive commands and passwords that have been entered on the command line. Therefore users, whenever possible, should not enter sensitive command line information that they would not like to show on this drill-down report.

## User Comments - Sharable

Sharable user comments are all comments except for inspection engine, installed policy, and audit process results comments. For each sharable user comment, this report lists the date created, the type of object referenced (an alert, for example), the object description, the user who created the comment, and the contents of the comment.

Note: Comments defined for inspection engines, installed policies, or audit process results can be viewed from the individual definitions, but they cannot be displayed on a report.

| Domain             | Based on Query   | Main Entity   |
|--------------------|------------------|---------------|
| Comments           | Comments Defined | Comments      |
| Run-Time Parameter | Operator         | Default Value |
| Period From        | >=               | NOW -2 MONTH  |
| Period To          | <=               | NOW           |

## User To-Do Lists

Displays for each Guardium audit process: a description, login name, action required (review or approve), status, user who has signed or reviewed, and execution date of the specified task.

| Domain                   | Based on Query   | Main Entity   |
|--------------------------|------------------|---------------|
| Internal - not available | Users To-do List | Not available |
| Run-Time Parameter       | Operator         | Default Value |
| Period From              | >=               | NOW -1 DAY    |
| Period To                | <=               | NOW           |

## Unit Utilization Levels

The following default reports provide unit utilization data:

- Unit Utilization: Displays the maximum unit utilization level for each unit in the given timeframe. There is a drill-down that displays details for a unit across all periods within the timeframe of the report.
- Unit Utilization Distribution: Per-unit, this report displays the percent of periods in the report timeframe with utilization levels of low, medium, and high.
- Utilization Thresholds: This predefined report displays all low and high threshold values for all unit utilization parameters.
- Unit Utilization Daily Summary: Provides a daily summary of unit utilization data.

| Domain                   | Based on Query                | Main Entity             |
|--------------------------|-------------------------------|-------------------------|
| Internal - not available | Unit Utilization Distribution | Unit Utilization Levels |
| Run-Time Parameter       | Operator                      | Default Value           |
| Period From              | >=                            | NOW -24 HOUR            |
| Period To                | <=                            | NOW                     |

## Values Changed

For the reporting period, this report provides detailed information about monitored value changes. All attribute values displayed are from the Monitor Values entity. The query this report is based upon has a non-standard sorting sequence, as follows:

- Server IP
- DB Type
- Audit Timestamp
- Audit Table Name
- Audit Owner

The query this report is based upon has a number of run-time parameters, all of which use the LIKE operator and default to the value %, meaning all values will be selected.

For each monitored value selected, a row of the report lists the Timestamp, Server IP, DB Type, Service Name, Database Name, Audit Login Name, Audit Timestamp, Audit Table Name, Audit Owner, Audit Action, Audit Old Value, Audit New Value, SQL Text, Triggered ID, and a count of Change Columns entities for that row.

| Domain             | Based on Query | Main Entity     |
|--------------------|----------------|-----------------|
| Value Changed      | Values Changed | Changed Columns |
| Run-Time Parameter | Operator       | Default Value   |
| Audit Action       | LIKE           | %               |
| Audit Login Name   | LIKE           | %               |
| Audit Owner        | LIKE           | %               |
| Audit Table Name   | LIKE           | %               |
| DB Type            | LIKE           | %               |
| Period From        | >=             | NOW -1 DAY      |
| Period To          | <=             | NOW             |
| Server IP          | LIKE           | %               |

## Predefined user reports

This section provides a short description of all predefined reports for users with default user access.

Note: If data level security at the observed data level is enabled (see [Data level security filtering](#)), then the audit process output is filtered so users see only the information about their databases.

### Active Users Last Login

Last login recorded during the reporting period for each member of the Active Users group. All members of the group will be listed, even if there were no logins during the reporting period. This is unlike most other reports based on members of a group. In the "normal" case, if no activity is found for a member, that member is not listed.

Each row lists a DB User Name, Client IP, Server IP, Server Type, Source Program, last login time (the maximum value of the Session Start attribute), and the count of sessions for the row.

The Active Users group is empty at installation time. It must be populated by someone at your location. The query that this report is based upon, Active Users Last Logins, cannot be accessed from the Query-Report Builder.

### Active Users with no Activity

Listing of members in the Active Users group who have had no activity during the reporting period. This report will be empty if all users have had activity during the reporting period.

The Active Users group is pre-defined, but empty at installation time. It must be populated by someone at your location. The query that this report is based upon, Active Users with no Activity, cannot be accessed from Query-Report Builder.

### Activity By Client IP

For each Client IP address seen during the reporting period, a row counts the number of SQL Verbs, Object Names, and the total number of sessions.

### Administrative Commands Usage

For each SQL Verb included in the Administrative Commands group that was seen during the reporting period, this report lists the SQL Verb, Depth, Object Name, and Client IP, and a count of objects referenced.

### Administrative Objects Usage

For each Object Name included in the Administration Objects group that was seen during the reporting period, each row lists the Object Name, Client IP, Server IP, Service Name, Database Name, Source Program, DB User Name, and Count of Objects for that row.

### Admin Users Login

For each DB User Name included in the Admin Users group, who had one or more sessions during the reporting period, each row lists the Client IP, DB User Name, Source Program, Session Start time, and Count of Sessions for that row.

### ALTER Commands Execution

All ALTER commands issued. The report displays the client IP from which the DDL was requested, server IP address, service name, database user name, source program, database name, object name, and main SQL verb (a specific DDL command) for each combination of client IP/DDL command listed on that specific line.

For each SQL Verb from the ALTER Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

### Archive Candidates

This report lists objects (database tables or stored procedures, for example) that have not been accessed for an extended period of time. You cannot access the query this report is based upon.

### BACKUP Commands Execution

For each SQL Verb from the BACKUP Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

### Classification Process Results

Lists classification process tasks.

### Client IP Activity Summary

This report displays reporting period activity from a single Client IP address, which is specified as a run time parameter. Each row of the report displays the Client IP, Source Program, SQL Verb, Depth (of sentence within the SQL command), an Object Name, and a count of times that object was referenced for that row.

## Commands List

This report lists all SQL Verbs seen during the reporting period. At the outermost level, commands are grouped by the Period Start time from the Access Period entity, which is usually one hour, on the hour. Your Guardium administrator can modify the access period length by changing the logging granularity, which is one hour by default. For each Access Period in the reporting period, each row lists the access Period Start time, a SQL Verb, Depth of the verb in the SQL statement, Parent (a pointer to the owning verb), and a count of occurrences for the row.

## Cosmos Full SQL

For the Azure Cosmos database, the Diagnostics setting includes DataPlaneRequests and a QueryRuntimeStatistics log that you can stream to an event hub.

For DataPlaneRequests, data is mapped between Cosmos and Guardium as follows:

- activityId maps to FULL SQL"."More Information"
- clientIpAddress maps to Guardium "Client/Server"."Client IP"
- database account is extracted from resourceId and maps to "Client/Server"."Server Host Name"
- duration maps to "FULL SQL"."RESPONSE\_TIME"
- operationName, requestResourceId, requestResourceType, resourceTokenPermissionId, responseLength, and statusCode are concatenated and mapped to "FULL SQL"."Full Sql"
- region is mapped to "Client/Server"."Server Description"
- time is mapped to "FULL SQL"."Timestamp"
- userAgent is mapped to "Client/Server"."Source Program"

For QueryRuntimeStatistics, data is mapped as follows:

- database account is extracted from resourceId and maps to "Client/Server"."Server Host Name"
- time maps to "FULL SQL"."Timestamp"
- databasename, collectionname, and querytext are concatenated and maps to "FULL SQL"."Full Sql"
- activityId and maps to "FULL SQL"."More Information"

When LOG\_FULL\_DETAILS action is selected, DataPlaneRequests and QueryRuntimeStatistics are saved as separate "FULL SQL" records, and the Cosmos Full SQL report correlates QueryRuntimeStatistics "FULL SQL" records to corresponding DataPlaneRequests "FULL SQL" records with the same activityId and then concatenates them both as "FULL SQL"."Full Sql".

| Domain | Based on Query  | Main Entity |
|--------|-----------------|-------------|
| Access | Cosmos Full SQL | FULL SQL    |

## CREATE Commands Execution

For each SQL Verb from the CREATE Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## Databases Discovered

For the reporting period, for each Discovered Port entity where the DB Type attribute value is NOT LIKE Unknown, this report lists the Probe Timestamp, Server IP, Server Host Name, DB Type, Port, Port Type, and count of Discovered Ports for the row.

| Domain             | Based on Query       | Main Entity     |
|--------------------|----------------------|-----------------|
| Auto-discovery     | Databases Discovered | Discovered Port |
| Run-Time Parameter | Operator             | Default Value   |
| Period From        | >=                   | NOW -1 DAY      |
| Period To          | <=                   | NOW             |

## Database Servers

For each Server IP address accessed during the reporting period, a row of the report displays the Server Type, Database Name, Service Name, a count of source programs accessing that server, and the total number of sessions for that row.

## Data Set z/OS Sensitive Object Activity

Displays all access to data sets in group z/OS Data Set Sensitive Objects.

| Domain             | Based on Query                | Main Entity   |
|--------------------|-------------------------------|---------------|
| Access             | DSz Sensitive Object Activity | FULL SQL      |
| Run-Time Parameter | Operator                      | Default Value |
| Period From        | >=                            | NOW -3 HOUR   |
| Period To          | <=                            | NOW           |
| pgm                | LIKE                          | %             |
| likeDSname         | LIKE                          | %             |

## Data Set z/OS Privileged User Activity

Displays all access by users in group z/OS Data Set Privileged Users.

| Domain | Based on Query               | Main Entity |
|--------|------------------------------|-------------|
| Access | DSz Privileged User Activity | FULL SQL    |

| Domain             | Based on Query               |               | Main Entity |
|--------------------|------------------------------|---------------|-------------|
| Access             | DSz Privileged User Activity |               | FULL SQL    |
| Run-Time Parameter | Operator                     | Default Value |             |
| Period From        | >=                           | NOW -3 HOUR   |             |
| Period To          | <=                           | NOW           |             |
| pgm                | LIKE                         | %             |             |
| likeDSname         | LIKE                         | %             |             |

## Data Sources

This report appears on the default layout for both administrators and users. See Data Sources on the Predefined Reports - Common page.

## Data Source Version History

This report appears on the default layout for both administrators and users. See Data Source Version History on the Predefined Reports - Common page.

## DB Predefined Users Login

For each DB User Name included in the DB Predefined Users group, who had one or more sessions during the reporting period, each row lists the DB User Name, Client IP, Server IP, Source Program, Database Name, Service Name, and Count of Sessions for that row.

## DBCC Commands Execution

For each SQL Verb from the DBCC Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, SQL statement, and Count of Objects referenced in the row.

## Db2 z/OS Sensitive Object Activity

Displays all access to tables in group z/OS DB2 Sensitive Objects for Reports.

| Domain             | Based on Query                 |               | Main Entity |
|--------------------|--------------------------------|---------------|-------------|
| Access             | Db2z Sensitive Object Activity |               | FULL SQL    |
| Run-Time Parameter | Operator                       | Default Value |             |
| Period From        | >=                             | NOW -3 HOUR   |             |
| Period To          | <=                             | NOW           |             |

## Db2 z/OS Privileged User Activity

Displays all access by users in group z/OS DB2 Privileged Users.

| Domain             | Based on Query                |               | Main Entity |
|--------------------|-------------------------------|---------------|-------------|
| Access             | Db2z Privileged User Activity |               | FULL SQL    |
| Run-Time Parameter | Operator                      | Default Value |             |
| Period From        | >=                            | NOW -3 HOUR   |             |
| Period To          | <=                            | NOW           |             |
| FullSQLLike        | LIKE                          | %             |             |
| Db2Subsystem       | LIKE                          | %             |             |
| NetwrkProtocol     | LIKE                          | %             |             |
| DbUser             | LIKE                          | %             |             |

## DDL Commands

All DDL commands sent to the database. The report displays the client IP from which the DDL was requested, the main SQL verb (a specific DDL command), and the total objects accessed for that record.

For each SQL Verb from the DDL Commands group seen during the reporting period, this report displays the Client IP, Server IP, Server Type, SQL Verb, and Count of Commands referenced in the row.

## DDL Distribution

This bar graph displays the distribution of commands seen from the DDL Commands group during the reporting period. For each command seen, a single bar represents the total number of objects affected.

## DML Execution on Administrative Objects

For each SQL Verb from the DML Commands group that references an Object Name in the Administration Objects group, this report displays a row for the DB User Name, Client IP, Server IP, Server Type, Service Name, Database Name, SQL Verb, Object Name, and Count of Objects referenced in the row.

## DML Execution on Sensitive Objects

For each SQL Verb from the DML Commands group that references an Object Name in the Sensitive Objects group, this report displays a row for each Access Period, Client IP, and Source Program, with a total count of objects referenced in that row. Although the report title contains the word Executions, there is no guarantee that all commands reported were actually executed.

## DROP Commands Execution

---

For each SQL Verb from the DROP Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## DW Dormant Objects

---

Shows all the members of one group that are not members in a second group, with a focus on dormant tables. For example, this report shows objects that are in the all objects group, but have not been used in a Select.

## DW Dormant Objects/Fields

---

Shows all the members of one group that are not members in a second group, with a focus on dormant tables and columns. In this instance, groups are a 2-tuple type (members that are a composite of a pair of value attributes). For example, this report shows objects that are in the all objects and fields group, but have not been used in a Select.

## DW EXECUTE Object Access

---

Use this report to populate the group called DW EXECUTE Objects with a set of stored procedure names that being executed. Then use indirect mapping in Group Builder/Auto Generate Calling Prox to generate all the objects being used within these procedures.

## DW SELECT Object Access

---

This report shows all object names that have been accessed through a SELECT statement.

## DW SELECT Object-Field Access

---

This report shows all object and field names that have been accessed through a SELECT statement.

## Exception Count

---

The total number of exceptions (Exception entities) logged during the reporting period.

## Exceptions Distribution

---

Each wedge of the pie chart represents the proportion of exceptions for each Exception Description attribute value (from the Exception Type entity) that was logged during the reporting period.

As with any chart, you can drill down on the pie chart to display the tabular version of the query on which the chart is based. There are several exceptions reports that are accessible from this tabular report (or drill-downs from it) that are available here, but are not included on any menu.

## Exceptions Monitor

---

A count of exceptions logged during the reporting period. One datapoint is created each time that you refresh the report on your portal.

## Excessive Errors per period

---

Display #Errors/Period; E.g., more than N errors in 60min for the same Client IP address, Server IP address, Server Type, database user name.

## Failed User Login Attempts

---

For each failed login attempt during the reporting period, lists the User Name, Source Address, Destination Address, and Database Protocol Type for the server the user was attempting to log into.

## Flat LOG List

---

Lists flat log processing tasks.

## Full SQL By Client IP

---

This report displays reporting period Full SQL attribute values that have been logged for a single Client IP, which is specified as a run time parameter. Each row of the report displays the Full SQL ID, Timestamp (of the Full SQL entity), Client IP, DB User Name, Session Start, Source Program, Full SQL, and a count of occurrences for the row.

## Full SQL By DB User Name

---

This report displays reporting period Full SQL attribute values that have been logged for a single DB User Name, which is specified as a run time parameter. Each row of the report displays the Full SQL ID, Timestamp (of the Full SQL entity), Client IP, DB User Name, Session Start, Source Program, Full SQL, and a count of occurrences for the row.

## GRANT Commands Execution

---

For each SQL Verb from the GRANT Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## Guardium Job Queue

---

Displays the Guardium Job Queue. For each job, lists the Process Run ID, Process Type, Status, Cls/Asmt Process Id, Report Result Id, Cls/Asmt Description, Audit Task Description, Queue Time, Start Time, End Time, and Data Sources.

| Domain                   | Based on Query     | Main Entity   |
|--------------------------|--------------------|---------------|
| internal - not available | Guardium Job Queue | not available |
| Run-Time Parameter       | Operator           | Default Value |
| Job Description          | LIKE               | %             |
| Period From              | >=                 | NOW -1 DAY    |
| Period To                | <=                 | NOW           |

## Hourly Access Details

---

This report produces a highly detailed listing for each DB User Name seen in the reporting period, which is one hour by default for this report. Each row of the report lists a DB User Name, Client IP, Server IP, Period Start, Source Program, SQL (from the SQL entity), and a count of occurrences during the access period.

## IMS Access (z/OS)

---

Use this to report to view details of access to the IMS (z/OS®).

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Access             | IMS Access     | Client Server |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -2 HOUR   |
| Period To          | <=             | NOW           |

## IMS Object (z/OS)

---

Use this to report to view an object-level view of access to the IMS (z/OS).

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Access             | IMS Object     | Object        |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -2 HOUR   |
| Period To          | <=             | NOW           |

## IMS Event (z/OS)

---

Use this to report for a summary of the type of access (such as DLI), and the command and object mapping of IMS (z/OS) events.

| Domain             | Based on Query | Main Entity   |
|--------------------|----------------|---------------|
| Access             | IMS Event      | SQL           |
| Run-Time Parameter | Operator       | Default Value |
| Period From        | >=             | NOW -2 HOUR   |
| Period To          | <=             | NOW           |

## IMS Data Access Details (z/OS)

---

This report uses the Full SQL Entity as the main entity and provides full details of each access to the IMS (z/OS).

| Domain             | Based on Query          | Main Entity   |
|--------------------|-------------------------|---------------|
| Access             | IMS Data Access Details | Full SQL      |
| Run-Time Parameter | Operator                | Default Value |
| Period From        | >=                      | NOW -2 HOUR   |
| Period To          | <=                      | NOW           |
| Client IP          | LIKE                    |               |
| DBUserName         | LIKE                    |               |
| IMS Name           | LIKE                    |               |
| ServerIP           | LIKE                    |               |

## IMS z/OS - Privileged User Activity

Displays all access by users in group z/OS IMS Privileged Users for Reports.

| Domain             | Based on Query                |               | Main Entity |
|--------------------|-------------------------------|---------------|-------------|
| Access             | IMSz Privileged User Activity |               | FULL SQL    |
| Run-Time Parameter | Operator                      | Default Value |             |
| Period From        | >=                            | NOW -3 HOUR   |             |
| Period To          | <=                            | NOW           |             |
| ServiceName        | LIKE                          | %             |             |
| IMSUserID          | LIKE                          | %             |             |
| FullSQL            | LIKE                          | %             |             |

## IMS z/OS - Sensitive Object Activity

Displays all access to segments in group z/OS IMS Sensitive Objects for Reports.

| Domain             | Based on Query                 |               | Main Entity |
|--------------------|--------------------------------|---------------|-------------|
| Access             | IMSz Sensitive Object Activity |               | FULL SQL    |
| Run-Time Parameter | Operator                       | Default Value |             |
| Period From        | >=                             | NOW -3 HOUR   |             |
| Period To          | <=                             | NOW           |             |
| ServiceName        | LIKE                           | %             |             |
| IMSUserID          | LIKE                           | %             |             |
| FullSQL            | LIKE                           | %             |             |
| IMSDBD             | LIKE                           | %             |             |

## KILL Commands Execution

For each SQL Verb from the KILL Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## Logged R/T Alerts

This report displays a bar representing the total number of alerts logged during the reporting period, for each type of real-time alert logged, based on the Access Rule Description attribute of the Policy Rule Violation entity.

## Logged Threshold Alerts

This report displays a bar representing the total number of alerts logged during the reporting period, for each type of threshold alert logged, based on the Alert Description attribute of the Threshold Alert Details entity.

## Long Running Queries

For the reporting period, this report lists the longest running queries, with the longest average execution time first. For each query, lists the Client IP, Server IP, SQL, Period Start (from the Access Period entity), Average Execution Time, and the count of occurrences for this row. You cannot access the query this report is based upon.

## Number of Active Privacy Set Tasks

Number of active Guardium audit processes that contain one or more privacy set tasks. When central management is used, this report contains data on the Central Manager only, and is empty on all managed units (the standard message, No data found for requested query, displays). This report has non-standard run time parameters: there are no from and to date parameters, so all audit processes containing one or more privacy set tasks will be reported. You can clone the query that this report is based upon (Number of Active Privacy Set Processes), but you cannot clone or regenerate the default report. The cloned query will have all of the standard run-time parameters (including the from and to dates).

## Number of Active Audit Processes

The number of active Guardium audit processes. When central management is used, this report contains data on the Central Manager only, and is empty on all managed units (the standard message, No data found for requested query, displays). This report has non-standard run time parameters: there are no from and to date parameters, so all active audit processes will be reported. You can clone the query that this report is based upon (Number of Active Processes), but you cannot clone or regenerate the default report. The cloned query will have all of the standard run-time parameters (including the from and to dates).

## Number of db per type

Displays the number of servers and clients for each monitored database type (default time period is the current day).

## Object Activity Summary

This report displays reporting period activity for a single Object Name, which is specified as a run time parameter. Each row of the report displays the Client IP, Source Program, SQL Verb, Depth (of sentence within the SQL command), an Object Name, and a count of times that object was referenced for that row.

## Objects List

---

This report lists all objects seen during the reporting period. At the outermost level, objects are grouped by the Period Start time from the Access Period entity, which is usually one hour, on the hour. Your SQL Guard administrator can modify the access period length by changing the logging granularity, which is one hour by default. For each Access Period in the reporting period, each row lists the access Period Start time, an Object Name, and the count of occurrences for that row.

## One User One IP

---

For each DB User Name for which session data was collected during the reporting period, each line of this report displays the count of Client IP addresses from which the user logged in, and a total number of sessions.

## Outstanding Audit Process Reviews

---

For each Guardium user Login Name, this report lists the number and type of outstanding Guardium audit processes. An outstanding audit process has a Status attribute value (in the Task Results To-Do-List entity) other than Reviewed or Signed. This report has non-standard run time parameters: there are no from and to dates, which means that all outstanding task results will be reported. You can clone the query that this report is based upon (it has the same name), but you cannot clone or regenerate the default report. The cloned query will have all of the standard run-time parameters (including the from and to dates).

## Policy Violation Count

---

For the reporting period, this report displays the number of policy violations logged.

## Privileged Account Utilization

---

Show User, Verb, and the Count of Periods within which the Verb was performed by a User in the group Admin Users

## Privileged User Access of Business Objects

---

Show User, Verb, Object where the User in Admin Users and the Verb was performed by the on an Object that is in a selected group of Business Objects

## Policy Violations

---

For every policy rule violation logged during the reporting period, this report provides the Timestamp from the Policy Rule Violation entity, Access Rule Description, Client IP, Server IP, DB User Name, Full SQL String from the Policy Rule Violation entity, Severity Description, and a count of violations for that row. You cannot access the query that this report is based upon (Policy Violations List with Severity), but you can clone the report.

## Request Rate

---

By default, displays the request rate for the last two hours. This graphical report is intended to display recent activity only. If you alter the From and To run-time parameters to include a longer timeframe, you may receive a message indicating that there is too much data. (Use a tabular report to display a larger time period.)

## RESTORE Commands Execution

---

For each SQL Verb from the BACKUP Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## REVOKE Commands Execution

---

For each SQL Verb from the REVOKE Commands group seen during the reporting period, this report displays the Client IP, Server IP, Service Name, DB User Name, Source Program, Database Name, Object Name, SQL Verb, and Count of Objects referenced in the row.

## Sensitive Objects Usage

---

For each object in the Sensitive Objects group, displays a row for each Client IP and Source Program that referenced the object during the reporting period, and a count of object references.

The Sensitive Objects group is empty at installation time. Someone at your company must populate the group with the appropriate set of members.

## Sessions By Server Type

---

For each server type (DB2®, Informix®, etc.), a row of this report displays the total number of sessions that were open during the reporting period (by default, the last three hours).

## Sessions List

---

This report lists all database sessions for the reporting period. For each session, the report displays the session (entity) Timestamp, the Session Start (timestamp), Server Type, Client IP, Server IP, Client Port, Server Port, Network Protocol, DB Protocol, DB Protocol Version, DB User Name username, Source Program, and Count of Sessions for that row (which should always be 1).

As with most reports, drill-down reports are available. There are a number of session reports that are accessible from this report, but are not included on any menu. This includes the following reports, with the run time parameters for those reports set by using values from the selected row of the report:

| <b>Report</b>              | <b>Run-time Parameters</b> |
|----------------------------|----------------------------|
| Sessions by Client IP      | Server IP, Server Type     |
| Sessions by Server IP      | Server Type                |
| Sessions by Source Program | Server Type, Server IP     |
| Sessions by User           | Server Type, Server IP     |
| Sessions Details by Server | Server Type, Server IP     |

## SQL Errors

For each SQL error during the reporting period, displays the Client IP address, Server IP address, Server Type, database user name, database error text, and error occurrence total for that record.

## Terminated Users Failed Login Attempts

Lists failed login attempts by database users who are members of the Terminated DB User group. This report will be empty if there were no failed login attempts by anyone in this group during the reporting period.

The Terminated DB Users group is pre-defined, but empty at installation time. It must be populated by someone at your location. The built-in query for this report cannot be accessed. The query that this report is based upon (Terminated Users Failed Login Attempts) cannot be accessed from any query builder.

## Terminated Users Logins

Lists all logins by database users who are members of the Terminated DB User group. Each row lists a DB User Name, Client IP, Server IP, Server Type, Source Program, last login time (the maximum value of the Session Start attribute), and the count of sessions for the row.

The Terminated DB Users group is empty at installation time. It must be populated by someone at your location. The query that this report is based upon, Terminated Users Logins, cannot be accessed from the Query-Report Builder.

## Throughput

This report produces a count of all Server IPs seen, and total accesses, during the reporting period. At the outermost level, accesses are grouped by the Period Start time from the Access Period entity, which is usually one hour, on the hour. Your Guardium® administrator can modify the access period length by changing the logging granularity, which is one hour by default. Each row lists the Period Start time, the count of Server IPs seen, and a total count of accesses for the row.

You can restrict the output of this report using the Server IP run time parameter, which by default is set to "%" to select all IP addresses.

## Throughput (Graphical)

This report is a Distributed Label Line chart version of the tabular Throughput report, plotting the total number of accesses over the reporting period, one data point per Period Start time.

You can restrict the output of this report using the Server IP run time parameter, which by default is set to "%" to select all IP addresses.

## Users inactive since

Show User and Last Session Start for all users having Access records and having max Session Start time earlier than 90 days ago. (an inactive user is missed if they never once logged in, or if all their old logins have been purged)

## Violations/Incidents

See [Incident Management](#).

## View Installed Policy

In the Currently Installed Policy panel, this special report displays the information about the installed policy such as the policy name, the number of rules it contains, and its policy definition settings. You cannot access the query this report is based upon.

## Predefined common reports

This section provides a short description of all predefined reports available for users with either default user access rights or default admin access rights.

The common reports are:

- Data Source Version History
- Data Sources

## Status Monitor

The Status Monitor graphical report displays the current state of the guardium appliance: how many packets per second and requests per second it is processing, how much disk space and memory is being used, and so forth. Each field is described in the following table.

The box displays the output of the Linux® VMSTAT command. If you are familiar with that command, these statistics should be familiar to you.

| Field                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| (n)pps / (m)rps                 | In the arrow next to the Analysis Engine, two averages are calculated for the last five seconds: <b>n</b> is the average number of network packets per second, and <b>m</b> is the average number of network database requests per second.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Analysis Engine (q-d) ----- (p) | For the Analysis Engine, the first line lists the total number of messages queued for processing ( <b>q</b> ), followed by the number of messages dropped ( <b>d</b> ) because the buffer was in danger of becoming filled. The second line lists the total number of messages processed ( <b>p</b> ). The number processed will be reset to zero whenever the inspection engine is restarted.                                                                                                                                                                                                                                                                                                                                  |
| Server Type (q) ---- (p)        | For each server type, the number of messages awaiting processing ( <b>q</b> ) is listed and the number of messages processed ( <b>p</b> ) is listed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| DB n% Full                      | The percentage of the database space allocation that is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Files/Other                     | The Files/Other portion of Status Monitor represents the data accumulated in nondb-sql logger.<br>Nondb-sql logger logs close session events arriving to the Analyzer from "ignored" sessions that have been internally closed by the Analyzer (INACTIVE_FLAG=-1). The Analyzer has the ability to close connections by timeout (if session has been inactive for a long time). If close session data arrives to the Analyzer from "ignored" session that has been closed by timeout, it is recorded in the nondb-sql-logger section.<br><br>Analyzer never records data directly to database. This section also represents number of DB requests sent by Analyzer to Logger, as well as other supported protocols such as SCP. |

## Data Source Version History

Default Layout Location

- admin: available as drill-down from the Data Sources report
- user: Discover > DB Discovery

## Data Sources

Lists all datasources defined: Data -Source Type, Data-Source Name , Data-Source Description, Host, Port, Service Name, User Name, Database Name, Last Connect, Shared, and Connection Properties..

You can restrict the output of this report using the Data Source Name run time parameter, which by default is set to "%" to select all datasources.

| Domain                   | Based on Query | Main Entity   |
|--------------------------|----------------|---------------|
| internal - not available | Data-Sources   | not available |
| Run-Time Parameter       | Operator       | Default Value |
| Data Source Name         | LIKE           | %             |
| Period From              | >=             | NOW -1 DAY    |
| Period To                | <=             | NOW           |

## Predefined Audit Processes

---

There is one predefined audit process named Appliance Monitoring, which contains the proceeding reports listed. This audit process is inactive by default. The administrator can activate and schedule it according to his or her needs.

Note: When scheduling this audit process, check that the FROM/TO dates for each report make sense for the process interval being defined (for example, it doesn't make sense to have a reporting period of one day if the audit process runs only once a week - you will miss six days of activity).

The Appliance Monitoring audit process contains the following reports:

- Failed Logins to Guardium
- Active Guardium Users
- Aggregation/Archive Errors
- Policy Related Changes
- Inspection Engines and S-TAP Changes
- Data Source Changes
- CAS Instance Configuration Changes
- CAS Instances
- CAS Templates
- Scheduled Jobs Excep

---

## Creating dashboards and adding reports

You can create one or more dashboards, add reports to them, and configure their appearance.

### Before you begin

---

Think about how you want to organize the reports that you view regularly. Do you want to view them in one dashboard, or in several dashboards? Do you want to group and order them according to their purpose, how critical they are, or some other approach? You can always rearrange your dashboards or create new ones.

### Procedure

---

1. Click My Dashboards  Create New Dashboard to open a new dashboard.
2. Enter a descriptive name in the Name field. This name is used in the list of dashboards in the menu.
3. Click Add Report  to display a list of available reports. If you have designated certain reports as favorites, you can check the My Favorites box to see only a list of those reports. If you want to see only graphical reports, check the Chart Only box.  
The Add a Report dialog shows a list of all reports that meet your criteria. You can browse the list of reports, or type a string in the Filter field. The list of reports is updated as you type.
4. Click the title of a report to add it to your dashboard. Continue adding as many reports as you want. When you are finished adding reports, click Close.
5. Click Edit mode to add the toolbar to individual reports so you can modify the reports. (See [Viewing reports](#).)

### Results

---

You have a dashboard that gives you easy access to some selected reports.

### What to do next

---

Review the appearance of your dashboard. Is it easy to use, and to find the information that you want? If not, you can configure it further.

### Customize your dashboard

---

Learn how to customize your dashboard.

#### Procedure

1. Change the dashboard by clicking  and entering the new name.
2. Select the number of column in the upper right corner. The default is two columns.
3. Rearrange the reports. To move a report, place your cursor on the report's title bar, and drag it to a new location.
4. Resize your reports. Drag the resize icon to make a report longer or shorter, narrower or wider.
5. Designate specific reports as favorites by clicking  (in edit mode only).
6. Delete a dashboard by clicking Delete dashboard.

---

## Opening the investigation dashboard, filtered for report entities

### About this task

---

From tabular reports that include columns related to the investigation dashboard filter fields (for example: DB User, Server IP, Database, Source Program), you can open the investigation dashboard, filtered for those values.

## Procedure

Right-click the row of a report and select Investigate In Dashboard.

## Results

The investigation dashboard opens, filtered for the values in that row of the report. If the "from date" and "to date" run time parameters are defined, the dashboard uses the values. If they are not defined, the dashboard opens with "Last 1 Hour" time filter.

## Viewing reports

There are several ways to view a report, including your dashboard and UI search.

You can view a report in several ways:

- If you have saved the report to a dashboard, open the dashboard to view the report.
- You can add the report to a dashboard. Open the dashboard and click Add Report, then choose the report from the list.
- Add the report to your custom reports.
- Some reports are listed in categories in the Reports lifecycle.
- Some reports are listed under the lifecycle to which they are most relevant.
- You can use the user interface (UI) search function to find a report that is in a lifecycle or in a dashboard. On the banner, choose User Interface from the drop-down list next to the Search box. Enter the name of the report into the Search box. Results begin to appear after you type a few characters. Choose the report from the list of results.

After upgrading from pre-v10.6 to v10.6 and higher: If you had multiple reports based on the same query, upon upgrade there is one query for every report whose name is the same as the report in the pre-upgrade version.

The following choices (icons) give access to editing and configuring the report:

|  |                                                                                                                                                                                                                                                                                                          |
|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  | Edit the query for this report ( <a href="#">Using the Query-Report Builder</a> ).                                                                                                                                                                                                                       |
|  | Opens a new Query-report page with a copy of the report, except for the name. Modify and save as relevant. See <a href="#">Using the Query-Report Builder</a> .                                                                                                                                          |
|  | Opens the Data Mart Configuration dialog. For more information, see <a href="#">Data Mart</a> .                                                                                                                                                                                                          |
|  | <a href="#">Ad-hoc process for run once now</a>                                                                                                                                                                                                                                                          |
|  | Opens the report in a new window.                                                                                                                                                                                                                                                                        |
|  | <a href="#">Modifying the report display</a>                                                                                                                                                                                                                                                             |
|  | Configure report columns: add or remove columns.                                                                                                                                                                                                                                                         |
|  | Configure runtime parameters. A run-time parameter provides a value to be used in a query condition. There is a default set of run-time parameters for all query-reports, and any number of run-time parameters can be defined in the query-report. ( <a href="#">Modifying the runtime parameters</a> ) |
|  | Add to favorites                                                                                                                                                                                                                                                                                         |
|  | Stops generation of a report (relevant for reports that take a longer time to generate)                                                                                                                                                                                                                  |
|  | Refresh the report. See <a href="#">Refreshing reports</a>                                                                                                                                                                                                                                               |

You can hide columns from view. Click the columns icon and clear the check boxes for the columns that you want to hide.

You can sort report data by the contents of any column. Click the title of the column on which you want to sort. To reverse the order, click the title again. Sorting is always performed on the actual data values, ignoring any aliases that are defined.

You can print a report while you are viewing it. Click Export > Full printable report to open a printable copy of the report in a new tab. Click the printer icon on the new tab to print the report. You can also print a report by exporting it to a PDF file and printing the PDF file.

Note: For an instance where the PDF text is too small to read, the PDF report has a physical limit on how much it can expand horizontally given how wide the page is. Since each line of the PDF report has to fit on one line, the typeface size changes to fit the data, and may force a very small typeface size in order to display all the data. Graphical reports can be customized by clicking the Customize Chart icon. The choices include converting the data to a line chart, changing the X-axis and Y-axis orientation, converting the report to a pie chart or a stacked column chart.

When viewing reports that display Oracle information, occasionally the ? question mark character is used to inform the viewer that the login information was not available. Again when viewing reports that display Oracle information, the appearance of the number -1 signifies that an unknown number of records are affected. All Oracle sessions are recorded, even with missed logins.

The OS user does not appear in reports if a Linux system or a Windows system using remote connections did not send the OS user with the login packet. For Linux local connections, UID chain can be used to identify the user. See which systems support UID chains in [S-TAP support matrix](#).

Viewing Big Data Intelligence reports has a few differences.

- Reports present data in batches of 1000 items. Each page contains the number of rows defined in the lower right corner. The page numbers under the report show the page within the batch. Page through the batch using the page numbers. Proceed to the next batch with Next batch. You can move forward in the batches. Run the query again to view earlier batches.

Note: If you sort the report, either by clicking a column name or by setting the sort order in the query-report itself, you only see one batch.

- Clicking Refresh reruns the query.

- [Modifying the runtime parameters](#)

You can modify the runtime parameters to control the contents and presentation of a report.

- [Refreshing reports](#)

Some reports are configured to refresh their data automatically. On other reports, you can refresh the data manually through the UI.

- [Exporting a report](#)  
You can export a report to a PDF file or a comma-separated values file.
- [Viewing Drill-Down Reports](#)  
Many reports provide access to drill-down reports that provide more granular data.
- [Ad-hoc process for run once now](#)  
This process creates and runs an ad-hoc audit process report.

## Modifying the runtime parameters

You can modify the runtime parameters to control the contents and presentation of a report.

This table lists the standard runtime parameters. A report may have additional parameters.

| Runtime Parameter      | Default                                         | Description                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enter Period From      | NOW -3 HOUR.                                    | Required. Start time of the report. The default is NOW -3 HOUR. For Big Data intelligence, the default is NOW -1 DAY. Predefined reports may have different defaults.                                                 |
| Enter Period to        | NOW                                             | Required. End time of the report. The default is NOW. Predefined reports may have different defaults.                                                                                                                 |
| Guardium appliance     | All                                             | Big Data Intelligence only. Data is retrieved for all Guardium appliances (default) or the selected one.                                                                                                              |
| Time Zone              | The time zone of your Guardium system.          | Big Data Intelligence only. Data is retrieved according to this time zone and date fields are presented in this time zone.                                                                                            |
| Remote Data Source     | None                                            | In a Central Manager environment, you can run a report on a managed unit by selecting that Guardium system from the Remote Data Source list.                                                                          |
| Show Aliases           | None (meaning the system-wide default is used). | Select On to always display aliases, or Off to never display aliases. Select Both to display both the original and alias value. Select Default to revert to the system-wide default (controlled by the administrator) |
| Refresh Rate (seconds) | 0                                               | Rate at which the report is refreshed, in seconds. 0 means the report is not refreshed automatically.                                                                                                                 |

Use the GuardAPI command, `list_parameter_names_by_report_name`. This function takes a report name as an input parameter and returns a list of runtime parameter names for that report.

1. Access the report.
2. Click Configure runtime parameters .
3. Modify the parameters as relevant and click OK.

## Refreshing reports

Some reports are configured to refresh their data automatically. On other reports, you can refresh the data manually through the UI.

There are several ways to refresh report data manually:

- Click Refresh  on the report toolbar.
- Use any toolbar button to print a report, download report data, or write the report to a PDF file. The report data is refreshed before performing any of these actions.
- Set a time interval for periodic refreshing, by setting the `refreshRate` parameter value. To perform this task:
  - Click  on the report toolbar.
  - In the Configuration dialog, set the `refreshRate` parameter to the number of seconds after which the report data is to be updated. The default value of zero indicates that the report data is not refreshed on a scheduled basis.
  - Click OK.

## Exporting a report

You can export a report to a PDF file or a comma-separated values file.

You can export the contents of a report to:

- PDF. When you generate a large PDF file, the process can cause the UI to time out. If you plan to generate large PDF files, consider doing so as part of an audit process, or increasing the UI timeout value to avoid this problem.
- CSV of all records
- CSV of the display records (the data currently displayed)

Restriction: PDFs generated manually or using an audit process are limited to 5,000 rows. Manually exported CSV files are limited to 30,000 rows (this default is configurable using the `store csv_max_size` CLI command). Any number of rows can be exported to CSV when using an audit process.

1. Access the report.
2. Click Export in the toolbar, and select one of:
  - Download all records: CSV of all records. You can save and/or view the file.
  - Download display records: CSV of the display records (the data currently displayed). You can save and/or view the file.
  - Full printable report: Opens a new browser window with all the report details.
  - Download as PDF: You can save and/or view the file.

# Viewing Drill-Down Reports

Many reports provide access to drill-down reports that provide more granular data.

If any drill down actions are available on a tabular report, you can see them by right-clicking on a row of the grid. The context-menu appears with any available drill-down actions.

To be available as a drill-down report:

- All of the runtime parameters for the drill-down report must be available from the report that is being viewed.
- If security roles have been assigned, you must have access to the drill-down report.

## Related tasks

- [Modifying the query drilldown control](#)

## Ad-hoc process for run once now

This process creates and runs an ad-hoc audit process report.

## About this task

The behavior of this process is as follows:

1. If a new process, one or a number of email receivers can be created in the list (if any) with a content type as indicated in the emailContentType parameter. It also creates a user receiver for the user logged in (invoking the API) if the includeUserReceiver parameter is true.
2. If an existing process, all email receivers are removed and replaced with the emails from the new list (if any) with the content type as defined in the emailContentType parameter. If the list is empty, it removes all email address receivers. If there is already a receiver for the user it is NOT even if the includeUserreceiver is false, however if the parameter is true and there is no such receiver then it is added.

Once the audit process is generated it automatically executes (similar to a Run Once Now) and users should expect an item on their to-do list for that audit process. The GuardAPI that creates ad hoc audit process keeps results to 7 days (instead of 1 day). Results are deleted after 7 days. For further information on parameters, see the GuardAPI command, `create_ad_hoc_audit_and_run_once`, in the GuardAPI Input Generation help topic.

## Procedure

1. Click the Ad-hoc process for Run Once Now icon  .
2. In the Ad-hoc dialog, fill in as relevant, then click OK.
  - Email Addresses: comma separated list of email addresses.
  - Content type for email receiver: PDF or CSV (a radio button 0 - PDF / 1 -CSV)
  - Add user as Receiver (check box)

## Using the Query-Report Builder

If the predefined reports do not meet your needs, create a query from scratch, or clone and modify an existing query.

Before you start writing a query, plan carefully what you want the report to describe. There are two general use cases:

- You want to identify a specific occurrence in your system. This type of query has two parts. An event, or events, occurred in your system: this is defined by the conditions. What do you want to know about the system when this event occurred? These are the details (columns) presented in the report.
- You want status on some part of your system. In this case, you probably only need to specify the columns you want in the report.

First find the domain that covers the data you want. A domain contains a set of data related to a specific function or purpose, for example: data access, exceptions, policy violations. Each query is based on, and returns data from, one domain. For a description of all domains, see [Entities and Attributes in the domains](#). Each domain has one or more entities, which are groupings of attributes. Attributes are the fields that can be used as columns in the report. Some entities are included in more than one domain, to give you access to the relevant data. For example, the Session Entity is in both the Access domain and the Exceptions domain.

Data is tracking who did what, and when. Some details are static, some are dynamic. The entities, within the domain from top to bottom in the UI, start with static details, followed by non-static details. For example, in the Access domain, the first entity is client/server. Each client/server pair is saved once. The next entity is Session. The client/server pair has multiple sessions with non-static details, for example, session start and inactive flag. This creates a one-to-many relationship between the client/server and the sessions. To see each value of session start, you would need multiple rows. Instead of making your report unnecessarily long with each session start, you can use the count option to show the number of occurrences of session starts, and then drill down to see a more detailed report. The rule of thumb is: the higher up your main entity is in the GUI, the fewer rows and values you'll have in your report. The report is more manageable, and you can always drill down to see more details. For more information on how domains function in a query, and optimizing queries, see [Optimizing queries](#).

If you need details from two entities that are not included in one domain, you can create a custom domain (see [Custom Domains](#)).

A query returns data from one domain only. When the query is defined, one entity within that domain is designated as the main entity of the query. Each row of data returned by a query contains a count of occurrences of the main entity matching the values returned for the selected attributes, for the requested time period. This allows for the creation of two-dimensional reports from entities that do not have a one-to-one relationship.

Once you identify the domain, check the predefined reports in that domain to see if there is one close to what you want. If yes, you can clone and modify it. If not, create the query from scratch.

Define the report data (columns). You can choose columns from all the entities in the domain.

Optionally, define the conditions. Conditions, if you use them, are triggers for including the specific data in the report. A query on status, for example, does not need a trigger; you simply want to know the status of an element in your system. On the other hand, if you want to identify specific actions by a specific user on a group of databases, these are the query conditions. The conditions use the attributes in the domain, with operators. There is no intrinsic relationship between the conditions and the report columns. You can choose to add the attributes in the conditions as columns, or not.

You can also optionally defined build expressions or Having clauses on SQL statements.

Reports are the presentation of that data, created when you save your query, with the same name as the query. Default reports are tabular reports that reflects the structure of the query, with each attribute displayed in a separate column. All runtime parameters and presentation components of a tabular report can be customized.

The query builder has six rows for configuring the various aspects of the query, explained in the following sections.

There are buttons at the bottom of the Query-Report Builder page:

- Add to Dashboard: click to add the displayed report to a defined dashboard
- Add to My Custom Reports: Click to add to Reports > My Custom Reports
- Query Summary: Click to open a textual summary of the query

**A Caution about Full SQL Attributes in Queries** Beware of using the Full SQL attribute in a query. It may produce excessively large reports, because each distinct value of the attribute (the complete SQL query string in this case) will be returned in a separate row. On the other hand, the report may contain no information at all, or many blank columns where you are expecting Full SQL strings. Guardium captures Full SQL only when directed to do so by policy rules - and the rules may not have been triggered during the reporting period. Do not confuse the Full SQL attribute with the ability to drill down to the SQL for most queries in the Data Access domain having anything to do with SQL requests.

- [\*\*Optimizing queries\*\*](#)

To understand how to optimize queries, it is imperative to have an understanding of how queries work and how reported data is stored internally on the appliance. Each domain is associated with a particular predefined set of data. For example, Access domain for captured traffic, Exception domain for captured errors from the database server, or Guardium activity domain to monitor activities that are performed by Guardium users.

- [\*\*Creating a new query, modifying an existing query\*\*](#)

Search through all existing queries, or by domain, to copy and modify an existing query, or create a query from scratch.

- [\*\*Defining the query name and attributes\*\*](#)

Select the domain, then set the query name, the main entity, and configure roles, datamart, drilldown control, and API assignments.

- [\*\*Selecting the column display\*\*](#)

Choose the columns for your report from the attributes in all of the entities in the domain, and define the sort hierarchy.

- [\*\*Setting the sort order\*\*](#)

- [\*\*Defining the Query Conditions\*\*](#)

- [\*\*Adding a build expression on query condition\*\*](#)

Use this feature when you need to add a condition (including a user-defined string or a mathematical expression) that is based not on the entire content of the attribute as is, but on part of the attribute, a function of the attribute, or a function that combines more than one attribute.

- [\*\*Having conditions\*\*](#)

This row is available if "Group by" is required; when one or more columns use one of the following functions: count, min, max, average, sum.

- [\*\*Modifying the report display\*\*](#)

You can select the report type (tabular or chart), change the column names, and configure the color indication rules.

## Optimizing queries

---

To understand how to optimize queries, it is imperative to have an understanding of how queries work and how reported data is stored internally on the appliance. Each domain is associated with a particular predefined set of data. For example, Access domain for captured traffic, Exception domain for captured errors from the database server, or Guardium activity domain to monitor activities that are performed by Guardium users.

Most of the domains deal with small amounts of data and are irrelevant for this performance description. The Access domain is one domain that deals with large amounts of data that is used often. This domain contains database activity data that is captured by an appliance. This domain is composed of many tables with many millions of rows of data in each table. Carefully consider your decisions when you are designing queries in this domain. Each entity in the domain corresponds to an underlying table and has a list of attributes. Attributes correspond to fields in the table. When you select fields (attributes) from the Session entity and some other fields from the SQL entity, these two entities are joined to retrieve the data that you request. The more entities that are joined in your query, the more complex the final query is and the longer it takes to produce the results.

Guardium monitors and captures numerous details about database user activity. All of this information can be put into the following major categories.

- Who: Describes a connection to a database, who made a connection, and when the connection was made.
- What: Contains the SQL statements that ran on the database.

Connection details include attributes (fields), such as Server IP, DB Type, DB User Name. This information is recorded in the Client/Server and Session entities. Two entities are used: even though the login information (for example, IP, user name) of a user stays the same for every connection, every connection has unique information, for example, login time or client port. The relatively static, repeatable login information is stored in the Client/Server entity and the unique, connection-specific information is stored in the Session entity. Splitting information between two entities helps to reduce data redundancy and saves disk space.

In addition to login information, Guardium captures the SQL statements that are issued by the user or an application. The SQL statements are recorded in the SQL entity. To create queries with conditions on specific groups of tables, or sets of commands, Guardium parses captured SQLs to commands, objects, and fields, and places this information in three other entities: Commands, Objects, and Fields.

If you want to create a query that shows only the activity on a particular table, you can create a query with a condition, such as

```
WHERE OBJECT.OBJECT_NAME =
```

```
'myTable'
```

Or, if you want to create a query that shows only DML activity, you can create query condition, such as

```
WHERE COMMAND.VERB in group 'DML'
```

```
commands'
```

The redundancy here helps to create more efficient queries. When you create a query, you first enter a query name, then you select a main entity. It is important to select a main entity that indicates to the Query-Report builder the focal point for the new query and how to construct a query. Ultimately, it might also affect query performance.

For example, you can create two queries with identical fields, one with the main entity as Session, and the other with Command. The attributes are:

- Session start time
- Session end time
- Client IP
- Server IP
- DB user name
- Source program

The following query is generated by the Query-Report builder with the Session main entity:

```
select ... from GDM_ACCESS, GDM_SESSION where.... The following query is generated by the Query-Report builder with the Command main entity:
select
... from GDM_ACCESS, GDM_SESSION, GDM_CONSTRUCT_INSTANCE, GDM_SENTENCE where...
```

Both queries have the same columns. However, the first query joins two tables to produce the results and the second query has four tables that participated. The second query takes longer to complete. Even more important, most likely the second report has more records and some of the rows appear multiple times.

When Command is selected as the main entity, the Query-Report builder defines the report with the focus on "command". A session usually has many commands. Each command appears on the report in a separate row. Even if a session has no commands, there is a row for the session in the report, with an empty Command column. Main entities are organized hierarchically from high-level details to more granular. The main entity defines the level of details in the report. Selecting a main entity on too high a level in the list might limit your ability to select fields to report. An example is a single SQL statement with multiple fields. If you select SQL as a main entity, your level of detail is an SQL statement and each line in the report is dedicated to one SQL statement. This means that you cannot display fields in the same line because there is no space for multiple fields.

However, you can use the Count function to display total count of the fields in an SQL statement or the Max function to display the highest field value. If you query definition has SQL as the main entity for database activity, you cannot add the SQL Verb field from the Command entity because the Command entity is positioned lower than SQL entity in the entity list. Therefore, you cannot use the field value directly but you can apply the value to one of the math functions, such as Count, Min, or Max.

When you are designing a new query, consider the relationships between entities to avoid data redundancy in reports.

Certain database operations (such as GROUP BY, DISTINCT, ORDER BY, or HAVING clauses) provide flexibility to the Query-Report builder. However, these operations might take more processor time. If you have report performance issues, consider revising your report to limit the usage of these database operations.

In general, the data volume that is stored on the appliance is the major factor that can affect the report performance. When you tune the report performance, consider the following points:

- Define the purge process to run nightly.
- Configure the data retention period to the minimum that is allowed by your business requirements.
- Record Full SQL only when it is necessary (for example, to monitor sensitive objects or privileged users). Full SQL tables can add data volume quickly.
- Reduce the period of the report to have a positive effect on the report run time.

In centrally managed environments, reports frequently run on the aggregators instead of the collectors. Data that is exported from the collectors nightly in one-day chunks is transferred to the aggregator. On an aggregator, data from multiple collectors and multiple days is merged for reports. For efficiency reasons, not all of the data that is presented on an aggregator is merged and made available for reports. The merge period defines the date range that you can use in reports. It shows on top of every report you run. The default merge period is 14 days for interactive reports. The merge period is a derived internally. The merge period doesn't impact the date range available for audit processes.

Tip: Keep your purge period at a maximum of 90 days, and the maximum number of collectors that report to an aggregator at 10 to ensure timely data aggregation (and keep the merge period at 14).

## Creating a new query, modifying an existing query

Search through all existing queries, or by domain, to copy and modify an existing query, or create a query from scratch.

### About this task

Each domain contains a set of data related to a specific purpose or function (data access, exceptions, policy violations, and so forth). The names are self-explanatory, so you can easily select the relevant domain. For a description of all domains, see [Entities and Attributes in the domains](#).

### Procedure

1. Open the Query Builder by navigating to Investigate > Exceptions > Query-Report Builder, or Reports > Report Configuration Tools > Query-Report Builder.  
The list under Queries-Reports contains all queries in all the domains. Use the search to find a query.
2. Create a query using these guidelines:
  - Select an pre-defined query. A dialog box opens and you can choose to:
    - Open the original query (click Open original) to modify some attributes (for example: [Managing query security roles](#), [Adding a query to a datamart](#), [Modifying the query drilldown control](#), [Modifying the API assignment](#), [Creating dashboards and adding reports](#)). You cannot modify its query attributes or conditions.
    - Make a copy by clicking Make copy and giving it a new name. Continue with [Defining the query name and attributes](#).
  - Select the domain you want to query from the Select Domain drop-down. Select one for copying or click New . The New Query page opens. Continue with [Defining the query name and attributes](#).

- Select a user-defined query. Its properties open in the right hand pane. You can edit the query, or click  to copy the query. Continue with any query configuration tasks.
- Create a new query: Click New . The New Query page opens. Continue with [Defining the query name and attributes](#).

## Defining the query name and attributes

Select the domain, then set the query name, the main entity, and configure roles, datamart, drilldown control, and API assignments.

### About this task

When creating a query from scratch, the next step is to select the main entity (from the domain). The main entity that you select determines:

- The level of detail for the report. There is one row of data for each occurrence of the main entity included in the report. The location of the main entity within the hierarchy of entities is important in terms of what values can be displayed. Attributes in an entity at a higher level in the hierarchy can have a field mode of type value. Attributes in an entity at a lower level in the hierarchy cannot have a field mode of type value. You can see the hierarchy in the entities list in the query-report builder. The hierarchy is exactly as the list displays, from top to bottom.
- The time fields against which the Period From and Period To runtime parameters are compared to select the data in the report. The Query-Report Builder uses the main entity (among other parameters) to determine which time fields are used when defining the Period From and Period To values. This can be important for long-running sessions, such as when pooled sessions are kept open by an application server. When applicable, the Period Start/Period End from the Access Period entity is used, in other cases it chooses period values according to the main entity:
  - Session - the time stamp used is for the last update that is made to the session entity
  - Session Start - the starting time of the session entity is used
  - Session End - the ending time of the session entity is used
  - Full SQL - time stamp from Full SQL domain; query includes rows from the Full SQL domain even if not linked to values (for example - when Log Full Details is set, there are no values)
  - Full SQL Values - time stamp from the Full SQL domain; query includes rows only if they have values from the Full SQL domain even if not linked to the Field domain
  - Field SQL Values - time stamp from the Full SQL domain; query includes rows only if they have values from the Full SQL domain and they are linked to the Field domain

Other options in this row are:

- Partition optimization is enabled by default and improves query performance with partitioned database tables. You can disable this feature by clearing the Partition optimization check box. Partition optimization should not be disabled without the direction of Guardium support.
  - Run in Two Stages. Use this selection for two-stage execution for Audit tasks of type report. This applies to reports on queries on specific tables only. This two-stage mechanism applies to running queries as audit processes with columns and conditions only on the following entities: Access (client/server), Session, Access Period, Construct (SQL), Object, and Sentence (Command). This two-stage mechanism is not used if the query contains a condition with the **Like Group** operator or any alias-related operator (such as **In Aliases Group**) or the condition uses Having. By default, queries run in one stage. To disable two stage queries system wide, create the file: /var/log/guard/DontRunInTwoStages. Existence of this file indicates that the two stage method is NOT used.
- Note: Fields containing tuples (combined fields) in the Two Stages execution is not supported.

Note: The Main Entity drop-down list includes only primary entities. However, access to secondary entities (for example Session Start and Session End) can be done through its corresponding primary entity (for example, Session for Session Start and Session End).

### Procedure

1. For both cloned and new reports, in the right pane, enter a unique query name in the query name textbox. (You can use Ctrl+V to paste, or type the query name; right-click to copy the query name is not supported.)
2. Select the main entity from the drop-down list.
3. Click Next to select columns and save the query. Once the query is saved, additional buttons in this row become available, as relevant.
  - [Managing query security roles](#)  
By default, only the user that defines a query has access to the query. You can add and remove other roles (or all roles) to provide access to a query.
  - [Adding a query to a datamart](#)
  - [Modifying the query drilldown control](#)  
By default, the drill-down menu for a report includes all reports with run-time parameters that can be supplied by attributes from the report, which is given the usual security role restrictions.
  - [Modifying the API assignment](#)  
By default, the Guardium application comes with setup data that links many of the API functions to reports; providing users, through the GUI, with prepared calls to APIs from reporting data. Use API Assignment to link additional API functions to predefined Guardium reports or custom reports.

## Managing query security roles

By default, only the user that defines a query has access to the query. You can add and remove other roles (or all roles) to provide access to a query.

### About this task

The user that defines a query can grant access to additional users. Queries are completely filtered from the UI for users that do not have access to the query.

### Procedure

1. In the Query Name row, click Roles.  
The Assign Security Roles dialog opens.
2. Select or clear individual roles, or select All Roles to grant access to all roles.
3. Click OK.  
The roles are updated and the panel closes.

## Adding a query to a datamart

### About this task

If there is a predefined datamart based on the query, the predefined datamart output structure may not exactly match the query definition. For example, the predefined datamart **Export:Full SQL** does not have the field Original Timezone, but the predefined query **Export:Full SQL** does have the field. If you create a new datamart based on the query, it matches the query structure.

### Procedure

1. In the Query Name row, click Datamart.  
The Datamart Configuration dialog opens.
2. Select an existing datamart, or click New to create a new datamart.
3. Configure the extraction and click Apply.

## Modifying the query drilldown control

By default, the drill-down menu for a report includes all reports with run-time parameters that can be supplied by attributes from the report, which is given the usual security role restrictions.

### About this task

Drilldown control is accessed under Advanced Options in the Query Name row.

### Procedure

1. In the Query Name row, under Advanced options, click Drilldown Control to open the report's Drilldown Control panel.
2. Mark the checkbox for any report to be disabled, or clear the checkbox for any report to be enabled.
3. Click Apply. The system displays a message saying your changes were applied successfully.
4. Click Done when you are finished.

## Modifying the API assignment

By default, the Guardium application comes with setup data that links many of the API functions to reports; providing users, through the GUI, with prepared calls to APIs from reporting data. Use API Assignment to link additional API functions to predefined Guardium reports or custom reports.

### About this task

For more information on using linked API functions, see the documentation on GuardAPI Input Generation.

### Procedure

1. In the Query Name row, click show advanced options, then click API Assignment to open the API Assignment panel; showing the current API functions that are mapped to the selected report. If there are no fields in the report that are linked to API parameters, it might be irrelevant to link an API function to a report. The mapping of API parameters to report fields can be accomplished through both the GUI and the CLI. For additional information on mapping API parameters to report fields, see Mapping GuardAPI Parameters to Domain Entities and Attributes in the GuardAPI Input Generation section.
2. Click an API function to display a pop-up window of the current API - Report Parameter Mapping; showing the API parameters, if the API parameters are required, any default values, and if any of the report fields are currently mapped to those parameters.
3. Click the greater-than sign '>' to add the selected API function to the current list of functions that are assigned to this report.
4. Click Apply to save the changes.

## Selecting the column display

Choose the columns for your report from the attributes in all of the entities in the domain, and define the sort hierarchy.

### About this task

The number of columns cannot exceed:

- 30 string columns
- 25 numeric columns
- 6 text columns
- 8 date columns

## Procedure

---

1. In the Columns to Display area, select the columns you want to appear in the report. The drop-down list contains all the entities in the domain.
  2. Click an entity to open a list of its attributes, select all the attributes you want from all of the entities, and click Add.
  3. Optionally select Distinct to display one-row-per-value in the report (there is one row in the report for each combination of the column values). This option yields condensed reports, but option can impact performance.
  4. Optionally select Count. The Count option adds a count column (#) to the report, with the number of occurrences of the set of values in any one row. This count can be used for sorting. When using Count, you can have up to 4 columns in the report, including count.
  5. Arrange the attributes in the order you want them to display in the report, using the up and down arrows. Top to bottom in the UI is left to right in the report.
  6. For each attribute, select what to print for the field: its Value, Count (number of distinct values), Min, Max, Average (AVG) or Sum.
- 

## Setting the sort order

### About this task

---

The Sort by Count option is enabled if you selected the Count checkbox in the Selected Columns row. It sorts the rows by frequency of occurrence.

## Procedure

---

1. Open the Sort Results row.
  2. To sort by count, select Sort results by count.
  3. To sort by column:
    - a. Select Sort results by column.
    - b. Click and select the column that is the primary sort criterion. The ascending/descending dropdown defaults to ascending. Modify as relevant.
    - c. Repeat for additional columns, adding rows by clicking Then by.
    - d. Remove a column by clicking in the row.
- 

## Defining the Query Conditions

### About this task

---

Query conditions have the format: <And/Or> <Field> <Operator> <Value/Parameter/Group> <Value>

where:

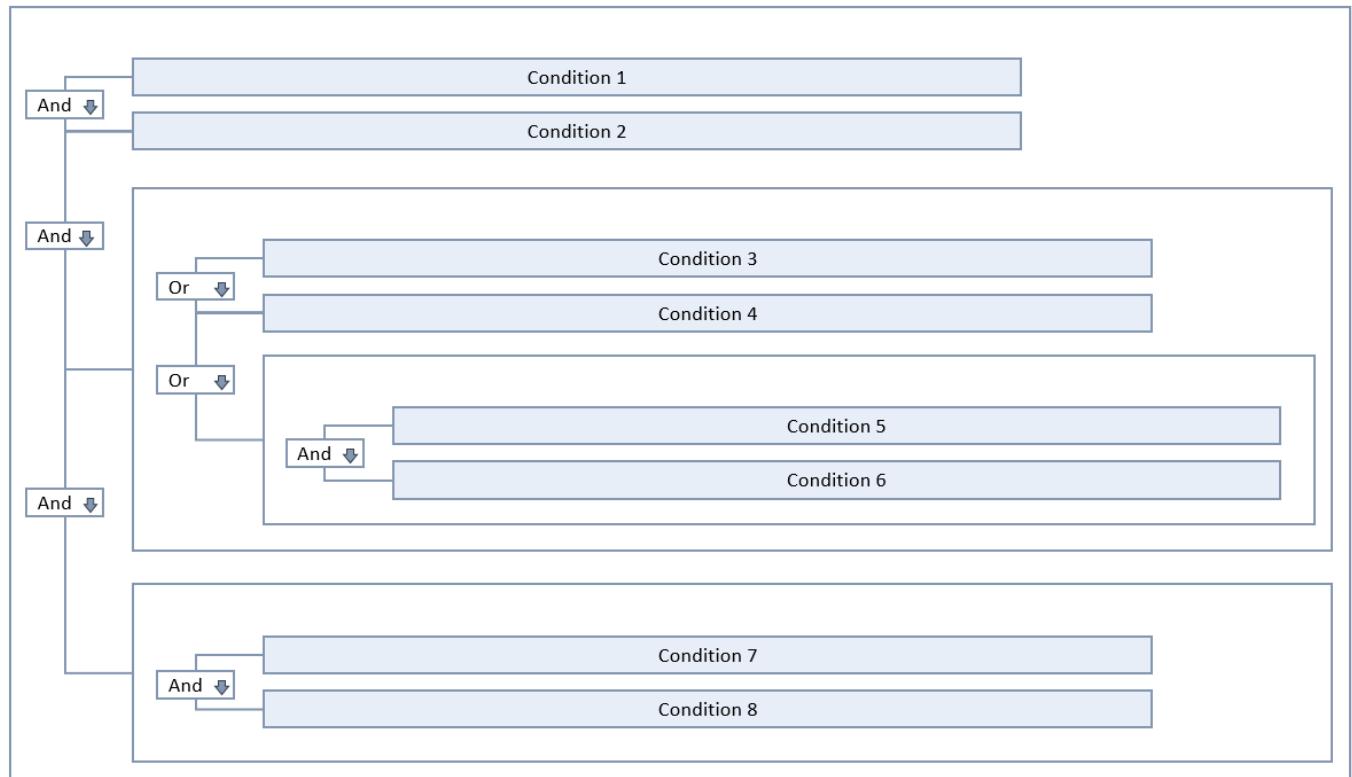

- And/Or: determines the relationship between the conditions or condition groups. The default is Add.
- Field: one of the fields in the query's domain
- Operator: the operator types depend on the selected field. For example, attributes that cannot be associated with groups do not have any of the group options (IN GROUP, LIKE GROUP).

| Operator                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <                        | Less than                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <=                       | Less than or equal to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <>                       | Not equal to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| =                        | Equal to                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
