| CATEGORIZED AS           | Member of a group belonging to the category selected from the drop-down list, which appears when a group operator is selected.                                                                                                                                                                                                                                                                                                                                                                                    |
| CLASSIFIED AS            | Member of a group belonging to the classification selected from the drop-down list, which appears when a group operator is selected.                                                                                                                                                                                                                                                                                                                                                                              |
| IN ALIASES GROUP         | The operator works on a group of the same type as IN GROUP, however assumes the members of that group are aliases. Note that the IN GROUP/IN ALIASES GROUP operators expect the group to contain actual values or aliases respectively. An alias provides a synonym that substitutes for a stored value of a specific attribute type. It is commonly used to display a meaningful or user-friendly name for a data value. For example, Financial Server might be defined as an alias for IP address 192.168.2.18. |
| IN DYNAMIC ALIASES GROUP | The operator works on a group of the same type as IN DYNAMIC GROUP, however assumes the members of that group are aliases.                                                                                                                                                                                                                                                                                                                                                                                        |
| IN DYNAMIC GROUP         | Member of a group that is selected from the drop-down list in the runtime parameter column, which appears when a group operator is selected.                                                                                                                                                                                                                                                                                                                                                                      |
| IN GROUP                 | Member of the group that is selected from the drop-down list in the runtime parameter column, which appears when a group operator is selected. IN GROUP or IN ALIASES GROUP cannot both be used at the same time.                                                                                                                                                                                                                                                                                                 |
| IN PERIOD                | For a time stamp only, is within the selected time period                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IS NOT NULL              | Attribute value exists, but might be blank or unprintable                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IS NULL                  | Empty attribute                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| LIKE                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Operator                     | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LIKE GROUP                   | Matches a like value that is specified in the boxes. A like value uses the percent sign as a wildcard character, and matches all or part of the value. Alphabetic characters are not case-sensitive. For example, %tea% would match tea, TeA, tEam, steam. If no percent signs are included, the comparison operation is an equality operation (=). |
| NOT IN ALIASES GROUP         | The operator works on a group of the same type as NOT IN GROUP, however assumes the members of that group are aliases.                                                                                                                                                                                                                              |
| NOT IN DYNAMIC ALIASES GROUP | The operator works on a group of the same type as NOT IN DYNAMIC GROUP, however assumes the members of that group are aliases.                                                                                                                                                                                                                      |
| NOT IN DYNAMIC GROUP         | Not equal to any member of a group, which is selected from the drop-down list in the runtime parameter column, which appears when a group operator is selected.                                                                                                                                                                                     |
| NOT IN GROUP                 | Not equal to any member of the specified group, which is selected from the drop-down list in the runtime parameter column, which appears when a group operator is selected.                                                                                                                                                                         |
| NOT IN PERIOD                | For a time stamp only, not within the selected time period                                                                                                                                                                                                                                                                                          |
| NOT LIKE                     | Not like the specified value (see the description of LIKE)                                                                                                                                                                                                                                                                                          |
| NOT LIKE GROUP               | Not like the value that is specified in LIKE GROUP                                                                                                                                                                                                                                                                                                  |
| NOT REGEXP                   | Not matched by the specified regular expression                                                                                                                                                                                                                                                                                                     |
| REGEXP                       | Matched by the specified regular expression For detailed information about how to use regular expressions, see Regular Expressions.                                                                                                                                                                                                                 |

- Value/Parameter/Group: depends on the operator.
  - Value: A constant with which the field is compared.
  - Parameter: The name of a parameter that gets its value in run time. The parameter name cannot be any of: QUERY\_FROM\_DATE, QUERY\_TO\_DATE, REMOTE\_SOURCE, SHOW\_ALIASES, FETCHSIZE, REFRESHRATE, current\_title, action, user, group, role, js\_peid, eventsubmit\_doupdate, page, \_skin, template, media-type. The parameter name must start with a letter and can only contain letters, digits, and underscore.
  - Group: A drop-down list of the groups that match the type of the field. The groups with the same type as the field appear first, in alphabetic order. Then groups with all types appear, grouped by their type. The group types are ordered alphabetically and so are the groups under each type. Note that in some cases there may be several group types that match the field type. For example, there are several group types that match Client IP: Client IP/DB User, Client IP/Src App./DB User, Client IP/Src App./DB User/ServerIP/Svc. Name
- Value: depends on the Operator and the Value/Parameter/Group

Query conditions can include both individual conditions and groups of conditions. When adding a condition or a condition to a group, the default conjunction is Add. You can change this to Or. Each condition group is processed as though it is in parenthesis. The following figure presents a query with two conditions and two condition groups specifying: condition 1 **and** condition 2 **and** (condition 3 **or** condition 4 **or** (condition 5 **and** condition 6) **and** (condition 7 **and** condition 8)).

**Escaping backslash (\) characters:** To correctly escape a backslash character for use in a query condition, use four backslash characters. For example, to specify domain\user you would enter domain\\\\\\user.

## Procedure

1. In the Conditions row, click Edit. The Conditions area expands.
2. To add a condition, click Add Condition and select values in the drop-downs for the first query condition.
3. To add a condition group, click Add Condition Group and select values in the drop-downs for the conditions in the group.
4. Repeat as relevant.

5. Click Save.

## Adding a build expression on query condition

Use this feature when you need to add a condition (including a user-defined string or a mathematical expression) that is based not on the entire content of the attribute as is, but on part of the attribute, a function of the attribute, or a function that combines more than one attribute.

Once the query conditions are saved, there is an Add Expression icon  icon, next to the query conditions, that opens the Build Expression pane. Use it to add user-defined strings and mathematical expressions.

When there is a build expression defined, there is a red asterisk next to the Build Expression icon .

An example:

Return the location of the string **150 . 1**, from the value **192.150.1.x.**, where the string **150 . 1** is at the fifth character of the value. The string **150 . 1** represents all instances of Client IP matching the 5 characters listed.

When the function is run in the Expression field, it returns a value, and that value should be in the entry box.

Use the function, **INSTR(:attribute, '150 . 1')** with a "5" value in the entry box next to the Add Expression icon to return the records with **150 . 1** in the fifth location.

If the function is **INSTR(:attribute, '150 . 1') = 5**, then it becomes a Boolean phrase, and the only values in the entry box are 0 or 1.

Type the **INSTR(:attribute, '150 . 1')** expression in the separate Build Expression window.

Test the validity of the expression in the Build Expression window.

Another example: **LENGTH(:attribute) >= 40**, which returns the length of any SQL statement greater than 40 characters. The expression might or might not contain references to the actual attribute and can also contain references to other attributes.

## Having conditions

This row is available if "Group by" is required; when one or more columns use one of the following functions: count, min, max, average, sum.

Having Conditions function like other query conditions, except that they have an additional aggregation function field. Their format is: <And/Or> <field> <aggregation function> <operator> <value/parameter/group> <value>. The aggregation function can have the values:

- Count
- Min
- Max
- Avg.
- Having

The operators available in the Having clause are:

- Smaller than (<)
- Smaller than or equal to (<=)
- Not equal to (<>)
- Equal to (=)
- Greater than (>)
- Greater than or equal to (>=)

## Modifying the report display

You can select the report type (tabular or chart), change the column names, and configure the color indication rules.

### About this task

The Chart type report is available only if one of these is true:

- The Count checkbox is selected on the query level.
- All the columns in the query are numeric.

### Procedure

1. Select the report type. By default it is Tabular. If you select Chart, choose a chart type from the type drop-down list.
2. In the Column Heading section, you can change the names of the columns from the attribute name to a name of your choice.
3. In the Color Indication Rules section:

- a. Create a rule by clicking , and assign a color to the rule. The first match (from top to bottom) determines the color in the report.
- b. Add more rules by clicking , and assign a color to the rule.
- c. Modify the rule order using  and .

# Domains, Entities, and Attributes

Each domain contains a set of data stored in Guardium that relates to a specific purpose or function (data access, exceptions, policy violations, and so forth). The data is grouped by entities. An entity is a set of related attributes, and an attribute is basically a field value.

Access to the domains is controlled by security roles. Each Guardium role typically has access to a subset of domains, depending on the function of that role within the company. Guardium admin role users typically have access to all reporting domains.

Some domains are available only when optional components (CAS, or Classification, for example) are installed. Other domains are available by default to Guardium admin role users only, for example report information pertaining to the Guardium appliance such as archiving activity.

Similarly, not all attributes are available for all database protocols. When using the query builder, if you notice that an entity or attribute described in the documentation does not appear in the UI, that entity or attribute is not available for the selected database type.

- [\*\*Entities and Attributes in the domains\*\*](#)

This topic contains a description of the entities and attributes in each domain.

## Entities and Attributes in the domains

This topic contains a description of the entities and attributes in each domain.

For z/OS data sources (Db2, Data Sets, and IMS), there are data-source-specific attributes and the meaning of existing attributes may differ than what is described here. For more information on entities and attributes specific to z/OS data sources, see the following:

- [\*\*Report entities and attributes for Data Sets\*\*](#)
- [\*\*Report entities and attributes for DB2 for z/OS\*\*](#)
- [\*\*Report entities and attributes for IMS\*\*](#)

- [\*\*Access domain\*\*](#)

This domain contains traffic data collected by the inspection engines and other sources such as universal connectors and streaming data sources, every time a request is sent to a server being monitored. It includes all of the client/server, session, SQL, and access periods related data. This topic describes the domain's entities and attributes.

- [\*\*Access Policy domain\*\*](#)

Use the Access Policy domain to track all available policies on system. This topic describes the domain's entities and attributes.

- [\*\*Aggregation/Archive domain\*\*](#)

Aggregation and archiving activity: archive, send, purge, and so on. This topic describes the domain's entities and attributes.

- [\*\*Alert domain\*\*](#)

This domain contains data on alerts generated and sent by Guardium. This topic describes the domain's entities and attributes.

- [\*\*Analytic Threat Analytics domain\*\*](#)

This domain has detailed descriptions of active threat analytics. This topic describes the domain's entities and attributes.

- [\*\*Analytic Outlier Details domain\*\*](#)

This domain has detailed descriptions of activities and errors that have been identified as outliers. This topic describes the domain's entities and attributes.

- [\*\*Analytic Outliers Status domain\*\*](#)

This domain describes the outlier mining process and its results. This topic describes the domain's entities and attributes.

- [\*\*Analytic Outlier Summary domain\*\*](#)

A summary of the outliers that occurred during the last hour on a source. This topic describes the domain's entities and attributes.

- [\*\*Application Data domain\*\*](#)

Connection, session, and application data recorded for special non-Guardium application (Siebel and SAP, for example). This topic describes the domain's entities and attributes.

- [\*\*Audit Process domain\*\*](#)

The execution of audit processes and the distribution of results. : entities and attributes

- [\*\*Auto-discovery domain\*\*](#)

Database auto-discovery activity, including all processes that have been run, and the hosts and ports discovered. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Buff Usage Monitor domain\*\*](#)

Shows the aggregate of all Sniffer Buffer Usage Entities. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Classification Process Log domain\*\*](#)

Reports on classifier process logs. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Classifier Results domain\*\*](#)

Reports on classifier process results. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Databases Discovered domain\*\*](#)

Reports on discovered databases. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Discovered Instances domain\*\*](#)

Reports on instances that have been discovered by GIM. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Exception domain\*\*](#)

All of the exceptions and exception-related data. These are SQL exceptions sent from a database server and collected by inspection engines, as well as exceptions generated by Guardium itself. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Full SQL domain\*\*](#)

You can create full SQL entities by using only the following policy rule actions: Log Full Details, Log Full Details With Values, Log Full Details Per Session, or Log Full Details Per Session With Values.

- [\*\*BigData Intelligence Installed Patches domain\*\*](#)

Reports on installed patches. This topic describes the domain's entities and attributes.

- [\*\*BigData Intelligence Instance domain\*\*](#)  
This domain contains traffic data collected by the inspection engines every time a request is sent to a server being monitored. It includes all of the client/server, session, SQL, and access periods related data. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence Outliers List Enhanced domain\*\*](#)  
Detailed description of activities and errors that have been identified as outliers. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence Outliers Summary Enhanced domain\*\*](#)  
A summary of the outliers in one hour granularity. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence Policy Violations domain\*\*](#)  
All policy violation data, for all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence Session domain\*\*](#)  
Reports on Client/Server database session. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence STAP Status domain\*\*](#)  
Reports on status of S-TAPs. This topic describes the domain's entities and attributes.
- [\*\*BigData Intelligence System Info domain\*\*](#)
- [\*\*BigData Intelligence VA Results domain\*\*](#)
- [\*\*CAS Changes domain\*\*](#)  
Tracks changes to monitored items (files, registry variables, etc.). This topic describes the domain's entities and attributes.
- [\*\*CAS Config domain\*\*](#)  
Tracks CAS host configurations, where a configuration is the application of one or more template sets to a specific database server host. From configuration instances you can see which items within template sets are enabled or disabled, or exactly which files are selected and monitored (or not) by file name pattern templates. This topic describes the domain's entities and attributes.
- [\*\*CAS Host History domain\*\*](#)  
Tracks CAS host events, including servers or clients going in or out of service. This topic describes the domain's entities and attributes.
- [\*\*CAS Templates domain\*\*](#)  
Track CAS template definitions. Templates identify items to be monitored for changes. Monitored items can be files, environment or registry variables, OS or SQL script output sets, or the set of logged on users. This topic describes the domain's entities and attributes.
- [\*\*Catalog domain: entities and attributes\*\*](#)  
The Guardium catalog tracks where every archive or backup is sent. The catalog domain presents catalog details.
- [\*\*Classification Process Results domain\*\*](#)  
Reports on classifier process runs and results. This topic describes the domain's entities and attributes.
- [\*\*CM Buffer Usage Monitor domain\*\*](#)  
Shows the aggregate of all Sniffer Buffer Usage Entities that have been uploaded to the central manager. This topic describes the domain's entities and attributes.
- [\*\*Comments domain\*\*](#)  
User defined comments for various Guardium components. This topic describes the domain's entities and attributes.
- [\*\*Custom DB Usage domain\*\*](#)  
Custom DB statistics. This topic describes the domain's entities and attributes.
- [\*\*DB Default Users Enabled domain\*\*](#)  
Details on whether default users are enabled. This topic describes the domain's entities and attributes.
- [\*\*Discovered Instances domain\*\*](#)  
Instances that have been discovered by GIM. This topic describes the domain's entities and attributes.
- [\*\*Distributed Datamart domain\*\*](#)  
Data on distributed data marts. This topic describes the domain's entities and attributes.
- [\*\*Eagle Eye domain\*\*](#)  
Data on the Threat Detection Analytics. This topic describes the domain's entities and attributes.
- [\*\*Exceptions domain\*\*](#)  
This domain contains traffic details: all of the exceptions and exception-related data. These are SQL exceptions sent from a database server and collected by inspection engines, as well as exceptions generated by Guardium itself. This topic describes the domain's entities and attributes.
- [\*\*FAM domain\*\*](#)  
This domain describes file entitlement (privileges) reports. This topic describes the domain's entities and attributes.
- [\*\*FAM groups domain\*\*](#)  
FAM groups are used in cases where file privileges are given to user groups that are under users domain. This domain has entities for mapping from users to groups. Only local groups are supported. This topic describes the domain's entities and attributes.
- [\*\*FAM System domain\*\*](#)  
The FAM system domain describes FAM configurations. This topic describes the domain's entities and attributes.
- [\*\*File Activity Monitor domain\*\*](#)  
This domain contains file entitlement and classification entities. This topic describes the domain's entities and attributes.
- [\*\*Flat Log domain\*\*](#)  
Flat log processing activity. This topic describes the domain's entities and attributes.
- [\*\*GIM Clients domain\*\*](#)  
This topic describes the domain's entities and attributes.
- [\*\*GIM Events domain\*\*](#)
- [\*\*Group domain\*\*](#)  
Membership in Guardium groups. This topic describes the domain's entities and attributes.
- [\*\*Guard Process Log domain\*\*](#)  
Logs of processes running on Guardium. This topic describes the domain's entities and attributes.
- [\*\*Guardium Activity domain\*\*](#)  
All modifications performed by Guardium users to any Guardium entity, such as a report or query definition or modification. This topic describes the domain's entities and attributes.
- [\*\*Guardium Jobs Queue domain\*\*](#)  
This topic describes the domain's entities and attributes.
- [\*\*Guardium Login domain\*\*](#)  
All Guardium user login and logout information. This topic describes the domain's entities and attributes.
- [\*\*IMS Event domain\*\*](#)  
This topic describes the domain's entities and attributes.
- [\*\*Installed Patches domain\*\*](#)  
Reports on installed patches. This topic describes the domain's entities and attributes.
- [\*\*Installed Policy domain\*\*](#)  
Description of policy parameters and rules for the installed policy. The Installed Policy domain supports multiple policies and multiple actions per rule. This topic describes the domain's entities and attributes.

- **[Managed units domain](#)**  
The managed units domain describes the managed units and the managed unit groups in your environment. This topic describes the domain's entities and attributes. This domain cannot be used as custom domain
- **[Parser Errors domain](#)**  
This topic describes the domain's entities and attributes.
- **[Policy Violations domain](#)**  
All policy violation data, for all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes.
- **[Policy Violations Summary domain](#)**  
All policy violation data, for a summary of all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes.
- **[Query Rewrite domain](#)**  
This topic describes the domain's entities and attributes.
- **[Runtime Sensitive Object Identifier domain](#)**  
This topic describes the entities and attributes for the Runtime Sensitive Object Identifier domain.
- **[Security Assessment Result domain](#)**  
Records the results of vulnerability assessment processes. This topic describes the domain's entities and attributes.
- **[Sniffer Buffer Usage Monitor domain](#)**  
Inspection engine statistics. This topic describes the domain's entities and attributes.
- **[S-TAP Status domain](#)**  
This topic describes the domain's entities and attributes.
- **[S-TAP status history domain](#)**  
This topic describes the domain's entities and attributes.
- **[S-TAP Statistics domain](#)**  
This topic describes the domain's entities and attributes.
- **[S-TAP verification domain](#)**  
This topic describes the domain's entities and attributes.
- **[Unit Utilization Levels domain](#)**  
This topic describes the domain's entities and attributes.
- **[User/Role/Application domain](#)**  
Relates Guardium users, roles and applications (to report on who has access to which Guardium applications). This topic describes the domain's entities and attributes.
- **[VA Summary domain](#)**  
This topic describes the domain's entities and attributes.
- **[VA Tests domain](#)**  
Reports on tests that are available for security assessments.
- **[Value Change domain](#)**  
All changes tracked by the trigger-based value change application. This topic describes the domain's entities and attributes.

## Access domain

This domain contains traffic data collected by the inspection engines and other sources such as universal connectors and streaming data sources, every time a request is sent to a server being monitored. It includes all of the client/server, session, SQL, and access periods related data. This topic describes the domain's entities and attributes.

Available to roles: all

## Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                    |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                               |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                               |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP. |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                              |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                        |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Client OS                  | <p>Client operating system.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p>                                                                                                                                         |
| DB Protocol                | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB Protocol Version        | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DB User Name               | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Last Used                  | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Network Protocol           | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| OS User                    | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Description         | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server Host Name           | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP                  | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server IP/DB user          | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server IP/Svc Name/DB User | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server OS                  | <p>Server operating system.</p> <p>For Informix, the OS may appear as follows:</p> <p>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type                | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name               | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                                         |
| Source Program             | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Client/ Server by session  | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp                  | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date             | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Time             | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Weekday          | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Year             | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute       | Description                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID       | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                   |
| Client Port     | Client port number.                                                                                                                                                                                                                            |
| Database Name   | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view. |
| Duration (secs) | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                       |
| Global ID       | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                         |
| Ignored Since   | Timestamp created when starting to ignore this session.                                                                                                                                                                                        |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inactive Flag         | <ul style="list-style-type: none"> <li>-1: Session closed by timeout.</li> <li>0 (default): Open for sessions generated by SQL package.</li> <li>1: Closed (disconnect/ logout received).</li> <li>2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                                  |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End.                 |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <b>su</b> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                   |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Client/Server Session Entity

| Attribute                                                     | Description                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> . |
| Server IP/Server Port                                         | Server IP/Server Port                                                                               |

## PIM Session Entity

The Privileged Information Management (PIM) entity. For more information, see [PIM Integration with Guardium DAM](#).

| Attribute          | Description                 |
|--------------------|-----------------------------|
| Checkin Timestamp  | Time of credential checkin  |
| Checkout Timestamp | Time of credential checkout |
| Credential Tag     |                             |
| Global Id          |                             |
| Justification      |                             |

| Attribute    | Description                                           |
|--------------|-------------------------------------------------------|
| Resource Tag |                                                       |
| Session Id   |                                                       |
| User name    | The name of the user who checked out the credentials. |

## Access Period Entity

Access Periods are related to Sessions. By default, an access period is one hour long, but this can be changed by the Guardium administrator in the Inspection Engine Configuration (it corresponds to the Logging Granularity).

| Attribute              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event ID   | The application event ID if set from the API. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Avg Execution Ack Time | Average Execution Acknowledged time in milliseconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Avg Records Affected   | The average number of records affected. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Application User       | Can be one of the following attributes: <ul style="list-style-type: none"> <li>The Application User when identified by <a href="#">application user translation</a>.</li> <li>The Application Event Str when identified by the GuardAppUser API.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Average Execution Time | The average command execution time during the period. This is for SQL statements only. It does not apply to FTP traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Construct ID           | Uniquely identifies a command construct (for example, select a from b). Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Egress Kbyte count     | Records the number of bytes in responses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Failed Sqls            | The number of failed SQL requests. See note at the end of the table. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Ingress Kbyte count    | Records the number of bytes in requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Instance ID            | Uniquely identifies an instance of a construct. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Original Timezone      | The UTC offset.<br>This is to point out that a UTC offset should be set so that the time from two different collectors that are in two different time zones aggregate correctly. If the offset was not set then there would exist a condition where users would not really be able to determine or see a true representation of when things happened in relation to time.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Period End             | The time on the collector when the period, as defined by the logging granularity on the appliance (default 1 hour), ended.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Period End Date        | Date only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Period End Time        | Time only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Period End Weekday     | Weekday only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Period Start           | The time on the collector when the period, as defined by the logging granularity on the appliance (default 1 hour), started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Period Start Date      | Date only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Period Start Time      | Time only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Period Start Weekday   | Weekday only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Response Length        | The length of the sniffer response for a SQL instance. Not supported for Db2 z/OS systems. For more information, see <a href="#">store log_general_response_length</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Session ID             | Uniquely identifies a session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Show Seconds           | If a the number of accesses per second is being tracked, this contains counts for each second in the access period (usually one hour).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Successful Sqls        | The number of successful SQL requests. See note at the end of the table. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp              | The time on the collector when an SQL construct was executed most recently <i>within a session and within a time period</i> . If the same SQL construct is run 10 times within the same session and time period, it shows the time of the most recent run for all 10 SQLs. This timestamp is the most appropriate to use along with the SQL attribute in reports.<br><br>Note: Universal Connector traffic may be delayed. In those cases the Timestamp is the time of on the Collector for the most recent update to the SQL construct record for the session within a time period. Period start still reflects the time of SQL execution according to the audit data source, not the time of record update.                               |
| Total Access           | Total count of construct instances for this access period. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Total Records Affected | The total number of records affected. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Attribute                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Total Records Affected (Desc) | <p>If the Total Records Affected attribute is a character string instead of a number, that value appears here (for example, Large Results Set, or N/A). Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.</p> <p>Records affected - Result set of the number of records which are affected by each execution of SQL statements.</p> <p>Note: The records affected option is a sniffer operation which requires sniffer to process additional response packets and postpone logging of impacted data which increases the buffer size and might potentially have a adverse effect on overall sniffer performance. Significant impact comes from really large responses. To prevent large amount of overhead associated with this operation, Guardium uses a set of default thresholds that allows sniffer to decide to skip processing operation when exceeded.</p> <p>You can use the <b>store max_results_set_size</b>, <b>store max_result_set_packet_size</b>, and <b>store max_tds_response_packets</b> CLI commands to set levels of granularity.</p> <p>Example of result set values:</p> <ul style="list-style-type: none"> <li>Case 1, record affected value, positive number. This represents correct size of the result set.</li> <li>Case 2, record affected value, -2. This means number of records exceeded configurable limit (This can be tuned through CLI commands).</li> <li>Case 3, record affected value, -1. This shows any unsupported cases of packets configurations by Guardium.</li> <li>Case 4, record affected value, -2. If the result set is sent by streaming mode.</li> <li>Case 5, record affected value, less than -2. Intermediate result during record count to update user about current value, ends up with positive number of total records. For example, the server returns 1000 records in 4 packets: <ul style="list-style-type: none"> <li>Packet #1 250</li> <li>Packet #2 200</li> <li>Packet #3 250</li> <li>Packet #4 200</li> </ul> </li> </ul> <p>Then records affected are reported as</p> <ul style="list-style-type: none"> <li>Packet #1 -250</li> <li>Packet #2 -500</li> <li>Packet #3 -750</li> <li>Packet #4 1000</li> </ul> |

## Changed Data Value Entity

This entity is used with the IBM InfoSphere Change Data Capture (InfoSphere CDC) replication solution that allows the replication to and from supported databases. Maintenance of replicated databases can be used to reduce processing overheads and network traffic.

IBM® Guardium® Customers with Database Activities Monitoring will have access to InfoSphere CDC.

This Guardium feature uses Java CDC user exit to send value change information to the Guardium collector.

User exits for InfoSphere CDC lets the user define a set of actions the InfoSphere CDC can run before or after a database event occurs on a specified table.

| Attribute   | Description                         |
|-------------|-------------------------------------|
| Full SQL ID | Unique identifier for the Full SQL. |
| Table Name  | Table Name from database            |
| Column Name | Column Name from database           |
| Old Value   | Value before the change.            |
| New Value   | Value after the change.             |
| Timestamp   | Time the record was created.        |

Two files that need to be installed on the Database Server are for the Guardium agent that interfaces with IBM's InfoSphere Change Data Capture (InfoSphere CDC) application. They are in the sources/apps/GuardCDC/lib/ directory of the build. These files are: protobuf-java-2.4.1.jar; and, GuardCdc.jar

### Instructions for installation

Prerequisites - the InfoSphere Change Data Capture (InfoSphere CDC) application must already be installed on the DB Server.

Steps to install the Guardium agent on the Database server:

1. Copy these two files to the RepEngine/lib/ directory of the cdchome directory. An example of the full path would be /cdchome/cdc6.5.2/RepEngine/lib/
2. Unzip each file
3. Edit the guard\_cdc\_user\_exit\_config.xml file to add the Guardium\_Host name. An example of where this file would be located is /cdchome/cdc6.5.2/RepEngine/lib/com/guardium/cdc/userexit/
4. Configure InfoSphere CDC to write to the GuardiumAgent. There are multiple steps to set up and configure the CDC application. These steps can be obtained from the InfoSphere CDC development/support team at IBM.

## App User Name Entity

This entity displays the username from the App Event if the App Event exists. Otherwise, the user name displays from the Construct Instance.

| Attribute     | Description                                      |
|---------------|--------------------------------------------------|
| APP User Name | Unique identifier for this App User Name entity. |

## FULL SQL Values Entity

These entities are created only by the following policy rule actions: Log Full Details With Values, and Log Full Details Per Session With Values.

| Attribute | Description                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Values    | One or more values from the logged construct.                                                                                            |
| Timestamp | The time on the DB server that the SQL was executed. Traffic must be captured with log full details policy action to see this timestamp. |

## FULL SQL Entity

Full SQL entities are created only by the following policy rule actions: Log Full Details, Log Full Details With Values, Log Full Details Per Session, or Log Full Details Per Session With Values.

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Rule Description | Description of the policy rule whose action triggered the logging of the Full SQL record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Ack Response Time       | Acknowledged Response Time in milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Auto-Commit             | Entries are automatically numbered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Bind Variables Values   | For DB2/zOS, a list of comma-separated bind variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Full Sql                | The logged SQL statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Full SQL ID             | Unique identifier for the Full SQL. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Instance ID             | Unique identifier for the Full SQL instance. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Original Timezone       | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).                         |
| Records Affected        | The number of records affected for each session. On reports using this attribute, we suggest that you turn on aliases to properly display special cases such as Large Result Set or N/A.<br>Records affected only supports find statements for MongoDB, and does not support insert, update, and delete statements.                                                                                                                                                                                                                                                                                                                  |
| Records Affected (Desc) | When the Records Affected is a string value instead of a number, that string is stored here. For example: Large Result Set or N/A.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Response Length         | The length of the sniffer response for a SQL instance. Not supported for Db2 z/OS systems. For more information, see <a href="#">store log_general_response_length</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Response Time           | The response time for the request in milliseconds. When requests are monitored in network traffic, the response times are an accurate reflection of the time taken to respond to the request (Guardium timestamps both the client request and the server response).                                                                                                                                                                                                                                                                                                                                                                  |
| Returned Data           | Data returned for this request (if any, and if available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Returned Data Count     | Number of rows returned from the SQL statement used in the policy rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Statement Type          | The type of SQL statement.<br>SQL: simple, direct SQL command, for example, typed directly into the CLI<br>RAW: PREPARE of a SQL statement for later execution, for example, conn.prepareStatement (select a from b where c=:value)<br>BIND: execution of a prepared statement including bound parameter values<br>Statement type is part of the FULL SQL entity and is only audited if you have configured Log Full Details for this statement within the policy.<br>You can not filter out specific statement types in the policy, for example, audit-only SQL and BIND statements. You can, however, filter these out in reports. |
| Succeeded               | Indicates if the call succeeded. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Timestamp               | The time when the SQL started running in the database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Application Events Entity

This entity is created each time that the system observes an Application Events API call (which sets these attribute values) or a stored procedure call that has been identified as a Custom Identification Procedure (which maps stored procedure parameters to these attributes).

| Attribute               | Description                                                                                                                                                                                                                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event ID    | Unique identifier for this application events entity. Only available to users with the admin role.                                                                                                                                                                                          |
| Event Date              | Datetime value, set by GuardAppEvent:Start. It displays in the format yyyy-mm-dd hh:mm:ss.<br>Note: If an attempt is made to set the event date using a format other than yyyy-mm-dd, it will contain all zeroes. The time portion (hh:mm:ss) is optional, and if omitted will be 00:00:00. |
| Event Release Date      | Datetime value, set by GuardAppEvent:Released. It displays in the format yyyy-mm-dd hh:mm:ss.                                                                                                                                                                                               |
| Event Release Type      | Type of event, set by GuardAppEvent: Released.                                                                                                                                                                                                                                              |
| Event Release User Name | User name, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                  |
| Event Release Value Num | Numeric value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                              |
| Event Release Value Str | String value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                               |
| Event Type              | Type of event, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                  |
| Event User Name         | User name, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                      |
| Event Value Str         | String value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                   |
| Event Value Num         | Numeric value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                  |

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Timestamp         | Created only once, when the event is logged. Do not confuse this attribute with the Event Date attribute, which can be set using an API call or from a stored procedure parameter. (See a description of the Application Events API in <a href="#">Identify Users with API</a> .)                                                                                                                                                                                                                                                                                                                        |

## SQL Entity

This entity is created for each unique string of SQL. Values are replaced by question marks - only the format of the string is stored.

| Attribute     | Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| Bind Info     | Bind information for this SQL string.                                                                           |
| Construct ID  | Uniquely identifies the construct in which the SQL appeared                                                     |
| Sql           | SQL string.                                                                                                     |
| Truncated SQL | Indicates if the SQL has been truncated or not where:<br>0 - false/no, not truncated<br>1 - true/yes, truncated |

## Command Entity

For each command, an entity is created for each parent node and position in which the command appears in a command construct.

| Attribute    | Description                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------|
| Command Id   | Uniquely identifies the command. Only available to users with the admin role.                           |
| Construct Id | Uniquely identifies the construct (e.g., select a from b). Only available to users with the admin role. |
| Depth        | Depth of the command in the SQL parse tree.                                                             |
| Parent       | Identifier of parent node in the parse tree.                                                            |
| SQL Verb     | Main verb in SQL command (e.g., select, insert, delete, etc.).                                          |

## Object Command Entity

Describes an object-command entity.

| Attribute      | Description                               |
|----------------|-------------------------------------------|
| Object/Command | An object value combined with a SQL verb. |

## Object Entity

An instance of this entity is created for each object in a unique schema.

| Attribute          | Description                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| App Object Module1 | Uniquely identifies the application object module.                                                                |
| Construct Id       | Uniquely identifies the construct in which the object is referenced. Only available to users with the admin role. |
| Object Id          | Uniquely identifies the object. Only available to users with the admin role.                                      |
| Object Name        | Name of the object.                                                                                               |
| Schema             | Database schema for the object.<br>Note: This attribute is deprecated since it is never populated                 |

## Join Entity

A join table is a way of implementing many-to-many relationships. Use join entity to join tables in a SELECT SQL statement.

| Attribute    | Description                                               |
|--------------|-----------------------------------------------------------|
| Construct ID | Identifies the construct in which the join is referenced. |
| Join ID      | Unique identifier                                         |
| Join SQL     | Join tables                                               |
| Timestamp    | Date and Time that the Join Entity was created.           |
| Where SQL    | Where clause (join conditions)                            |

## Field SQL Value Entity

These entities are created only by policy rule actions that log with values, for example: Log Full Details With Values, and Log Full Details Per Session With Values. The field value logged may or may not be associated with a field name. For example, field names are available (in the Field entity) if the following statement is logged:

insert into t1 (foo, bar) (10, 20)

But not available when the following statement is logged:

insert into t2 (10, 20)

| Attribute | Description                              |
|-----------|------------------------------------------|
| Value     | A field value from the logged construct. |

## Object Field Entity

---

Describes an object-field entity. Note fields with no objects will not show up in reports that include the object.

| Attribute    | Description                                  |
|--------------|----------------------------------------------|
| Object/Field | An object value combined with a field value. |

## Field Entity

---

Each time Guardium encounters a new field, it creates a field entity.

| Attribute    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Command ID   | Uniquely identifies the main command from the construct in which it was referenced. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                              |
| Construct ID | Uniquely identifies the construct in which it was referenced. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                    |
| Field ID     | Uniquely identifies the field. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Field Name   | Name of the field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| List Clause  | Use these attributes to order complex SQL queries.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Where Clause | Example of SQL queries:<br><br>Order by<br>SELECT * FROM dept_costs<br>WHERE dept_total ><br>ON Clause<br>(SELECT avg FROM avg_cost)<br>ORDER BY department<br>Having<br>SELECT column_name1, SUM(column_name2)<br>FROM table_name<br>GROUP BY column_name1<br>HAVING (numerical function condition)<br>Group By<br>SELECT column_name1, SUM(column_name2)<br>FROM table_name<br>GROUP BY column_name1<br>Where<br>SELECT FirstName, LastName, City<br>FROM Users<br>WHERE City = Los Angeles |
| Object ID    | Uniquely identifies the object from the construct in which it was referenced. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                    |

## Qualified Object Entity

---

A *tuple* allows multiple attributes to be combined together to form a single group member. In this case, the fields Server IP, Service name, DB name, DB user and Object are combined together. For more information, see [Tuple groups](#).

| Attribute        | Description                                               |
|------------------|-----------------------------------------------------------|
| Qualified Object | Tuple - Server IP, Service name, DB name, DB user, Object |

## Access Policy domain

---

Use the Access Policy domain to track all available policies on system. This topic describes the domain's entities and attributes.

Available to roles: all

## Access Policy Entity

---

Similar to the Installed Policies entity used for all installed policies on system.

| Attribute | Description |
|-----------|-------------|
|           |             |

| <b>Attribute</b>      | <b>Description</b>                                         |
|-----------------------|------------------------------------------------------------|
| Policy ID             | Uniquely identifies an access policy                       |
| Policy Description    | Describes the access policy                                |
| Selective Audit Trail | Indicates if this is a selective audit trail policy (T/F). |
| Audit Pattern         | Test pattern used for a selective audit trail policy.      |
| Timestamp             | Timestamp for the creation of the record.                  |

## Rule Entity

---

Can be used for Installed policy rule entity or access policy rule entity. There is one for each rule of the installed policy/policies or access policy/policies. Apart from the ID fields (which uniquely identify components on the internal database), all of these fields are described in the Policies help topic.

- GDM\_INSTALLED\_POLICY\_RULES\_ID - Identifies an installed policy rule.
- ACCESS\_RULE\_ID - Identifies an access rule.
- Rule Description - From the policy definition.
- Rule Position - Position within the policy.
- Rule Type - Access, Exception, or Extrusion.
- LAST\_ACCESED - Last
- Client IP - From the rule definition.
- Client Net Mask - From the rule definition.
- Client IP Group - From the rule definition.
- Server IP - From the rule definition.
- Server IP Mask - From the rule definition.
- Client MAC - From the rule definition.
- Net Protocol - From the rule definition.
- Net Protocol Group - From the rule definition.
- Field - From the rule definition.
- Field Group - From the rule definition.
- Object - From the rule definition.
- Object Group - From the rule definition.
- Command - From the rule definition.
- Command Group - From the rule definition.
- Object-Field Group - From the rule definition.
- DB Type - From the rule definition.
- Service Name - From the rule definition.
- Service Name Group - From the rule definition.
- DB Name - From the rule definition.
- DB Name Group - From the rule definition.
- DB User - From the rule definition.
- DB User Group - From the rule definition.
- App. User - From the rule definition.
- App User Group - From the rule definition.
- OS User - From the rule definition.
- OS User Group - From the rule definition.
- Src App. - From the rule definition.
- Source Program Group - From the rule definition.
- Pattern/ XML Pattern - From the rule definition.
- Period - From the rule definition.
- Min. Ct. - From the rule definition.
- Reset Interval - From the rule definition.
- Continue to next Rule/ Revoke - From the rule definition.
- Rec. Vals. - From the rule definition.
- App Event Exists - From the rule definition.
- Event Type - From the rule definition.
- App Event Text Value - From the rule definition.
- App Event Date Value - From the rule definition.
- Event User Name - From the rule definition.
- Error Code - From the rule definition.
- Exception Type - From the rule definition.
- Category Name- From the rule definition.
- Classification Name - From the rule definition.
- Severity - From the rule definition.
- Data Pattern - From the rule definition.
- SQL Pattern - From the rule definition.
- Masking Pattern - From the rule definition.
- Client IP/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Sever IP/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Net Protocol/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Field Name/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Object Name/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Command/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Service Name/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- DB Name/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- App. User/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- OS User/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Source Program/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- Error Code/ Group - Provides the ability to display a single attribute and its related (if any) in a single column of the report.
- App. Event Text/ Numeric/ Date - The application events text, numeric, and date attributes.

- Category/ Classification - The combined category and classification for the rule.
- GDM\_Installed\_Policy\_Header\_ID - Identifies an installed policy header.

Note: GDM\_INSTALLED\_POLICY\_RULES\_ID and ACCESS\_RULE\_ID are available to users with the admin role only.

## Rule Action Entity

Can be used Installed policy rule action entity or access policy rule action entity. There is one for each rule of the installed policy/policies or access policy/policies .

- Sequence - Sequence of the action within the rule.
- Action
  - Block the request - See Blocking Actions in Policies.
  - Log or ignore the violation or the traffic - See Log or Ignore Actions in Policies.
  - Alert - See Alerting Actions in Policies.

## Alert Notification Entity

Describes a policy alert notification.

| Attribute               | Description                                                                     |
|-------------------------|---------------------------------------------------------------------------------|
| ALERT_NOTIFICATION_ID   | Identifies the alert notification. Only available to users with the admin role. |
| ALERT_ID                | Identifies the alert definition. Only available to users with the admin role.   |
| Alert Notification Type | Type of alert from the policy rule definition.                                  |
| Alert User              | Receiver of the alert.                                                          |
| Alert Destination       | Type of alert (EMAIL, SNMP, SYSLOG, CUSTM).                                     |
| Timestamp               | Timestamp alert record created.                                                 |

## Aggregation/Archive domain

Aggregation and archiving activity: archive, send, purge, and so on. This topic describes the domain's entities and attributes.

Available to roles: admin

## Activity Types Entity

Available only from the Aggregation/Archive domain, which by default is available to users assigned the admin role only. The Activity Types entity can be accessed only from the owning Aggregation/Import/Export Log Entity. It identifies a type of action (Prepare for Aggregation, Encrypt, Send, etc.).

| Attribute     | Description                                           |
|---------------|-------------------------------------------------------|
| Activity Type | Description of an aggregation/import/export activity. |

## Agg/Archive Log Entity

Available only from the Aggregation/Archive domain, which by default is available to users assigned the admin role only. One or more Aggregation/Import/Export Log entities are created for each activity. For example, when an aggregator system imports data, you typically see at least four activities: Prepare for Aggregation, Check Duplicate Import (one per file exported to this aggregator), Extract (one per file to be merged), Merge (one per file merged)

| Attribute          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Comment            | Additional comment for the activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| End Time           | Ending time of activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| File Name          | Name of file used for the activity. Files created by the archive and export operations are named as follows:<br><br><daysequence>-<scp_host>-w<run_datestamp>-d<data_date>.dbdump.enc<br><br>For example:<br><br>732423-g1.guardium.com-w20050425.040042-d2005-04-22.dbdump.enc<br><br>The date of the data contained on the file, in yyyy-mm-dd format is data_date, near the end of the file name (just before .dbdump.enc). Take care that you do not confuse this date with the run date, which appears earlier in the file name, and is the date that the data was archived or exported.                |
| Guardium Host Name | The name of the Guardium host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Original Timezone  | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Period End         | Ending time for the activity being acted upon.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Period Start       | Starting time for the data being acted upon. Each archiving or aggregation activity operates on one full day of activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Records Purged     | If the activity type is Purge, the number of records purged. Otherwise, N/A.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Status             | Status of the aggregation/import/export log activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Start Time         | Starting time of activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Timestamp          | Updated at the start and end of the activity being logged (prepare for archiving, encrypt, send, etc.).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Attribute | Description                               |
|-----------|-------------------------------------------|
| User Name | User name under which activity initiated. |

## Agg/Archive Debug Log Entity

| Attribute              | Description                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aggregation Date       | Date for the data being acted upon. Each archiving or aggregation activity operates on one full day of activity.                                                                                      |
| Aggregation Duration   | Duration of the activity described by Aggregation Stage.                                                                                                                                              |
| Aggregation Exception  | If there was any exception during the activity it is presented in this field.                                                                                                                         |
| Aggregation Stage      | Stage of the aggregation activity, for example, "Initialization", "Post Purge - START"                                                                                                                |
| Aggregation Status     | Status of the Stage, for example, D: done, I: info, W: warning, E: exception                                                                                                                          |
| Aggregation Table Name | The name of the table, on which the activity is done.                                                                                                                                                 |
| Details                | Additional info, for example, "Max age is -1, age is 60. 0 days had been found"                                                                                                                       |
| Job Group              | Aggregation process name. For example:<br><br>ARCHIVE<br>ARCHIVE_RESULTS<br>CLEANUP_ORPHANS<br>DISCARD_RESULTS<br>EXPORT<br>IMPORT<br>MAINTENANCE<br>PARTITION<br>PURGE<br>RESTORE<br>RESTORE_RESULTS |
| Records Deleted        | The number of records deleted from the table described in "Aggregation Table Name" in this Aggregation Stage                                                                                          |
| Records Inserted       | The number of records inserted to the table described in "Aggregation Table Name" in this Aggregation Stage                                                                                           |
| Records Updated        | The number of records updated in the table described in "Aggregation Table Name" in this Aggregation Stage                                                                                            |
| Run Log Id             | Used Internally.                                                                                                                                                                                      |
| Timestamp              | Time when the record was inserted in the Agg/Archive Log                                                                                                                                              |

## Alert domain

This domain contains data on alerts generated and sent by Guardium. This topic describes the domain's entities and attributes.

Available to roles: all

## Activity Types Entity

Available only from the Aggregation/Archive domain, which by default is available to users assigned the admin role only. The Activity Types entity can be accessed only from the owning Aggregation/Import/Export Log Entity. It identifies a type of action (Prepare for Aggregation, Encrypt, Send, etc.).

| Attribute     | Description                                           |
|---------------|-------------------------------------------------------|
| Activity Type | Description of an aggregation/import/export activity. |

## Threshold Alert Details Entity

This entity is created each time that a correlation alert is triggered.

| Attribute         | Description                                                                                |
|-------------------|--------------------------------------------------------------------------------------------|
| Alert Log ID      | Uniquely identifies the alert details entity. Only available to users with the admin role. |
| Query Value       | Value returned by query.                                                                   |
| Base Value        | Value assigned for the statistical alert.                                                  |
| Checked From Date | The starting date and time checked for by the alert condition.                             |
| Checked To Date   | The ending date and time checked for by the alert condition.                               |
| Alert Threshold   | Alert threshold defined for the alert.                                                     |
| Notification Sent | Text of notification sent.                                                                 |
| Timestamp         | Created only once, when the statistical alert is logged.                                   |
| Alert Description | The description contained in the alert definition.                                         |

## Message Text Entity

For a threshold alert, the text of the message.

| Attribute       | Description                                          |
|-----------------|------------------------------------------------------|
| Message Text ID | Uniquely identifies the message text                 |
| Message Subject | Message subject (for an email message, for example). |
| Message Text    | Message text.                                        |

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Messages Sent Entity

For each threshold alert message sent, the message type, recipients, status, and date of that message.

| Attribute          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message ID         | Uniquely identifies the message                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Message Type       | Type of message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Sent To            | One or more recipients of message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Message Status     | Status of message:<br>FAIL The send operation failed.<br><br>WAIT The message has not yet been sent.<br><br>SENT The message was sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Message Date       | Date message sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Message Context    | Message type:<br>INFO Informational message.<br><br>WARNING Possible error condition.<br><br>ALERT Real time or threshold alert.<br><br>ERROR Software or hardware error condition.<br><br>DEBUG Debugging message.                                                                                                                                                                                                                                                                                                                                                                                      |
| Message Originator | The module creating the message; for example monitor or GuardiumJetspeedUser.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Original Timezone  | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Analytic Threat Analytics domain

This domain has detailed descriptions of active threat analytics. This topic describes the domain's entities and attributes.

Available to roles: admin

## Analytic Source Entity

This entity describes the source on which the case occurred.

| Attribute   | Description                                                 |
|-------------|-------------------------------------------------------------|
| DB User     | DB user whose actions were observed in creating this case.  |
| Database    | Database whose actions were observed in creating this case. |
| OS User     | OS User whose actions were observed in creating this case.  |
| Privileged  | Whether user is privileged or not                           |
| Server IP   | Server IP on which the actions were observed.               |
| Source Type | Source Type on which the actions were observed.             |

## Analytic Case entity

This entity describes the case details.

| Attribute              | Description                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------|
| Actual severity        | The actual severity level defined by the user. This allows the user to give feedback to the system.  |
| Actual threat category | The actual threat category defined by the user. This allows the user to give feedback to the system. |
| Case Number            | Case number assigned by Guardium®                                                                    |
| Date                   | Date case was opened                                                                                 |
| Closed by              | User name that closed the case                                                                       |
| Create Date            | Date on which Guardium created the case.                                                             |
| Originating Unit       | The unit on which the observation occurred.                                                          |
| Period Start           | The first observation occurred during the time period that started as indicated.                     |
| Severity               | Case severity assigned by Guardium: low medium, high.                                                |

| Attribute       | Description                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Threat Category | Type of threat, for example: anomaly, account takeover, denial of service, data tampering, schema tampering, data leak, malicious stored procedure, SQL injection |
| Timestamp       | Timestamp when Analytic Case info was last modified                                                                                                               |

## Analytic Case Observation entity

This entity describes the observations that spawned the case.

| Attribute   | Description                                       |
|-------------|---------------------------------------------------|
| Case Number | Case number assigned by Guardium                  |
| Observation | Potential attack symptoms, identified by Guardium |
| Priority    | Symptom Priority                                  |

## Analytic Outlier Details domain

This domain has detailed descriptions of activities and errors that have been identified as outliers. This topic describes the domain's entities and attributes.

Available to roles: admin

### Analytic Outlier Details Entity

| Attribute               | Description                                                                                      |
|-------------------------|--------------------------------------------------------------------------------------------------|
| Anomaly Score           | Final anomaly score                                                                              |
| Client hostname         | Client host name.                                                                                |
| Client IP               | Client IP address.                                                                               |
| DB User Name            | DB user that executed the activity.                                                              |
| Error Outlier           | Whether or not the outlier is of type error. True/False.                                         |
| High Volume Outlier     | Whether or not the outlier is of type high volume. True/False.                                   |
| New Outlier             | Whether or not the outlier is of type new. True/False.                                           |
| Number of Instances     | Activity volume.                                                                                 |
| OS User                 | OS user that executed the activity.                                                              |
| OS user                 | OS user account for the interaction.                                                             |
| Object                  | Object on which the user executed the activity.                                                  |
| Objects/Verbs           | The object/verb combination that was used in the activity.                                       |
| Outlier Type            | Deprecated                                                                                       |
| Period Start            | Start time of the period in which the activity occurred.                                         |
| Server IP               | IP of server on which the activity occurred.                                                     |
| Server Type             | Type of server on which the activity occurred.                                                   |
| Service Name            | The service name that was used in the activity.                                                  |
| Source Program          | Source Program in which the activity occurred.                                                   |
| Temp Outlier            | Whether or not the outlier is of type temp. True/False. Deprecated from v11.1.                   |
| Textual description     | Description of the outlier activity; may include, for example, database name, user name, object. |
| Timestamp               | Timestamp of the activity.                                                                       |
| Verb                    | The verb used in the activity.                                                                   |
| Vulnerable obj. Outlier | Whether or not the outlier is of type vulnerable object. True/False.                             |

## Analytic Outliers Status domain

This domain describes the outlier mining process and its results. This topic describes the domain's entities and attributes.

Available to roles: admin

### Analytic Status Entity

| Attribute                    | Description                                                          |
|------------------------------|----------------------------------------------------------------------|
| Details                      | Details related to the current status                                |
| End Analysis Time            | Time at which the analysis completed.                                |
| Number of databases analyzed | Number of DBs on which analysis was run.                             |
| Number of outliers           | Number of outliers found in the period.                              |
| Number of records analyzed   | Number of rows, after aggregation, that were analyzed in the period. |
| Number of users analyzed     | Number of users in the analysis.                                     |
| Period Analyzed              | Period start time.                                                   |

| Attribute           | Description                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Process name        | One of: <ul style="list-style-type: none"><li>• Reconfig: setting up parameters, or requesting information about parameters.</li><li>• Analysis: outlier mining</li><li>• Active Analytics: active threat analytics</li><li>• Enable Outlier: enabling outliers</li><li>• Disable Outlier: disabling outliers</li></ul> |
| Run by              | The user who ran the process.                                                                                                                                                                                                                                                                                           |
| Start Analysis Time | Time at which the analysis started, after receiving all the data from the collectors.                                                                                                                                                                                                                                   |
| Status              | E: Error (error listed in details); D: Done (completed successfully); P: Pending (waiting for data from collectors); R: Running; W: Warning (not a blocker).                                                                                                                                                            |
| Timestamp           | Last time at which the row was updated.                                                                                                                                                                                                                                                                                 |

## Analytic Outlier Summary domain

A summary of the outliers that occurred during the last hour on a source. This topic describes the domain's entities and attributes.

Available to roles: admin

### Analytic Outlier Summary Entity

| Attribute                           | Description                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------|
| Alert Feedback ID                   | ID of rule that caused this feedback alert.                                                |
| Anomaly Score                       | Final anomaly score for this activity.                                                     |
| DB User Name                        | DB user that executed the activity.                                                        |
| Diverse Outlier                     | Whether or not the outlier is of type diverse. True/False.                                 |
| Error Outlier                       | Whether or not the outlier is of type error. True/False.                                   |
| High Volume Outlier                 | Whether or not the outlier is of type high volume. True / False.                           |
| New Messages Average                | Average number of new messages by the entity that caused the outlier.                      |
| New Messages Score                  | Measure of new activity abnormality.                                                       |
| New Messages SD                     | Deprecated                                                                                 |
| New Outlier                         | Whether or not the outlier is of type new outlier. True/False.                             |
| Number of Fails                     | Number of failed activities.                                                               |
| Number of New Messages              | Number of new types of new activities.                                                     |
| Number of Sensitive Objects         | Number of sensitive objects touched by in this interval.                                   |
| Number of Temporary Objects         | Number of temporary objects used in this interval.                                         |
| Number of Temporary Source Programs | Deprecated                                                                                 |
| OS User                             | OS user that executed the activity.                                                        |
| Ongoing Outlier                     | Whether or not the outlier is of type ongoing. True/False.                                 |
| Original Host Name                  | Client hostname.                                                                           |
| Outliers Summary ID                 | Unique ID.                                                                                 |
| Period Start                        | Date and time of the period start.                                                         |
| Privileged User                     | Whether or not the activity was performed by a privileged user. True/False.                |
| Rarity and Volume Score             | Deprecated                                                                                 |
| Server IP                           | IP of server on which the activity occurred.                                               |
| Server Type                         | DAM or FAM.                                                                                |
| Service Name                        | The service name that was used in the activity.                                            |
| Source ID                           | The source ID from which the activity occurred                                             |
| Temp Outlier                        | Whether or not the outlier is of type temp. True/False.                                    |
| Temporary Objects Average           | Average of above statistic in recent hours.                                                |
| Temporary Objects Score             | Measure of temporary objects usage abnormality.                                            |
| Temporary Objects SD                | Standard deviation of number of temporary objects used in this interval from recent hours. |
| Temporary Source Programs Score     | Deprecated                                                                                 |
| Timestamp                           | Timestamp of the activity.                                                                 |
| Type of Temporary Source Programs   | Deprecated                                                                                 |
| Type Volume Rarity                  | Deprecated                                                                                 |

## Application Data domain

Connection, session, and application data recorded for special non-Guardium application (Siebel and SAP, for example). This topic describes the domain's entities and attributes.

Available to roles: admin

### Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP.                                                                                                                                                                                                                                                                                                                                             |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Client OS                                    | Client operating system.<br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format                                                                                                                                          |
| DB Protocol                                  | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| DB Protocol Version                          | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB User Name                                 | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Last Used                                    | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Network Protocol                             | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| OS User                                      | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server Description                           | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Host Name                             | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server IP                                    | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Server IP/DB user                            | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server IP/Svc Name/DB User                   | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Server OS                                    | Server operating system.<br>For Informix, the OS may appear as follows:<br><br>IEEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha<br><br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format |
| Server Type                                  | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Service Name                                 | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                       |
| Source Program                               | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Attribute                 | Description                                                                                                                                                                                                                                                                               |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client/ Server by session | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                             |
| Timestamp                 | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance. |
| Timestamp Date            | Date only from the timestamp.                                                                                                                                                                                                                                                             |
| Timestamp Time            | Time only from the timestamp.                                                                                                                                                                                                                                                             |
| Timestamp Weekday         | Weekday only from the timestamp.                                                                                                                                                                                                                                                          |
| Timestamp Year            | Year only from the timestamp.                                                                                                                                                                                                                                                             |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID             | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Client Port           | Client port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Database Name         | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                                                                                                                                                                                                                           |
| Duration (secs)       | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Global ID             | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ignored Since         | Timestamp created when starting to ignore this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Inactive Flag         | <ul style="list-style-type: none"> <li>• -1: Session closed by timeout.</li> <li>• 0 (default): Open for sessions generated by SQL package.</li> <li>• 1: Closed (disconnect/ logout received).</li> <li>• 2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>• 3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                        |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is be the same time as the Session End.              |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Attribute            | Description                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TTL                  | Only available to users with the admin role.                                                                                                                                                                                                                                 |
| Uid Chain            | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> . |
| Uid Chain Compressed | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                           |

## Application Data Entity

Used for the SAP and Siebel reports.

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Data ID | Unique identifier for this data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Application Code    | The application type code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Full SQL ID         | Identifies the full SQL data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Application Type    | Application type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| User                | Application user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Operation Type      | The type of operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Change Date         | Date of the change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Time Stamp          | Time stamp for this record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Item Name           | Name of the item affected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Transaction Code    | Transaction code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| System ID           | Unique identifier for the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Record Detail 4     | Varies by item type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| VBKey               | The VBKey value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Original Timezone   | <p>The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.</p> <p>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).</p> |

## Audit Process domain

The execution of audit processes and the distribution of results. : entities and attributes

Available to roles: all

## Audit Process Entity

This entity contains basic definition parameters for an audit process.

| Attribute             | Description                                                |
|-----------------------|------------------------------------------------------------|
| Active                | Indicates if the process is active (able to be scheduled). |
| Keep Result Days      | The number of days the results are kept by the system.     |
| Keep Results Quantity | The number of results sets that are kept by the system.    |
| Process Description   | Description from audit process definition.                 |

## Audit Process Comments Entity

This entity has comments attached to an audit process definition. Comments attached to audit process results are contained the Audit Process Results Comments entity.

| Attribute                       | Description                 |
|---------------------------------|-----------------------------|
| Audit Process Comment           | The text of the comment.    |
| Audit Process Comment Creator   | The creator of the comment. |
| Audit Process Comment Timestamp | Timestamp for the comment.  |

## Audit Task Entity

This entity describes a single audit task (within an audit process).

| Attribute        | Description                                |
|------------------|--------------------------------------------|
| Task Description | Name of the task from the task definition. |

| Attribute | Description                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Task Type | A numeric value indicates whether the task is a report, security assessment, entity audit trail, privacy set, or classification process. Aliases are defined for these types, so reports with Aliases on will simplify reading of the report output. |

## Audit Process Result Entity

This entity contains the execution date for a set of audit process results.

| Attribute      | Description                              |
|----------------|------------------------------------------|
| Execution Date | The date the audit process was executed. |

## Task Receiver Entity

Indicates the action required by the results receiver.

| Attribute       | Description                              |
|-----------------|------------------------------------------|
| Action Required | Indicates if signing action is required. |

## Task Results To-Do List Entity

Indicates the current status of the results.

| Attribute              | Description                                  |
|------------------------|----------------------------------------------|
| Action Required        | Indicates if signing action is required.     |
| (Esca) Action Required | Indicates if to-do list action is required.  |
| Status                 | Indicates the current status of the results. |

## User Entity

Identifies the Guardium user defined as an audit process results receiver.

| Attribute     | Description                                  |
|---------------|----------------------------------------------|
| EMAIL Address | Email address defined for the Guardium user. |
| First Name    | First name for the Guardium user.            |
| Last Active   | Timestamp for last activity for this user.   |
| Last Name     | Last name for the Guardium user.             |
| Login Name    | Guardium user name.                          |

## Audit Process Results Comments Entity

This entity has comments attached to an audit process results. Comments attached to an audit process definition are contained the Audit Process Comments entity.

| Attribute                       | Description                 |
|---------------------------------|-----------------------------|
| Audit Process Comment           | The text of the comment.    |
| Audit Process Comment Creator   | The creator of the comment. |
| Audit Process Comment Timestamp | Timestamp for the comment   |

## Auto-discovery domain

Database auto-discovery activity, including all processes that have been run, and the hosts and ports discovered. This topic describes the domain's entities and attributes.

Available to roles: all

## Auto-discovery Scan Entity

This entity identifies when a scan executed.

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scan Timestamp    | The time the scan executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Discovered Host Entity

This entity identifies a discovered host.

| Attribute | Description |
|-----------|-------------|
|           |             |

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server IP         | IP address of the discovered host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server Host Name  | Host name of the discovered host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Discovered Port Entity

This entity identifies a discovered port.

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Port              | Discovered port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Probe Attempted   | Indicates if a probe for a supported database service has been attempted on this port. T=yes, F=no.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Port Type         | Indicates the port type (usually TCP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB Type           | If a probe of the port has found a supported database type, indicates the type (DB2®, Informix®, MS SQL Server etc.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Probe Timestamp   | The date and time that this specific port was probed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## BigData Intelligence Buff Usage Monitor domain

Shows the aggregate of all Sniffer Buffer Usage Entities. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Buff Usage Monitor Entity

| Attribute                      | Description                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------|
| % CPU Mysql                    | Percentage of CPU used by MySQL.                                                    |
| % CPU Sniffer                  | Percentage of CPU used by sniffer.                                                  |
| % Mem Mysql                    | Percentage of memory used by MySQL.                                                 |
| % Mem Sniffer                  | Percentage of memory used by sniffer                                                |
| ALP                            | Analyzer Lost Packets                                                               |
| Analyzer Queue Length          | Size of the analyze queue.                                                          |
| Analyzer Rate                  | Rate at which messages are analyzed.                                                |
| DB Open FDs                    | Database open File Descriptors.                                                     |
| Eth0 Received                  | Messages received on the primary interface.                                         |
| Eth0 Sent                      | Messages sent on the primary interface.                                             |
| Extra Info                     | Internal sniffing engine data. Not usually used in queries.                         |
| Flat Log Requests              | Flat Log Requests                                                                   |
| Free Buffer Space              | Amount of free buffer space.                                                        |
| Guardium Appliance             | Host name of collector that reported this data.                                     |
| Handler Data                   | Internal sniffing engine data.                                                      |
| Logger Dbs Monitored           | List of database types currently being monitored.                                   |
| Logger Packets Ignored By Rule | Packets ignored by policy rule action.                                              |
| Logger Queue Length            | Size of logger queue.                                                               |
| Logger Rate                    | Rate at which messages are logged.                                                  |
| Logger Session Count           | Count of sessions logged.                                                           |
| Mem Sniffer                    | Amount of memory used by sniffer.                                                   |
| Mysql Disk Usage               | MySQL disk usage.                                                                   |
| Mysql Is Up                    | Boolean indicator for internal database restart (1=was restarted, 0=not restarted). |
| Open FDs                       | Open File Descriptors.                                                              |
| Promiscuous Received           | Rate of received packets through the sniffing network cards (non-interface ports).  |
| Session Direct Closed          | Count of sessions directly closed.                                                  |
| Session Guessed                | Count of sessions guessed.                                                          |
| Session Ignored                | Count of sessions ignored by sniffer.                                               |
| Session Queue Length           | Size of session queue.                                                              |
| Session Timeout                | Count of sessions timed-out.                                                        |

| Attribute                 | Description                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------|
| Session Total             | Total number of sessions.                                                                                   |
| Sessions Normal           | Count of normal sessions.                                                                                   |
| Sniffer Connections Ended | Total number of connections that were monitored and have ended since inspection engine was restarted.       |
| Sniffer Connections Used  | Total number of connections currently being monitored since inspection engine was restarted.                |
| Sniffer Packets Ignored   | Packets ignored by sniffer.                                                                                 |
| Sniffer Packets Throttled | Total number of connections that have been ignored due to throttling since inspection engine was restarted. |
| SNO                       | Session Not Opened                                                                                          |
| SPD                       | Sniffer Packets Dropped                                                                                     |
| System Cpu Load           | System CPU utilization.                                                                                     |
| System Memory Usage       | System memory utilization.                                                                                  |
| System Root Disk Usage    | System Root disk utilization.                                                                               |
| System Uptime             | Time since last start-up.                                                                                   |
| System Var Disk Usage     | System var disk utilization.                                                                                |
| TID                       | PID of sniffer process                                                                                      |
| Time Sniffer              | Elapsed time used by sniffer.                                                                               |
| Timestamp                 | Timestamp of activity                                                                                       |
| UTC Offset                | The difference in time between UTC time and time of collector that reported that data                       |
| Analyzer Queue Drops      | The number of analyzer queue entries dropped by the sniffer.                                                |
| Priority Queue Drops      | The number of priority queue entries dropped by the sniffer.                                                |

## BigData Intelligence Classification Process Log domain

Reports on classifier process logs. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Classification Process Log Entity

| Attribute                | Description                                                                            |
|--------------------------|----------------------------------------------------------------------------------------|
| Datasources              | Datasource list for the job.                                                           |
| Details                  | Information about the Log Event: error messages or statistics.                         |
| End Date                 | Date at end of job.                                                                    |
| End Date Time            | Timestamp at end of job.                                                               |
| Guardium Appliance       | Host name of collector that reported this data.                                        |
| Guardium Job Description | Local copy of Global Process description.                                              |
| Message                  | Information about the Log Event: error messages or statistics.                         |
| Message Type             | Type of message.                                                                       |
| Process Id               | The process ID of the client that initiated the connection (not always available).     |
| Process Run Id           | Classification process run ID.                                                         |
| Process Type             | Classification process type.                                                           |
| Queue Date               | Date in the timestamp when the job was submitted to the classifier/assessment queue.   |
| Queue Date Time          | Timestamp when the job was submitted to the classifier/assessment queue.               |
| Report Result Id         | Identifies the report result.                                                          |
| Start Date               | Date in the timestamp at start of job.                                                 |
| Start Date Time          | Timestamp at start of job.                                                             |
| Status                   | Job status.                                                                            |
| Task Description         | Name of the task from the task definition.                                             |
| UTC Offset               | The difference in time between UTC time and time of collector that reported that data. |

## BigData Intelligence Classifier Results domain

Reports on classifier process results. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Classifier Results Entity

| Description         | Description                       |
|---------------------|-----------------------------------|
| Catalog             | Catalog location for results set. |
| Category            | Category for the rule.            |
| Classification Name | Classification for the rule.      |

| Description            | Description                                                                           |
|------------------------|---------------------------------------------------------------------------------------|
| Column Name            | Column name from the rule definition.                                                 |
| Comments               | Any comments added to this rule definition.                                           |
| Datasource Description | Datasource for the rule.                                                              |
| Guardium Appliance     | Host name of collector that reported this data.                                       |
| Process Description    | Local copy of Global Process description                                              |
| Rule Description       | The classifier policy rule description.                                               |
| Schema                 | Schema name if applicable.                                                            |
| Start Date             | Date in the timestamp at start of job.                                                |
| Start DateTime         | Timestamp at start of job.                                                            |
| Table Name             | Table name from the rule definition.                                                  |
| UTC Offset             | The difference in time between UTC time and time of collector that reported that data |

## BigData Intelligence Databases Discovered domain

Reports on discovered databases. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

### Databases Discovered Entity

| Attribute            | Description                                                                           |
|----------------------|---------------------------------------------------------------------------------------|
| DB Type              | Type of database that was discovered.                                                 |
| Guardium Appliance   | Host name of collector that reported this data.                                       |
| Port                 | Port used when discovering the database                                               |
| Port Type            | Indicates the port type.                                                              |
| Probe Timestamp      | The date and time that this specific port was probed.                                 |
| Probe Timestamp Date | Date in the timestamp of the probe.                                                   |
| Server Host Name     | Host name of the discovered host.                                                     |
| Server IP            | IP address of the discovered host.                                                    |
| UTC Offset           | The difference in time between UTC time and time of collector that reported that data |

## BigData Intelligence Discovered Instances domain

Reports on instances that have been discovered by GIM. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

### BigData Discovered Instances Entity

| Attribute                      | Description                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------|
| Client                         | IP address/mask of client                                                             |
| DB Install Dir                 | Database Install Directory                                                            |
| DB2 Shared Mem Adjustment      | Packet header size                                                                    |
| DB2 Shared Mem Client Position | Client I/O area offset                                                                |
| DB2 Shared Mem Size            | DB2 shared memory segment size                                                        |
| Exclude Client                 | IP address/mask of clients to exclude                                                 |
| Guardium Appliance             | Host name of collector that reported this data.                                       |
| Host                           | Host name for this instance                                                           |
| Informix Version               | Informix version                                                                      |
| Instance name                  | Name of the discovered instance                                                       |
| KTAP DB Port                   | Database port for KTAP                                                                |
| Named Pipe                     | Pipe name used by database                                                            |
| Port Max                       | Port range, maximum port number for inspection-engines                                |
| Port Min                       | Port range, minimum port number for inspection-engines                                |
| Proc Name                      | Process name                                                                          |

## BigData Intelligence Exception domain

All of the exceptions and exception-related data. These are SQL exceptions sent from a database server and collected by inspection engines, as well as exceptions generated by Guardium itself. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

### BigData Exception Entity

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP will be used for the source. If both included in the query, then Client IP takes precedence.                                                                              |
| App User Name                                | Application user name.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Client Host Name                             | Client hostname                                                                                                                                                                                                                                                                                                                                                                                                             |
| Database Error Text                          | A database error code followed by a short text description of the error. The error code is taken from the Exception Description attribute of the Exception entity. Using the error code as a key, the error text is obtained from an internal table on the Guardium appliance, which contains the most common error messages (about 54,000 of them).<br>Example: ORA-00942: table or view does not exist                    |
| Database Name                                | Database Name                                                                                                                                                                                                                                                                                                                                                                                                               |
| Database Protocol                            | Database protocol for the exception.                                                                                                                                                                                                                                                                                                                                                                                        |
| DB User Name                                 | The DB user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                         |
| Description                                  | For a database exception, this is an error code from the database management system. For most common messages (about 54,000 of them), a longer text description is available in the Database Error Text attribute. That text comes from the internal Guardium database table of error messages, not from the exception itself.                                                                                              |
| Destination Address                          | Destination IP address.                                                                                                                                                                                                                                                                                                                                                                                                     |
| Error Code                                   | The database error code.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Exception Date                               | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                               |
| Exception ID                                 | Uniquely identifies the exception.                                                                                                                                                                                                                                                                                                                                                                                          |
| Exception Timestamp                          | Date and time when this Exception entity was logged.                                                                                                                                                                                                                                                                                                                                                                        |
| Exception Type                               | Uniquely identifies the exception type.                                                                                                                                                                                                                                                                                                                                                                                     |
| Guardium Appliance                           | Host name of collector that reported this data.                                                                                                                                                                                                                                                                                                                                                                             |
| Link to more information about the exception | Link that is sometimes available, depending on the exception source.                                                                                                                                                                                                                                                                                                                                                        |
| OS User                                      | OS user account for the interaction                                                                                                                                                                                                                                                                                                                                                                                         |
| Server Host Name                             | Server Host Name                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server IP                                    | Server IP address                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server Port                                  | Server port number                                                                                                                                                                                                                                                                                                                                                                                                          |
| Server Type                                  | DB2, Oracle, Sybase, and so on.                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name                                 | Service name for the interaction. In some cases (AIX® shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session will be logged as two sessions.<br>For Teradata, Service name contains the session logical host ID value. |
| Session Id                                   | Uniquely identifies the session                                                                                                                                                                                                                                                                                                                                                                                             |
| Source Address                               | Source IP address of the exception.                                                                                                                                                                                                                                                                                                                                                                                         |
| Source Program                               | Source program for the interaction                                                                                                                                                                                                                                                                                                                                                                                          |
| SQL string that caused the Exception         | The SQL string that caused the exception.                                                                                                                                                                                                                                                                                                                                                                                   |
| User Name                                    | Database user name.                                                                                                                                                                                                                                                                                                                                                                                                         |
| UTC Offset                                   | The difference in time between UTC time and time of collector that reported that data                                                                                                                                                                                                                                                                                                                                       |

## BigData Intelligence Full SQL domain

You can create full SQL entities by using only the following policy rule actions: Log Full Details, Log Full Details With Values, Log Full Details Per Session, or Log Full Details Per Session With Values.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

### BigData Intelligence Full SQL Entity

Table 1. The following table describes the domain's entities and attributes.

| Attribute          | Description                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Analyzed Client IP | Applies only to encrypted traffic; when set, client IP is set to zeros.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP is used for the source. If both included in the query, then Client IP takes precedence. |
| Client Host Name   | Client hostname                                                                                                                                                                                                                                                                                                                          |
| Database Name      | Database name                                                                                                                                                                                                                                                                                                                            |
| DB User Name       | Database username                                                                                                                                                                                                                                                                                                                        |
| Full Sql           | Full SQL statement with values.                                                                                                                                                                                                                                                                                                          |
| Guardium Appliance | Hostname of the collector that reported this data.                                                                                                                                                                                                                                                                                       |
| Instance ID        | Unique identifier for the Full SQL instance.                                                                                                                                                                                                                                                                                             |
| Network Protocol   | Network Protocol                                                                                                                                                                                                                                                                                                                         |
| OS User            | OS User                                                                                                                                                                                                                                                                                                                                  |
| Records Affected   | The number of records affected for each session. For reports that use this attribute, it's recommended to turn on aliases to properly display special cases such as Large Result Set or N/A.                                                                                                                                             |
| Response Time      | The response time for the request in milliseconds. When you monitor requests in network traffic, the response times accurately reflect the time that is taken to respond to the request (Guardium timestamps both the client request and the server response).                                                                           |
| Server Host Name   | Server hostname                                                                                                                                                                                                                                                                                                                          |
| Server IP          | Server IP                                                                                                                                                                                                                                                                                                                                |
| Server Port        | Server port                                                                                                                                                                                                                                                                                                                              |
| Server Type        | Server type                                                                                                                                                                                                                                                                                                                              |
| Service Name       | Service name                                                                                                                                                                                                                                                                                                                             |
| Session Id         | The numeric key value that Guardium assigns to uniquely identify a session. It is used to search the activities generated during the session.                                                                                                                                                                                            |
| Source Program     | Source Program                                                                                                                                                                                                                                                                                                                           |
| Succeeded          | Indicates whether the call succeeded.                                                                                                                                                                                                                                                                                                    |
| Timestamp          | The time when the SQL was executed in the database server.                                                                                                                                                                                                                                                                               |
| UTC Offset         | The difference in time between Coordinated Universal Time (UTC) time and the time of the collector that reported that data.                                                                                                                                                                                                              |

## BigData Intelligence Installed Patches domain

Reports on installed patches. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Installed Patches Entity

| Attribute           | Description                                                                           |
|---------------------|---------------------------------------------------------------------------------------|
| Creation Date       | The patch creation date.                                                              |
| Guardium Appliance  | Host name of collector that reported this data.                                       |
| Guardium Version    | Guardium software version                                                             |
| Installed By        | CM, SA, or CLI                                                                        |
| Patch Dependencies  | Guardium version or patch, which has to be installed before this patch.               |
| Patch Description   | Patch Description                                                                     |
| Patch Number        | Patch Number                                                                          |
| Requested Date Time | The date/time the patch should be installed                                           |
| Status              | 0/1 for success or failure                                                            |
| Status Description  | Patch                                                                                 |
| Timestamp           | Timestamp the status was updated.                                                     |
| Upload Date         | The date the patch was uploaded for installation                                      |
| UTC Offset          | The difference in time between UTC time and time of collector that reported that data |

## BigData Intelligence Instance domain

This domain contains traffic data collected by the inspection engines every time a request is sent to a server being monitored. It includes all of the client/server, session, SQL, and access periods related data. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Instance Entity

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Rule Description | Description from the access policy rule definition.                                                                                                                                                                                                                                                                                                                                                                   |
| Analyzed Client IP      | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP will be used for the source. If both included in the query, then Client IP takes precedence.                                                                        |
| App User Name           | Unique identifier for this App User Name entity.                                                                                                                                                                                                                                                                                                                                                                      |
| Application Event ID    | Unique identifier for this application events entity.                                                                                                                                                                                                                                                                                                                                                                 |
| Average Execution Time  | The average command execution time during the period. This is for SQL statements only. It does not apply to FTP traffic.                                                                                                                                                                                                                                                                                              |
| Client Host Name        | Client Host Name                                                                                                                                                                                                                                                                                                                                                                                                      |
| Construct Id            | Uniquely identifies the construct in which the object is referenced.                                                                                                                                                                                                                                                                                                                                                  |
| Database Name           | Name of database for the session (MSSQL or Sybase only).<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                 |
| DB User Name            | User that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                          |
| Failed Sqls             | The number of failed SQL requests. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                 |
| Guardium Appliance      | Host name of collector that reported this data.                                                                                                                                                                                                                                                                                                                                                                       |
| Instance ID             | Unique identifier for the instance of a construct or SQL instance. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                       |
| Network Protocol        | Network protocol used (for example, TCP, UDP, etc. For K-TAP on Oracle, this displays as either IPC or BEQ).                                                                                                                                                                                                                                                                                                          |
| Objects and Verbs       | Name of the object and SQL verb tuples separated by semi colon.                                                                                                                                                                                                                                                                                                                                                       |
| Original SQL            | original SQL sent by user.                                                                                                                                                                                                                                                                                                                                                                                            |
| OS User                 | OS user account for the interaction.                                                                                                                                                                                                                                                                                                                                                                                  |
| Period Start            | Period start attribute.                                                                                                                                                                                                                                                                                                                                                                                               |
| Period Start Date       | Date only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                            |
| Server Host Name        | Server Host Name                                                                                                                                                                                                                                                                                                                                                                                                      |
| Server IP               | Server IP address                                                                                                                                                                                                                                                                                                                                                                                                     |
| Server Port             | Server port number                                                                                                                                                                                                                                                                                                                                                                                                    |
| Server Type             | For example: DB2, Oracle, Sybase...                                                                                                                                                                                                                                                                                                                                                                                   |
| Service Name            | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value. |
| Session Id              | Uniquely identifies the session. Available only to users with the admin role.                                                                                                                                                                                                                                                                                                                                         |
| Source Program          | Source program for the interaction.                                                                                                                                                                                                                                                                                                                                                                                   |
| Successful Sqls         | The number of successful SQL requests. Appears only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                   |
| Timestamp               | Timestamp this record was created.                                                                                                                                                                                                                                                                                                                                                                                    |
| Timestamp Date          | Date in the timestamp                                                                                                                                                                                                                                                                                                                                                                                                 |
| Total Records Affected  | The total number of records affected. Appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                     |
| UTC Offset              | The time difference between UTC time and time of the collector that reported that data.                                                                                                                                                                                                                                                                                                                               |

## BigData Intelligence Outliers List Enhanced domain

Detailed description of activities and errors that have been identified as outliers. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Outliers List Enhanced Entity

| Attribute           | Description                                                    |
|---------------------|----------------------------------------------------------------|
| Anomaly Score       | Final anomaly score.                                           |
| DB Name             | Name of DB on which the activity occurred.                     |
| DB User Name        | DB User Name associated with the activity.                     |
| Error Outlier       | Whether or not the outlier is of type error. True/False.       |
| Guardium Appliance  | Host name of collector that reported this data.                |
| High volume Outlier | Whether or not the outlier is of type high volume. True/False. |
| New Outlier         | Whether or not the outlier is of type new. True/False.         |
| Number of Instances | Activity volume.                                               |

| Attribute         | Description                                                                           |
|-------------------|---------------------------------------------------------------------------------------|
| Object            | The object on which the activity was performed.                                       |
| Period Start      | Time of period start                                                                  |
| Period Start Date | Date of period start.                                                                 |
| Records Affected  | The number of records affected by the activity.                                       |
| Server IP         | IP of server on which the activity occurred.                                          |
| Server Type       | Type of server on which the activity occurred.                                        |
| Source Program    | Source program associated with the activity.                                          |
| Temp Outlier      | Whether or not the outlier is of type temp. True/False.                               |
| UTC Offset        | The difference in time between UTC time and time of collector that reported that data |
| Verb              | Verb used in the activity.                                                            |

## BigData Intelligence Outliers Summary Enhanced domain

A summary of the outliers on a one hour granularity. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Outliers Summary Enhanced Entity

| Attribute           | Description                                                                            |
|---------------------|----------------------------------------------------------------------------------------|
| Anomaly Score       | Final anomaly score for this alert.                                                    |
| DB Name             | Name of DB on which the activity occurred.                                             |
| DB User Name        | DB User Name associated with the activity.                                             |
| Diverse Outlier     | Whether or not the outlier is of type diverse. True/False.                             |
| Error Outlier       | Whether or not the outlier is of type error. True/False.                               |
| Guardium Appliance  | Host name of collector that reported this data.                                        |
| High volume Outlier | Whether or not the outlier is of type high volume. True/False.                         |
| New Outlier         | Whether or not the outlier is of type new. True/False.                                 |
| Ongoing Outlier     | Whether or not the outlier is of type ongoing. True/False.                             |
| Period Start        | Date and time of period start.                                                         |
| Period Start Date   | Date of period start.                                                                  |
| Privileged User     | Whether or not the activity was performed by a privileged user. True/False.            |
| Server IP           | IP of server on which the activity occurred.                                           |
| Server Type         | Type of server on which the activity occurred.                                         |
| Temp Outlier        | Whether or not the outlier is of type temp. True/False.                                |
| UTC Offset          | The difference in time between UTC time and time of collector that reported that data. |

## BigData Intelligence Policy Violations domain

All policy violation data, for all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes. This topic describes the domain's entities and attributes.

This entity is created each time that a policy rule violation is logged. Not all policy rule violations are logged - see the description of the rule actions in [Policy rule actions](#). The access rule causing the violation is available in the dependent Access Rule Entity (described earlier).

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Policy Violations Entity

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Rule Description | The description of the rule from its definition.                                                                                                                                                                                                                                                                                               |
| Analyzed Client IP      | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP will be used for the source. If both included in the query, then Client IP takes precedence. |
| Client Host Name        | Client Host Name                                                                                                                                                                                                                                                                                                                               |
| DB User Name            | Database user name. The user that connected to the database, either local or remote.                                                                                                                                                                                                                                                           |
| Full SQL String         | SQL string that caused the policy rule violation.                                                                                                                                                                                                                                                                                              |
| Guardium Appliance      | Host name of collector that reported this data.                                                                                                                                                                                                                                                                                                |
| Objects and Verbs       | Database user name. The DB user name is the person who connected to the database, either local or remote.                                                                                                                                                                                                                                      |

| Attribute        | Description                                                                                 |
|------------------|---------------------------------------------------------------------------------------------|
| OS User          | OS user that caused the policy rule violation.                                              |
| Server Host Name | Server on which the policy rule violation occurred.                                         |
| Server IP        | Server IP on which the policy rule violation occurred.                                      |
| Server Type      | Server type on which the policy rule violation occurred.                                    |
| Service Name     | Service Name in which the policy rule violation occurred.                                   |
| Severity         | Severity of the policy rule violation.                                                      |
| Source Program   | Source Program in which the policy rule violation occurred.                                 |
| Timestamp        | Created when the policy rule violation is logged. Not all policy rule violations are logged |
| Timestamp Date   | Date in the timestamp                                                                       |
| UTC Offset       | The difference in time between UTC time and time of collector that reported that data       |
| Violation Log Id | Unique identifier of the violation log                                                      |

## BigData Intelligence Session domain

Reports on Client/Server database session. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## BigData Intelligence Session Entity

| Attribute          | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Id          | Uniquely identifies the access period.                                                                                                                                                                                                                                                                                                                                                                                 |
| Analyzed Client IP | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP is used for the source. If both are included in the query, then the Client IP takes precedence.                                                                      |
| Client Host Name   | Client Host Name                                                                                                                                                                                                                                                                                                                                                                                                       |
| Client Port        | Client port number                                                                                                                                                                                                                                                                                                                                                                                                     |
| Database Name      | Name of database for the session (MSSQL or Sybase only).<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                  |
| DB User Name       | User that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                           |
| Guardium Appliance | Host name of collector that reported this data.                                                                                                                                                                                                                                                                                                                                                                        |
| Ignored Flag       |                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Login Succeeded    |                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Network Protocol   | Network protocol used (for example, TCP, UDP. For K-TAP on Oracle, this displays as either IPC or BEQ).                                                                                                                                                                                                                                                                                                                |
| OS User            | OS user account for the interaction.                                                                                                                                                                                                                                                                                                                                                                                   |
| Sender IP          | Sender IP                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Host Name   | Server Host Name                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server IP          | Server IP                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Port        | Server port number                                                                                                                                                                                                                                                                                                                                                                                                     |
| Server Type        | For example: DB2, Oracle, Sybase...                                                                                                                                                                                                                                                                                                                                                                                    |
| Service Name       | Service name for the interaction. In some cases (AIX® shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value. |
| Session End        | Date and time the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                            |
| Session End Date   | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                        |
| Session ID         | Uniquely identifies the session.                                                                                                                                                                                                                                                                                                                                                                                       |
| Session Ignored    | Indicates whether or not some part of the session was ignored (beginning at any point in time).                                                                                                                                                                                                                                                                                                                        |
| Session Start      | Date and time session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                            |
| Session Start Date | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                      |
| Source Program     | Source program for the interaction.                                                                                                                                                                                                                                                                                                                                                                                    |
| Uid Chain          | For a session reported by Unix S-TAP (K-Tap mode only), this shows the chain of OS users, when users su with a different user name. The values that appear here vary by OS platform; for example, under AIX the string IBM IBM IBM may appear as a prefix.<br>For Solaris Zones, user ids may be reported instead of user names in the Uid Chain.                                                                      |
| UTC Offset         | The time difference between UTC time and the time of the collector that reported that data.                                                                                                                                                                                                                                                                                                                            |

## BigData Intelligence STAP Status domain

Reports on status of S-TAPs. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

### BigData Intelligence STAP Status Entity

| Attribute                    | Description                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------|
| App Server                   | Whether or not an App server is installed. Yes / No.                                       |
| CAS Server Name              | Name of the CAS server.                                                                    |
| DB Port max                  | Ending port number of the range of listening ports for the database.                       |
| DB Port min                  | Starting port number of the range of listening ports for the database.                     |
| DB Server Type               | Protocol of the DB server.                                                                 |
| DB Tee Real DB Port          | The port to which S-TAP forwards traffic when using Tee.                                   |
| Encrypted?                   | Whether or not communication from S-TAP is encrypted. Unencrypted / encryption type.       |
| Guardium Appliance           | Name of the collector that reported this data.                                             |
| Guardium Hosts               | IP addresses or hostnames of the Guardium systems that act as the host/s for the S-TAP.    |
| Hunter DBS                   | Deprecated                                                                                 |
| I Name                       |                                                                                            |
| KTAP                         | Whether or not K-TAP is installed on the S-TAP. Yes / No.                                  |
| KTAP Version                 | Version of the installed K-TAP.                                                            |
| Last Response Received       | Last status response received from the S-TAP. For example synchronizing, active.           |
| Last Response Time           | Time of the last status response.                                                          |
| LHMON                        | Deprecated in v10.5. Whether or not LHMON driver is installed.                             |
| MSS Shm                      | Shared Memory Driver Installed. Yes / No.                                                  |
| Pipes                        | Whether or not a named pipes driver is installed on the S-TAP. Yes / No.                   |
| Policy                       |                                                                                            |
| Primary Host Name            | Name of the Guardium appliance to which the S-TAP sends data.                              |
| STAP Changed                 |                                                                                            |
| S-TAP Host                   | IP address or hostname for the database server system on which S-TAP is installed          |
| STAP Verification Status     | Verification not run / Verification run                                                    |
| S-TAP Version                | Version of the S-TAP software                                                              |
| Status                       | S-TAP status. One of:Active, Inactive, Synchronizing.                                      |
| Tap Identifier               | Unique inspection engine identifier.                                                       |
| TAP IP                       | IP address for the database server system on which S-TAP is installed.                     |
| TAP Type                     | The type of installed S-TAP agent:<br>stap=UNIX<br><br>wstab = Windows<br>ztap=Z/OS        |
| TEE                          | Deprecated. Whether or not Tee is enabled. Yes / No.                                       |
| Time Differential            |                                                                                            |
| Timestamp                    |                                                                                            |
| Total Bytes Dropped So Far   | Total Bytes Dropped So Far                                                                 |
| Total Bytes Ignored          | Total Bytes Ignored                                                                        |
| Total Bytes So Far           | Total Bytes So Far                                                                         |
| Total Response Bytes Ignored | Total Response Bytes Ignored                                                               |
| Use TLS                      | Encrypted with TLS. Yes / No.                                                              |
| UTC Offset                   | The difference in time between UTC time and time of the collector that reported that data. |

## BigData Intelligence System Info domain

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI. This topic describes the domain's entities and attributes.

### BigData Intelligence System Info Entity

| Attribute                | Description                                                |
|--------------------------|------------------------------------------------------------|
| Archive at Age           | Age of data, in days, at which it is archived.             |
| Archive Destination Dir  | Target location of archive operation.                      |
| Archive Destination Host | Target host of archive operation: IP or hostname.          |
| Archive Destination User | User that has read/write credentials for target directory. |
| Archive Max Age          | Maximum age of data that is archived, in days.             |

| Attribute               | Description                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------|
| Archive Selected        |                                                                                              |
| Archive Values          | Whether or not archived data includes SQL strings (yes), or are replaced with "?" (no).      |
| Auth LDAP Type          |                                                                                              |
| Auth Server Type        |                                                                                              |
| Export at Age           | Age of data, in days, at which it is exported.                                               |
| Export Destination Host | Target location of export operation.                                                         |
| Export Max Age          | Maximum age of data that is exported, in days.                                               |
| Export Selected         |                                                                                              |
| Export Values           | Whether or not exported data includes SQL strings (yes), or are replaced with ? (no).        |
| gid                     | The same as Global ID.                                                                       |
| Global ID               | Global ID.                                                                                   |
| Guardium Appliance      | Host name of collector that archived/exported this data.                                     |
| Guardium Model          | Model of host.                                                                               |
| Guardium Version        | Version of host.                                                                             |
| Host Mac Address        | Host Mac Address                                                                             |
| Import Selected         |                                                                                              |
| Manager IP              | IP Address of the unit's Central Manager.                                                    |
| Purge at Age            | Age of data, in days, at which data is purged.                                               |
| Purge if Archived       | Data is purged                                                                               |
| Purge if Exported       |                                                                                              |
| Purge Selected          |                                                                                              |
| Restore Selected        |                                                                                              |
| System Domain           |                                                                                              |
| Timestamp               | Date and time this change record was created on the server (Guardium appliance server clock) |
| Tomcat Hostname         | System Hostname                                                                              |
| Tomcat IP               | System IP Address                                                                            |
| Unique ID Prefix        | Unique Global Identifier                                                                     |
| Unit Type               | Unit type, for example, standalone, managed, manager, aggregator.                            |
| UTC Offset              | The difference in time between UTC time and time of collector that reported that data        |

## BigData Intelligence VA Results domain

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI. This topic describes the domain's entities and attributes.

### BigData Intelligence VA Results Entity

| Attribute              | Description                                                                                    |
|------------------------|------------------------------------------------------------------------------------------------|
| Assessment Description | Assessment name from the definition.                                                           |
| Category               | Category for the test result.                                                                  |
| Datasource Name        | Name of the datasource.                                                                        |
| Datasource Type        | Database type, for example: Oracle, MS-SQL, DB2, Sybase, Informix...                           |
| DB Name                | Database name                                                                                  |
| Description            | Datasource description.                                                                        |
| Execution Date         | Date that the assessment was run.                                                              |
| Guardium Appliance     | Host name of collector that reported this data.                                                |
| Host                   | Host name of the datasource.                                                                   |
| Patch Level            | Patch level of the datasource.                                                                 |
| Port                   | Port number on the host.                                                                       |
| Recommendation         | Recommendation returned for the task.                                                          |
| Result Text            | Text returned by the test.                                                                     |
| Score Description      | Description of the score.                                                                      |
| Service Name           | Service name for the datasource.                                                               |
| Severity               | Severity of the incident or policy violation. One of: INFO, LOW, MED, HIGH.                    |
| Test Description       | Description from the test definition.                                                          |
| Test Score             | Returned test score.                                                                           |
| UTC Offset             | The difference in time between UTC time and the time of the collector that reported that data. |
| Version Level          | Version level of the database.                                                                 |

## CAS Changes domain

Tracks changes to monitored items (files, registry variables, etc.). This topic describes the domain's entities and attributes.

Available to roles: all

## Monitored Changes Entity

This entity is created each time a monitored item changes. It identifies the monitored item within the CAS instance, and points to the saved data for the change.

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change Identifier     | Unique identifier for the change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Sample Time           | Timestamp (date and time on host) that sample was taken.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Audit Config Id       | Identifies the host configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Saved Data Id         | Identifies the Saved Data entity for this change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Audit State Label Id  | Identifies the Host Configuration entity for this change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp             | Date and time this change record was created on the server (Guardium appliance server clock).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| MD5                   | Indicates whether or not the comparison is done by calculating a checksum using the MD5 algorithm and comparing that value with the value calculated the last time the item was checked. The default is to not use MD5. If MD5 is used but the size of the raw data is greater than the MD5 Size Limit configured for the CAS host, the MD5 calculation and comparison will be skipped. Regardless of whether or not MD5 is used, both the current value of the last modified timestamp for the item and the size of the item are compared with the values saved the last time the item was checked. |
| Owner                 | Unix only. If the item type is a file, the file owner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Permissions           | Unix only. If the item type is a file, the file permissions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Size                  | File size, but there are special values as follows:<br>-1 = File exists, but has a zero bytes<br><br>0 (zero) = File does not exist, but this file name is being monitored (it never existed or may have been deleted)                                                                                                                                                                                                                                                                                                                                                                               |
| Last Modified         | Timestamp for the last modification, taken from the file system at the sample time..                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Last Modified Date    | Date for the last modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Last Modified Time    | Time for the last modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Last Modified Weekday | Day of week for the last modification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Group                 | Unix only. If the item type is a file, the group owner.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Host Configuration Entity

A Host Configuration entity is created for each item in a CAS instance.

| Attribute            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Audit State Label Id | Unique numeric identifier for the configuration item                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Timestamp            | Timestamp for creation of the entity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Host Name            | Database server host name or IP address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| OS Type              | Operating system: Unix or Windows                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DB Type              | Database type: Oracle, MS-SQL, DB2®, Sybase, Informix®, or N/A if the change is to an operating system instance                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Instance Name        | Name of the template set instance                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Type                 | Type of monitored item that changed.<br><br>OS Script or SQL Script: A change triggered by the OS script contained in the monitored item template definition.<br><br>Environment Variable: An environment variable (Unix only)<br><br>Registry Variable: A registry variable (Windows only)<br><br>File: A specific file. There is no host configuration entity for a file pattern defined in the template set used by the instance. Instead, there is a separate host configuration entity for each file that matches the pattern. |
| Monitored Item       | The name of the changed item, from the Description (if entered), otherwise a default name depending on the Type (a file name, for example).                                                                                                                                                                                                                                                                                                                                                                                         |

## Saved Data Entity

A Saved Data entity is created each time a change is detected for an item being monitored, if the Keep data box is marked for that item in the item template definition.

| Attribute         | Description                                                                   |
|-------------------|-------------------------------------------------------------------------------|
| Saved Data ID     | Unique numeric identifier for the saved data item.                            |
| Saved Data        | The actual data saved.                                                        |
| Timestamp         | Timestamp for when the saved data entity was recorded in the server database. |
| Change Identifier | Identifies the monitored changes entity for this saved data entity.           |

Saved Data ID is only available to users with the admin role.

## CAS Config domain

Tracks CAS host configurations, where a configuration is the application of one or more template sets to a specific database server host. From configuration instances you can see which items within template sets are enabled or disabled, or exactly which files are selected and monitored (or not) by file name pattern templates. This topic describes the domain's entities and attributes.

Available to roles: all

## Host Entity

---

Identifies a CAS host (a database server) and the current status of CAS (online/offline). A CAS Host entity is created the first time that CAS is seen on a database server host. It is updated each time that the online/offline status changes. The Host entity is available in the CAS Host History domain and the CAS Config domain.

| Attribute | Description                                             |
|-----------|---------------------------------------------------------|
| Host Id   | Host ID                                                 |
| Host Name | Database server host name (might display as IP address) |
| IP        | Host IP                                                 |
| Is Online | Online status (Yes/No) when record was written          |
| OS Type   | Operating system: UNIX or WIN                           |

## Instance Config entity

---

An Instance Config Entity is created each time that an instance configuration is defined. This entity defines how the CAS instance connects to the database (if necessary), and identifies the template set used by the instance.

| Description     | Description                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------|
| DB Type         | Database Type (Oracle, MS-SQL, DB2®, Sybase, Informix®, etc.) or N/A for an operating system instance.   |
| Instance        | The name of the instance.                                                                                |
| User            | The user name that CAS uses to log onto the database; or N/A for an operating system instance.           |
| Port            | The port number CAS uses to connect to the database; this can be empty for an operating system instance. |
| DB Home Dir     | The home directory for the database; this can be empty for an operating system instance.                 |
| Template Set ID | Identifies the template set used by this instance.                                                       |

## Datasource entity

---

| Attribute             | Description                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Connection Properties | Reported only if additional connection properties are included on the JDBC URL to establish a JDBC connection with this datasource. |
| Data-Source Severity  | Severity Classification (or impact level) if defined for the datasource.                                                            |
| Database Name         | If defined for the datasource: schema name for DB2 or Oracle datasource. Database name for others.                                  |
| Database Description  | Longer description of the datasource, if defined.                                                                                   |
| Database ID           | Database ID                                                                                                                         |
| Database Name         | If defined for the datasource: schema name for DB2 or Oracle datasource. Database name for others.                                  |
| Database Type         | The datasource type.                                                                                                                |
| Host                  | Host name or IP address                                                                                                             |
| Last Connect          |                                                                                                                                     |
| Port                  | Port, if defined for the datasource                                                                                                 |
| Service Name          | For a DB2 datasource, the database name. For Oracle, Informix, and IBM ISeries, the service name.                                   |
| Shared                | True/false. True indicates that this datasource is shared with other applications.                                                  |
| User Name             | User name, if defined for this datasource.                                                                                          |

## CAS Host History domain

---

Tracks CAS host events, including servers or clients going in or out of service. This topic describes the domain's entities and attributes.

Available to roles: all

## Host Entity

---

Identifies a CAS host (a database server) and the current status of CAS (online/offline). A CAS Host entity is created the first time that CAS is seen on a database server host. It is updated each time that the online/offline status changes. The Host entity is available in the CAS Host History domain and the CAS Config domain.

| Attribute | Description                                             |
|-----------|---------------------------------------------------------|
| Host Id   | Host ID                                                 |
| Host Name | Database server host name (might display as IP address) |
| IP        | Host IP                                                 |
| Is Online | Online status (Yes/No) when record was written          |
| OS Type   | Operating system: UNIX or WIN                           |

## Host Event Entity

---

Date and time of an event in the CAS client/server relationship. A host event entity is created each time an event is detected or signaled (see the event types) by CAS.

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Audit Host Event Id | Identifies the host event entity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Audit Host Id       | Identifies the host                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Event Time          | Date and time that the event was recorded                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Event Type          | Identifies the event being recorded:<br>Client Up - CAS started on database server host<br><br>Client Down - CAS stopped on database server host<br><br>Failover Off - A server is available (following a disruption), so CAS data is being written to the server<br><br>Failover On - The server is not available, so CAS data is being written to the failover file<br><br>Server Down - The database server stopped<br><br>Server Up - The database server started                                                                                                                                        |
| Original Timezone   | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Timestamp           | Timestamp for creation of the entity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## CAS Templates domain

Track CAS template definitions. Templates identify items to be monitored for changes. Monitored items can be files, environment or registry variables, OS or SQL script output sets, or the set of logged on users. This topic describes the domain's entities and attributes.

Available to roles: all

### Template Set entity

Describes a template set definition. A Template Set entity is created for each template set, which is a set of template items for a particular operating system or database.

| Attribute         | Description                                                                                                                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Template Set ID   | A unique identifier for the template set, numbered sequentially                                                                                                                                                                                                                       |
| OS Type           | Operating system: Unix or Windows                                                                                                                                                                                                                                                     |
| DB Type           | Database Type (Oracle, MS-SQL, DB2®, Sybase, Informix®, etc.) or N/A for an operating system template                                                                                                                                                                                 |
| Template Set Name | The template name                                                                                                                                                                                                                                                                     |
| IsDefault         | Indicates whether or not this template is the default for the specified OS type and DB type combination                                                                                                                                                                               |
| Editable          | Indicates whether or not this template can be modified. The default Guardium® templates cannot be modified. In addition, once a template set has been used in a CAS instance, it cannot be modified. However, a template set can always be cloned and the cloned set can be modified. |
| Timestamp         | Date and time the template was last updated                                                                                                                                                                                                                                           |

### Template entity

Describes a template item within a template set.

| Attribute                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Template ID               | A unique identifier for the template set, numbered sequentially                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Access Name               | Depending on the Audit Type, this is the OS or SQL script, environment or registry value, or a file name or a file name pattern                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Audit Type                | The type of monitored item                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Audit Frequency (minutes) | The maximum interval (in minutes) between tests                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Use MD5                   | Indicates whether or not the comparison is done by calculating a checksum using the MD5 algorithm and comparing that value with the value calculated the last time the item was checked. The default is to not use MD5. If MD5 is used but the size of the raw data is greater than the MD5 Size Limit configured for the CAS host, the MD5 calculation and comparison will be skipped. Regardless of whether or not MD5 is used, both the current value of the last modified timestamp for the item and the size of the item are compared with the values saved the last time the item was checked. |
| Save Data                 | Indicates if the Keep Data checkbox has been marked. If so, previous versions of the item can be compared with the current version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Description               | Optional description of the template                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp                 | Date and time the template was last updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Catalog domain: entities and attributes

The Guardium catalog tracks where every archive or backup is sent. The catalog domain presents catalog details.

### Entry entity

| Attribute                 | Description                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aggregator                | Aggregator from which archive or backup was created.                                                                                                      |
| Audit Process Description | Description of the audit process that was archived/backed up.                                                                                             |
| Comment                   | User added comment.                                                                                                                                       |
| Disk Space                |                                                                                                                                                           |
| From Date                 | Start date of the data that is archived.                                                                                                                  |
| Global ID                 | Unique ID.                                                                                                                                                |
| Guardium version          | Version of managed unit.                                                                                                                                  |
| Run Number                | Audit process results run number.                                                                                                                         |
| Step                      | Entry can archived and purged, or archived not purged. If the archive has a catalog entry location, then also where it's archived stored the credentials. |
| Timestamp                 | Last time table was updated.                                                                                                                              |
| To Date                   | End date of the data that is archived.                                                                                                                    |
| Type                      | Data or audit process result can also be a system backup.                                                                                                 |

## Location Entity

How to determine what days are not archived

catalog entry

Use a query (Tools tab > Report Building > Report Builder > query Location View) that can be modified to create a report showing the files that are archived. This report lists all the files with archive dates. Dates not on this report indicate that those dates have not been archived. Run archive for the dates not on the list, if required.

| Attribute | Description                               |
|-----------|-------------------------------------------|
| Host      | Host name where backup/archive is stored. |
| Path      | Path to backup/archive files.             |
| Retention |                                           |
| User Name | User that has access to this location.    |

## Used By entity

| Attribute     | Description |
|---------------|-------------|
| Mount Event   |             |
| Mount Time    |             |
| Request Count |             |
| Used By       |             |

## Destination entity

| Attribute   | Description                                                            |
|-------------|------------------------------------------------------------------------|
| Class ID    | The system name. Can also be a storage system, ESM, Amazon, and so on. |
| System Type | related                                                                |

## Classification Process Results domain

Reports on classifier process runs and results. This topic describes the domain's entities and attributes.

Available to roles: all

## Classification Process Run Entity

This entity describes a classification process job execution.

| Attribute           | Description                                                              |
|---------------------|--------------------------------------------------------------------------|
| Process Description | From the process definition.                                             |
| Status              | Job status.                                                              |
| Queue DateTime      | Timestamp when the job was submitted to the classifier/assessment queue. |
| Start DateTime      | Timestamp at start of job.                                               |
| End DateTime        | Timestamp at end of job.                                                 |
| Data Sources        | Timestamp at end of job.                                                 |

## Classification Process Results Entity

This entity is created for each classification process rule that is fired.

| Attribute | Description                       |
|-----------|-----------------------------------|
| Catalog   | Catalog location for results set. |

| Attribute               | Description                                 |
|-------------------------|---------------------------------------------|
| Schema                  | Schema name if applicable.                  |
| Table Name              | Table name from the rule definition.        |
| Column Name             | Column name from the rule definition.       |
| Rule Description        | The classifier policy rule description.     |
| Comments                | Any comments added to this rule definition. |
| Classification Name     | Classification for the rule.                |
| Category                | Category for the rule.                      |
| Data Source Description | Data source for the rule.                   |

## CM Buffer Usage Monitor domain

Shows the aggregate of all Sniffer Buffer Usage Entities that have been uploaded to the central manager. This topic describes the domain's entities and attributes.

### CM Buffer Usage Monitor entity

| Attribute                      | Description                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------|
| Sniffer Buffer Usage ID        | Unique ID.                                                                                                  |
| Timestamp                      | Time the record was created.                                                                                |
| Sniffer CPU PCT                | Percentage of CPU used by sniffer.                                                                          |
| Sniffer Mem PCT                | Percentage of memory used by sniffer.                                                                       |
| MySQL CPU PCT                  | Percentage of CPU used by MySQL.                                                                            |
| MySQL MEM PCT                  | Percentage of memory used by MySQL.                                                                         |
| PID                            | Sniffer process identifier.                                                                                 |
| Memory                         | Amount of memory used by sniffer.                                                                           |
| Time                           | Elapsed time used by sniffer.                                                                               |
| Free Buffer                    | Amount of free buffer space.                                                                                |
| Analyzer Rate                  | Rate at which messages being analyzed.                                                                      |
| Analyzer Queue                 | Size of the analyze queue.                                                                                  |
| Analyzer Total                 | Total number of messages analyzed.                                                                          |
| Logger Queue                   | Size of logger queue.                                                                                       |
| Logger Total                   | Total number of message logged.                                                                             |
| Session Queue                  | Size of session queue.                                                                                      |
| Session Total                  | Total number of sessions.                                                                                   |
| Handler Data                   | Internal sniffing engine data.                                                                              |
| Extra STR                      | Internal sniffing engine data.                                                                              |
| Sniffer Connections Used       | Total number of connections currently being monitored since inspection engine was restarted.                |
| Sniffer Packets Dropped        | Packets dropped by sniffer.                                                                                 |
| Sniffer Packets Ignored        | Packets ignored by sniffer.                                                                                 |
| Sniffer Packets Throttled      | Total number of connections that have been ignored due to throttling since inspection engine was restarted. |
| Sniffer Connections Ended      | Total number of connections that were monitored and have ended since inspection engine was restarted.       |
| Logger Session Count           | Count of sessions logged.                                                                                   |
| Logger Packets Ignored by Rule | Packets ignored by policy rule action.                                                                      |
| Analyzer Lost Packets          | Packets lost by analyzer.                                                                                   |
| Logger Dbs Monitored           | List of database types currently being monitored.                                                           |
| Mysql Is Up                    | Boolean indicator for internal database restart (1=was restarted, 0=not restarted).                         |
| System Cpu Load                | System CPU utilization.                                                                                     |
| System Uptime                  | Time since last start-up.                                                                                   |
| Mysql Disk Usage               | MySQL disk usage.                                                                                           |
| System Memory Usage            | System memory utilization.                                                                                  |
| System Var Disk Usage          | System var disk utilization.                                                                                |
| System Root Disk Usage         | System Root disk utilization.                                                                               |
| Eth0 Received                  | Messages received on the primary interface.                                                                 |
| Eth0 Sent                      | Messages sent on the primary interface.                                                                     |
| Promiscuous Received           | Rate of received packets through the sniffing network cards (non-interface ports).                          |
| Open FDs                       | Open File Descriptors.                                                                                      |
| Open FDs MySQL                 | Database open File Descriptors                                                                              |
| Sessions normal                | Count of normal sessions.                                                                                   |
| Sessions not opened            | Count of sessions not opened by sniffer.                                                                    |
| Sessions timeout               | Count of sessions timed-out.                                                                                |
| Sessions ignored               | Count of sessions ignored by sniffer.                                                                       |
| Session Direct closed          | Count of sessions directly closed .                                                                         |
| Session guessed                | Count of sessions guessed.                                                                                  |
| SqlGuard Timestamp             | The time that the record is inserted into the custom table                                                  |
| Datasource Name                | Name of the data source used to upload the record                                                           |
| Analyzer Queue Drops           | The number of analyzer queue entries dropped by the sniffer.                                                |

| Attribute            | Description                                                  |
|----------------------|--------------------------------------------------------------|
| Priority Queue Drops | The number of priority queue entries dropped by the sniffer. |

## Comments domain

User defined comments for various Guardium components. This topic describes the domain's entities and attributes.

Available to roles: all

### Comments Entity

This entity describes a user comment. It is available in the Comments domain only, which is restricted to admin users. This domain includes only sharable comments, which are all comments except for those that run locally (see [Local Comments Entity](#)).

| Attribute           | Description                                                                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Comment Creator     | The Guardium® user who created the comment.                                                                                                         |
| Comment Reference   | Indicates the element to which the comment is attached - a query, audit process result, or another comment, for example.                            |
| Content of Comment  | The complete comment text.                                                                                                                          |
| Timestamp           | Date and time the comment was created.                                                                                                              |
| Timestamp Year      | Year only from the timestamp.                                                                                                                       |
| Timestamp WeekDay   | Weekday only from the timestamp.                                                                                                                    |
| Timestamp Time      | Time only from the timestamp.                                                                                                                       |
| Timestamp Date      | Date only from the timestamp.                                                                                                                       |
| Object Description  | The name of the object from which the comment was defined. For example, a comment defined on a policy has an object description of ACCESS_RULE_SET. |
| Record Associations | A list of records that this comment is associated with.                                                                                             |

### Local Comments Entity

This entity describes a local comment. It is available in the Comments domain only, which is restricted to admin users. This entity includes only local comments, for processes and results sets that run locally. Comments that are sharable are defined in the Comments entity.

| Attribute           | Description                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Comment Creator     | The Guardium user who created the comment.                                                                                                      |
| Comment Reference   | Indicates the element to which the comment is attached - a query, audit process result, or another comment, for example.                        |
| Content of Comment  | The complete comment text.                                                                                                                      |
| Timestamp           | Date and time the comment was created.                                                                                                          |
| Timestamp Year      | Year only from the timestamp.                                                                                                                   |
| Timestamp WeekDay   | Weekday only from the timestamp.                                                                                                                |
| Timestamp Time      | Time only from the timestamp.                                                                                                                   |
| Timestamp Date      | Date only from the timestamp.                                                                                                                   |
| Object Description  | The name of the object from which the comment was defined. For example, a comment defined on an incident has an object description of INCIDENT. |
| Record Associations | A list of records that this comment is associated with.                                                                                         |

## Custom DB Usage domain

Custom DB statistics. This topic describes the domain's entities and attributes.

Available to roles: admin

### Custom DB Disk Usage Entity

| Attribute                        | Description                                            |
|----------------------------------|--------------------------------------------------------|
| Number of InnoDB Tables          | Number of InnoDB Tables                                |
| Number of MyISAM Tables          | Number of MyISAM Tables                                |
| Number of Tables                 | Number of Tables                                       |
| Timestamp                        | Timestamp when the data on this row is created/updated |
| Total Size of InnoDB Tables (MB) | Total Size of InnoDB Tables in MB                      |
| Total Size of MyISAM Tables (MB) | Total Size of MyISAM Tables in MB                      |

## Custom Table Disk Usage entity

---

| Attribute         | Description             |
|-------------------|-------------------------|
| Custom Table Name | Custom table name       |
| Table Size (MB)   | Size of the table in MB |
| Table Type        | Table type              |

---

## DB Default Users Enabled domain

Details on whether default users are enabled. This topic describes the domain's entities and attributes.

Available to roles: admin

Non-credential Scan: A process to scan a list of databases and check whether default users are enabled. The default users as well as the list of servers to scan are provided as parameters to the API. A default group is provided for each database type with the default users and passwords created by the database on every installation, customers can add/remove from that list. The groups are of type DB User/DB Password and the names of the default groups are:

ORACLE Default Users; DB2 Default Users; SYBASE Default Users; MS SQL SERVER Default Users; INFORMIX Default Users; MYSQL Default Users; TERADATA Default Users; IBM ISERIES Default Users; POSTGRESQL Default Users; NETEZZA Default Users

## DB Default Users Enabled Entity

---

| Attribute     | Description                  |
|---------------|------------------------------|
| DB Type       | Database type                |
| DB Version    | Database version             |
| Host Name     | Host name of this database   |
| Instance Name | Database instance name       |

## Discovered Instances domain

Instances that have been discovered by GIM. This topic describes the domain's entities and attributes.

Available to roles: all

## Discovered Instances Entity

---

This entity identifies discovered instances.

| Attribute                      | Description                                                                                                           |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Timestamp                      | A timestamp value created when Guardium® records this instance of the entity (every instance has a unique timestamp). |
| Host                           | Host name for this instance                                                                                           |
| Protocol                       | Protocol specific to this instance                                                                                    |
| Port Min                       | Port range, minimum port number for inspection-engines                                                                |
| Port Max                       | Port range, maximum port number for inspection-engines                                                                |
| Client IP                      | IP address/mask of client                                                                                             |
| Exclude Client IP              | IP address/mask of clients to exclude                                                                                 |
| Proc Names                     | Name of database executable                                                                                           |
| Named Pipe                     | Pipe name used by database                                                                                            |
| KTAP DB Port                   | Database port for KTAP                                                                                                |
| DB Install Dir                 | Database Install Directory                                                                                            |
| Proc Name                      | Process name                                                                                                          |
| DB2 Shared Mem Adjustment      | Packet header size                                                                                                    |
| DB2 Shared Mem Client Position | Client I/O area offset                                                                                                |
| DB2 Shared Mem Size            | DB2 shared memory segment size                                                                                        |
| Instance Name                  | Name of the discovered instance                                                                                       |
| Informix Version               | Major version of the database version                                                                                 |
| Unix Socket                    | UNIX socket                                                                                                           |
| DB User                        | The name of the database user                                                                                         |
| DB Version                     | The database version                                                                                                  |

---

## Distributed Datamart domain

Data on distributed data marts. This topic describes the domain's entities and attributes.

## Distributed Datamart status Entity

| Attribute                       | Description                                                                   |
|---------------------------------|-------------------------------------------------------------------------------|
| Datamart ID                     | Distributed Datamart unique ID.                                               |
| Datamart Name                   | Distributed Datamart name.                                                    |
| Details                         | Distributed Datamart execution details.                                       |
| End Time                        | The time when the distributed datamart finished collecting data on this unit. |
| Hostname                        | Host name of unit from which the distributed datamart collected data from.    |
| Query ID                        | ID of the query based on which the distributed datamart is defined.           |
| Report ID                       | ID of the report based on which the distributed datamart is defined.          |
| Report Title                    | Title of the report based on which the distributed datamart is defined.       |
| Run ID                          | Distributed datamart execution unique ID.                                     |
| Send to Secondary Target Status | Status of data consolidation on the second target.                            |
| Start Time                      | The time when the distributed datamart started to collect data on this unit.  |
| Status                          | Status of data collection on the primary target.                              |
| Status Id                       | Distributed datamart status unique ID.                                        |
| Timestamp                       | Timestamp of distributed datamart status change.                              |
| User Id                         | User that owns the distributed datamart.                                      |

## Eagle Eye domain

Data on the Threat Detection Analytics. This topic describes the domain's entities and attributes.

Available to roles: admin.

### Case entity

| Attribute       | Description                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------|
| Seen From       | First recorded symptom for this suspected attack.                                            |
| Case End        | Last recorded symptom for this suspected attack.                                             |
| Case ID         | Unique identifier for the suspected attack.                                                  |
| Case Type Id    | Attack type, for example: SP (malicious STP), SQLI (SQL injection).                          |
| Confidence(%)   | Certainty that this is an attack and not legitimate activity                                 |
| Creation Time   | Time of the first recorded symptom for this suspected attack.                                |
| DB Type         | Type of DB that is the target of the suspected attack.                                       |
| DB User Name    | DB Name that was used to perform the suspicious activity.                                    |
| Risk            | Risk that the suspected attack can compromise sensitive data: 1 (low), 2 (medium), 3 (high). |
| STP Id          | In case of malicious SP, the unique identifier of the stored procedure.                      |
| Server IP       | IP address that is the target of the suspected attack.                                       |
| Service Name    | Service Name that is the target of the suspected attack.                                     |
| Source Program  | Source program that is the target of the suspected attack.                                   |
| TimeStamp       | Creation time of this record.                                                                |
| Additional Info | Additional details about the suspected attack.                                               |

### Case Type entity

Metadata table of threat detection cases.

| Attribute      | Description                              |
|----------------|------------------------------------------|
| Case Type Id   | Attack ID.                               |
| Case Type Name | Attack name.                             |
| Description    | General information about the case type. |
| Timestamp      | Timestamp of this record.                |

### Case Symptom Link entity

Link table.

| Attribute  | Description |
|------------|-------------|
| Case Id    | Case ID.    |
| Symptom Id | Symptom ID. |

### Case Symptom entity

| Attribute | Description |
|-----------|-------------|
|           |             |

| Attribute       | Description                                                             |
|-----------------|-------------------------------------------------------------------------|
| Construct Id    | The related SQL construct ID.                                           |
| Count           | Number of occurrences of this symptom.                                  |
| Description     | Symptom description.                                                    |
| Details         | Additional details.                                                     |
| Error           | The suspected SQL error that generated the symptom.                     |
| Original SQL    | The suspected SQL statement that generated the symptom.                 |
| STP Id          | In case of malicious SP, the unique identifier of the stored procedure. |
| Seen From       | Time this symptom was first recorded.                                   |
| Severity        | Assigned score, used when calculating the risk.                         |
| Symptom End     | Time this symptom was last recorded.                                    |
| Symptom Id      | Unique identifier for this symptom.                                     |
| Symptom Type Id | Unique identifier for this symptom type.                                |
| TimeStamp       | Timestamp of this record.                                               |
| Additional Info |                                                                         |

## Symptom Type entity

Metadata table, except for "Is Active"

| Attribute                  | Description                                     |
|----------------------------|-------------------------------------------------|
| Description                | Text description.                               |
| Is Active                  | Whether or not Guardium scans for this symptom. |
| Symptom Description Prefix | Symptom Description Prefix.                     |
| Symptom Group              | Symptom Group                                   |
| Symptom Name               | Text name of symptom.                           |
| Symptom type Id            | Unique identifier for symptom type.             |
| TimeStamp                  | Timestamp of this record.                       |

## Exceptions domain

This domain contains traffic details: all of the exceptions and exception-related data. These are SQL exceptions sent from a database server and collected by inspection engines, as well as exceptions generated by Guardium itself. This topic describes the domain's entities and attributes.

Available to roles: all

## Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                    |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                               |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                               |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP. |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                              |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                        |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client OS                  | <p>Client operating system.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p>                                                                                                                                         |
| DB Protocol                | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB Protocol Version        | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DB User Name               | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Last Used                  | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Network Protocol           | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| OS User                    | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Description         | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server Host Name           | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP                  | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server IP/DB user          | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server IP/Svc Name/DB User | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server OS                  | <p>Server operating system.</p> <p>For Informix, the OS may appear as follows:</p> <p>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type                | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name               | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                                         |
| Source Program             | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Client/ Server by session  | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp                  | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date             | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Time             | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Weekday          | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Year             | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute       | Description                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID       | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                   |
| Client Port     | Client port number.                                                                                                                                                                                                                            |
| Database Name   | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view. |
| Duration (secs) | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                       |
| Global ID       | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                         |
| Ignored Since   | Timestamp created when starting to ignore this session.                                                                                                                                                                                        |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inactive Flag         | <ul style="list-style-type: none"> <li>-1: Session closed by timeout.</li> <li>0 (default): Open for sessions generated by SQL package.</li> <li>1: Closed (disconnect/ logout received).</li> <li>2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                                  |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End.                 |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <b>su</b> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                   |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Client/Server Session Entity

| Attribute                                                     | Description                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> . |
| Server IP/Server Port                                         | Server IP/Server Port                                                                               |

## Exception Type Entity

There is a fixed set of exception types, one of which is associated with each exception logged. These are available for reporting only from the owning Exception Entity.

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

| <b>Attribute</b>      | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Exception Description | <p>A text description of the exception type, from the following list. Most of these should never be seen.</p> <p>A new construct was used</p> <p>Alert Process threw an exception</p> <p>Custom Alerting Processing Exception</p> <p>Database Server returned an error</p> <p>For this message, a database error code will be stored in the Exception Description attribute of the Exception entity, and a text version of the database error message will be available in the Database Error Text attribute of the Database Error Text entity.</p> <p>DB Protocol Exception</p> <p>Debug prints through the EXCEPTIONs mechanism</p> <p>Dropped database requests</p> <p>Session information was dropped due to excess traffic.</p> <p>Error During Configuration Auditing System Process</p> <p>Error During Classification Process</p> <p>Invalid Query Invocation</p> <p>Login Failed</p> <p>Low-level DB protocol Exception</p> <p>QRW_EXCEPTION</p> <p>Scheduled job threw an exception</p> <p>Security Assessment Exception</p> <p>Security Exception</p> <p>For this message, a custom class exception has been raised when breaching code execution is blocked; such as when users use the Java™ API to define their own alerts or assessments.</p> <p>Session closed prematurely</p> <p>SQL Parser Exception</p> <p>S-TAP Connectivity reconnect</p> <p>For this message, the IP address or DNS name of the database server will be available in the Exception Description attribute of the Exception entity</p> <p>S-TAP Connectivity timeout</p> <p>For this message, the IP address or DNS name of the database server will be available in the Exception Description attribute of the Exception entity</p> <p>TCP ERROR</p> <p>For this message, additional information about the error will be included in the Exception Description attribute of the Exception entity</p> <p>Turbine class threw an exception</p> <p>Unable to purge report</p> |

## Exception Entity

This entity is created for each exception encountered.

| <b>Attribute</b>    | <b>Description</b>                   |
|---------------------|--------------------------------------|
| App User Name       | Application user name.               |
| Collector Id        |                                      |
| DB2 i Current User  |                                      |
| DB2 i/z Database    |                                      |
| DB2 i/z Program     |                                      |
| Database Protocol   |                                      |
| Destination Address | Destination IP address.              |
| Destination Port    | Destination port number.             |
| Database Protocol   | Database protocol for the exception. |
| Event Microsec      |                                      |
| Exception Date      | Date only from the timestamp.        |

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Exception Description                        | Description of the exception.<br>For an S-TAP reconnect or timeout exception, this field contains the IP address or DNS name of the database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                              | For a database exception, this is an error code from the database management system. For most common messages (about 54,000 of them), a longer text description is available in the Database Error Text attribute. That text comes from the internal Guardium® database table of error messages, not from the exception itself.                                                                                                                                                                                                                                                                          |
|                                              | For Db2 z/OS systems, this field returns the Event ID return code if a negative SQL code is not available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Exception ID                                 | Uniquely identifies the exception. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Exception Time                               | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Exception Timestamp                          | The time on the DB Server (if the exception is from monitored traffic, for example, an SQL exception on the database) or Collector (if the exception is related to the collector for example, a parser error).                                                                                                                                                                                                                                                                                                                                                                                           |
| Exception Type ID                            | Uniquely identifies the exception type. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Exception Weekday                            | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Exception Year                               | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Global Id                                    | Global identifier for the exception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Link to more information about the exception | Optional link that is sometimes available, depending on the exception source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Original Timezone                            | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| SQL string that caused the Exception         | The SQL string that caused the exception.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| User Name                                    | Database user name. On encrypted traffic, where correlation is required, this value may not be available, but it is always available from the DB User Name attribute in the Client/Server entity.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Database Error Text Entity

The text of each common database error message is stored in a table in the Guardium internal database. It is available for reporting only from the owning Exception Entity for each exception that is a database error. Some types of exceptions, for example S-TAP disconnects or reconnects, do not have a database error text.

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Database Error Text | A database error code followed by a short text description of the error. The error code is taken from the Exception Description attribute of the Exception entity. Using the error code as a key, the error text is obtained from an internal table on the Guardium appliance, which contains the most common error messages (about 54,000 of them).<br>For example: ORA-00942: table or view does not exist |
| Error Code          | Displays the database error code.                                                                                                                                                                                                                                                                                                                                                                            |

## FAM domain

This domain describes file entitlement (privileges) reports. This topic describes the domain's entities and attributes.

Available to roles: admin, fam.

## FAM File Entity

| Attribute          | Description                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Classification     | Classification from the FAM classification.                                                                                                               |
| Content Type       | Content Type                                                                                                                                              |
| Creation Time      | Creation Time                                                                                                                                             |
| Delete Groups      | Groups that have delete permission on the file.                                                                                                           |
| Delete Users       | Users that have delete permission on the file.                                                                                                            |
| Effective End Time |                                                                                                                                                           |
| Execute Groups     | Groups that have execute permission on the file.                                                                                                          |
| Execute Users      | Users that have execute permission on the file.                                                                                                           |
| File Full Name     | File Full Name                                                                                                                                            |
| File ID            | A unique field added by the sniffer.                                                                                                                      |
| File Id            | Created by the FAM crawler. This is a non-unique combination of server IP and file path. It's used to identify a specific file and to update its details. |

| <b>Attribute</b>      | <b>Description</b>                             |
|-----------------------|------------------------------------------------|

| Scan Id           |                                                        |
| Timestamp         | Time the file was discovered and recorded in Guardium. |

## FAM groups domain

FAM groups are used in cases where file privileges are given to user groups that are under users domain. This domain has entities for mapping from users to groups. Only local groups are supported. This topic describes the domain's entities and attributes.

## FAM Event Group Entity

| <b>Attribute</b> | <b>Description</b>                                                                                                          |
|------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Event ID         | Event ID if set from the API. These attributes appear only when the main entity for the query permits this level of detail. |
| Timestamp        | Timestamp of the event                                                                                                      |

## FAM System domain

The FAM system domain describes FAM configurations. This topic describes the domain's entities and attributes.

### FAM Status Entity

| Attribute                     | Description                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Classification Decision Plans | The Classification categories and rules. For example: HIPAA{HIPAA_match,CreditCard,Name};PCI{PCI_match}                  |
| Classification Thread Count   | System parameter for ICM                                                                                                 |
| Crawler Max Depth             | The Discovery and Classification Directory depth of scanning.                                                            |
| Excluded Directories Paths    | The list of directories to exclude from the Discovery and Classification process.                                        |
| Excluded Files Paths          | The list of files to exclude from the Discovery and Classification process.                                              |
| Files Crawler Host            | The file server host name.                                                                                               |
| Files Crawler IP              | The file server ip.                                                                                                      |
| ICM URL                       | System parameter. Classification runs on local server. Usually: http://localhost:18087                                   |
| Is Content Discovery Active   | True - Enable classification on files based on their content.<br>False – Metadata and access permission extraction only. |
| Is Crawler Active             | 0: FAM Discovery agent is disabled.<br>1: FAM Discovery agent is enabled.<br>2: FAM Discovery agent is restarted.        |
| Scheduler Hour Interval       | Interval between scans in hours.                                                                                         |
| Scheduler Is Repeat           | True: scan repeats<br>False: scan does not repeat.                                                                       |
| Scheduler Minute Interval     | Interval between scans in minutes.                                                                                       |
| Scheduler Start Time          | Activation time for scanning.                                                                                            |
| Server IP                     | The Guardium server IP                                                                                                   |
| Source Directories Paths      | Directory paths on which to run scan. For example: /home/ab                                                              |
| Status ID                     | Internal ID                                                                                                              |
| Timestamp                     | Time the scan started.                                                                                                   |

## File Activity Monitor domain

This domain contains file entitlement and classification entities. This topic describes the domain's entities and attributes.

### Scan Entity

| Attribute             | Description                             |
|-----------------------|-----------------------------------------|
| Host IP               | Fileserver host IP.                     |
| Host Name             | Fileserver host name.                   |
| OS                    | Operating system.                       |
| Scan Time             | The scan start time.                    |
| Source Directory ID   | Source directory ID.                    |
| Source Directory Path | Source directory path.                  |
| Timestamp             | Time the data was uploaded to Guardium. |

### Directory entity

| Attribute      | Description                                                   |
|----------------|---------------------------------------------------------------|
| Creation Time  | Directory creation time.                                      |
| Delete Groups  | List of groups that have Delete permission on this directory. |
| Delete Users   | List of users that have Delete permission on this directory   |
| Directory      | Not in use.                                                   |
| Directory ID   | Directory ID                                                  |
| Directory Name | Directory name                                                |
| Directory Path | Directory path                                                |

| Attribute                | Description                                                            |
|--------------------------|------------------------------------------------------------------------|
| Display Size             | The directory Size on the UI.                                          |
| Effective End Time       | Internal parameter                                                     |
| Execute Groups           | List of groups that have Execute permission on this directory          |
| Item Permissions         | Not in use.                                                            |
| Item Type                | Not in use.                                                            |
| Modification Time        | The directory modification time.                                       |
| Owner                    | The directory owner.                                                   |
| Parent Directory ID      | Parent directory ID.                                                   |
| Read Groups              | List of groups that have Read permission on this directory.            |
| Read Users               | List of groups that have Execute permission on this directory.         |
| Scan Time                | The time that the scan started on this directory.                      |
| Size                     | Directory size.                                                        |
| Timestamp                | The time of uploading the directory details to the Guardium appliance. |
| Write Groups Write Users | List of users and groups that have Write permission on this Directory  |
| is Removed               | Whether or not this directory was deleted from the last scan.          |

## File Entity

---

| Attribute          | Description                                                       |
|--------------------|-------------------------------------------------------------------|
| Classification     | The Classification category and entities found.                   |
| Content type       | The file content type.                                            |
| creation Time      | The file creation time.                                           |
| Delete Groups      | List of groups that have Delete permission on this Directory.     |
| Delete Users       | List of users that have Delete permission on this Directory.      |
| Directory ID       | Directory ID.                                                     |
| Directory Path     | The file directory Path.                                          |
| Display Size       | The directory size on the UI.                                     |
| Effective End Time | Internal parameters                                               |
| Execute Groups     | List of groups that have Execute permission on this directory.    |
| Execute Users      | List of users that have Execute permission on this directory.     |
| FAM File Id        | File ID.                                                          |
| File Full Name     | File full name (full path and filename)                           |
| File Id            | File ID.                                                          |
| File Name          | File name.                                                        |
| Is Removed         | Was this file deleted in from last scan?                          |
| Is Symbolic        | Whether or not this is a symbolic link.                           |
| Item Permissions   | Not in use.                                                       |
| Item Type          | Not in use.                                                       |
| Modification Time  | The file modification time.                                       |
| Owner              | The file owner                                                    |
| Read Groups        | List of groups that have Read permission on this directory.       |
| Read Users         | List of users that have Read permission on this directory.        |
| Scan Time          | Time the file was scanned.                                        |
| Size               | File size.                                                        |
| Timestamp          | Time of the file details were uploaded to the Guardium appliance. |
| Write Groups       | List of groups that have Write permission on this directory.      |
| Write Users        | List of users that have Write permission on this directory.       |

## Classification Entity

---

| Attribute | Description                                                   |
|-----------|---------------------------------------------------------------|
| Category  | The Classification category                                   |
| Entities  | The rules of the classification category                      |
| File Id   | The file ID                                                   |
| Timestamp | The time the classification was added to the Guardium system. |

## Flat Log domain

---

Flat log processing activity. This topic describes the domain's entities and attributes.

Available to roles: all

## Client/Server Entity

---

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP.                                                                                                                                                                                                                                                                                                                                            |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Client OS                                    | Client operating system.<br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format                                                                                                                                         |
| DB Protocol                                  | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DB Protocol Version                          | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DB User Name                                 | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Last Used                                    | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Network Protocol                             | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| OS User                                      | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server Description                           | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server Host Name                             | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Server IP                                    | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Server IP/DB user                            | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP/Svc Name/DB User                   | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Server OS                                    | Server operating system.<br>For Informix, the OS may appear as follows:<br><br>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha<br><br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format |
| Server Type                                  | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Service Name                                 | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                      |
| Source Program                               | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Client/ Server by session                    | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Attribute         | Description                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp         | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance. |
| Timestamp Date    | Date only from the timestamp.                                                                                                                                                                                                                                                             |
| Timestamp Time    | Time only from the timestamp.                                                                                                                                                                                                                                                             |
| Timestamp Weekday | Weekday only from the timestamp.                                                                                                                                                                                                                                                          |
| Timestamp Year    | Year only from the timestamp.                                                                                                                                                                                                                                                             |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID             | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Client Port           | Client port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Database Name         | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                                                                                                                                                                                                                           |
| Duration (secs)       | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Global ID             | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ignored Since         | Timestamp created when starting to ignore this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Inactive Flag         | <ul style="list-style-type: none"> <li>• -1: Session closed by timeout.</li> <li>• 0 (default): Open for sessions generated by SQL package.</li> <li>• 1: Closed (disconnect/ logout received).</li> <li>• 2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>• 3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                        |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End.                 |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Attribute            | Description                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Uid Chain            | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> . |
| Uid Chain Compressed | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                           |

## Flat Log Entity

This entity describes flat log processing activity.

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Full SQL              | The full SQL logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | Date and time stamp when logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Timestamp Date        | Date portion of the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Time        | Time portion of the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Response Time         | Response time for the request in milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Records Affected      | The number of records affected by the request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Succeeded             | Indicates if request was successful (True/False).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Statement Type        | <p>The type of SQL statement</p> <p>SQL: simple, direct SQL command, for example, typed directly into the CLI</p> <p>RAW: PREPARE of a SQL statement for later execution, for example, conn.prepareStatement (select a from b where c=:value)</p> <p>BIND: execution of a prepared statement including bound parameter values</p> <p>Statement type is part of the FULL SQL entity and is audited only if you have configured Log Full Details for this statement within the policy.</p> <p>You can not filter out specific statement types in the policy, for example, audit-only SQL and BIND statements. You can, however, filter these out in reports.</p> |
| Returned Data         | Data returned (if any)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Bind Info             | Bind information for the request                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Bind Variables Values | For DB2/zOS, contains a list of comma separated bind variable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Original Timezone     | <p>The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.</p> <p>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).</p>                                            |

## GIM Clients domain

This topic describes the domain's entities and attributes.

Available to roles: admin.

### GIM Clients entity

| Attribute                    | Description                                                               |
|------------------------------|---------------------------------------------------------------------------|
| GIM Client IP                | Client IP address                                                         |
| GIM Client Name              | Client hostname                                                           |
| GIM Client OS                | Client Operating System (for example, Linux)                              |
| GIM Client OS Vendor         | Operating System Vendor (for example, Redhat)                             |
| GIM Client OS Vendor Version | Operating system kernel version (for example, 2.6.32-642.13.1.el6.x86_64) |
| GIM Client State Timestamp   | Time GIM client was created                                               |

### GIM Clients Modules State entity

| Attribute          | Description                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------|
| Connected To       | The appliance this module is connected to.                                                   |
| GIM Module Name    | Module name (for example, 'GIM')                                                             |
| GIM Module State   | Module state (for example, 'INSTALLED', 'FAILED')                                            |
| GIM Module Version | module's Guardium version                                                                    |
| Is Scheduled       | Is module scheduled for an installation/upgrade/uninstall. 0 – not scheduled, 1 - scheduled. |

### GIM Modules Heartbeats entity

| Attribute     | Description                      |
|---------------|----------------------------------|
| GIM Client Id | Client primary key (GIM_CLIENTS) |

| Attribute       | Description                      |
|-----------------|----------------------------------|
| GIM Module Id   | Module primary key (GIM_MODULES) |
| GIM Module Name | Module name                      |
| Last Update     | Last alive time (millisecs)      |
| State           | Modules state (UP/DOWN)          |

## GIM Events domain

Available to roles: all

### GIM Events Entity

This entity describes events that have occurred while using the Guardium Installation Manager (GIM).

| Attribute         | Description                                                                 |
|-------------------|-----------------------------------------------------------------------------|
| Event Generator   | IP address of the client (for example, DB-Server) that generated the event. |
| Event Description | Event Description.                                                          |
| Event Time        | The time when the event occurred.                                           |

## Group domain

Membership in Guardium groups. This topic describes the domain's entities and attributes.

Available to roles: all

### Group Type Entity

This entity describes a type of Guardium group (user, client IP address, command, etc.).

| Attribute  | Description                               |
|------------|-------------------------------------------|
| Group Type | Identifies the group type.                |
| Timestamp  | Date and time the group type was created. |

### Group Entity

This entity describes a group that has been defined to Guardium.

| Attribute         | Description                                 |
|-------------------|---------------------------------------------|
| Group Description | The name of the group.                      |
| Group Subtype     | Subtype, if any, defined for the group.     |
| Timestamp         | Date and time the group entity was created. |

### Group Member Entity

This entity describes a member of a group that has been defined to Guardium.

| Attribute         | Description                                            |
|-------------------|--------------------------------------------------------|
| Group Member      | The name of the group member.                          |
| Timestamp         | Date and time the group member was created or updated. |
| Timestamp Date    | Date only from the timestamp.                          |
| Timestamp Time    | Time only from the timestamp.                          |
| Timestamp Year    | Year only from the timestamp.                          |
| Timestamp Weekday | Weekday only from the timestamp.                       |

## Guard Process Log domain

Logs of processes running on Guardium. This topic describes the domain's entities and attributes.

Available to roles: admin.

### Guard Process Log Entity

| Attribute   | Description                 |
|-------------|-----------------------------|
| Comment     | Comment entered by user.    |
| Log Message | Message logged by Guardium. |

| Attribute    | Description                           |
|--------------|---------------------------------------|
| Process Name | Process name                          |
| Status       | Status                                |
| TIMESTAMP    | Date and time of the comment/message. |

## Guardium Activity domain

All modifications performed by Guardium users to any Guardium entity, such as a report or query definition or modification. This topic describes the domain's entities and attributes.

Available to roles: admin

### Guardium Activity Types

This entity describes the various user activities

| Attribute                 | Description                            |
|---------------------------|----------------------------------------|
| Activity Type Description | Description of the activity            |
| Activity Type ID          | Uniquely identifies the activity type. |

## Guardium User Activity Audit Entity

This entity is created for each Guardium user activity.

| Attribute          | Description                                                     |
|--------------------|-----------------------------------------------------------------|
| Login ID           | ID used for login.                                              |
| User Name          | Guardium® user name for the activity.                           |
| Timestamp          | Created when the activity was logged.                           |
| Modified Entity    | The Guardium entity modified (a group definition, for example). |
| Entity Key Used    | Key used to access the entity.                                  |
| Key Value          | New value of the entity.                                        |
| All Values         | All values altered.                                             |
| Object Description | The name of specific object altered.                            |
| Global ID          | A unique global ID for the session.                             |
| Host Name          | Host name of the user.                                          |

## Guardium Jobs Queue domain

This topic describes the domain's entities and attributes.

Available to roles: admin.

### Guardium jobs queue entity

| Attribute                | Description                             |
|--------------------------|-----------------------------------------|
| End Time                 | Date and time the job completed.        |
| Guardium Job Description | Guardium Job Description                |
| Process Id               | Unique ID                               |
| Process Run Id           | Job run ID                              |
| Process Type             | Process Type                            |
| Queue Time               | Date and time the job entered the queue |
| Report Result ID         |                                         |
| Start Time               | Date and time the job started.          |
| Status                   | Job status                              |
| Task Description         | Scheduled,                              |
| Timestamp                |                                         |
| CLS_LOG_TYPE_DESC        |                                         |
| DETAILS                  |                                         |
| MESSAGE                  |                                         |

## Guardium classification log

| Attribute                | Description |
|--------------------------|-------------|
| Datasources              |             |
| End Time                 |             |
| Guardium JOB Description |             |

| Attribute         | Description |
|-------------------|-------------|

## Guardium Login domain

All Guardium user login and logout information. This topic describes the domain's entities and attributes.

Available to roles: admin

### Guardium Users Login Entity

This entity is created each time a user logs in to the Guardium appliance.

| Attribute            | Description                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------|
| Login ID             | ID used for login.                                                                              |
| User Name            | Created when the Guardium® user logs in or out (there will be one entity per Guardium session). |
| Login Date And Time  | Date and time user logged in.                                                                   |
| Logout Date And Time | Date and time user logged out.                                                                  |
| Login Succeeded      | Indicates if login was successful.                                                              |
| Global Id            | A unique global ID for the session.                                                             |
| Host Name            | Host name of the user.                                                                          |
| Remote Address       | Remote address of the user.                                                                     |

## IMS Event domain

This topic describes the domain's entities and attributes.

Available to roles: all.

### Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                    |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                               |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                               |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP. |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                              |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                        |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client OS                  | <p>Client operating system.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p>                                                                                                                                         |
| DB Protocol                | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB Protocol Version        | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DB User Name               | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Last Used                  | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Network Protocol           | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| OS User                    | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Description         | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server Host Name           | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP                  | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server IP/DB user          | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server IP/Svc Name/DB User | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server OS                  | <p>Server operating system.</p> <p>For Informix, the OS may appear as follows:</p> <p>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type                | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name               | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                                         |
| Source Program             | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Client/ Server by session  | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp                  | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date             | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Time             | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Weekday          | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Year             | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute       | Description                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID       | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                   |
| Client Port     | Client port number.                                                                                                                                                                                                                            |
| Database Name   | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view. |
| Duration (secs) | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                       |
| Global ID       | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                         |
| Ignored Since   | Timestamp created when starting to ignore this session.                                                                                                                                                                                        |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inactive Flag         | <ul style="list-style-type: none"> <li>-1: Session closed by timeout.</li> <li>0 (default): Open for sessions generated by SQL package.</li> <li>1: Closed (disconnect/ logout received).</li> <li>2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                                  |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End.                 |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                             |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Access Period Entity

Access Periods are related to Sessions. By default, an access period is one hour long, but this can be changed by the Guardium administrator in the Inspection Engine Configuration (it corresponds to the Logging Granularity).

| Attribute              | Description                                                                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event ID   | The application event ID if set from the API. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                            |
| Avg Execution Ack Time | Average Execution Acknowledged time in milliseconds                                                                                                                                                                                                         |
| Avg Records Affected   | The average number of records affected. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                  |
| Application User       | Can be one of the following attributes: <ul style="list-style-type: none"> <li>The Application User when identified by <a href="#">application user translation</a>.</li> <li>The Application Event Str when identified by the GuardAppUser API.</li> </ul> |

| Attribute                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Average Execution Time        | The average command execution time during the period. This is for SQL statements only. It does not apply to FTP traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Construct ID                  | Uniquely identifies a command construct (for example, select a from b). Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Egress Kbyte count            | Records the number of bytes in responses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Failed Sqls                   | The number of failed SQL requests. See note at the end of the table. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Ingress Kbyte count           | Records the number of bytes in requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Instance ID                   | Uniquely identifies an instance of a construct. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Original Timezone             | <p>The UTC offset.</p> <p>This is to point out that a UTC offset should be set so that the time from two different collectors that are in two different time zones aggregate correctly. If the offset was not set then there would exist a condition where users would not really be able to determine or see a true representation of when things happened in relation to time.</p> <p>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Period End                    | The time on the collector when the period, as defined by the logging granularity on the appliance (default 1 hour), ended.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Period End Date               | Date only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Period End Time               | Time only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Period End Weekday            | Weekday only from the period end attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Period Start                  | The time on the collector when the period, as defined by the logging granularity on the appliance (default 1 hour), started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Period Start Date             | Date only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Period Start Weekday          | Weekday only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Response Length               | The length of the sniffer response for a SQL instance. Not supported for Db2 z/OS systems. For more information, see <a href="#">store log_general_response_length</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session ID                    | Uniquely identifies a session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Show Seconds                  | If a the number of accesses per second is being tracked, this contains counts for each second in the access period (usually one hour).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Successful Sqls               | The number of successful SQL requests. See note at the end of the table. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp                     | <p>The time on the collector when an SQL construct was executed most recently <i>within a session and within a time period</i>. If the same SQL construct is run 10 times within the same session and time period, it shows the time of the most recent run for all 10 SQLs. This timestamp is the most appropriate to use along with the SQL attribute in reports.</p> <p>Note: Universal Connector traffic may be delayed. In those cases the Timestamp is the time of on the Collector for the most recent update to the SQL construct record for the session within a time period. Period start still reflects the time of SQL execution according to the audit data source, not the time of record update.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Total Access                  | Total count of construct instances for this access period. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Total Records Affected        | The total number of records affected. Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Total Records Affected (Desc) | <p>If the Total Records Affected attribute is a character string instead of a number, that value appears here (for example, Large Results Set, or N/A). Appears only when the main entity for the query permits this level of detail. Not available if either Client/Server or Session is the main entity.</p> <p>Records affected - Result set of the number of records which are affected by each execution of SQL statements.</p> <p>Note: The records affected option is a sniffer operation which requires sniffer to process additional response packets and postpone logging of impacted data which increases the buffer size and might potentially have a adverse effect on overall sniffer performance. Significant impact comes from really large responses. To prevent large amount of overhead associated with this operation, Guardium uses a set of default thresholds that allows sniffer to decide to skip processing operation when exceeded.</p> <p>You can use the <b>store max_results_set_size</b>, <b>store max_result_set_packet_size</b>, and <b>store max_tds_response_packets</b> CLI commands to set levels of granularity.</p> <p>Example of result set values:</p> <ul style="list-style-type: none"> <li>• Case 1, record affected value, positive number. This represents correct size of the result set.</li> <li>• Case 2, record affected value, -2. This means number of records exceeded configurable limit (This can be tuned through CLI commands).</li> <li>• Case 3, record affected value, -1. This shows any unsupported cases of packets configurations by Guardium.</li> <li>• Case 4, record affected value, -2. If the result set is sent by streaming mode.</li> <li>• Case 5, record affected value, less than -2. Intermediate result during record count to update user about current value, ends up with positive number of total records. For example, the server returns 1000 records in 4 packets: <ul style="list-style-type: none"> <li>◦ Packet #1 250</li> <li>◦ Packet #2 200</li> <li>◦ Packet #3 250</li> <li>◦ Packet #4 200</li> </ul> </li> </ul> <p>Then records affected are reported as</p> <ul style="list-style-type: none"> <li>◦ Packet #1 -250</li> <li>◦ Packet #2 -500</li> <li>◦ Packet #3 -750</li> <li>◦ Packet #4 1000</li> </ul> |

## SQL Entity

This entity is created for each unique string of SQL. Values are replaced by question marks - only the format of the string is stored.

| Attribute     | Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| Bind Info     | Bind information for this SQL string.                                                                           |
| Construct ID  | Uniquely identifies the construct in which the SQL appeared                                                     |
| Sql           | SQL string.                                                                                                     |
| Truncated SQL | Indicates if the SQL has been truncated or not where:<br>0 - false/no, not truncated<br>1 - true/yes, truncated |

## FULL SQL Entity

Full SQL entities are created only by the following policy rule actions: Log Full Details, Log Full Details With Values, Log Full Details Per Session, or Log Full Details Per Session With Values.

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Rule Description | Description of the policy rule whose action triggered the logging of the Full SQL record.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Ack Response Time       | Acknowledged Response Time in milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Auto-Commit             | Entries are automatically numbered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Bind Variables Values   | For DB2/zOS, a list of comma-separated bind variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Full Sql                | The logged SQL statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Full SQL ID             | Unique identifier for the Full SQL. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Instance ID             | Unique identifier for the Full SQL instance. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Original Timezone       | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br><br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).                         |
| Records Affected        | The number of records affected for each session. On reports using this attribute, we suggest that you turn on aliases to properly display special cases such as Large Result Set or N/A.<br>Records affected only supports find statements for MongoDB, and does not support insert, update, and delete statements.                                                                                                                                                                                                                                                                                                                  |
| Records Affected (Desc) | When the Records Affected is a string value instead of a number, that string is stored here. For example: Large Result Set or N/A.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Response Length         | The length of the sniffer response for a SQL instance. Not supported for Db2 z/OS systems. For more information, see <a href="#">store log_general_response_length</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Response Time           | The response time for the request in milliseconds. When requests are monitored in network traffic, the response times are an accurate reflection of the time taken to respond to the request (Guardium timestamps both the client request and the server response).                                                                                                                                                                                                                                                                                                                                                                  |
| Returned Data           | Data returned for this request (if any, and if available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Returned Data Count     | Number of rows returned from the SQL statement used in the policy rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Statement Type          | The type of SQL statement.<br>SQL: simple, direct SQL command, for example, typed directly into the CLI<br>RAW: PREPARE of a SQL statement for later execution, for example, conn.prepareStatement (select a from b where c=:value)<br>BIND: execution of a prepared statement including bound parameter values<br>Statement type is part of the FULL SQL entity and is only audited if you have configured Log Full Details for this statement within the policy.<br>You can not filter out specific statement types in the policy, for example, audit-only SQL and BIND statements. You can, however, filter these out in reports. |
| Succeeded               | Indicates if the call succeeded. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Timestamp               | The time when the SQL started running in the database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## FULL SQL Values Entity

These entities are created only by the following policy rule actions: Log Full Details With Values, and Log Full Details Per Session With Values.

| Attribute | Description                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Values    | One or more values from the logged construct.                                                                                            |
| Timestamp | The time on the DB server that the SQL was executed. Traffic must be captured with log full details policy action to see this timestamp. |

## IMS application event link entity

| Attribute                            | Description                                    |
|--------------------------------------|------------------------------------------------|
| IMS Application Event Link ID        | Application Event Id.                          |
| IMS Correlation IMSID:Correlation ID | IMS Correlation IMSID field from S-TAP message |

## IMS application event entity

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event ID    | Unique identifier for this application events entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Event Date              | Datetime value, set by GuardAppEvent:Start. It displays in the format yyyy-mm-dd hh:mm:ss.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event Release Date      | Datetime value, set by GuardAppEvent:Released. It displays in the format yyyy-mm-dd hh:mm:ss.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Event Release Type      | Type of event, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Event Release User Name | User name, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event Release Value Num | Numeric value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Event Release Value Str | String value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Event Type              | Type of event, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event User Name         | User name, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Event Value Num         | Numeric value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event Value Str         | String value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Original Timezone       | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Timestamp               | Created only once, when the event is logged. Do not confuse this attribute with the Event Date attribute, which can be set using an API call or from a stored procedure parameter. (See a description of the Application Events API in <a href="#">Identify Users with API</a> .)                                                                                                                                                                                                                                                                                                                        |

## Command Entity

For each command, an entity is created for each parent node and position in which the command appears in a command construct.

| Attribute    | Description                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------|
| Command Id   | Uniquely identifies the command. Only available to users with the admin role.                           |
| Construct Id | Uniquely identifies the construct (e.g., select a from b). Only available to users with the admin role. |
| Depth        | Depth of the command in the SQL parse tree.                                                             |
| Parent       | Identifier of parent node in the parse tree.                                                            |
| SQL Verb     | Main verb in SQL command (e.g., select, insert, delete, etc.).                                          |

## Object Entity

An instance of this entity is created for each object in a unique schema.

| Attribute          | Description                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| App Object Module1 | Uniquely identifies the application object module.                                                                |
| Construct Id       | Uniquely identifies the construct in which the object is referenced. Only available to users with the admin role. |
| Object Id          | Uniquely identifies the object. Only available to users with the admin role.                                      |
| Object Name        | Name of the object.                                                                                               |
| Schema             | Database schema for the object.<br>Note: This attribute is deprecated since it is never populated                 |

## Field Entity

Each time Guardium encounters a new field, it creates a field entity.

| Attribute    | Description                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| Command ID   | Uniquely identifies the main command from the construct in which it was referenced. Only available to users with the admin role. |
| Construct ID | Uniquely identifies the construct in which it was referenced. Only available to users with the admin role.                       |
| Field ID     | Uniquely identifies the field. Only available to users with the admin role.                                                      |
| Field Name   | Name of the field.                                                                                                               |

| Attribute       | Description                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------|
| List Clause     | Use these attributes to order complex SQL queries.                                                                         |
| Where Clause    | Example of SQL queries:                                                                                                    |
| Order by Clause | Order by                                                                                                                   |
| Having Clause   | SELECT * FROM dept_costs                                                                                                   |
| Group By Clause | WHERE dept_total >                                                                                                         |
| On Clause       | (SELECT avg FROM avg_cost)<br>ORDER BY department                                                                          |
|                 | Having                                                                                                                     |
|                 | SELECT column_name1, SUM(column_name2)                                                                                     |
|                 | FROM table_name                                                                                                            |
|                 | GROUP BY column_name1                                                                                                      |
|                 | HAVING (numerical function condition)                                                                                      |
|                 | Group By                                                                                                                   |
|                 | SELECT column_name1, SUM(column_name2)                                                                                     |
|                 | FROM table_name                                                                                                            |
|                 | GROUP BY column_name1                                                                                                      |
|                 | Where                                                                                                                      |
|                 | SELECT FirstName, LastName, City                                                                                           |
|                 | FROM Users                                                                                                                 |
|                 | WHERE City = Los Angeles                                                                                                   |
| Object ID       | Uniquely identifies the object from the construct in which it was referenced. Only available to users with the admin role. |

## Field SQL Value Entity

These entities are created only by policy rule actions that log with values, for example: Log Full Details With Values, and Log Full Details Per Session With Values. The field value logged may or may not be associated with a field name. For example, field names are available (in the Field entity) if the following statement is logged:

```
insert into t1 (foo, bar) (10, 20)
```

But not available when the following statement is logged:

```
insert into t2 (10, 20)
```

| Attribute | Description                              |
|-----------|------------------------------------------|
| Value     | A field value from the logged construct. |

## Installed Patches domain

Reports on installed patches. This topic describes the domain's entities and attributes.

Available to roles: all.

This domain is available in Guardium systems that have a defined datasource of type GBDI.

## Available Patch Entity

| Attribute          | Description                                                                           |
|--------------------|---------------------------------------------------------------------------------------|
| Creation Date      | The patch creation date.                                                              |
| Guardium Version   | Guardium software version                                                             |
| Patch Dependencies | Guardium version or patch, which has to be installed before this patch.               |
| Patch Description  | Patch Description                                                                     |
| Patch Number       | Patch Number                                                                          |
| Upload Date        | The date the patch was uploaded for installation                                      |
| UTC Offset         | The difference in time between UTC time and time of collector that reported that data |

## Installed Patch Entity

| Attribute | Description |
|-----------|-------------|
|           |             |

| Attribute              | Description                                                             |
|------------------------|-------------------------------------------------------------------------|
| Additional information |                                                                         |
| Creation Date          | The patch creation date.                                                |
| Guardium Version       | Guardium software version                                               |
| Installed By           | CM, SA, or CLI                                                          |
| Patch Dependencies     | Guardium version or patch, which has to be installed before this patch. |
| Patch Description      | Patch Description                                                       |
| Patch Number           | Patch Number                                                            |
| Requested Received     | The date/time the patch should be installed                             |
| Requested Schedule     |                                                                         |
| Status                 | 0/1 for success or failure                                              |
| Status Description     | Patch                                                                   |
| Timestamp              | Timestamp the status was updated.                                       |

## Installed Policy domain

Description of policy parameters and rules for the installed policy. The Installed Policy domain supports multiple policies and multiple actions per rule. This topic describes the domain's entities and attributes.

Available to roles: all

### Installed Policy entity

Describes the installed policy.

| Attribute             | Description                                                           |
|-----------------------|-----------------------------------------------------------------------|
| Audit Pattern         | Test pattern used for a selective audit trail policy.                 |
| ID                    | Identifies the policy installation record.                            |
| Policy Description    | Description from the policy definition.                               |
| Rule Set Id           | Identifies the set of rules.                                          |
| Selective Audit Trail | Indicates if this is a selective audit trail policy (T/F).            |
| Sequence              | Sets the order of sequence when there is multiple installed policies. |
| Timestamp             | Timestamp for the creation of the record.                             |

### Installed Rule entity

| Attribute                                                          | Description                                                                              |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| ACCESS_RULE_ID                                                     | Identifies an access rule.                                                               |
| App Event Date Value                                               | From the rule definition.                                                                |
| App Event Exists                                                   | From the rule definition.                                                                |
| App Event Numeric Value                                            |                                                                                          |
| App Event Text / Numeric / Date                                    | The application event's text, numeric, and date attributes.                              |
| App Event Text Value                                               | From the rule definition.                                                                |
| App User                                                           | From the rule definition.                                                                |
| App User / Group                                                   | A single attribute and a related attribute (if any) in a single column of the report.    |
| App User Group                                                     | From the rule definition.                                                                |
| Category / Classification                                          | The combined category and classification for the rule.                                   |
| Category Name                                                      | From the rule definition.                                                                |
| Classification Name                                                | From the rule definition.                                                                |
| Client IP                                                          | From the rule definition.                                                                |
| Client IP / Group                                                  | A single attribute and a related attribute (if any) in a single column of the report.    |
| Client IP Group                                                    | From the rule definition.                                                                |
| Client IP/Src App/DB User/Server IP/Svc Name Group                 |                                                                                          |
| Client IP/Src App/DB User/Server IP/Svc Name/OS User/DB Name Group |                                                                                          |
| Client MAC                                                         | From the rule definition.                                                                |
| Client Net Mask                                                    | From the rule definition.                                                                |
| Command                                                            | From the rule definition.                                                                |
| Command / Group                                                    | A single attribute and a related attribute (if exists) in a single column of the report. |
| Command Group                                                      | From the rule definition.                                                                |
| Continue to next Rule / Revoke                                     | From the rule definition.                                                                |
| DB Name                                                            | From the rule definition.                                                                |
| DB Name / Group                                                    | A single attribute and a related attribute (if exists) in a single column of the report. |
| DB Name Group                                                      | From the rule definition.                                                                |
| DB Type                                                            | From the rule definition.                                                                |
| DB User                                                            | From the rule definition.                                                                |

| Attribute                      | Description                                                                                                                                                                                                                                         |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB User / Group                | A single attribute and a related attribute (if exists) in a single column of the report.                                                                                                                                                            |

## Installed Rule Action entity

| Attribute      | Description                             |
|----------------|-----------------------------------------|
| Access Rule Id | Identifies the Access Rule.             |
| Action         | Block, Log or Alert.                    |
| Sequence       | Sequence of the action within the rule. |
| Template Name  | Template Name.                          |

## Installed Alert Notification entity

| Attribute             | Description                                                                     |
|-----------------------|---------------------------------------------------------------------------------|
| ALERT_ID              | Identifies the alert definition. Only available to users with the admin role.   |
| ALERT_NOTIFICATION_ID | Identifies the alert notification. Only available to users with the admin role. |
| ALERT_TYPE            | Type of alert.                                                                  |

| Attribute               | Description                                      |
|-------------------------|--------------------------------------------------|
| Alert Destination       | For example: EMAIL, SNMP, SYSLOG, CUSTM.         |
| Alert Notification Type | Type of alert from the policy rule definition.   |
| Alert User              | Receiver of the alert.                           |
| Timestamp               | Timestamp at which the alert record was created. |

## Managed units domain

The managed units domain describes the managed units and the managed unit groups in your environment. This topic describes the domain's entities and attributes. This domain cannot be used as custom domain

### Managed Unit Groups Entity

| Attribute           | Description                          |
|---------------------|--------------------------------------|
| Group Name          | The name of the managed units group. |
| Management Group ID | The ID of the managed units group.   |

### Managed Units Entity

| Attribute        | Description                                                                                  |
|------------------|----------------------------------------------------------------------------------------------|
| Host Name        | Host name of the managed unit.                                                               |
| Installed Policy | Policy installed on the managed unit.                                                        |
| Last Patch       | The last patch that was installed on the managed unit.                                       |
| Last Ping        | The last successful ping to the managed unit.                                                |
| Mac Address      | The Mac address of the managed unit.                                                         |
| Model            | The hardware model of the managed unit.                                                      |
| Online           | Whether or not the managed unit is online                                                    |
| Port             | The communication port on the managed unit.                                                  |
| Status           | The last status of the managed unit.                                                         |
| Unit IP          | The IP of the managed unit.                                                                  |
| Unit Type        | The type of the managed unit. The IP mode of the managed unit. Example: IPv4, IPv6, or dual. |
| Version          | The software running on the managed unit.                                                    |

## Parser Errors domain

This topic describes the domain's entities and attributes.

Available to roles: admin.

### Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                    |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                               |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                               |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP. |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                              |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                             |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                        |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Client OS                  | <p>Client operating system.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p>                                                                                                                                         |
| DB Protocol                | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB Protocol Version        | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DB User Name               | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Last Used                  | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Network Protocol           | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| OS User                    | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Server Description         | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server Host Name           | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP                  | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Server IP/DB user          | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server IP/Svc Name/DB User | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server OS                  | <p>Server operating system.</p> <p>For Informix, the OS may appear as follows:</p> <p>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type                | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name               | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                                         |
| Source Program             | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Client/ Server by session  | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp                  | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date             | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Time             | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Timestamp Weekday          | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Year             | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute       | Description                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID       | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                   |
| Client Port     | Client port number.                                                                                                                                                                                                                            |
| Database Name   | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view. |
| Duration (secs) | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                       |
| Global ID       | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                         |
| Ignored Since   | Timestamp created when starting to ignore this session.                                                                                                                                                                                        |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inactive Flag         | <ul style="list-style-type: none"> <li>-1: Session closed by timeout.</li> <li>0 (default): Open for sessions generated by SQL package.</li> <li>1: Closed (disconnect/ logout received).</li> <li>2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                                  |
| Old Session ID        | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone     | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID            | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End.                 |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                             |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Parser Error entity

| Attribute    | Description |
|--------------|-------------|
| Construct Id |             |
| Count        |             |
| DB Protocol  |             |
| Description  |             |
| Error Id     |             |
| Error Type   |             |
| SQL          |             |
| Session Id   |             |
| Timestamp    |             |

## Policy Violations domain

All policy violation data, for all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes.

Available to roles: all

## Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP.                                                                                                                                                                                                                                                                                                                                            |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Client OS                                    | Client operating system.<br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format                                                                                                                                         |

| Last Used                                    | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Network Protocol                             | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| OS User                                      | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Server Description                           | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server Host Name                             | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Server IP                                    | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Server IP/DB user                            | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Server IP/Svc Name/DB User                   | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Server OS                                    | Server operating system.<br>For Informix, the OS may appear as follows:<br><br>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha<br><br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format |
| Server Type                                  | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Attribute                 | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Name              | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value. |
| Source Program            | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                               |
| Client/ Server by session | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                         |
| Timestamp                 | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                             |
| Timestamp Date            | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Time            | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Weekday         | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp Year            | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                         |

## Incident Status Entity

Describes the status of an Incident entity.

| Attribute          | Description                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status Description | One of the following:<br>OPEN - The incident has not yet been assigned to a user.<br><br>ASSIGNED - The incident has been assigned.<br><br>CLOSED - The incident is closed. |

## Incident Severity Entity

The incident severity description for an incident.

| Attribute                     | Description                                     |
|-------------------------------|-------------------------------------------------|
| Incident Severity Description | Severity code, one of :<br>INFO, LOW, MED, HIGH |

## User Entity

Identifies the Guardium user defined as an audit process results receiver.

| Attribute     | Description                                  |
|---------------|----------------------------------------------|
| EMAIL Address | Email address defined for the Guardium user. |
| First Name    | First name for the Guardium user.            |
| Last Active   | Timestamp for last activity for this user.   |
| Last Name     | Last name for the Guardium user.             |
| Login Name    | Guardium user name.                          |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID         | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Client Port       | Client port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Database Name     | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                                                                                                                                                                                                                           |
| Duration (secs)   | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Global ID         | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ignored Since     | Timestamp created when starting to ignore this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Inactive Flag     | <ul style="list-style-type: none"> <li>• -1: Session closed by timeout.</li> <li>• 0 (default): Open for sessions generated by SQL package.</li> <li>• 1: Closed (disconnect/ logout received).</li> <li>• 2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>• 3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                        |
| Old Session ID    | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID        | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Server Port           | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Encrypted     | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session End           | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Session End Date      | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Time      | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Weekday   | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Year      | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session ID            | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Session Ignored       | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start         | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Start Date    | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is be the same time as the Session End. |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Severity Entity

The incident severity for an incident or policy violation

| Attribute            | Description                                          |
|----------------------|------------------------------------------------------|
| Severity Description | The severity code is one of:<br>INFO, LOW, MED, HIGH |

## Incident Entity

Incident entities are created by incident generation processes, or manually by assigning a policy violation to an incident.

| Attribute       | Description                              |
|-----------------|------------------------------------------|
| Category Name   | Category assigned to the incident.       |
| Incident Number | Incident number (assigned sequentially). |
| Timestamp       | Time the incident was created.           |

## Client/Server Session Entity

| Attribute                                                     | Description                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> . |
| Server IP/Server Port                                         | Server IP/Server Port                                                                               |

## Policy Rule Violation Entity

This entity is created each time that a policy rule violation is logged. Not all policy rule violations are logged, see the description of the rule actions in [Policy rule actions](#). The access rule causing the violation are available in the dependent Access Rule Entity (described earlier).

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event Id    | Application event ID (if any - these are set using the application events API)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Application User Name   | Name of the user creating the policy rule violation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Access Rule Description | The description of the rule from its definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Category Name           | Category defined for the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Classification Name     | Name of classification process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CLS Process Run ID      | Classification process job execution ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Construct ID            | Uniquely identifies the construct in which it was referenced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Full SQL String         | SQL string causing the policy rule violation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Incident Number         | If assigned to an incident, this is the incident number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Message Sent            | The text of the policy rule violation message that was sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Original Timezone       | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Severity                | Severity defined for the rule (the severity of an incident to which this is assigned may be different).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Timestamp               | The time on the DB Server that the SQL triggering a policy violation was executed. Traffic must be captured with an alerting policy action to see this timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Timestamp Date          | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time          | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday       | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year          | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Total Occurrences       | Occurrence count that triggered the violation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Violation Log Id        | Uniquely identifies the violation entity. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Application Events Entity

This entity is created each time that the system observes an Application Events API call (which sets these attribute values) or a stored procedure call that has been identified as a Custom Identification Procedure (which maps stored procedure parameters to these attributes).

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Application Event ID    | Unique identifier for this application events entity. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Event Date              | Datetime value, set by GuardAppEvent:Start. It displays in the format yyyy-mm-dd hh:mm:ss.<br>Note: If an attempt is made to set the event date using a format other than yyyy-mm-dd, it will contain all zeroes. The time portion (hh:mm:ss) is optional, and if omitted will be 00:00:00.                                                                                                                                                                                                                                                                                                              |
| Event Release Date      | Datetime value, set by GuardAppEvent:Released. It displays in the format yyyy-mm-dd hh:mm:ss.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Event Release Type      | Type of event, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Event Release User Name | User name, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event Release Value Num | Numeric value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Event Release Value Str | String value, set by GuardAppEvent: Released.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Event Type              | Type of event, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Event User Name         | User name, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Event Value Str         | String value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Event Value Num         | Numeric value, set by GuardAppEvent:Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Original Timezone       | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Timestamp               | Created only once, when the event is logged. Do not confuse this attribute with the Event Date attribute, which can be set using an API call or from a stored procedure parameter. (See a description of the Application Events API in <a href="#">Identify_Users_with_API</a> .)                                                                                                                                                                                                                                                                                                                        |

## SQL Entity

This entity is created for each unique string of SQL. Values are replaced by question marks - only the format of the string is stored.

| Attribute     | Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| Bind Info     | Bind information for this SQL string.                                                                           |
| Construct ID  | Uniquely identifies the construct in which the SQL appeared                                                     |
| Sql           | SQL string.                                                                                                     |
| Truncated SQL | Indicates if the SQL has been truncated or not where:<br>0 - false/no, not truncated<br>1 - true/yes, truncated |

## Command Entity

---

For each command, an entity is created for each parent node and position in which the command appears in a command construct.

| Attribute    | Description                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------|
| Command Id   | Uniquely identifies the command. Only available to users with the admin role.                           |
| Construct Id | Uniquely identifies the construct (e.g., select a from b). Only available to users with the admin role. |
| Depth        | Depth of the command in the SQL parse tree.                                                             |
| Parent       | Identifier of parent node in the parse tree.                                                            |
| SQL Verb     | Main verb in SQL command (e.g., select, insert, delete, etc.).                                          |

## Object Entity

---

An instance of this entity is created for each object in a unique schema.

| Attribute          | Description                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| App Object Module1 | Uniquely identifies the application object module.                                                                |
| Construct Id       | Uniquely identifies the construct in which the object is referenced. Only available to users with the admin role. |
| Object Id          | Uniquely identifies the object. Only available to users with the admin role.                                      |
| Object Name        | Name of the object.                                                                                               |
| Schema             | Database schema for the object.<br>Note: This attribute is deprecated since it is never populated                 |

## Field Entity

---

Each time Guardium encounters a new field, it creates a field entity.

| Attribute       | Description                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------|
| Command ID      | Uniquely identifies the main command from the construct in which it was referenced. Only available to users with the admin role. |
| Construct ID    | Uniquely identifies the construct in which it was referenced. Only available to users with the admin role.                       |
| Field ID        | Uniquely identifies the field. Only available to users with the admin role.                                                      |
| Field Name      | Name of the field.                                                                                                               |
| List Clause     | Use these attributes to order complex SQL queries.                                                                               |
| Where Clause    | Example of SQL queries:                                                                                                          |
| Order by Clause | Order by                                                                                                                         |
| Having Clause   | SELECT * FROM dept_costs                                                                                                         |
| Group By Clause | WHERE dept_total >                                                                                                               |
| On Clause       | (SELECT avg FROM avg_cost)                                                                                                       |
|                 | ORDER BY department                                                                                                              |
|                 | Having                                                                                                                           |
|                 | SELECT column_name1, SUM(column_name2)                                                                                           |
|                 | FROM table_name                                                                                                                  |
|                 | GROUP BY column_name1                                                                                                            |
|                 | HAVING (numerical function condition)                                                                                            |
|                 | Group By                                                                                                                         |
|                 | SELECT column_name1, SUM(column_name2)                                                                                           |
|                 | FROM table_name                                                                                                                  |
|                 | GROUP BY column_name1                                                                                                            |
|                 | Where                                                                                                                            |
|                 | SELECT FirstName, LastName, City                                                                                                 |

## Policy Violations Summary domain

All policy violation data, for a summary of all violations of the policy detected by the Guardium inspection engines or STAPs. This topic describes the domain's entities and attributes.

Available to roles: all

### Client/Server Entity

This entity describes a specific client-server connection. An instance is created each time a unique set of attributes (excluding the Timestamp) is detected.

Note: For Access Tracking only, Client/Server Entity name appears in the menu as two possible entities - Client/Server and Client/Server By Session. Client/Server By Session gets its count from the Client/Server and date conditions from the Session.

Client/Server gets its count from the Client/Server and date conditions also from the Client/Server.

If you select Client/Server, then the query is populated with ATTRIBUTE\_ID = 1. If you select Client/Server By Session, then the query is populated with MAIN\_ATTRIBUTE\_ID = 0.

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID                                    | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP contains the IP for encrypted sessions. For unencrypted sessions Analyzed Client IP will be the same as Client IP.                                                                                                                                                                                                                                                                                                                                                                  |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Client IP                                    | Client IP address. For ASO traffic, CLIENT_IP is not the actual client IP; use the Analyzed Client IP, which is the correct IP. For Oracle ASO encrypted IPv6 traffic (local as well as remote), use the Client Host Name to identify the actual client session, due to limitations. For SSL traffic, Client IP is not the actual client IP and there is no Analyzed Client IP.                                                                                                                                                                                                    |
| ClientIP / DBUser                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Client IP/Src App/DB User/Server IP/Svc Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client IP/Src App/User                       | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Client OS                                    | Client operating system.<br>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:<br><br>IBM MAINFRAME // IBM mainframe data format<br><br>HONEYWELL MAINFRAME // Honeywell mainframe data format<br><br>AT&T 3B2 // AT&T 3B2 data format.<br><br>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)<br><br>VAX // VAX data format<br><br>AMDAHL // Amdahl data format |
| DB Protocol                                  | Protocol specific to the database server For example, DRDA (Db2), TNS (Oracle), or TDS (MS SQL Server).                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DB Protocol Version                          | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DB User Name                                 | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Last Used                                    | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Network Protocol                             | Network protocol used (such as TCP or UDP. For K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| OS User                                      | OS user as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Server Description                           | Server description (if any). For example, displays cluster name of the Cloudera Data Platform.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Server Host Name                             | Server host name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Server IP                                    | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Server IP/DB user                            | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Server IP/Svc Name/DB User                   | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Attribute                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server OS                 | <p>Server operating system.<br/>For Informix, the OS may appear as follows:</p> <p>IEEEM indicating Unix or JDBCIEEEI indicating WindowsDEC indicating DEC Alpha</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type               | The type of database monitored, such as Dd2, Oracle, or Teradata.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Service Name              | Service name for the interaction. In some cases (AIX shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.<br>For Teradata, Service name contains the session logical host id value.                                                                                                                                                                                                                                                                                                                      |
| Source Program            | Source program as reported by the database client where supported by the database type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Client/ Server by session | Client/Server by session is also a Main Entity. Access this secondary entity by clicking on the Client/Server primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp                 | The time on the collector when the client <b>first</b> connected to the server. For example, if a client is connecting to the server in the same way many days in a row this timestamp will be the time of the first connection. This may even be before the purge days of the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Timestamp Date            | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Time            | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp Weekday         | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp Year            | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Client/Server Session Entity

| Attribute                                                     | Description                                                                                         |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name | A tuple group containing the named fields. For more information, see <a href="#">Tuple groups</a> . |
| Server IP/Server Port                                         | Server IP/Server Port                                                                               |

## Policy Rule Violations Summary Entity

| Attribute                 | Description                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Access Rule Desc          |                                                                                                                                               |
| Client IP                 |                                                                                                                                               |

## Policy Rule Violation Entity

This entity is created each time that a policy rule violation is logged. Not all policy rule violations are logged, see the description of the rule actions in [Policy rule actions](#). The access rule causing the violation are available in the dependent Access Rule Entity (described earlier).

| Attribute               | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| Application Event Id    | Application event ID (if any - these are set using the application events API) |
| Application User Name   | Name of the user creating the policy rule violation.                           |
| Access Rule Description | The description of the rule from its definition.                               |
| Category Name           | Category defined for the rule.                                                 |

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Classification Name | Name of classification process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| CLS Process Run ID  | Classification process job execution ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Construct ID        | Uniquely identifies the construct in which it was referenced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Full SQL String     | SQL string causing the policy rule violation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Incident Number     | If assigned to an incident, this is the incident number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Message Sent        | The text of the policy rule violation message that was sent.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Original Timezone   | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Severity            | Severity defined for the rule (the severity of an incident to which this is assigned may be different).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Timestamp           | The time on the DB Server that the SQL triggering a policy violation was executed. Traffic must be captured with an alerting policy action to see this timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Timestamp Date      | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time      | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday   | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year      | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Total Occurrences   | Occurrence count that triggered the violation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Violation Log Id    | Uniquely identifies the violation entity. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Session Entity

This entity is created for each Client/Server database session.

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access ID           | A unique identifier for this unique set of client/server connection attributes. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Client Port         | Client port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Database Name       | Name of database for the session.<br>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.                                                                                                                                                                                                                                                                                                                                                           |
| Duration (secs)     | Indicates the length of time between the Session Start and the Session End (in seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Global ID           | Uniquely identifies the session - access. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Ignored Since       | Timestamp created when starting to ignore this session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Inactive Flag       | <ul style="list-style-type: none"> <li>• -1: Session closed by timeout.</li> <li>• 0 (default): Open for sessions generated by SQL package.</li> <li>• 1: Closed (disconnect/ logout received).</li> <li>• 2: Closed due to timeout on Guardium system. The session is reopened when traffic is regenerated in the session.</li> <li>• 3: For sessions generated from non-SQL packets.</li> </ul>                                                                                                                                                                                                        |
| Old Session ID      | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Original Timezone   | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |
| Process ID          | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Server Port         | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Encrypted   | Whether the session is encrypted. 0: no; 1: yes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End         | The time on the DB server when the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Session End Date    | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Time    | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session End Weekday | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session End Year    | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Session ID          | Uniquely identifies the session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Ignored     | A Yes indicates that the session was ignored using the IGNORE SESSION policy action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start       | The time on the DB server when the session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date  | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Attribute             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session Start Time    | Time only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Session Start Weekday | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Start Year    | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Terminal Id           | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Timestamp             | The time on the collector when the session information was most recently updated. Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you are probably more interested in the Session Start and Session End attributes than the Timestamp attribute. If the session is closed it is the same time as the Session End. |
| Timestamp Date        | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Time        | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Timestamp Weekday     | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Year        | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| TTL                   | Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Uid Chain             | For a session reported by Unix S-TAP (K-TAP mode only), or FAM on Windows, this shows the chain of OS users, when users <code>su</code> with a different user name. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                             |
| Uid Chain Compressed  | The UID chain excluding the first user and the last user. For more information, see <a href="#">Linux-Unix: UID chains</a> and <a href="#">UID chain for FAM</a> .                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Severity Entity

The incident severity for an incident or policy violation

| Attribute            | Description                                          |
|----------------------|------------------------------------------------------|
| Severity Description | The severity code is one of:<br>INFO, LOW, MED, HIGH |

## Query Rewrite domain

This topic describes the domain's entities and attributes.

### Query Rewrite Log Entity

| Attribute                   | Description                            |
|-----------------------------|----------------------------------------|
| Applied QR Definition IDs   | Applied query rewrite definition ID    |
| Applied QR Definition Names | Applied query rewrite definition name. |
| Input SQL                   | Input SQL                              |
| Instance ID                 | Instance ID                            |
| Output SQL                  | Query rewrite result SQL               |
| QR Log Details              | Query rewrite detail log               |
| QR Log ID                   | Query rewrite log ID                   |
| Query Rewrite Log           | Query rewrite log                      |

## Client/Server Entity

| Attribute                                    | Description                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Id                                    | A unique identifier for this client/server connection.                                                                                                                                                                                                                                                                                    |
| Analyzed Client IP                           | Applies only to encrypted traffic; when set, client IP is set to zeroes.<br>Analyzed Client IP has a map for CEF source. If the query used for the CEF does NOT contain the Client IP but contains the analyzed client IP, the analyzed client IP is used for the source. If both included in the query, then Client IP takes precedence. |
| Client Host Name                             | Client host name.                                                                                                                                                                                                                                                                                                                         |
| Client IP                                    | Client IP address                                                                                                                                                                                                                                                                                                                         |
| Client IP/DB User                            | Paired attribute value consisting of the client IP address and database user name.                                                                                                                                                                                                                                                        |
| Client IP/Src App/DB User/Server IP/Svc Name | Client IP address / Source Application Program / Database User Name/ Server IP address / Service Name                                                                                                                                                                                                                                     |
| Client IP/Src App/User                       | Client IP address / Source Application Program / user name                                                                                                                                                                                                                                                                                |
| Client MAC                                   | Client hardware address.                                                                                                                                                                                                                                                                                                                  |

| Attribute                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Client OS                  | <p>Client operating system.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data are stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p>                                                                                                                                                 |
| DB Protocol                | Protocol specific to the database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DB Protocol Version        | Protocol version for the DB Protocol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DB User Name               | Database user name: user that connected to the database, either local or remote.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Network Protocol           | Network protocol used (e.g., TCP, UDP, etc. Note that for K-TAP on Oracle, this displays as either IPC or BEQ)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| OS User                    | OS user account for the interaction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Server Description         | Server description (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Server Host Name           | Server Host Name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Server IP                  | Server IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Server IP/DB User          | Paired attribute value consisting of Server IP address and database user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Server IP/Svc Name/DB User | Server IP address / Service Name / Database user name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Server OS                  | <p>Server operating system.</p> <p>For Informix, the OS may appear as follows:</p> <p>IEEEEM indicating Unix, or JDBCIEEEI indicating Windows, or DEC indicating DEC Alpha.</p> <p>For Teradata, as there is no direct information about client/server OS, instead, the data format type is used; indicating how integer data is stored during db session. This has a close relation to the platform being used and may appear as follows:</p> <p>IBM® MAINFRAME // IBM mainframe data format</p> <p>HONEYWELL MAINFRAME // Honeywell mainframe data format</p> <p>AT&amp;T 3B2 // AT&amp;T 3B2 data format.</p> <p>INTEL 8086 // Intel 8086 data format (IBM PC or compatible)</p> <p>VAX // VAX data format</p> <p>AMDAHL // Amdahl data format</p> |
| Server Type                | DB2, Oracle, Sybase, etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Service Name               | <p>Service name for the interaction. In some cases (AIX® shared memory connections, for example), the service name is an alias that is used until the actual service is connected. In those cases, once the actual service is connected, a new session is started - so what the user experiences as a single session is logged as two sessions.</p> <p>For Teradata, Service name contains the session logical host id value.</p>                                                                                                                                                                                                                                                                                                                     |
| Source Program             | Source program for the interaction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Timestamp                  | Since all attributes in this entity contain static information, this timestamp is created only once, when Guardium observes a request on the defined client-server connection for the first time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date             | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Time             | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Timestamp Weekday          | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp Year             | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Session Entity

| Attribute       | Description                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access Id       | A unique identifier for this client/server connection.                                                                                                                                                                                                                           |
| Client Port     | Client port number.                                                                                                                                                                                                                                                              |
| Collector Id    | The identifier of Guardium collector.                                                                                                                                                                                                                                            |
| Database Name   | <p>Name of database for the session (MSSQL or Sybase only).</p> <p>For Oracle, Database Name may contain additional and application specific information such as the currently executing module for a session that has been set in the MODULE column of the V\$SESSION view.</p> |
| Duration (secs) | The length of time between the Session Start and the Session End (in seconds).                                                                                                                                                                                                   |
| Encryption Type | The network traffic encryption type. This field is populated only for some database types. It is not an accurate indication of whether encryption is used, or the type of encryption.                                                                                            |
| Failover Flag   |                                                                                                                                                                                                                                                                                  |
| Global Id       | Uniquely identifies the session - access.                                                                                                                                                                                                                                        |
| Ignored Since   | Timestamp created when starting to ignore this session.                                                                                                                                                                                                                          |

| Inspection Engine Name | Name of inspection engine reporting this data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Last Used              | The timestamp of the last time the data was used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Login Succeeded        | Whether or not the login succeeded                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| MS/ TD SID             | Microsoft / Teradata Session ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Old session Id         | Points to the session from which this session was created. Zero if this is the first session of the connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Original Timezone      | <p>The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.</p> <p>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00. This means that these events occurred 3 hours apart, but at the same respective local time (9 PM).</p> |
| Process ID             | The process ID of the client that initiated the connection (not always available).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Sender IP              | Sender's IP address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Server Port            | Server port number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Session End            | Date and time the session ended. Session End is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session End Date       | Date only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session End Time       | Time only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session End Weekday    | Weekday only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Session End Year       | Year only from the Session End.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Session Id             | Uniquely identifies the session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Session Ignored        | Indicates whether or not some part of the session was ignored (beginning at some point in time).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Session Start          | Date and time session started. Session Start is also a Main Entity. Access this secondary entity by clicking on the Session primary entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Start Date     | Date only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Session Start Weekday  | Weekday only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Session Start Year     | Year only from the Session Start.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| TTL                    | Reserved for admin role use only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Terminal Id            | Terminal ID of the connection, used internally to resolve session information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp              | Initially, a timestamp created for the first request on a client-server connection where there is not an active session in progress. Later, it is updated when the session is closed, or when it is marked inactive following an extended period of time with no observed activity. When tracking Session information, you will probably be more interested in the Session Start and Session End attributes than the Timestamp attribute.                                                                                                                                                                           |
| Timestamp Date         | Date only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Timestamp Time         | Time only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Timestamp WeekDay      | Weekday only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Timestamp Year         | Year only from the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Uid Chain              | <p>For a session reported by Unix S-TAP (KTap mode only), this shows the chain of OS users, when users su with a different user name. The values that appear here vary by OS platform - for example, under AIX the string IBM IBM IBM may appear as a prefix.</p> <p>Note: For Solaris Zones, user ids may be reported instead of user names in the Uid Chain.</p>                                                                                                                                                                                                                                                  |
| Uid Chain Compressed   | Values compressed. See Uid Chain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Access Period Entity

| Attribute              | Description                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application Event Id   | The application event ID if set from the API. These attributes appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.                             |
| Application User       | Application user name.                                                                                                                                                                                                                                 |
| Average Execution Time | The average command execution time during the period. This is for SQL statements only. It does not apply to FTP traffic.                                                                                                                               |
| Avg Execution Ack Time | The average command execution time during the period. This is for SQL statements only. It does not apply to FTP traffic.                                                                                                                               |
| Avg Records Affected   | The average number of records affected. See note at the end of the table. These attributes appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity. |
| Collector Id           | The identifier of the Guardium collector.                                                                                                                                                                                                              |
| Construct Id           | Uniquely identifies a command construct (for example, select a from b). Only available to users with the admin role.                                                                                                                                   |

| Attribute                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Period Start Weekday          | Weekday only from the period start attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Session Id                    | Uniquely identifies a session. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Show Seconds                  | If a the number of accesses per second is being tracked, this contains counts for each second in the access period (usually one hour).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Successful SQLs               | The number of successful SQL requests. These attributes appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp                     | Initially, the Timestamp value is set the first time that a request is observed on a client-server connection during an access period. By default, an access period is one hour long, but this can be changed by the Guardium administrator in the Inspection Engine Configuration. Thereafter, for each subsequent request, it is updated when the system updates the average execution time and the command count for this period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Timestamp Date                | Date of the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Timestamp Time                | Time of the timestamp.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Total Records Affected        | <p>The total number of records affected. These attributes appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.</p> <p>If the Total Records Affected attribute is a character string instead of a number, that value appears here (for example, Large Results Set, or N/A).</p> <p>Records affected - Result set of the number of records which are affected by each execution of SQL statements.</p> <p>Note: The records affected option is a sniffer operation which requires sniffer to process additional response packets and postpone logging of impacted data which increases the buffer size and might potentially have a adverse effect on overall sniffer performance. Significant impact comes from really large responses. To prevent large amount of overhead associated with this operation, Guardium uses a set of default thresholds that allows sniffer to decide to skip processing operation when exceeded.</p> <p>You can use the store max_results_set_size, store max_result_set_packet_size, and store max_tds_response_packets CLI commands to set levels of granularity.</p> <p>Example of result set values:</p> <ul style="list-style-type: none"> <li>• Case 1, record affected value, positive number - this represents correct size of the result set.</li> <li>• Case 2, record affected value, -2 - This means number of records exceeded configurable limit (This could be tuned through CLI interface).</li> <li>• Case 3, record affected value, -1 - This shows any unsupported cases of packets configurations by Guardium.</li> <li>• Case 4, record affected value, -2 - If the result set is sent by streaming mode.</li> <li>• Case 5, record affected value, -2 - Intermediate result during record count to update user about current value, ends up with positive number of total records.</li> </ul> |
| Total Records Affected (Desc) | These attributes appear only when the main entity for the query permits this level of detail. These are not available if either Client/Server or Session is the main entity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Total Access                  | Total count of construct instances for this access period. Only available to users with the admin role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Runtime Sensitive Object Identifier domain

This topic describes the entities and attributes for the Runtime Sensitive Object Identifier domain.

Available to roles: all

## Object entity

---

This entity describes the object attributes available for runtime sensitive object identifier processing.

| Attribute    | Description                   |
|--------------|-------------------------------|
| Construct Id | The related SQL construct ID. |
| Object Name  | From the rule definition.     |

## Runtime Sensitive Object Identifier entity

---

This entity describes the attributes available for runtime sensitive object identifier processing.

| Attribute           | Description                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Database Name       | The database for this record.                                                                                                                                |
| Database Type       | The database type.                                                                                                                                           |
| Matched Patterns    | From the rule definition. A match pattern is similar to a search pattern but uses regular expressions to match the defined pattern in any part of the value. |
| Sensitive Hit Count | The total number of hits for the matched patterns.                                                                                                           |
| Server IP           | The Guardium server IP.                                                                                                                                      |
| Timestamp           | Timestamp of this record.                                                                                                                                    |

## Related tasks

## Security Assessment Result domain

---

Records the results of vulnerability assessment processes. This topic describes the domain's entities and attributes.

Available to roles: admin

## Assessment Result Header Entity

---

This entity is created for each task in the assessment results set.

| Attribute               | Description                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------|
| Assessment Result ID    | Identifies the assessment results set. Only available to users with the admin role.                  |
| Assessment ID           | Identifies the assessment. Only available to users with the admin role.                              |
| Task ID                 | Identifies the task within the assessment. Only available to users with the admin role.              |
| Parameter Modified Flag | Indicates if parameters modified since last run.                                                     |
| Execution Date          | Date that the assessment was run.                                                                    |
| Received By All         | Indicates whether or not these results have been received by all receivers on the distribution list. |
| Overall Score           | Overall score for the assessment.                                                                    |
| From Date               | From date for the assessment.                                                                        |
| To Date                 | To date for the assessment.                                                                          |
| Assessment Description  | Assessment name from the definition.                                                                 |
| Filter Client IP        | Clients selected: exact IP address, address with wildcards (*), or empty to select all.              |
| Filter Server IP        | Servers selected: exact IP address, address with wildcards (*), or empty to select all.              |
| Recommendation          | Recommendation returned for the task.                                                                |

## Test Result Entity

---

This entity is created for each set of test results.

| Attribute               | Description                                                                         |
|-------------------------|-------------------------------------------------------------------------------------|
| Test Result Id          | Identifies the test result. Only available to users with the admin role.            |
| Assessment Result Id    | Identifies the assessment results set. Only available to users with the admin role. |
| Test Id1                | Identifies the test.                                                                |
| Assessment Test Id      | Identifies the assessment test (task). Only available to users with the admin role. |
| Test Score              | Returned test score.                                                                |
| Report Result Id        | Identifies the report result.                                                       |
| Parameter Modified Flag | Indicates if parameters were modified since the last test.                          |
| Result Text             | Text returned by the test.                                                          |
| Test Description        | Description from the test definition.                                               |

| Attribute                         | Description                                                                                |
|-----------------------------------|--------------------------------------------------------------------------------------------|
| Recommendation                    | Recommendation returned by the test.                                                       |
| Score Description                 | Description of the score.                                                                  |
| Threshold String                  | The threshold prompt for the test (e.g. Maximum Number of Different IP's Allowed per user) |
| Severity                          | Severity assigned for the test result.                                                     |
| Category                          | Category for the test result.                                                              |
| Assessment Result data source Id1 | Identifies the test result data source.                                                    |
| Result Details                    | Details of the test.                                                                       |
| Exceptions Group Desc             | Exceptions Group Description. Populated when test is executed.                             |

## VA summary entity

| Attribute                | Description                                           |
|--------------------------|-------------------------------------------------------|
| Cumulative Fail Age      | Number of days in fail status since first run         |
| Cumulative Pass Age      | Number of days in pass status since first run         |
| Current Score            | Score of the last run                                 |
| Current Score Since      | Date when the current score became effective          |
| Data Source Name         | Name of the datasource                                |
| Db Host                  | Database host                                         |
| Db Type                  | Database type                                         |
| First Execution Datetime | Date and time on which the test was first executed    |
| First Fail Datetime      | Date and time when the test failed for the first time |
| First Pass Datetime      | Date and time when the test passed for the first time |
| Last Execution Datetime  | Last date and time the test was executed              |
| Last Fail Datetime       | Last date and time the test failed                    |
| Last Pass Datetime       | Last date and time the test passed                    |
| Port                     | Database port                                         |
| Service Name             | Database service name                                 |
| Test Description         | Description of the test                               |
| Test Id                  | ID of the test                                        |
| Timestamp                | When was this specific summary record updated         |
| VA Summary ID            | Id of the Summary record                              |

## Assessment Result CVSS info Entity

| Attribute                   | Description                 |
|-----------------------------|-----------------------------|
| CVSS Access Complexity      | CVSS Access Complexity      |
| CVSS Access Vector          | CVSS Access Vector          |
| CVSS Authentication         | CVSS Authentication         |
| CVSS Availability Impact    | CVSS Availability Impact    |
| CVSS Confidentiality Impact | CVSS Confidentiality Impact |
| CVSS Generated Date Time    | CVSS Generated Date Time    |
| CVSS Integrity Impact       | CVSS Integrity Impact       |
| CVSS Score                  | CVSS Score                  |
| CVSS Source                 | CVSS Source                 |

## Assessment Result CVE reference Entity

| Attribute            | Description          |
|----------------------|----------------------|
| CVE Reference Source | CVE Reference Source |
| Reference HREF       | Reference HREF       |
| Reference Type       | Reference Type       |

## Assessment Result Datasource Entity

This entity is identifies a datasource accessed by the assessment test.

| Attribute                        | Description                                                                              |
|----------------------------------|------------------------------------------------------------------------------------------|
| Assessment Result data source ID | Identifies a results set for a datasource. Accessible only by users with the admin role. |
| Assessment Result ID             | Identifies the result. Accessible only by users with the admin role.                     |
| DB Type                          | Database type: Oracle, MS-SQL, DB2®, Sybase, Informix®, etc.                             |
| DB Name                          | Database name.                                                                           |
| Version Level                    | Version level of the database.                                                           |
| Patch Level                      | Patch level of the database.                                                             |
| Full Version Info                | Full version information for the datasource                                              |
| Datasource name                  | Name of the datasource.                                                                  |
| Description                      | Datasource description.                                                                  |
| Host                             | Host name for the datasource.                                                            |

| Attribute    | Description                           |
|--------------|---------------------------------------|
| Port         | Port number on the host.              |
| Service Name | Service name for the datasource.      |
| User Name    | User name used for datasource access. |

## Severity Entity

---

The incident severity for an incident or policy violation

| Attribute            | Description                                          |
|----------------------|------------------------------------------------------|
| Severity Description | The severity code is one of:<br>INFO, LOW, MED, HIGH |

## Assessment Log Entity

---

This entity is created each time that an assessment is run.

| Attribute               | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Assessment Log ID       | Uniquely identifies the assessment. Accessible only by users with the admin role.                                                                                                                                                                                                                                                                           |
| Timestamp               | Timestamp for the assessment.                                                                                                                                                                                                                                                                                                                               |
| Timestamp Date          | Date portion of timestamp.                                                                                                                                                                                                                                                                                                                                  |
| Timestamp Time          | Time portion of the timestamp.                                                                                                                                                                                                                                                                                                                              |
| Assessment Log Type     | Predefined, query or custom test.                                                                                                                                                                                                                                                                                                                           |
| Assessment Log Severity | The assessment test severity: Critical, Major, Minor, Cautionary, Informational. This is an ordered list of the level of severity classifications. Assessment test severity: Critical, Major, Minor, Cautionary, Informational. The highest severity is the first classification in this list. The lowest severity is the last classification in this list. |
| Assessment Result Id1   | Identifies the assessment results set.                                                                                                                                                                                                                                                                                                                      |
| Message                 | Message returned by the assessment.                                                                                                                                                                                                                                                                                                                         |
| Details                 | Details for this assessment.                                                                                                                                                                                                                                                                                                                                |

## Sniffer Buffer Usage Monitor domain

---

Inspection engine statistics. This topic describes the domain's entities and attributes.

Available to roles: none

## Sniffer Buffer Usage Entity

---

The system creates this entity at the interval set by the **store monitor buffer usage interval** CLI command (every 60 seconds by default).

| Attribute          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp          | The time the data was collected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| % CPU Sniffer      | A normalized representation of sniffer CPU usage. For example, 50% sniffer usage on an 8-core appliance means that the sniffer is using 400% CPU (four cores).% CPU Sniffer can be used as a proxy to identify other problems, or to see if an appliance isn't at its "normal" values, indicating that something changed. For example, often if the sniffer CPU is high the analyzer queue would be higher, meaning the number of flat log requests is high. The number of flat log requests however is a more direct indicator. Higher sniffer CPU can also indicate a change in traffic volume or type.                                                                                            |
| % Mem Sniffer      | Percentage of memory that is used by the running sniffer process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| % CPU Mysql        | A normalized representation of the running MySQL CPU usage.% CPU Mysql can be used as a proxy to identify other problems, or to see if an appliance is not at its "normal" values, indicating something changed. For example, when % CPU Mysql is high the logger queue might be higher, meaning more chance of sniffer restarts. But checking for sniffer restarts is a more direct observation. % CPU Mysql can also be higher due to other non-sniffer processes running on the system like aggregation or audit processes.                                                                                                                                                                       |
| % Mem Mysql        | The percentage of total system memory that is used by the MySQL database. Provides general background information. This value goes up or down depending on usage of the system. The exact value is not important unless a problem was identified.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Sniffer Process ID | The sniffer process ID. The PID value in this column changes when the sniffer restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Mem Sniffer        | Sniffer memory usage in kB. Sniffer memory usage is always greater than 0 when the sniffer is running. The memory usage increases as more data is held in the logger queue. Memory that is allocated to the sniffer is not released until the sniffer restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Time Sniffer       | Elapsed time used by sniffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Free Buffer Space  | The percentage of free buffer space for the sniffer process. The sniffer buffer engine is only used in implementations that use SPAN ports, Network TAPs, or S-TAP PCAP. If the native S-TAP drivers are used, this value usually remains at 100%.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Analyzer Rate      | An approximate representation of the amount of data that is processed by the Analyzer/Parser per minute. The unit of data that is represented is an internal structure that is closely analogous to a packet. The maximum analyzer rate that a specific appliance can handle is a function of several variables, such as the appliance hardware, the type of data that is analyzed and parsed, and the type of rules that are used in the policy. Therefore, analyzer rate alone is not a good indicator of sniffer load, but it can be a good way to identify the busiest times of the day. The Analyzer Rate does not have a generic value that is problematic or a generic 'best practice' value. |

| Attribute                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logger Rate                    | A rough representation of the amount of data that is processed by the logger per minute. The units here represent the parsed components of the SQL traffic that is inserted into the appliance's internal MySQL database. As with analyzer rate, the logger rate an appliance can handle depends on many factors, such as the appliance hardware, size of SQL statements that are logged, type of policy, and overall load on MySQL imposed by reports, and alerts.                                                                                                                                                                              |
| Analyzer Queue Length          | Indicates the amount of data that is in the Analyzer/Parser buffer. This value is one of the most direct indicators of sniffer performance. Ideally, the value remains at, or close to, zero. The analyzer queue might grow temporarily during temporary periods of high traffic, but should never remain elevated for more than five or six rows (5 - 6 minutes) in the Buffer Usage Monitor report. The Analyzer/Parser buffer is circular. When the analyzer goes over 80% of queue full, it starts to drop data or put it into flat log, depending on the system configuration. For more information, see <a href="#">Flat log process</a> . |
| Analyzer Total                 | Total number of messages already analyzed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Logger Queue Length            | The amount of SQL data that is in the logger buffer and waiting to be inserted into the collector's database. Similar to the analyzer queue, a consistently high amount of data in the logger queue indicates that the appliance is unable to cope with the amount of traffic that is monitored. Temporary spikes in buffered data are normal, provided the buffer is flushed within several minutes.                                                                                                                                                                                                                                            |
| Logger Total                   | Total number of messages already logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Session Queue Length           | The total number of open sessions that are monitored by the sniffer. This information is important because sniffer must allocate a certain amount of memory for each session that is monitored, and it cannot monitor more than 4000 simultaneous sessions.                                                                                                                                                                                                                                                                                                                                                                                      |
| Session Total                  | The overall number of sessions that were opened and closed since the last sniffer restart. Session total can be useful to correlate a spike with other statistics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Handler Data                   | Internal sniffing engine data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Extra information              | Internal sniffing engine data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Sniffer Packets Dropped        | Packets dropped by sniffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Sniffer Packets Ignored        | Packets ignored by sniffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Sniffer Packets Throttled      | Total number of connections that were ignored due to throttling since inspection engine was restarted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| System Cpu Load                | A normalized representation of total system CPU usage. System CPU load is derived from % CPU Sniffer and % CPU Mysql, plus other loads on the CPU. Since CPU load is derived from a few measurements, it does not indicate a specific problem. When higher than normal, it can indicate an underlying problem in many areas.                                                                                                                                                                                                                                                                                                                     |
| System Memory Usage            | System memory utilization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| System Root Disk Usage         | System Root disk utilization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| System Uptime                  | Time since last start-up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| System Var Disk Usage          | The utilization of the /var partition. Most of files that are generated by the appliance are stored in /var.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Sessions normal                | Count of normal sessions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Sessions not opened            | Count of sessions not opened by sniffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Sessions timeout               | Count of sessions timed-out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Flat Log Requests | Number of requests that were flat logged. <b>Flat log requests indicate that the sniffer is dropping packets.</b> The sniffer usually drops packets due to an analyzer queue overflow problem caused by high traffic. <b>Flat log requests do not increase in a system that is working correctly.</b> If Flat log requests go over the threshold once it is a concern. Flat Log, when configured, takes the overflow from the buffer and stores it in a flat log, then inputs it later to the sniffer, with full analysis according to the policies. For more information, see <a href="#">Flat log process</a> . |

## S-TAP Status domain

This topic describes the domain's entities and attributes.

### STAP Properties entity

Note: View the S-TAP properties by creating a new report in the Query-Report Builder page. Select the main entity as S-TAP Properties and query as S-TAP Status. Some of the properties are listed in the below table.

| Attribute                 | Description                                                                                                                                          |

| Acknowledged by S-TAP     |                                                                                                                                                      |
| App Server Installed      | Whether or not an App server is installed. Yes / No                                                                                                  |
| DB2 Shm                   | Whether or not a DB2 shared memory driver is installed. Yes / No.                                                                                    |
| Encrypted?                | Whether or not communication from S-TAP is encrypted. Unencrypted / encryption type.                                                                 |
| Firewall Installed        | Whether or not a firewall is installed on the S-TAP. Yes or No.                                                                                      |
| Guardium® Hosts           | Lists the primary Guardium host, followed by all additional Guardiumhosts (for UNIX: tertiary and so on, in descending order).                       |
| Hunter DBS                | Deprecated.                                                                                                                                          |
| Ktap Installed            | Whether or not K-TAP is installed on the S-TAP. Yes / No.                                                                                            |
| Local TCP                 | Whether or not the S-TAP is running TCP locally. Yes / No.                                                                                           |
| MSS Shm                   | Whether or not MSS shared memory driver is installed. Yes / No.                                                                                      |
| Pipes                     | Whether or not a named pipes driver is installed on the S-TAP. Yes / No.                                                                             |
| Primary Host Name         | IP or hostname of the primary Guardium system receiving data from this S-TAP.                                                                        |
| Sender IP                 |                                                                                                                                                      |
| Software Tap Host         | IP or hostname of the DB hosting this S-TAP                                                                                                          |
| TEE installed             | Deprecated.                                                                                                                                          |
| Tap Version               | The S-TAP software version.                                                                                                                          |
| Timestamp                 | Timestamp of the S-TAP status.                                                                                                                       |
| DB Install Dir            | For DB2, Informix, or Oracle: the full path name for the database installation directory. For example: /home/oracle10. All other database types: NA. |
| DB Port max               | Ending port number of the range of listening ports for the database.                                                                                 |
| DB Port min               | Starting port number of the range of listening ports that are configured for the database.                                                           |
| DB Server type            | Protocol of the DB server                                                                                                                            |
| Inspection Engine Name    | Inspection Engine Name.                                                                                                                              |
| Instance Name             | The name of the database instance.                                                                                                                   |
| Port Range                | The monitored port range.                                                                                                                            |
| Sequence                  | The sequence number of the inspection engine.                                                                                                        |
| Status                    | S-TAP status. One of: Active, Inactive , Synchronizing.                                                                                              |
| Tap ID                    | Inspection engine identifier.                                                                                                                        |
| Timestamp                 | Timestamp of the report.                                                                                                                             |
| Unix Domain Socket Marker | The UNIX domain sockets marker for Oracle, MySQL and Postgres.                                                                                       |

### STAP DB server entity

| Attribute              | Description                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| DB Exec File           | Database service executable that is monitored.                                                                                                      |
| DB Install Dir         | For DB2, Informix, or Oracle: the full path name for the database installation directory. For example: /home/oracle10. All other database types: NA |
| DB Port max            | Ending port number of the range of listening ports for the database.                                                                                |
| DB Port min            | Starting port number of the range of listening ports that are configured for the database.                                                          |
| DB Server Type         | Protocol of the DB server                                                                                                                           |
| Inspection Engine Name | Name of the inspection engine                                                                                                                       |
| Instance Name          | The name of the database instance                                                                                                                   |
| Port Range             | The monitored port range.                                                                                                                           |
| Sequence               | The sequence number of the inspection engine.                                                                                                       |
| Status                 | S-TAP status. One of: Active, Inactive , Synchronizing.                                                                                             |
| Tap ID                 | Inspection engine identifier                                                                                                                        |
| Timestamp              | Timestamp of the report.                                                                                                                            |

| Attribute                 | Description                                                    |
|---------------------------|----------------------------------------------------------------|
| Unix Domain Socket Marker | The UNIX domain sockets marker for Oracle, MySQL and Postgres. |

## S-TAP status history domain

This topic describes the domain's entities and attributes.

### STAP Properties history entity

| Attribute             | Description                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Acknowledged by S-TAP |                                                                                                                                                     |
| App Server Installed  | Whether an App server is installed. Yes / No.                                                                                                       |
| Change Time           |                                                                                                                                                     |
| DB2 Shm               | Whether a DB2 shared memory driver is installed. Yes / No.                                                                                          |
| Encrypted?            | Whether communication from S-TAP is encrypted. Unencrypted / encryption type.                                                                       |
| Firewall Installed    | Whether a firewall is installed on the S-TAP. Yes / No.                                                                                             |
| Hunter DBS            |                                                                                                                                                     |
| Ktap Installed        | Whether K-TAP is installed on the S-TAP. Yes / No.                                                                                                  |
| Local TCP             | Whether the S-TAP is running TCP locally. Yes / No.                                                                                                 |
| MSS Shm               | Whether a MSS shared memory driver is installed on the S-TAP. Yes / No.                                                                             |
| Pipes                 | Whether a named pipes driver is installed on the S-TAP. Yes / No.                                                                                   |
| Primary Host Name     | IP or hostname of the primary Guardium system receiving data from this S-TAP.                                                                       |
| S-TAP Changed         |                                                                                                                                                     |
| Software Tap Host     | IP or hostname of the DB hosting this S-TAP.                                                                                                        |
| TEE installed         | Whether Tee is installed on the S-TAP. Yes / No.                                                                                                    |
| Tap Version           | The S-TAP software version.                                                                                                                         |
| Timestamp             | Timestamp of the status record                                                                                                                      |
| DB Install Dir        | For DB2, Informix, or Oracle: the full path name for the database installation directory. For example: /home/oracle10. All other database types: NA |
| DB Port max           | Ending port number of the range of listening ports for the database.                                                                                |
| DB Port min           | Starting port number of the range of listening ports that are configured for the database.                                                          |
| DB Server type        | Protocol of the DB server                                                                                                                           |
| Instance Name         | The name of the database instance                                                                                                                   |
| Port Range            | Range of ports monitored                                                                                                                            |
| Sequence              |                                                                                                                                                     |
| Status                | S-TAP status. One of: Active, Inactive , Synchronizing.                                                                                             |
| Tap Identifier        | Inspection engine identifier                                                                                                                        |
| Timestamp             | Timestamp of the report                                                                                                                             |

### STAP DB Server History entity

| Attribute      | Description                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| DB Exec File   | Database service executable that is monitored.                                                                                                      |
| DB Install Dir | For DB2, Informix, or Oracle: the full path name for the database installation directory. For example: /home/oracle10. All other database types: NA |
| DB Port Max    | Ending port number of the range of listening ports for the database.                                                                                |
| DB Port Min    | Starting port number of the range of listening ports that are configured for the database.                                                          |
| DB Server type | Protocol of the DB server                                                                                                                           |
| instance Name  | The name of the database instance                                                                                                                   |
| Port Range     | Range of ports monitored                                                                                                                            |
| Sequence       |                                                                                                                                                     |
| Status         | S-TAP status                                                                                                                                        |
| Tap Identifier | Inspection engine identifier                                                                                                                        |
| Timestamp      | Timestamp of the status report                                                                                                                      |

## S-TAP Statistics domain

This topic describes the domain's entities and attributes.

Available to roles: all

### STAP statistics entity

| Attribute | Description |
|-----------|-------------|
|           |             |

| Attribute                           | Description                                                                                   |
|-------------------------------------|-----------------------------------------------------------------------------------------------|
| Activated ATAPs                     | List of A-TAPs that are activated                                                             |
| Buffer Recycled                     | How many times the S-TAP buffer has overflowed                                                |
| Erroneous ATAPs                     | A-TAPs that don't look right: activated but look deactivated, deactivated but look activated. |
| IOCTL Requests                      | Number of ioctls sent to K-TAP                                                                |
| Non-activated ATAPs                 | List of A-TAPs that are not activated                                                         |
| Software Tap Host                   | IP or hostname of the DB server                                                               |
| Stap CPU Percent                    | CPU percentage used by STAP as comes from ps                                                  |
| Stap Statistics Identifier          |                                                                                               |
| Stap Total Priority Packets Dropped | The number of priority packets dropped.                                                       |
| System CPU Idle Percent             | CPU idle percentage, as comes from ps                                                         |
| System CPU Percent                  | CPU percentage used by system, as comes from ps                                               |
| Timestamp                           | Timestamp of the statistics                                                                   |
| Total Buffer Init                   | In the K-TAP part, number of times the buffer initialized                                     |
| Total Bytes Dropped So Far          | In the K-TAP part, amount of bytes dropped                                                    |
| Total Bytes Ignored                 | In the K-TAP part, amount of bytes ignored                                                    |
| Total Bytes So Far                  | In the K-TAP part, amount of bytes captured                                                   |
| Total Response Bytes Ignored        | In the K-TAP part, amount of S2C bytes ignored                                                |

## S-TAP verification domain

This topic describes the domain's entities and attributes.

### STAP verification header entity

| Attribute                   | Description                                                     |
|-----------------------------|-----------------------------------------------------------------|
| Datasource Id               | Primary key from the mysql turbine database table – Datasources |
| IE Database Type            | Inspection Engine Database Type                                 |
| Last Verification Time      | The time at which the S-TAP verification was run.               |
| Next Verification Date Time | The time at which the next S-TAP verification should run.       |
| STAP Host                   | Host name of the server where the S-TAP is installed.           |
| STAP IP Address             | IP address of the server where the S-TAP is installed.          |
| STAP Instance Name          | Name of the S-TAP instance                                      |
| STAP Port                   | The port on the DB server that the S-TAP monitors               |
| STAP Verification HeaderID  | S-TAP verification header table primary key.                    |
| STAP Verification Result    | The result of the verification.                                 |
| STAP Verification Status    | The status of the verification.                                 |
| TAP DB Server Type          | The database server type                                        |
| Timestamp                   |                                                                 |
| Verification Scheduled      | Whether or not verification is scheduled.                       |
| Verification Type           | The type of verification: advanced or normal.                   |

### STAP verification result entity

| Attribute                  | Description                                                     |
|----------------------------|-----------------------------------------------------------------|
| Datasource Description     | The description of the datasource (from the datasources table). |
| Datasource ID              | The primary key of the datasources table.                       |
| Datasource Service Name    | Service Name running on the datasource                          |
| Datasource Severity        |                                                                 |
| Datasource Type            | Datasource type of the inspection engine being verified.        |
| STAP Database Type         | Type of database on which the S-TAP is installed.               |
| STAP Host                  | Host name of the server where the S-TAP is installed.           |
| STAP IP Address            | IP address of the server where the S-TAP is installed.          |
| STAP Instance Name         | Name of the S-TAP instance                                      |
| STAP Port                  | The port on the DB server that the S-TAP monitors               |
| STAP Verification HeaderID | S-TAP verification header table primary key.                    |
| STAP Verification Result   | The result of the verification.                                 |
| STAP Verification Status   | The status of the verification.                                 |
| STAP Verification Time     | The time of the verification.                                   |
| Timestamp                  |                                                                 |
| Verification Type          | The type of verification: advanced or normal.                   |

## Unit Utilization Levels domain

This topic describes the domain's entities and attributes.

Available to roles:

## Unit Utilization Level entity

Several unit utilization reports are provided by default at Manage > Reports > Unit Utilization, including:

- Unit Utilization: Displays the maximum unit utilization level for each unit in the given timeframe. There is a drill-down that displays details for a unit across all periods within the timeframe of the report.
- Unit Utilization Distribution: Per-unit, this report displays the percent of periods in the report timeframe with utilization levels of low, medium, and high.
- Utilization Thresholds: This predefined report displays all low and high threshold values for all unit utilization parameters.
- Unit Utilization Daily Summary: Provides a daily summary of unit utilization data.

In addition, Units Utilization Levels tracking enables users to create custom queries and reports.

Tip: Enable aliases for all custom and pre-defined reports using unit utilization data to ensure that unit utilization levels are displayed as meaningful strings instead of numbers. For example, low, medium, and high instead of 1, 2, or 3.

The list of attributes includes:

| Attribute                         | Description |
|-----------------------------------|-------------|
| Analyzer Queue                    |             |
| Analyzer Queue Level              |             |
| Free Buffer Space                 |             |
| Free Buffer Space Level           |             |
| Host Name                         |             |
| Logger Queue                      |             |
| Logger Queue Level                |             |
| Mysql Disk Usage                  |             |
| Mysql Disk Usage Level            |             |
| Number of Exceptions              |             |
| Number of Exceptions Level        |             |
| Number Of Flat Log Requests       |             |
| Number Of Flat Log Requests Level |             |
| Number Of Full SQLs               |             |
| Number Of Full SQLs Level         |             |
| Number Of Policy Violations       |             |
| Number Of Policy Violations Level |             |
| Number Of Requests                |             |
| Number Of Requests Level          |             |
| Number Of restarts                |             |
| Number Of restarts Level          |             |
| Overall Unit Utilization Level    |             |
| Percent Mysql Memory              |             |
| Percent Mysql Memory Level        |             |
| Period Start                      |             |
| Sniffer Memory                    |             |
| Sniffer Memory Level              |             |
| System CPU Load                   |             |
| System CPU Load Level             |             |
| System Var Disk Usage             |             |
| System Var Disk Usage Level       |             |

## User/Role/Application domain

Relates Guardium users, roles and applications (to report on who has access to which Guardium applications). This topic describes the domain's entities and attributes.

Available to roles: admin

### Guardium roles Entity

This entity (under User Entity) identifies a Guardium role.

| Attribute       | Description            |
|-----------------|------------------------|
| Role Identifier | ID of role identified. |
| Role            | Guardium role listed.  |

### Guardium Applications Entity

This entity (under User Entity) identifies a Guardium application.

| Attribute | Description |
|-----------|-------------|
|           |             |

| Attribute              | Description                                                                    |
|------------------------|--------------------------------------------------------------------------------|
| Application Identifier | ID of application identified.                                                  |
| Application            | Guardium application listed (for example, Query-Report, Policy Builder, etc.). |

## User Entity

---

Identifies the Guardium user defined as an audit process results receiver.

| Attribute     | Description                                  |
|---------------|----------------------------------------------|
| EMAIL Address | Email address defined for the Guardium user. |
| First Name    | First name for the Guardium user.            |
| Last Active   | Timestamp for last activity for this user.   |
| Last Name     | Last name for the Guardium user.             |
| Login Name    | Guardium user name.                          |

---

## VA Summary domain

This topic describes the domain's entities and attributes.

Available to roles: user

### VA summary entity

---

| Attribute                | Description                                           |
|--------------------------|-------------------------------------------------------|
| Cumulative Fail Age      | Number of days in fail status since first run         |
| Cumulative Pass Age      | Number of days in pass status since first run         |
| Current Score            | Score of the last run                                 |
| Current Score Since      | Date when the current score became effective          |
| Data Source Name         | Name of the datasource                                |
| Db Host                  | Database host                                         |
| Db Type                  | Database type                                         |
| First Execution Datetime | Date and time on which the test was first executed    |
| First Fail Datetime      | Date and time when the test failed for the first time |
| First Pass Datetime      | Date and time when the test passed for the first time |
| Last Execution Datetime  | Last date and time the test was executed              |
| Last Fail Datetime       | Last date and time the test failed                    |
| Last Pass Datetime       | Last date and time the test passed                    |
| Port                     | Database port                                         |
| Service Name             | Database service name                                 |
| Test Description         | Description of the test                               |
| Test Id                  | ID of the test                                        |
| Timestamp                | When was this specific summary record updated         |
| VA Summary ID            | Id of the Summary record                              |

---

## VA Tests domain

Reports on tests that are available for security assessments.

### Assessment Tests Entity

---

This entity contains entries for available tests.

| Attribute               | Description                                                                           |
|-------------------------|---------------------------------------------------------------------------------------|
| Test Description        | Text description of the test                                                          |
| Test Type               | Type of assessment test (Observed, Predefined, Custom, Query based, CVE)              |
| Datasource Type         | Type of Datasource (DB2®, Informix®, MYSQL, ORACLE, SYBASE, etc.)                     |
| Threshold               | User defined threshold, to override the value define upon the test's creation         |
| Threshold Default Value | Default threshold that defines the success/fail criteria                              |
| Severity                | Severity of the assessment (Critical, Major, Minor, Caution, Info)                    |
| Category                | Category of the assessment (Privilege, Authentication, Configuration, Version, Other) |
| Timestamp               | Timestamp test was created                                                            |

## SQL Based Assessment Definition

---

This entity describes a SQL based assessment definition

| Attribute                | Description                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bind Out Var             | Optional. Determines if the entered text in SQL statement is a procedural block of code that will return a value that should be bound to an internal Guardium® variable that will be used in the comparison to the Compare to value. |
| Compare To Value         | Compare value that will be used to compare against the return value from the SQL statement using the compare operator.                                                                                                               |
| External Reference       | Reference to the Center for Internet Security (CIS) or Common Vulnerabilities and Exposures (CVE).                                                                                                                                   |
| Operator                 | Operator that will be used for the condition.                                                                                                                                                                                        |
| Recommendation Text Fail | The Recommended text for fail that will be displayed when the test fails.                                                                                                                                                            |
| Recommendation Text Pass | The Recommended text for pass that will be displayed when the test passes.                                                                                                                                                           |
| Result Text Fail         | The Result text for fail that will be displayed when the test fails.                                                                                                                                                                 |
| Result Text Pass         | The Result text for pass that will be displayed when the test passes.                                                                                                                                                                |
| Return Type              | The Return type that will be returned from the SQL statement.                                                                                                                                                                        |
| Short Description        | The short description for the assessment test.                                                                                                                                                                                       |
| SQL For Details          | A SQL Statement for Detail, a SQL statement that retrieves a list of strings to generate a detail string of Detail prefix + list of strings.                                                                                         |
| SQL                      | The SQL statement that will be executed for the test.                                                                                                                                                                                |

## Value Change domain

All changes tracked by the trigger-based value change application. This topic describes the domain's entities and attributes.

Available to roles: admin

## Monitor Values Entity

A monitor values entity is created for each insert, update or delete recorded, contains the details of the change (table name, action, SQL text, etc.).

| Attribute               | Description                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp               | Date and time the change was recorded on the Guardium® appliance. This timestamp is created during the data upload operation. It is not the time that the change was recorded on the audit database. To obtain that time, use the Audit Timestamp entity. |
| Timestamp Date          | Date only from the timestamp.                                                                                                                                                                                                                             |
| Timestamp Time          | Time only from the timestamp.                                                                                                                                                                                                                             |
| Timestamp Year          | Year only from the timestamp.                                                                                                                                                                                                                             |
| Timestamp Weekday       | Weekday only from the timestamp.                                                                                                                                                                                                                          |
| Server IP               | IP address of the database server.                                                                                                                                                                                                                        |
| DB Type                 | Database type.                                                                                                                                                                                                                                            |
| Service Name            | Oracle only. Database service name.                                                                                                                                                                                                                       |
| Database Name           | DB2®, Informix®, Sybase, MS SQL Server only. Database name.                                                                                                                                                                                               |
| Audit PK                | For Sybase and MS SQL Server only. A primary key used to relate old and new values (which must be logged separately for these database types).                                                                                                            |
| Audit Login Name        | Database user name defined in the datasource.                                                                                                                                                                                                             |
| Audit Table Name        | Name of the table that changed.                                                                                                                                                                                                                           |
| Audit Owner             | Owner of the changed table.                                                                                                                                                                                                                               |
| Audit Action            | Insert, Update or Delete.                                                                                                                                                                                                                                 |
| Audit Old Value         | A comma-separated list of old values, in the format:column-name=column_value,                                                                                                                                                                             |
| Audit New Value         | A comma-separated list of new values, in the format:column-name=column_value,                                                                                                                                                                             |
| SQL Text                | Available only with Oracle 9. The complete SQL statement causing the value change.                                                                                                                                                                        |
| Triggered ID            | Unique ID (on this audit database) generated for the change.                                                                                                                                                                                              |
| Audit Timestamp         | Date and time that the trigger was executed.                                                                                                                                                                                                              |
| Audit Timestamp Date    | Date portion of Audit Timestamp.                                                                                                                                                                                                                          |
| Audit Timestamp Time    | Time portion of Audit Timestamp.                                                                                                                                                                                                                          |
| Audit Timestamp WeekDay | Day of week of the Audit Timestamp.                                                                                                                                                                                                                       |
| Audit Timestamp Year    | Year of the Audit Timestamp.                                                                                                                                                                                                                              |

| Attribute         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Original Timezone | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Changed Columns Entity

This entity describes a changed column.

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Changed Column Name | Name of the changed column on the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Old Value           | Value before the change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| New Value           | Value after the change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Original Timezone   | The UTC offset. This is done in particular for aggregators that have collectors in different time zones and so that activities that happened hours apart do not seem as if they happened at the same time when imported to the aggregator.<br>For instance, on an aggregator that aggregates data from different time zones, you can see session start of one record that is 21:00 with original timezone UTC-02:00 and another record where session start is 21:00 with original timezone UTC-05:00, This means that these events occurred 3 hours apart, but at the same respective local time (9 PM). |

## Database Entitlement Reports

You can use database entitlement reports to verify that users have access only to the appropriate data. Your Guardium system includes predefined database entitlement reports for several database types.

Note: DB Entitlements Reports are optional components that are enabled by a product key. If these components have not been enabled, the following entitlement reports do not appear in the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections.

The predefined entitlement reports are listed as follows. They appear as domain names in the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections:

- Oracle DB Entitlements Domains
- MYSQL DB Entitlements Domains
- DB2® DB Entitlements Domains
- DB2 for i 6.1 and 7.1 DB Entitlements Domains
- SYBASE DB Entitlements Domains
- Informix® DB Entitlements Domains
- Microsoft SQL Server Entitlements Domains
- Netezza® DB Entitlements Domains
- Teradata DB Entitlements Domains
- PostgreSQL DB Entitlements Domains
- Azure SQL DB Entitlement Domains
- Neo4j Entitlement Domains
- Apache Cassandra Entitlement Domains
- DataStax Cassandra Entitlement Domains
- 12.1 and later Cockroach DB Entitlement Domains

See also [Entitlement Optimization](#).

## Oracle DB Entitlements

The following domains are provided to facilitate uploading and reporting on Oracle DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

Oracle

- ORA Accnts of ALTER SYSTEM - Accounts with ALTER SYSTEM and ALTER SESSION privileges
- ORA Accnts with BECOME USER - Accounts with BECOME USER privileges
- ORA All Sys Priv and admin opt - Report showing all system privilege and admin option for users and roles
- ORA Obj And Columns Priv - Object and columns privileges granted (with or without grant option)
- ORA Object Access By PUBLIC - Object access by PUBLIC
- ORA Object privileges - Object privileges by database account not in the SYS and not a DBA role
- ORA PUBLIC Exec Priv On SYS Proc - Execute privilege on SYS PL/SQL procedures assigned to PUBL
- ORA Roles Granted - Roles granted to users and roles
- ORA Sys Priv Granted - Hierarchical report showing system privilege granted to users including recursive definitions (i.e. privileges assigned to roles and then these roles assigned to users)
- ORA SYSDBA and SYSOPER Accnts - Accounts with SYSDBA and SYSOPER privileges

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

/\* Select privilege to these tables/views is required \*/

```

grant select on sys.dba_tab_privs to sqlguard;
grant select on sys.dba_roles to sqlguard;
grant select on sys.dba_users to sqlguard;
grant select on sys.dba_role_privs to sqlguard;
grant select on sys.dba_sys_privs to sqlguard;
grant select on sys.obj$ to sqlguard;
grant select on sys.user$ to sqlguard;
grant select on sys.objauth$ to sqlguard;
grant select on sys.table_privilege_map to sqlguard;
grant select on sys.dba_objects to sqlguard;
grant select on sys.v_$pwfile_users to sqlguard;
grant select on sys.dba_col_privs to sqlguard;

```

## MYSQL DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on MYSQL DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

MYSQL: The queries ending in ".40" use the most basic version of the mysql schema (for MySQL 4.0 and beyond). The information\_schema has not changed since it was introduced in MySQL 5.0, so there is a set of \_50 queries, but no \_51 queries. The \_50 queries work for MySQL 5.0 and 5.1 and for 6.0 when it comes out, since the information\_schema is not expected to change in 6.0. The queries ending in ".502" (MYSQL502) use the new information\_schema, which contains much more information and is much more like a true data dictionary.

- MYSQL Database Privileges 40
- MYSQL User Privileges 40
- MYSQL Host Privileges 40
- MYSQL Table Privileges 40
- MYSQL Database Privileges 500
- MYSQL User Privileges 500
- MYSQL Host Privileges 500
- MYSQL Table Privileges 500
- MYSQL Database Privileges 502
- MYSQL User Privileges 502
- MYSQL Host Privileges 502
- MYSQL Table Privileges 502

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

Note: In addition to the privileges required, the user should connect to the MYSQL database to upload the data.

The entitlement queries for all MySQL versions through MySQL 5.0.1 use this set of tables: mysql.db mysql.host mysql.tables\_priv mysql.user

Beginning with MySQL 5.0.2, and for all later versions, the entitlement queries use this set of tables: information\_schema.SCHEMA\_PRIVILEGES mysql.host information\_schema.TABLE\_PRIVILEGES information\_schema.USER\_PRIVILEGES

If a datasource has a MYSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all MYSQL databases the user has access to.

## DB2 DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on DB2 DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- DB2 Column-level Privileges (SELECT, UPDATE, ETC.)
- DB2 Database -level Privileges (CONNECT, CREATE, ETC.)
- DB2 Index-level Privilege (CONTROL)
- DB2 Package-level Privileges (on code packages – BIND, EXECUTE, ETC.)
- DB2 Table-level Privileges (SELECT, UPDATE, ETC.) DB2 Privilege Summary

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

```
/* Select privilege to these tables/views is required */
```

```
GRANT SELECT ON SYSCAT.COLAUTH TO SQLGUARD;
```

```

GRANT SELECT ON SYSCAT.DBAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.INDEXAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.PACKAGEAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.DBAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.TABAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.SCHEMAAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.PASSTHROAUTH TO SQLGUARD;

DB2 z/OS entitlements
The following domains are provided to facilitate uploading and reporting on DB2 for z/OS DB Entitlements.

DB2 zOS Executable Object Prvts Granted To PUBLIC
DB2 zOS Object Prvts Granted To PUBLIC
DB2 zOS System Prvts Granted To GRANTEE -V8
DB2 zOS System Prvts Granted To GRANTEE -V9
DB2 zOS System Prvts Granted To GRANTEE -V10 Up
DB2 zOS Database Prvts Granted To GRANTEE
DB2 zOS Schema Prvts Granted To GRANTEE -V9 Up
DB2 zOS Schema Prvts Granted To GRANTEE -V8 Only
DB2 zOS Database Resource Granted To GRANTEE
DB2 zOS Object Prvts Granted To GRANTEE
DB2 zOS System Prvts Granted With GRANT -V8
DB2 zOS System Prvts Granted With GRANT -V9
DB2 zOS System Prvts Granted With GRANT -V10 Up
DB2 zOS Database Resource Granted To PUBLIC
DB2 zOS Schema Prvts Granted To PUBLIC
DB2 zOS Database Prvts Granted To PUBLIC
DB2 zOS System Prvts Granted To PUBLIC -V10 Up
DB2 zOS System Prvts Granted To PUBLIC -V9
DB2 zOS System Prvts Granted To PUBLIC -V8
DB2 zOS Object Prvts Granted With GRANT
DB2 zOS Database Resource Granted With GRANT
DB2 zOS Schema Prvts Granted With GRANT-V8 Only
DB2 zOS Schema Prvts Granted With GRANT-V9 Up
DB2 zOS Database Prvts Granted With GRANT

```

## DB2 for i 6.1 and 7.1 DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on DB2 for i DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

Use the script, gdmmonitor-db2-IBMi.sql, to detail the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

Object privileges granted to grantee (Object type: Schema, Table, View, Package, Routine, sequence, column, global variable, and XML schema)

Object privileges granted to PUBLIC (Object type: Schema, Table, View, Package, Routine, sequence, column, global variable, and XML schema)

Executable Objects privileges granted to PUBLIC (Object type: package and Routine)

Object privileges granted to grantee with GRANT OPTION (Object type: Schema, Table, View, Package, Routine, sequence, column, global variable, and XML schema)

All of the object privileges exclude default system schemas from a predefined Guardium group called "DB2 for i exclude system schemas - entitlement report". Please add to this group for schema that should be excluded.

## SAP Hana Entitlements

---

The following domains are provided to facilitate uploading and reporting on SAP Hana Entitlements.

- SAP Application Access
- SAP HANA Analytical priv granted to grantee
- SAP HANA App Privilege granted to grantee
- SAP HANA Sys priv granted to grantee
- SAP HANA DB Object priv granted to grantee
- SAP HANA Exec Objects priv granted to PUBLIC
- SAP HANA Object priv granted to grantee with GRANT OPTION
- SAP HANA Object privileges granted to PUBLIC
- SAP HANA Role granted to grantee

Use the script, gdmonitor-SAP-Hana.sql, to detail the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

For more information on running a database entitlement report, see [Running database entitlement reports](#).

## SYBASE DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on SYBASE DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- SYBASE System Privilege and Roles Granted to User including Grant option
- SYBASE Role Granted to User and System Privileges Granted to user and role including Grant option
- SYBASE Object Access by Public
- SYBASE Execute Privilege on Procedure, function assigned To Public
- SYBASE Accounts with System or Security Admin Roles
- SYBASE Object and Columns Privilege Granted with Grant option
- SYBASE Role Granted To User

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

```
/* Select privilege to these tables/views is required */
```

```
/* These are required on MASTER database */
```

```
grant select on master.dbo.syslogins to sqlguard
```

```
grant select on master.dbo.syslogins to sqlguard
```

```
grant select on master.dbo.syssrvroles to sqlguard
```

```
/*These are required on every database, including MASTER */
```

```
grant select on sysprotects to sqlguard
```

```
grant select on sysusers to sqlguard
```

```
grant select on sysobjects to sqlguard
```

```
grant select on sysroles to sqlguard
```

If a datasource has a SYBASE database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all SYBASE databases the user has access to.

## SYBASE IQ Entitlements

---

Supported version: sybase IQ 15 and above.

The following custom table definitions are created to upload data: (You can ignore the id.)

- 139 | Sybase IQ Object Privileges By DB User
- 140 | Sybase IQ Object Privileges By Group
- 141 | Sybase IQ System Authority And Group Granted To User
- 142 | Sybase IQ System Authority And Group Granted To User And Group
- 143 | Sybase IQ Object Access By Public
- 144 | Sybase IQ Exec priv on proc func to PUBLIC
- 145 | Sybase IQ User Group With DBA Perms Admin etc
- 146 | Sybase IQ Table View priv granted with grant
- 147 | Sybase IQ Group granted to user and group
- 148 | Sybase IQ Login policy for user group with login

Corresponding query/reports are as follows: (You can ignore the id.)

- 597 | Sybase IQ Object Privileges By DB User
- 598 | Sybase IQ Object Privileges By Group
- 599 | Sybase IQ System Authority And Group Granted To User
- 600 | Sybase IQ System Authority And Group Granted To Users And Groups Grantee

- 601 | Sybase IQ Object Access By Public
- 602 | Sybase IQ Execute Privilege On Procedure and Function To PUBLIC
- 603 | Sybase IQ User Group With DBA/Perms Admin/User Admin/Remote DBA database authority
- 604 | Sybase IQ Table View Priv Granted With Grant
- 605 | Sybase IQ Group Granted To User And Group
- 606 | Sybase IQ Login Policy For User And Group With Login Option Setting

They can be found under db entitlements with the others.

---

Description of each - some of them are self explained. some may need a few extra words:

```
1 /*
Object privileges by database user.

Object include: Table, views, procedure and functions.

These are privilege granted to users only, not including group or membership in group.

*/
2. /*
Object privileges by group.

Object include: Table, views, procedure and functions.

These are privilege granted to group only.

*/
3 /* System Authority And Group Granted To Users.

*/
4 /* System Authority And Group Granted To Users And Groups Grantee.

*/
5 /* object access by public.

Including Tables, Views, Functions and Procedures

*/
6 /* Execute privilege on procedures and functions granted to PUBLIC:

*/
7 /* Users and groups with DBA, Perms Admin, User Admin or Remote DBA database authority.

*/
8 /* Tables and Views privileges granted with grant option to users and groups.

Note, this is the only grant option type allow in Sybase IQ. Routines cannot be grant with grant option.

*/
9 /* Group granted to users and group.

*/
10 /* Login policy assigned to user and group with login option setting */
```

## How to use GuardAPI to add a datasource to Sybase IQ reports

---

How to use GuardAPI to add a datasource to each of the Sybase IQ reports and how to execute them.

See the examples below on how to add a datasource to each of the new reports and then execute each report.

Add a datasource for all Sybase IQ Entitlement Reports

```
grdapicreate_datasource type="Sybase IQ" user=ent password=Guardium123 host=9.70.144.152 name="Sybase IQ entitlement6"
shared=true owner=admin application=CustomDomain port=2638 dbName=sn5qpuff
```

Add a datasource to all Sybase IQ Entitlement Reports

```
grdapicreate_datasourceRef_by_name application=CustomTables objName="Sybase IQ Exec priv on proc func to
PUBLIC"datasourceName="Sybase IQ entitlement 6"
grdapicreate_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Group granted to user and group"
datasourceName="Sybase IQ entitlement 6"
grdapicreate_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Login policy for user group with
login"datasourceName="Sybase IQ entitlement 6"
grdapicreate_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Object Access By Public" datasourceName="Sybase
IQ entitlement 6"
grdapicreate_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Object Privileges By DB User"
datasourceName="Sybase IQ entitlement 6"
```

```

grdapi create_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Object Privileges By Group"
datasourceName="Sybase IQ entitlement 6"
grdapi create_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ System Authority And Group Granted To
User"datasourceName="Sybase IQ entitlement 6"
grdapi create_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ System Authority And Group Granted To User And
Group"datasourceName="Sybase IQ entitlement 6"
grdapi create_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ Table View priv granted with
grant"datasourceName="Sybase IQ entitlement 6"
grdapi create_datasourceRef_by_name application=CustomTablesobjName="Sybase IQ User Group With DBA Perms Admin
etc"datasourceName="Sybase IQ entitlement 6"

```

Execute ALL SybaseIQ Entitlement Reports

```

grdapi upload_custom_data tableName=SYBASEIQ_EXEC_PRIV_ON_PROC_FUNC_TO_PUBLIC
grdapi upload_custom_data tableName=SYBASEIQ_GROUP_GRANTED_TO_USER_AND_GROUP
grdapi upload_custom_data tableName=SYBASE_OBJ_COL_PRIVS_GRANTED_WITH_GRAN
grdapi upload_custom_data tableName=SYBASEIQ_OBJECT_ACCESS_BY_PUBLIC
grdapi upload_custom_data tableName=SYBASEIQ_OBJECT_PRIVS_BY_DB_USER
grdapi upload_custom_data tableName=SYBASEIQ_OBJECT_PRIVILEGES_BY_GROUP
grdapi upload_custom_data tableName=SYBASEIQ_SYSTEM_AUTHORITY_AND_GROUP_GRANTED_TO_USER grdapi upload_custom_data
tableName=SYBASEIQ_SYSTEM_AUTHORITY_AND_GROUP_GRANTED_TO_USER_AND_GROUP grpapi upload_custom_data
tableName=SYBASEIQ_TABLE_VIEWS_PRIV_GRANTED_WITH_GRANT grpapi upload_custom_data
tableName=SYBASEIQ_USER_GROUP_WITH_DB_PERMS_ADMIN_ETC

```

## Informix DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Informix DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- Informix Object Privileges by database account not including system account and roles
- Informix database level privileges, roles and language granted to user including grant option
- Informix database level privileges, roles and language granted to user and role including grant option
- Informix Object Grant to Public
- Informix Execute Privilege on Informix procedure and function granted to Public
- Informix Account with DBA Privilege Informix Object and columns privileges granted with Grant option
- Informix Role Granted To User and Role

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements). The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
```

Since all users have sufficient privileges for system catalog SELECT privileges, there is no need to grant privilege to any user. Informix doesn't seem to like granting system catalog to users. The grant below would normally be used. But in this case they are not required.

```

grant select on systables to sqlguard;
grant select on systabauth to sqlguard;
grant select on sysusers to sqlguard;
grant select on sysroleauth to sqlguard;
grant select on syslangauth to sqlguard;
grant select on sysroutinelangs to sqlguard;
grant select on sysprocauth to sqlguard;
grant select on sysprocedures to sqlguard;
grant select on syscolauth to sqlguard;

```

If a datasource has a Informix database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all Informix databases the user has access to.

## Microsoft SQL Server 2005 and later DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Microsoft SQL Server 2005 and later DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

Note: Objects in Dynamic query Strings will NOT be shown in xxx\_DEPENDENCIES. An object in an EXECUTE IMMEDIATE SQL string called by a stored program unit does not show dependency. This query exclude schema owner defined in group ID 202 "Dependencies\_exclude\_schema-MSSQL". User has the ability to add or subtract schema name from this group for the dependencies query.

- Microsoft SQL Server Object privileges by database account not including default system user.
- Microsoft SQL Server Role/System privileges granted To User
- Microsoft SQL Server Role/System Privilege granted to user and role including grant option
- Microsoft SQL Server Object access by PUBLIC
- Microsoft SQL Server Execute Privilege on System Procedures and functions to PUBLIC
- Microsoft SQL Server Database accounts of db\_owner and db\_securityadmin Role

- Microsoft SQL Server Server account of sysadmin, serveradmin and security admin /\* only run against MASTER database \*/
- Microsoft SQL Server Object and columns privileges granted with grant option
- Microsoft SQL Server Role granted to user and role.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */

/*These are required on MASTER database */

grant select on sys.server_principals to sqlguard

/*These are required on every databases including MASTER */

grant select on sys.database_permissions to sqlguard
grant select on sys.database_principals to sqlguard
grant select on sys.all_objects to sqlguard
grant select on sys.database_role_members to sqlguard
grant select on sys.columns to sqlguard
```

If a datasource has a MSSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all MSSQL databases the user has access to.

## Netezza DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Netezza DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

Note: There is no DB error text translation for Netezza. The error appears in the exception description. Users can clone/add a report with the exception description for Netezza as needed.

- Netezza Obj Prvs by DB Username - Object privileges with or without grant option by database username excluding ADMIN account.
- Netezza Admin Prvs by DB Username - Admin privileges with or without grant option by database username excluding ADMIN account.
- Netezza Group /Role Granted To User - Group (Role) granted to user
- Netezza Obj Prvs By Group - Object privileges with or without grant option by GROUP excluding PUBLIC.
- Netezza Admin Prvs By Group - Admin privileges with or without grant option by GROUP excluding PUBLIC.
- Netezza Admin Prvs By DB Username, Group - Admin privileges with or without grant option by database username, group excluding ADMIN account and PUBLIC group.
- Netezza Obj Prvs Granted - Object privileges granted with or without grant option to PUBLIC.
- Netezza Admin Prvs Granted - Admin privileges granted with or without grant option to PUBLIC.
- Netezza Global Admin Priv To Users and Groups - Global admin privilege granted to users and groups excluding ADMIN account.
- Netezza Global Obj Priv To Users and Groups - Global object privilege granted to users and groups excluding ADMIN account.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

```
/* Select privilege to these tables/views is required */

/* This script must be run from the system database */

GRANT SELECT ON SYSTEM VIEW TO sqlguard;
GRANT LIST ON DATABASE TO sqlguard;
GRANT LIST ON USER TO sqlguard;
GRANT LIST ON GROUP TO sqlguard;
GRANT SELECT ON _V_CONNECTION TO sqlguard;
```

For Netezza entitlement queries, it is recommended to connect to SYSTEM database, especially when granting the privilege to the user who is going to run these reports. The granting privilege MUST take place from SYSTEM database or else the granted privilege will only take place on one particular database. When the granted privilege takes place from SYSTEM database, a special feature will allow the granted privilege to carry through to all the databases.

## Teradata DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Teradata DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

- Teradata Object privileges by database account not including default system users.
  - Teradata System privileges and roles granted to users including grant option.
  - Teradata Roles granted to users and roles including grant option.
  - Teradata Role granted to users and roles. System privileges granted to users and roles including grant option.
  - Teradata Objects and System privileges granted to public. Note role cannot be granted to public in Teradata.
  - Teradata Execute privileges on system database objects to public.
  - Teradata System admin, Security admin privileges granted to user and role.
- Note: There are no such role as System or Security admin in Teradata. User must create their own roles. These are some important system privileges that would normally not be granted to normal user: ABORT SESSION, CREATE DATABASE, CREATE PROFILE, CREATE ROLE,CREATE USER, DROP DATABASE, DROP PROFILE, DROP ROLE, DROP USER, MONITOR RESOURCE, MONITOR SESSION, REPLICATION OVERRIDE, SET SESSION RATE, SET RESOURCE RATE.
- Teradata Object privileges granted with granted option to users. Not including DBC and grantee = 'All'.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
GRANT SELECT ON DBC.AllRights TO sqlguard;
GRANT SELECT ON DBC.Tables TO sqlguard;
GRANT SELECT ON DBC.AllRoleRights TO sqlguard;
GRANT SELECT ON DBC.RoleMembers TO sqlguard;
```

## PostgreSQL DB and PostgreSQL EDB Entitlements

---

The following domains are provided to facilitate uploading and reporting on PostgreSQL DB and PostgreSQL EDB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

There are seven entitlement custom domains/queries/reports for PostgreSQL. They are as follows (each is listed with Report name, description, note):

- PostgreSQL Priv On. Databases Granted To Public User Role With Or Without Granted Option. Privilege on databases granted to public, user and role with or without granted option. Run this on any database, ideally PostgreSQL.
- PostgreSQL Priv On Language Granted To Public User Role With Or Without Granted Option. Privilege on Language granted to public, user and role with or without granted option. Run this per database.
- PostgreSQL Priv On Schema Granted To Public User Role With Or Without Granted Option. Privilege on Schema granted to public, user and role with or without granted option. Run this per database.
- PostgreSQL Priv On Tablespace Granted To Public User Role With Or Without Granted Option. Privilege on Tablespace granted to public, user and role with or without granted option. Run this on any database, ideally PostgreSQL.
- PostgreSQL Role Or User Granted To User Or Role (9.4 and below. For PostgreSQL DB only). Role or User granted to user or role including grant option. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Role Or User Granted To User Or Role (9.5 and above). Role or User granted to user or role including grant option. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Super User Granted To User Or Role. Super user granted to user or role. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Sys Privils Granted To User And Role. System privileges granted to user and role. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Table View Sequence and Function privs Granted To Public. Tables, Views, Sequence and Functions privileges granted to public. Run this per database. Run this per database.
- PostgreSQL Table View Sequence and Function Privils Granted With Grant Option. Tables, Views, Sequence and Functions privileges granted to user and role with grant option only. Exclude PostgreSQL account.
- PostgreSQL Table View Sequence Function Privils Granted To Roles. Tables, Views, Sequence and Functions privileges granted to roles. Not including public. Run this per database.
- PostgreSQL Table Views Sequence and Functions Privils Granted To Login. Tables, Views, Sequence and Functions privileges granted to logins. Not including postgres system user. Run this per database.

Note: As of version 8.3.6, PostgreSQL does not support grant admin option to public. There is only function, no store procedure. There is no support for column grant, only table grant. Public is a group, not user. Public does not show up in pg\_roles. The only privileges need to run all these queries is: GRANT CONNECT ON DATABASE PostgresSQL TO username;

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), for the entitlement to work.

```
/* Select privilege to these tables/views is required */
/*This is required on POSTGRES database*/
grant connect on database postgres to sqlguard;

/*These are required on every database, including POSTGRES (By default these are already granted to PUBLIC) */
grant select on pg_class to sqlguard;
```

```
grant select on pg_namespace to sqlguard;
grant select on pg_roles to sqlguard;
grant select on pg_proc to sqlguard;
grant select on pg_auth_members to sqlguard;
grant select on pg_language to sqlguard;
grant select on pg_tablespace to sqlguard;
grant select on pg_database to sqlguard;
```

If a datasource has a PostgreSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all PostgreSQL databases the user has access to.

## Azure SQL DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Oracle DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports.

- Azure SQL Database Role granted to user and role
- Azure SQL Database Object / Column privileges granted with grant option
- Azure SQL Database Accounts with db\_owner / db\_securityadmin role
- Azure SQL Database Role / System privileges granted to user and role
- Azure SQL Database Object privileges granted to PUBLIC
- Azure SQL Database Privileges on system procedures / functions granted to PUBLIC
- Azure SQL Database Object privileges granted to user and role

## Neo4j DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Oracle DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports.

- Neo4j roles granted to users
- Neo4j privileges for built-in roles
- Neo4j privileges for user roles (excluding built-in roles)
- Neo4j privileges denied to user roles

## Apache Cassandra DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Apache Cassandra DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports.

- Apache Cassandra SuperUser role
- Apache Cassandra Roles granted with AUTHORIZE permission
- Apache Cassandra Role granted to user role
- Apache Cassandra DB Object privileges granted to grantee

## DataStax Cassandra DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on DataStax Cassandra DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports.

- DataStax Cassandra SuperUser Role
- DataStax Cassandra Object privileges granted with grant option
- DataStax Cassandra Role granted to User Role
- DataStax Cassandra DB Object privileges granted to grantee

## Cockroach DB Entitlements

---

12.1 and later The following domains are provided to facilitate uploading and reporting on Cockroach DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports.

- CockroachDB Create privilege granted to User or Role
- CockroachDB Super User granted to User or Role
- CockroachDB Sys privileges granted to User or Role

- CockroachDB privileges granted to grantee (Cockroach DB version 24.1 and later)
- CockroachDB privileges granted to grantee (pre Cockroach DB version 24.1)  
Note: This entitlement is applicable for database versions earlier than 24.1.
- CockroachDB privileges granted with GRANT option

## Custom Domains

Custom domains allow for user defined domains and can define any tables of data uploaded to your Guardium system.

The usage for these custom entitlement (privileges) domains are for entitlement reports which are found if logged in as a user. To see these reports, go to the user tab DB Entitlements.

A number of custom domains have been predefined. You can use them to import data.

If you create a custom domain, and do not see it immediately after in the Custom Query-Report Builder, log out of the UI and log in again.

For details on using custom tables and custom domains, see [External data correlation](#).

## [Custom] Access

This domain contains all of the same entities as the standard Data Access domain. It is provided as a custom domain to allow additional user-defined domains to be built including information from this domain and any custom tables that have been uploaded by the user. [Custom]Access domain is meant to be cloned. This domain is updated on each version therefore is not advisable to create reports on this domain. For a description of the entities included in the Access domain, see the Access domain description in the Domains topic.

## S-TAP Info (Central Manager)

Report: See S-TAP Reports. On a Central Manager, an additional report, S-TAP Info, is available. This report monitors S-TAPs of the entire environment. Upload this data using the Custom Table Builder.

S-TAP info is a predefined custom domain which contains the S-TAP Info entity and is not modifiable.

When defining a custom query, go to upload page and click Check/Repair to create the custom table in CUSTOM database, otherwise save query will not validate it. This table loads automatically from all remote sources. A user cannot select which remote sources are used - it pulls from all of them.

Based on this custom table and custom domain, there are two reports:

Enterprise S-TAP view shows, from the Central Manager, information on an active S-TAP on a collector and/or managed unit (If there are duplicates for the same S-TAP engine, one being active and one being inactive, then the report will only use the active).

Detailed Enterprise S-TAP view shows, from the Central Manager, information on all active and passive S-TAPs on all collectors and/or managed units.

If the Enterprise S-TAP view and Detailed Enterprise S-TAP view look the same, it is because there only one S-TAP on one managed unit being displayed. The Detailed Enterprise S-TAP view would look different if there is more S-TAPs and more managed units involved.

These two reports can be chosen from the TAP Monitor tab of a standalone system, but they will display no information.

## DB Entitlement Domains

Along with authenticating users and restricting role-based access privileges to data, even for the most privileged database users, there is a need to periodically perform entitlement reviews, the process of validating and ensuring that users only have the privileges required to perform their duties. This is also known as database user rights attestation reporting.

Use Guardium's predefined database entitlement (privilege) reports (for example) to see who has system privileges and who has granted these privileges to other users and roles. Database entitlement reports are important for auditors tracking changes to database access and to ensure that security holes do not exist from lingering accounts or ill-granted privileges.

DB Entitlement Reports use the Custom Domain feature to create links between the external data on the selected database with the internal data of the predefined entitlement reports. See Database Entitlements Reports for further information on how to use predefined database entitlement reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

Note: DB Entitlements Reports are optional components enabled by product key. If these components have not been enabled, the choices do not appear in the Custom Domain Builder/Custom Query-Report Builder/Custom Table Builder selections.

The predefined entitlement reports are listed as follows. They appear as domain names in the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections.

- Oracle DB Entitlements
- MYSQL DB Entitlements
- DB2® DB Entitlements
- SYBASE DB Entitlements
- Informix® DB Entitlements
- Microsoft SQL Server DB Entitlements
- Netezza® DB Entitlements
- Teradata DB Entitlements
- PostgreSQL DB Entitlements

## Oracle DB Entitlements

The following domains are provided to facilitate uploading and reporting on Oracle DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

#### Oracle

- ORA Accnts of ALTER SYSTEM - Accounts with ALTER SYSTEM and ALTER SESSION privileges
- ORA Accnts with BECOME USER - Accounts with BECOME USER privileges
- ORA All Sys Priv and admin opt - Report showing all system privilege and admin option for users and roles
- ORA Obj And Columns Priv - Object and columns privileges granted (with or without grant option)
- ORA Object Access By PUBLIC - Object access by PUBLIC
- ORA Object privileges - Object privileges by database account not in the SYS and not a DBA role
- ORA PUBLIC Exec Priv On SYS Proc - Execute privilege on SYS PL/SQL procedures assigned to PUBL
- ORA Roles Granted - Roles granted to users and roles
- ORA Sys Priv Granted - Hierarchical report showing system privilege granted to users including recursive definitions (i.e. privileges assigned to roles and then these roles assigned to users)
- ORA SYSDBA and SYSOPER Accnts - Accounts with SYSDBA and SYSOPER privileges

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */

grant select on sys.dba_tab_privs to sqlguard;

grant select on sys.dba_roles to sqlguard;

grant select on sys.dba_users to sqlguard;

grant select on sys.dba_role_privs to sqlguard;

grant select on sys.dba_sys_privs to sqlguard;

grant select on sys.obj$ to sqlguard;

grant select on sys.user$ to sqlguard;

grant select on sys.objauth$ to sqlguard;

grant select on sys.table_privilege_map to sqlguard;

grant select on sys.dba_objects to sqlguard;

grant select on sys.v_$pwfile_users to sqlguard;

grant select on sys.dba_col_privs to sqlguard;
```

## MYSQL DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on MYSQL DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

MYSQL: The queries ending in \_40 use the most basic version of the mysql schema (for MySQL 4.0 and beyond). The information\_schema has not changed since it was introduced in MySQL 5.0, so there is a set of \_50 queries, but no \_51 queries. The \_50 queries work for MySQL 5.0 and 5.1 and for 6.0 when it comes out, since the information\_schema is not expected to change in 6.0. The queries ending in \_502 (MYSQL502) use the new information\_schema, which contains much more information and is much more like a true data dictionary.

- MYSQL Database Privileges 40
- MYSQL User Privileges 40
- MYSQL Host Privileges 40
- MYSQL Table Privileges 40
- MYSQL Database Privileges 500
- MYSQL User Privileges 500
- MYSQL Host Privileges 500
- MYSQL Table Privileges 500
- MYSQL Database Privileges 502
- MYSQL User Privileges 502
- MYSQL Host Privileges 502
- MYSQL Table Privileges 502

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

Note: In addition to the privileges required, the user should connect to the MYSQL database to upload the data.

The entitlement queries for all MySQL versions through MySQL 5.0.1 use this set of tables: mysql.db mysql.host mysql.tables\_priv mysql.user

Beginning with MySQL 5.0.2, and for all later versions, the entitlement queries use this set of tables: information\_schema.SCHEMA\_PRIVILEGES mysql.host information\_schema.TABLE\_PRIVILEGES information\_schema.USER\_PRIVILEGES

If a datasource has a MYSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all MYSQL databases the user has access to.

## DB2 DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on DB2 DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- DB2 Column-level Privileges (SELECT, UPDATE, ETC.)
- DB2 Database -level Privileges (CONNECT, CREATE, ETC.)
- DB2 Index-level Privilege (CONTROL)
- DB2 Package-level Privileges (on code packages – BIND, EXECUTE, ETC.)
- DB2 Table-level Privileges (SELECT, UPDATE, ETC.) DB2 Privilege Summary

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
GRANT SELECT ON SYSCAT.COLAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.DBAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.INDEXAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.PACKAGEAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.DBAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.TABAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.SCHEMAAUTH TO SQLGUARD;
GRANT SELECT ON SYSCAT.PASSTHROUAUTH TO SQLGUARD;
```

## SYBASE DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on SYBASE DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- SYBASE System Privilege and Roles Granted to User including Grant option
- SYBASE Role Granted to User and System Privileges Granted to user and role including Grant option
- SYBASE Object Access by Public
- SYBASE Execute Privilege on Procedure, function assigned To Public
- SYBASE Accounts with System or Security Admin Roles
- SYBASE Object and Columns Privilege Granted with Grant option
- SYBASE Role Granted To User

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
/* These are required on MASTER database */
grant select on master.dbo.sysloginroles to sqlguard
grant select on master.dbo.syslogins to sqlguard
grant select on master.dbo.syssrvroles to sqlguard

/*These are required on every database, including MASTER */
grant select on sysprotects to sqlguard
grant select on sysusers to sqlguard
grant select on sysobjects to sqlguard
grant select on sysroles to sqlguard
```

If a datasource has a SYBASE database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all SYBASE databases the user has access to.

## Informix DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Informix DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Query-Report Builder/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the DB Entitlements tab.

- Informix Object Privileges by database account not including system account and roles
- Informix database level privileges, roles and language granted to user including grant option
- Informix database level privileges, roles and language granted to user and role including grant option
- Informix Object Grant to Public
- Informix Execute Privilege on Informix procedure and function granted to Public
- Informix Account with DBA Privilege Informix Object and columns privileges granted with Grant option
- Informix Role Granted To User and Role

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements). The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
```

Since all users have sufficient privileges for system catalog SELECT privileges, there is no need to grant privilege to any user. Informix doesn't seem to like granting system catalog to users. The grant would normally be used. But in this case they are not required.

```
grant select on systables to sqlguard;
grant select on systabauth to sqlguard;
grant select on sysusers to sqlguard;
grant select on sysroleauth to sqlguard;
grant select on syslangauth to sqlguard;
grant select on sysroutinelangs to sqlguard;
grant select on sysprocauth to sqlguard;
grant select on sysprocedures to sqlguard;
grant select on syscolauth to sqlguard;
```

If a datasource has a Informix database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all Informix databases the user has access to.

## Microsoft SQL Server 2005 and later DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Microsoft SQL Server 2005 and later DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder, Custom Query-Report Builder, and Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

Note: Objects in Dynamic query Strings will NOT be shown in xxx\_DEPENDENCIES. An object in an EXECUTE IMMEDIATE SQL string called by a stored program unit does not show dependency. This query exclude schema owner defined in group ID 202 "Dependencies\_exclude\_schema-MSSQL". User has the ability to add or subtract schema name from this group for the dependencies query.

- Microsoft SQL Server Object privileges by database account not including default system user.
- Microsoft SQL Server Role/System privileges granted To User
- Microsoft SQL Server Role/System Privilege granted to user and role including grant option
- Microsoft SQL Server Object access by PUBLIC
- Microsoft SQL Server Execute Privilege on System Procedures and functions to PUBLIC
- Microsoft SQL Server Database accounts of db\_owner and db\_securityadmin Role
- Microsoft SQL Server Server account of sysadmin, serveradmin and security admin /\* only run against MASTER database \*/
- Microsoft SQL Server Object and columns privileges granted with grant option
- Microsoft SQL Server Role granted to user and role.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */
```

```
/*These are required on MASTER database */
```

```
grant select on sys.server_principals to sqlguard
```

```

/*These are required on every databases including MASTER */
grant select on sys.database_permissions to sqlguard
grant select on sys.database_principals to sqlguard
grant select on sys.all_objects to sqlguard
grant select on sys.database_role_members to sqlguard
grant select on sys.columns to sqlguard

```

If a datasource has a MSSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all MSSQL databases the user has access to.

## Netezza DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Netezza DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Domain Query/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

Note: There is no DB error text translation for Netezza. The error appears in the exception description. Users can clone/add a report with the exception description for Netezza as needed.

- Netezza Obj Privs by DB Username - Object privileges with or without grant option by database username excluding ADMIN account.
- Netezza Admin Privs by DB Username - Admin privileges with or without grant option by database username excluding ADMIN account.
- Netezza Group /Role Granted To User - Group (Role) granted to user
- Netezza Obj Privs By Group - Object privileges with or without grant option by GROUP excluding PUBLIC.
- Netezza Admin Privs By Group - Admin privileges with or without grant option by GROUP excluding PUBLIC.
- Netezza Admin Privs By DB Username, Group - Admin privileges with or without grant option by database username, group excluding ADMIN account and PUBLIC group.
- Netezza Obj Privs Granted - Object privileges granted with or without grant option to PUBLIC.
- Netezza Admin Privs Granted - Admin privileges granted with or without grant option to PUBLIC.
- Netezza Global Admin Priv To Users and Groups - Global admin privilege granted to users and groups excluding ADMIN account.
- Netezza Global Obj Priv To Users and Groups - Global object privilege granted to users and groups excluding ADMIN account.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```

/* Select privilege to these tables/views is required */

/* This script must be run from the system database */

GRANT SELECT ON SYSTEM VIEW TO sqlguard;

GRANT LIST ON DATABASE TO sqlguard;

GRANT LIST ON USER TO sqlguard;

GRANT LIST ON GROUP TO sqlguard;

GRANT SELECT ON _V_CONNECTION TO sqlguard;

```

For Netezza entitlement queries, it is recommended to connect to SYSTEM database, especially when granting the privilege to the user who is going to run these reports. The granting privilege MUST take place from SYSTEM database or else the granted privilege will only take place on one particular database. When the granted privilege takes place from SYSTEM database, a special feature will allow the granted privilege to carry through to all the databases.

## Teradata DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on Teradata DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Domain Query/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

- Teradata Object privileges by database account not including default system users.
- Teradata System privileges and roles granted to users including grant option.
- Teradata Roles granted to users and roles including grant option.
- Teradata Role granted to users and roles. System privileges granted to users and roles including grant option.

- Teradata Objects and System privileges granted to public. Note role cannot be granted to public in Teradata.
- Teradata Execute privileges on system database objects to public.
- Teradata System admin, Security admin privileges granted to user and role.  
Note: There are no such role as System or Security admin in Teradata. User must create their own roles. These are some important system privileges that would normally not be granted to normal user: ABORT SESSION, CREATE DATABASE, CREATE PROFILE, CREATE ROLE,CREATE USER, DROP DATABASE, DROP PROFILE, DROP ROLE, DROP USER, MONITOR RESOURCE, MONITOR SESSION, REPLICATION OVERRIDE, SET SESSION RATE, SET RESOURCE RATE.
- Teradata Object privileges granted with granted option to users. Not including DBC and grantee = 'All'.

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */

GRANT SELECT ON DBC.AllRights TO sqlguard;

GRANT SELECT ON DBC.Tables TO sqlguard;

GRANT SELECT ON DBC.AllRoleRights TO sqlguard;

GRANT SELECT ON DBC.RoleMembers TO sqlguard;
```

## PostgreSQL DB Entitlements

---

The following domains are provided to facilitate uploading and reporting on PostgreSQL DB Entitlements. Each of the following domains has a single entity (with the same name), and there is a predefined report for each domain. All of these domains are available from the Custom Domain Builder/Custom Domain Query/ Custom Table Builder selections. As with other predefined entities and reports, these cannot be modified, but you can clone and then customize your own versions of any of these domains or reports. To see entitlement reports, log on the user portal, and go to the **DB Entitlements** tab.

There are seven entitlement custom domains/queries/reports for PostgreSQL. They are as follows (each is listed with Report name, description, note):

- PostgreSQL Priv On Databases Granted To Public User Role With Or Without Granted Option. Privilege on databases granted to public, user and role with or without granted option. Run this on any database, ideally PostgreSQL.
- PostgreSQL Priv On Language Granted To Public User Role With Or Without Granted Option. Privilege on Language granted to public, user and role with or without granted option. Run this per database.
- PostgreSQL Priv On Schema Granted To Public User Role With Or Without Granted Option. Privilege on Schema granted to public, user and role with or without granted option. Run this per database.
- PostgreSQL Priv On Tablespace Granted To Public User Role With Or Without Granted Option. Privilege on Tablespace granted to public, user and role with or without granted option. Run this on any database, ideally PostgreSQL.
- PostgreSQL Role Or User Granted To User Or Role. Role or User granted to user or role including grant option. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Super User Granted To User Or Role. Super user granted to user or role. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Sys Prvs Granted To User And Role. System privileges granted to user and role. Run this once in any database. Ideally PostgreSQL.
- PostgreSQL Table View Sequence and Function prvs Granted To Public. Tables, Views, Sequence and Functions privileges granted to public. Run this per database. Run this per database.
- PostgreSQL Table View Sequence and Function Prvs Granted With Grant Option. Tables, Views, Sequence and Functions privileges granted to user and role with grant option only. Exclude PostgreSQL account.
- PostgreSQL Table View Sequence Function Prvs Granted To Roles. Tables, Views, Sequence and Functions privileges granted to roles. Not including public. Run this per database.
- PostgreSQL Table Views Sequence and Functions Prvs Granted To Login. Tables, Views, Sequence and Functions privileges granted to logins. Not including postgres system user. Run this per database.

Note: As of version 8.3.6, PostgreSQL does not support grant admin option to public. There is only function, no store procedure. There is no support for column grant, only table grant. Public is a group, not user. Public does not show up in pg\_roles. The only privileges need to run all these queries is: GRANT CONNECT ON DATABASE PostgreSQL TO username;

For entitlements to be able to upload data from various datasources, the general requirement is that the login, used to access the database, be able to read the tables used in the query (which is hidden for all entitlements).

The following list (with comment line heading) details the minimal privileges required, in the database table (or view of the database table), in order for the entitlement to work.

```
/* Select privilege to these tables/views is required */

/*This is required on POSTGRES database*/
```

```

grant connect on database postgres to sqlguard;

/*These are required on every database, including POSTGRES (By default these are already granted to PUBLIC) */

grant select on pg_class to sqlguard;
grant select on pg_namespace to sqlguard;
grant select on pg_roles to sqlguard;
grant select on pg_proc to sqlguard;
grant select on pg_auth_members to sqlguard;
grant select on pg_language to sqlguard;
grant select on pg_tablespace to sqlguard;
grant select on pg_database to sqlguard;

```

If a datasource has a PostgreSQL database type, but does not have a DB name (see Datasource Definitions, the database name under Location is blank), then the uploading data will loop through all PostgreSQL databases the user has access to.

## Data Mart

Use data marts to extract data for subsequent use. Use datamarts for more efficient storage of frequently accessed data; for data that you want to preserve after its purge time; for exporting data from Guardium; and for creating distributed reports.

The Data Mart extraction program runs in a batch according to the specified schedule. It summarizes the data to hours, days, weeks, or months according to the granularity requested and then it saves the results in the Guardium Datamart database. The data is accessible to the users via the standard Reports and Audit Process utilities, like any other domain/entity. The Data Mart extraction data is available under the DM domain. The Entity name is set according to the new table name specified for the data mart data. Using the standard Query-Report Builder, you can clone the query and edit the Query-Report.

The summarization of data shrinks the data volume significantly. It eliminates joins of many tables by storing the data analysis in un-normalized and pre-calculated tables.

There are two types of data marts:

- Extract data to table (in Guardium).
- Extract data to file, for exporting to an external system.

### Central Management and Data Mart

In a Central Management environment, the configuration is distributed automatically to the managed units. The extraction schedule is defined locally on each unit. In case of multiple Central Managers, the Data Mart definition can be cloned by using the Export/Import capability.

- [Viewing your data marts](#)  
The Data marts page is a handy reference for all the data marts defined in your system. You can filter by type, or free search, and you can view the related queries, the extraction log, and view the data mart configuration.
- [Extracting data mart to table](#)  
Use data mart tables, for example, for frequently accessed data, systems with large-scale data that you want available for reports, and data you want to preserve after the scheduled purge. Data marts improve the performance of online reports on Guardium® aggregators.
- [Extracting data mart to file](#)  
You can create your own data mart extractions to CSV file, for export to a destination host.
- [Manage predefined data extraction to file](#)  
Guardium has pre-defined data extractions to file that are disabled by default. You can enable the export extractions by scheduling them through GuardAPI commands.

## Viewing your data marts

The Data marts page is a handy reference for all the data marts defined in your system. You can filter by type, or free search, and you can view the related queries, the extraction log, and view the data mart configuration.

## Procedure

1. Go to Reports > Report Configuration Tools > Data Marts.
2. To filter the data marts, select a domain from the drop-down list, or click either the File or Table radio buttons, or type text in the Filter field.
3. To view the query associated with a data mart, select the data mart, and click Action > Open related query.
4. To view the extraction log for a data mart, select the data mart, and click Action > Open data mart extraction log.
5. To view the data mart configuration, select the data mart, and click Action > Open data mart config.
6. To view and manage the data mart queries, select the data mart, and click Action > List data mart queries. This action is available only for the data marts with type Table.

## Extracting data mart to table

Use data mart tables, for example, for frequently accessed data, systems with large-scale data that you want available for reports, and data you want to preserve after the scheduled purge. Data marts improve the performance of online reports on Guardium® aggregators.

## Before you begin

---

Prerequisite: Data Mart Builder access rights (User Role).

## About this task

---

There are no predefined data marts of the table type. You can create data mart tables from reports that have the data mart icon . The data mart summarizes the data by hours, days, weeks, or months according to the granularity you specify. When you create a table data mart, Guardium creates a query-report with the name you assigned. You can modify this query-report just as you modify any other query-report. You can copy the query-report and modify it to suit your exact needs. Guardium also creates a custom domain and a custom table of the same name. [External data correlation](#) describes using custom domains and custom tables.

You can use the parameters in these reports to run functions (API) to generate scripts. See [Working with API calls and reports](#).

**Data Mart persistency:** Changes to the original query or report do not affect the Data Mart; a snapshot of the originated analysis definition is saved together with the Data Mart upon creation.

When a data mart extraction runs (Scheduled or Run once now) for the first time, it extracts data from Initial start date to the current time based on the Time granularity. It saves the next period from in the DM\_EXTRACTION\_STATE table. On the next run, it extracts data starting from the next period from.

The extracted file name is <Global Id>\_<short host name of source machine>\_<file name defined by user>\_<period start date time short format in UTC>.gz; for example: 1762144738\_gibm32\_LOGS\_20181028230000\_COMPLETE.gz

You can track the extraction and see the overall datamart status in the pre-defined Datamart Extraction Log report. View the User Defined Extraction Log for details on user-defined extractions, for example, datamarts and distributed reports.

To see a list of all data marts to which you have access, navigate to: Reports > Report Configuration Tools > Data Mart. From that page, you can open and modify the data marts.

After a data mart is created, you can modify its Purge After days, its archive schedule, and its schedule. To access the data mart, access the report from which you created the data mart, click , select the data mart from the list of data marts based on this report, and use the instructions in this procedure. If you have a data mart selected, and you want to create a new data mart, click New.

## Procedure

---

1. Access the report you want to create a data mart from and click . The Data Mart dialog opens.
2. Enter a Data Mart name. Optionally, enter a description.
3. In the Extract result to row, verify that Table is selected.
4. Optionally, enter a Table Name. If not specified, it is saved as DM. It's helpful to define an intuitive name, since you can define indexes in the Custom Domain, and check table sizes using the GuardAPI.
5. Specify a time granularity. This is the granularity of the resulting data mart table. Match your granularity to the frequency at which you'll run the corresponding reports: hourly, daily, monthly.
6. The Archive/Export option controls whether the data from this data mart table is included in the data export and data archive, if these processes are configured on this unit. Select Yes if you want to enable data export and data archive for this data mart.
7. Set the number of purge days. The purge days should reflect your business case, for example, the number of days you need that data for your reports, the size of data, available disk space.
8. Select an initial start time from the calendar icon. This is the date/time from which you want the data extracted when the data mart extraction runs for the first time. For example, you define the data mart on Nov 5, 2018, but you need data from Nov 1, 2018. In this case, set Initial Start to Nov 1, 2018.
9. Click Apply to save the Data Mart.
10. To define data extraction on a regular basis, in the scheduling section click Modify Schedule, then define the data mart extraction schedule.
  - Start time: time of day the extraction starts
  - Restart: leave at Run only once
  - Schedule by: select Day/Week
  - Click Every day
  - Schedule Start Time: leave blank unless you want to start the datamart in the future. In that case, open the calendar and select the date on which to start exporting the data mart.
  - Automatically run dependent jobs. Leave unchecked. It is not relevant for data mart.
11. Select the user roles that have access to this datamart:
  - a. Click Roles.
  - b. In the Roles dialog, either select All Roles, or the individual roles.
  - c. Click Apply. The roles are saved and the dialog closes.
12. To temporarily stop report extraction click Pause, click Resume to resume report extraction.
13. To run the extraction once in real time, click Run Once Now.

## Related reference

---

- [Data mart APIs](#)

## Extracting data mart to file

---

You can create your own data mart extractions to CSV file, for export to a destination host.

## About this task

---

The names of extracted CSV files have the format <filename defined by user>\_<period start date time short format>.csv. For example, EXP\_SESSION\_LIST\_20180219060000.csv. They are stored in the location you specify when you define the extraction. After you define an extract to file, you can use all the GuardAPI commands on those extracts.

Data mart file names must follow Linux rules. For example, the file name can't include \$ because Linux does not support it. If you create a file with the name `my$file`, the saved file name is `my`.

Data mart file names must follow Linux rules for naming files. For example, file names can't include "\$' since Linux doesn't support it. If you try to create a file named `my$file`, the saved file name is `my`.

You can track the extraction and see the overall data mart status in the pre-defined Datamart Extraction Log report.

The data mart configuration commands are run only once per central manager, since all collectors can then receive this information from the central manager.

**Bundled data marts:** You can bundle a number of CSV export data marts together, both user-defined and pre-defined. Each bundle has a main data mart. Each data mart that is included in a bundle pulls out data based on its own scheduling. After the main data mart extracts data, it puts data files from all the data marts included in the bundle into the one tar file, and sends it to a destination server. The main data mart must have the latest scheduled extraction time of all the data marts in the bundle so that it can include all the other data marts' latest extracts. See [datamart copy file bundle](#).

If you are defining the export by API, you need to know which unit types are relevant for the various domains. Some guidelines for commonly used domains:

- Classification, discovered instances, outliers, vulnerability assessment: on the units where these processes are enabled or scheduled.
- Exceptions, groups, system information, unit utilization levels: all units.
- Access, policy violations, S-TAP status: collectors only.
- Datasources, users: central manager, standalone.

## Procedure

---

1. Access the report you want to create a data mart from and click . The Data Mart dialog opens.
2. In the Data Mart Configuration section, enter a Data Mart Name. The data mart name must start with **Export**:
3. Optional: Enter a Description.
4. In the Extract result to row, select File.
5. Enter a File Name. The file name must start with `EXP_`
6. Optional: Enter a File Path. If left blank, files are saved in: /opt/IBM/Guardium/data/dump/DATAMART/. The group `guarddatamart` or the group `guardaggpids` must have write access to the file location. The location must have all permissions for mysql and tomcat users; and is accessible from the file server. For example,
  - /var/IBM/Guardium/TSM/
  - /var/IBM/Guardium/data/exportdir/
7. Specify a Time Granularity for the resulting data mart table. Match your granularity to the frequency at which you run the corresponding reports: hourly, daily, monthly.
8. Select an Initial Start time from the calendar icon, indicating the date and time for the start of the data extraction. For example, you define the data mart on November 5, 2018, but you need data from November 1, 2018. In this case, set Initial Start to November 1, 2018.
9. Click Apply to save the Data Mart.
10. To define a regular data extraction, in the scheduling section click Modify Schedule. Define the data mart extraction schedule.
  - Start time: time of day the extraction starts
  - Restart: leave at Run only once
  - Schedule by: select Day/Week
  - Click Every day
  - Schedule Start Time: leave blank unless you want to start the data mart in the future. In that case, open the calendar and select the date on which to start exporting the data mart.
  - Automatically run dependent jobs. Leave cleared. It is not relevant for data mart.
11. Select the user roles that have access to this data mart:
  - a. Click Roles.
  - b. In the Roles dialog, either select All Roles, or the individual roles.
  - c. Click Apply. The roles are saved and the dialog closes.
12. To temporarily stop report extraction click Pause, click Resume to resume report extraction.

## Manage predefined data extraction to file

---

Guardium has pre-defined data extractions to file that are disabled by default. You can enable the export extractions by scheduling them through GuardAPI commands.

## About this task

---

The predefined extractions to file are listed in [Table 1](#). By default, extractions are hourly. You can modify the frequency, however, there are suggested execution times for the pre-defined extractions, based on internal Guardium processes. They are presented in [Table 2](#).

The format of the extracted file name is <Global Id>\_<short host name of source machine>\_<export job name>\_<period start date time short format in UTC>.gz, for example: 1762144738\_machine1\_EXP\_SESSION\_LOG\_20181028230000.gz

If a file transfer fails for any reason, for example if the target machine is down, then it retries the transfer on the next run. The backlog is kept in /var/exportdir directory, and the backlog purge interval is twice the data extraction log purge interval. Use the CLI command `show purge objects age` to view purge intervals. Set the datamart

extraction log purge interval using the CLI command store **purge object age 31 [age]** where [age] is the desired purge interval.

Full\_SQL data mart only works if log full details or log masked details is defined and installed.

Outlier data mart only works if outlier detection is enabled.

If data mart/s scheduler had been stopped for some time and you don't want the data to be extracted retroactively, then before you reschedule extractions to run again, set the correct "Initial Start" in the Data Mart Configuration screen.

Table 1. Predefined data mart export jobs

| Datamart Name / job description / objectName | Description                                                                                                                                                                                                                                                             | Report Title                                 | Unit Type                   | Datamart ID | jobname                   |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-----------------------------|-------------|---------------------------|
| Export:Access Log                            | Includes details of the connection information and the activity summary per hour. The log includes the OS and DB user, successful and failed SQLs, client and server IP and more.                                                                                       | Export: Access Log                           | Collector                   | 22          | DataMartExtract ionJob_22 |
| Export:Session Log                           | Includes details about datasources' sessions (login to logout). The log includes session start and end timestamps, OS and DB user of the session, source program and more.                                                                                              | Export: Session Log                          | Collector                   | 23          | DataMartExtract ionJob_23 |
| Export:Session Log Ended                     | Session may extend for long period. The extraction works hourly. This log sends the sessions that ended later than the hour started.                                                                                                                                    | Export: Session Log                          | Collector                   | 24          | DataMartExtract ionJob_24 |
| Export:Exception Log                         | Details the Exceptions / Errors captured by Guardium. The log will includes exception/error description, user name, source address, DB protocol and more.                                                                                                               | Export: Exception Log                        | Any                         | 25          | DataMartExtract ionJob_25 |
| Export:Full SQL                              | Includes the executed SQL details. The log includes full SQL, records affected, session ID and more.                                                                                                                                                                    | Export: Full SQL                             | Collector                   | 26          | DataMartExtract ionJob_26 |
| Export:Outliers List                         | Includes the outliers. The log includes server IP, DB user, Outlier type, DB and more.                                                                                                                                                                                  | Analytic Outliers List                       | Any                         | 27          | DataMartExtract ionJob_27 |
| Export:Outliers Summary by hour              | Includes an hour summary of outliers. The log includes server IP, DB user, DB and more.                                                                                                                                                                                 | Analytic Outliers Summary                    | Any                         | 28          | DataMartExtract ionJob_28 |
| Export:Group Members                         | Includes a log of all groups members. The log includes Group type, Group description, Group member and Tuple Flag.                                                                                                                                                      | Export:Group Members                         | Any                         | 29          | DataMartExtract ionJob_29 |
| Export:Export Extraction Log                 | Includes log of data relevant to all export or copy files having a name starting with "Export:"                                                                                                                                                                         | User Defined Extraction Log                  | Any                         | 31          | DataMartExtract ionJob_31 |
| Export:Policy Violations                     | Includes the details about logged violations, such as DB User, Source Program, Access Rule Description, Full SQL String and more.                                                                                                                                       | Export:Policy Violations                     | Collector                   | 32          | DataMartExtract ionJob_32 |
| Export:Buff Usage Monitor                    | Provides an extensive set of sniffer buffer usage statistics                                                                                                                                                                                                            | Buff Usage Monitor                           | Any                         | 33          | DataMartExtract ionJob_33 |
| Export:VA Results                            |                                                                                                                                                                                                                                                                         | Security Assessment Export                   | Any                         | 34          | DataMartExtract ionJob_34 |
| Export:Policy Violations - Detailed          | The same as Export Extraction Log, but has Object/Verb tuples. It is recommended that only one of them has to be used.                                                                                                                                                  | Export:Policy Violations                     | Collector                   | 38          | DataMartExtract ionJob_38 |
| Export:Access Log - Detailed                 | The same as Access Log, but also has the following fields from Application Event entity: Event User Name, Event Type, Event Value Str, Event Value Num, Event Date. It is recommended that Access Log or Access Log – Detailed should be used and not the both of them. | Export: Access Log                           | Collector                   | 39          | DataMartExtract ionJob_39 |
| Export:Discovered Instances                  | Provides the result of S-TAP Discovery application, which discovers database instances                                                                                                                                                                                  | Discovered Instances                         | Any                         | 40          | DataMartExtract ionJob_40 |
| Export:Databases Discovered                  |                                                                                                                                                                                                                                                                         | Databases Discovered                         | Any                         | 41          | DataMartExtract ionJob_41 |

| Export:STAP Status                         | 0 0/5 0 0/1 ? * 1,2,3,4,5,6,7 | Every 5 minutes |
| Export:Installed Patches                   | 0 0 5 ? * 1,2,3,4,5,6,7       | Daily at 5 AM   |
| Export:System Info                         | 0 0 5 ? * 1,2,3,4,5,6,7       | Daily at 5 AM   |
| Export:User - Role                         | 0 5 0/1 ? * 1,2,3,4,5,6,7     | 00:05           |
| Export:Classification Process Log          | 0 25 0/1 ? * 1,2,3,4,5,6,7    | 00:25           |
| Export:Outliers List - enhanced            | 0 10 0/1 ? * 1,2,3,4,5,6,7    | 00:10           |
| Export:Outliers Summary by hour - enhanced | 0 10 0/1 ? * 1,2,3,4,5,6,7    | 00:10           |

## Procedure

---

1. Enable the appropriate datamarts and point their output to your target server, for example:

```
grdapic datamart_update_copy_file_info destinationHost=<destination server name>
destinationPassword=<destination server PW>
destinationPath=<destination server> destinationUser=<destination server user>
Name="Export:Session Log" transferMethod=SCP
```

2. Schedule the extraction. Guardium schedulers are local to the appliance, so you need to run the GuardAPI scheduling command on each appliance from which data is extracted. For example, for each collector that needs to send session data you would run:

```
grdapic schedule_job jobType=dataMartExtraction cronString=0 45 0/1 ? * 1,2,3,4,5,6,7
objectName="Export:Session Log"
```

## Distributed Report Builder

---

This central manager feature provides a way to automatically gather data from all or a subset of the Guardium managed units that are associated with this particular central manager. Distributed reports are designed to provide a high-level view, to correlate data from across data sources, and to summarize views of the data. Continue to use aggregators for the row level data gathering across collectors.

This capability alleviates an issue that can arise in complex enterprise environments when users do not always know the exact managed unit that has the data that is required to for a particular report. This can happen because the link between Guardium collectors and databases can change over time, for example depending on configuration options such as load balancing. This is further complicated by considerations such as the time period and data retention policy on the aggregator and collectors.

It is easy to create a Distributed Report. Simply define it via the Distributed Report Configuration page, add to My Dashboard.

Distributed reports optionally make use of data marts on the central manager to enable scheduled collection of aggregated data over time. The distributed report data is stored as a flat table, so no complex joins are required to create the report you want. The report aggregates summarized and analyzed data from all units to enable a high-level/corporate view in a reasonable response time.

Distributed report data can be gathered from collectors, aggregators, and even central managers. The default distributed versions of the reports includes the host name of the unit responsible for that data.

There are two types of distributed reports:

- Immediate reports present a limited amount of data from each unit from its "gather data from" list. It does this on demand.
- Scheduled reports run in the background as defined by its schedule and time granularity and saves data in a table on primary and secondary, if defined, targets.

The following are predefined distributed reports:

- Enterprise S-TAP Verification
- Aggregation/Archive Log

- Failed User Login Attempts
- Scheduled Jobs Exceptions

Prerequisites – create group of Managed Units via the Central Management screen.

1. Create Distributed Report.
2. Review the data gathered.
3. Create additional summary reports on the data gathered.

Running Distributed reports: Immediate or scheduled

When you define a distributed report, run it immediately or schedule it to run in the background and gather the results to the Central Manager:

- **Immediate:** This mode gathers data on demand (upon execution via the GUI) and displays results while gathering the results from the relevant managed units. The distributed report includes a status indicator that data is still in transit or that all data has been received from a particular managed unit. In this mode, data is not saved on the Central Manager. As soon as the report is closed, the data is gone. Results for immediate reports are limited to 100 rows. Immediate reports have two export options: Download Display records and Download as PDF.
- **Scheduled:** This mode gathers data in advance in order to enable instant response. On the time interval you specify in the scheduler, all relevant, aggregated data from the specified managed units is sent to a designated data mart table on the Central Manager machine and creates a default report against this table. This table also has its own domain and entity to enable creation of additional queries and reports using the query builder. Those reports can be added to an audit process in order to run the process periodically and assign the results of the process to a Role, User and/or User Group for review or sign-off. Results for scheduled reports are limited to 10000 rows by default, but the limit is configurable using the **store scheduled\_distributed** CLI command. Scheduled reports have these export options: Download all records, Download display records, Full printable report, and Download as PDF.

Planning considerations for distributed reports

- In a mixed environment where the Central Manager is 32-bit and managed units are 64-bit, the Distributed Report will not show information from the 64-bit systems. To see information in this situation, the Central Manager needs to be upgraded to 64-bit.
- Because of the coordination of data to be sent to the Central Manager, it is critical that the clock time on all managed units is set to the real-time at the time zone where the managed units are located. Even a difference of ten minutes between the Central Manager and the managed units impact the performance and reliability of the distributed reports.
- Scheduled Distributed report definitions can be exported and imported, however immediate Distributed Report definitions cannot be exported or imported. The schedule itself is not included in the exported and imported definition. It is recommended that you keep a record of the definitions and scheduling if needed to re-create on another system such as a backup or test Central Manager. System backup does include distributed report configurations.
- If you specify that report data is collected from both aggregators and collectors, it is conceivable that the default distributed report includes duplicate data (although the Guardium host name is different). In this case, it is best to specify only collectors or only aggregators for the distributed report configuration.
- Distributed reports are based on existing non-distributed reports. When defining a distributed report in scheduled mode, if the original query includes run-time parameters, then you will be asked to provide those values (or wildcards, %).
- You can choose the target Guardium system for each scheduled distributed report. (By default, the target is the central manager. The list of available target systems is set by the GRDAPi command: **grdap set\_distributed\_report\_target target\_host\_name=[unit host name]**.) The target system will have data residing on its database that it did not have previous to the distributed report. Plan ahead for operational changes for purging, upgrades, and backup.

#### Edit and update

For distributed reports, edit and update the base report and update the distributed report based on the updated report structure.

If a user changes the columns in a base report, or adds or removes the where clause in the base report, and then saves and re-generates the report, then to update the distributed report based on this updated report, the user only needs to click on "Save report changes" on the existing distributed report for changes to take effect.

Should the user choose to update the existing report parameter, user should first click on "Apply report changes", then update the parameter value, then click on "Save report changes" for the updates to take effect.

#### More about time

When running a report, the report customizer lets you specify an absolute time window for the query (from 3-31-2014 8:00am to 3-31-2014 11:00am) or a relative time window (NOW -3 HOUR).

For absolute time, each Guardium system will run in its local time. For example, if a distributed report gathers data from Guardium systems in Eastern Standard Time (EST) and Pacific Standard Time (PST), then each system will execute the query based on local time. In the example (useful for checking morning peak hours, midnight or any specific absolute time), a system in New York will gather the results from 08:00 - 11:00 EST and a system in California will gather the results from 08:00 - 11:00 PST.

For a relative time specification, each system will run NOW -N according to the current time on that system. This is important for real-time reports. Absolute Time cannot be used for real-time or near real-time reports. Use the Immediate mode for real-time monitoring.

#### Viewing Distributed Report Status

Every distributed report is accompanied by a status report that shows the user what machines succeed in bringing in the results and what did not. The link to access the status report is highlighted when you navigate to the report in the GUI.

For scheduled reports, clicking on a line on the Status Report enables execution of API to rerun the report on the specific unit(s).

If the specific run for Distributed Report in Scheduled mode comes back with an error, you can rerun the report from the status report as follows:

1. Double click on one of the rows in the status report to bring up the Invoke menu. Click on Invoke.
2. Click the selection, rerun\_distributed\_report.
3. This will open up a pop-up screen that lets you choose the specific run to rerun. Any row of the report can be opened, but only rows with ERROR status can be rerun.

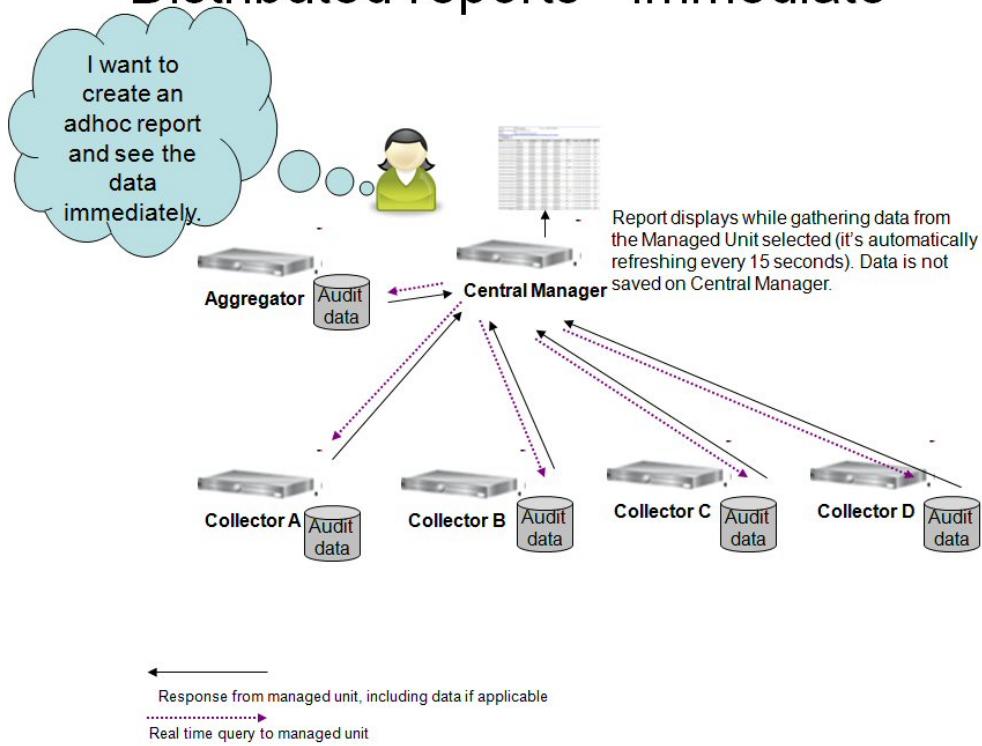

#### GuardAPI for Rerun Distributed Report

The retry command described in the GUI, for invoking the status report, can also be accessed via GuardAPI command.

#### Syntax

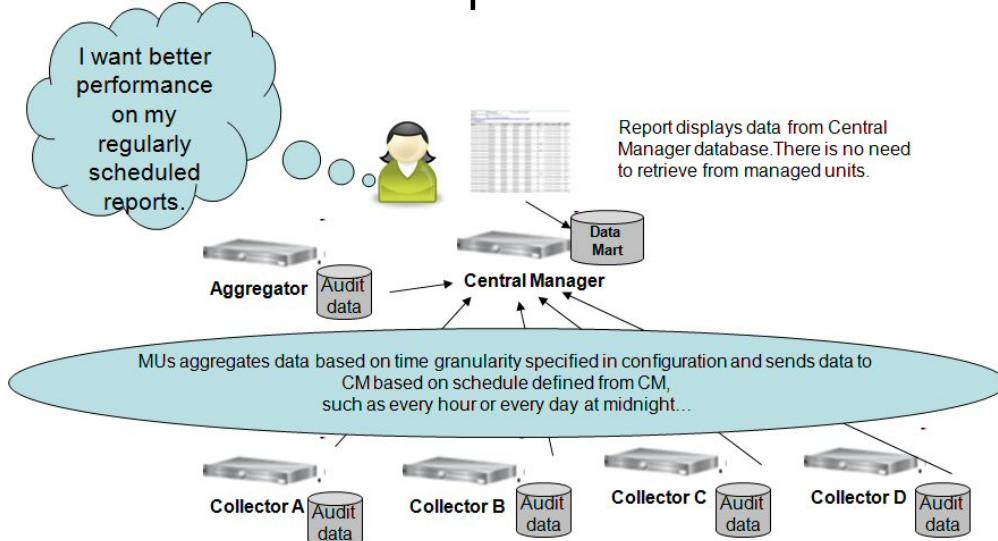

```
grdap rerun_distributed_report
```

# Distributed reports - Immediate

This diagram illustrates the process to run an Immediate Distributed Report.

# Distributed reports - scheduled

This diagram illustrates the process to schedule a Distributed Report.

Distributed Report enhancement - set Target system to any Guardium system

The Distributed Reports distributes the query request to the specified Guardium systems, it gathers the data into the Target system, consolidates the results and provides views on the consolidated results. The results are available via the Query Builder for additional queries definition.

The Distributed Report feature can now set the Target system to any Guardium system. The previous version does not allow setting the Target system and it always goes to the Central Manager (CM).

Requirement justification

In many cases the CM is overloaded (regardless of the Distributed Report) and the CM is sometime used as an Aggregator which adds load to the CM.

In those cases it will be much more efficient to enable the user to determine the target system.

Solution

- A target System can be set for each Distributed Report. A CLI command is available to set the optional Target systems. The list set via the CLI is shown in the Distributed Report builder GUI.
- Note: This change affects the Distributed Report Scheduled mode only. The Immediate mode is not included in this change! This means that the ad-hoc distributed report result viewer is accessible via the CM only.
- The Distributed Report definition is still editable via the CM only.

The CLI commands (available via the CM only)

1. Set System as a Target System

```
grdapic set_distributed_report_target target_host_name=[unit host name]
```

2. Cancel System to be a Target system

```
grdapic cancel_distributed_report_target target_host_name=[unit host name]
```

If there are still distributed reports with this unit as target then returns error and the list of such reports

3. Get list of Target systems

```
grdapic get_distributed_report_target_info
```

Additional CLI commands:

For scheduled distribute reports, store or show the value of a maximum number of rows per unit:

```
show scheduled_distributed
store scheduled_distributed
```

The **store** command has one parameter, maximum\_rows\_per\_unit. If the value of that parameter is greater than 15,000 or equals 0 (no limit), the following warning message displays:

Depending on number of collectors, setting maximum number of rows per unit to a high value might have negative impact on performance.

- [Creating a Distributed Report](#)

Create and modify distributed reports on a central manager.

## Related reference

## Creating a Distributed Report

Create and modify distributed reports on a central manager.

## Before you begin

If you want to collect data from a group of managed units, verify that the group is defined.

## About this task

In this example, you'll see how to get a broader view and correlation insight for Exceptions (for example, SQL Errors) that are recorded on specific collectors.

This screen capture shows an example of a distributed report: Correlate Total Exceptions By User (Distributed). This view sums the total exceptions per user from all databases that are associated with the Guardium Managed Units selected for this Distributed Report. Likewise, you can view the Total Failed Login Attempts system wide, or the Total Exceptions per Source Programs.

| Date                    | User Name | Exception Type Description                | Sum Of Count of Exceptions |
|-------------------------|-----------|-------------------------------------------|----------------------------|
| 2014-03-19 08:00:00.8SA |           | Database Server returned an error 5890076 | 5890076                    |

In this specific example, the report data is gathered hourly - there is no need to wait at least an hour to get the initial results.

Note: The line saying 'Distributed Report status - click here for details', shows the status of data gathering, if data is missing from managed units then the line is colored in red; clicking the line navigates to details report of status per units per hour.

## Procedure

1. Click Reports > Report Configuration Tools > Distributed Report Builder.
  2. Click New.
  3. Select a report from the Based on Report drop-down list as the base for this distributed report. In this example, choose Exceptions Details.

## Distributed Report Configuration

Based on Report

-----

## Gather Data From

● All Managed Units    ○ Group and Specific Managed Units

Group

All Aggregators  
All Collectors  
All Units group

Log

Based on Report \_\_\_\_\_

## Gather Data From

- In the Gather Data From section of the builder, choose All Managed Units (that the Central Manager is managing) or specify certain Group and Specific Managed Units, whose data will be included in the distributed report. If the Central Manager is also an Aggregator, it might need to be included. For this example, choose two groups from the Group list, and a few managed units from the Managed units list, but leave the 'Central Manager' unchecked.
  - In the Operation Mode, select the type of report: immediate or scheduled. The Immediate mode is mainly for online / real-time monitoring, such as, view the recent Failed Login Attempts, view recent Excessive Exception, or view real-time alerts. The Scheduled mode is an ongoing data-gathering that runs periodically based on the Schedule defined. This example summarizes the exceptions every hour. There is a requirement for filling in values for Exception Description and Destination Address.

## Operation Mode

Immediate  Schedule

Send Data To (primary)

Send Data To (secondary)

Time Granularity  Day

Purge After  Days

For Distributed Report in schedule mode, after clicking the Apply button, next define the schedule, and if needed, limit Roles.

Extraction is currently not scheduled.

### Roles

The Send data to and Send data to (secondary) fields define where distributed data is consolidated and made available for reports. By default, data is collected from managed units and made available on the central manager, but it is possible to send the data to any Guardium system using these fields. Send data to (secondary) defines a backup or secondary system where data is also sent. Either Send data to or Send data to (secondary) can identify a central manager, and it is possible for both fields to identify managed units if the data is not needed on a central manager.

6. Click Apply to create the Distributed Report.
7. Define the schedule by clicking Modify Schedule (this is mandatory to activate the process). A standard Schedule Definition window opens. Fill in all required details. See [Scheduling](#) for more information on scheduling.
8. Once applied, the new Distributed Report is added and highlighted in the list box.

## Distributed Report Configuration

Search

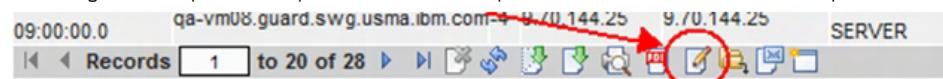

Aggregation/Archive Log - Distributed  
Enterprise Stap Verification  
**Exceptions Details-Distributed**  
Failed User Login Attempts - Distributed  
Scheduled Jobs - distributed  
Scheduled Jobs Exceptions - distributed

Based on Report : Exceptions Details

9. If you want to limit the roles for this report, click Roles to open the Assign Security Roles window; select the roles and click Apply.

## Results

The data is gathered from all the specified Managed Units and is stored in new designated entity (table). This entity is now available via the Query-Report Builder for use when creating additional queries. The option to build additional queries are available via the Distributed Report result screen as well. Click Edit the query for this report.

This default Report cannot be changed, click Clone, name it, remove all attributes and leave the Date, User Name, Exception Type Description, and Sum Of Count Of Exceptions.

## Working with API calls and reports

- [Mapping APIs to report results](#)

Guardium® comes with a battery of predefined reports and many of them are already mapped to GuardAPI functions to ease configuration. You can define additional reports, including custom reports, and map them to GuardAPI functions for each report.

- [How to Generate API Call from Reports](#)  
Generate Guard API calls from a report either from a single row within a report or based on the whole report
- [How to use Constants within API Calls](#)  
Create a new entity attribute to be used during an API function call.
- [How to use API Calls from Custom Reports](#)  
Link API functions to reports and map report fields to the API functional parameters.

## Mapping APIs to report results

Guardium® comes with a battery of predefined reports and many of them are already mapped to GuardAPI functions to ease configuration. You can define additional reports, including custom reports, and map them to GuardAPI functions for each report.

1. Open any predefined report from the Reports section.
2. From the Actions dropdown, select Add API mapping.
3. From Add API mapping, the following information displays:
  - Any API functions that are already mapped to this report. From Existing mapped API function, click Invoke to open a window from which you can enter the parameters for the selected function. You can either invoke the function immediately or generate and download a script to use as needed.
  - A search and filter mechanism to find the appropriate API command.
  - All of the API functions that are available to add to this report.
4. To add an API function, choose the function from the list, and then click Map Report Attributes to display the API-Report Parameter Mapping.
5. From API-Report Parameter Mapping, map the parameter name to the Report field.

Note: Sometimes you might want to include data that is not available in a Guardium report. In this case, you can create a constant to add to the report and use within the API parameter mappings. However, if you export a Guardium report that includes a constant, the constant is not exported.

To simplify the mapping between the GuardAPI parameters and Guardium attributes, the predefined report Query Entities & Attributes lists all of the Guardium attributes. This report provides a GUI interface and allows you to easily drill down from that report and create the linkages.

Existing Guardium attributes or user-defined constants can be mapped to the GuardAPI parameters of Existing Attributes or Constants.

Note: If a report has more than one GuardAPI attribute that is mapped to the same parameter, the API call picks the value in the first attribute (determined by the display order in the report).

### Mapping Existing Attributes

1. Go to the Query Entities & Attributes report to add the API parameter mappings. (Guardium Monitor > Query Entities & Attributes)
2. The Query Entities & Attributes report lists all of the Guardium attributes. Narrow down the records you are interested in by using Customize.
3. To create the mapping, double-click the attribute row to which to assign a parameter name.
4. Click Invoke.
5. Select the create\_api\_parameter\_mapping API function.
6. Enter the functionName and parameterName in the API Call Form.
7. Click Invoke now to create the API to Report Parameter Mapping.

For more information, see [How to use API calls from custom reports](#), which includes an example that maps GuardAPI parameters through the GUI.

### Mapping Constants

Sometimes you might want to include data that is not supplied within a Guardium report. For these instances, create a constant add it to the report, and then use it within the API parameter mappings.

1. Go to the Query Entities & Attributes report to add the API parameter mappings. (Guardium Monitor > Query Entities & Attributes).
2. The Query Entities & Attributes report is long because it lists all of the Guardium attributes. Narrow down the records you are interested in by using Customize.
3. To create a constant attribute, double-click any row for the entity for which you want to create a constant attribute.
4. Click Invoke.
5. Select the create\_constant\_attribute API.
6. Enter the constant value to use and specify the name (attributeLabel)
7. Click Invoke now to create the constant.
8. To create the mapping, double-click the newly created attribute row.
9. Click Invoke.
10. Select the create\_api\_parameter\_mapping API function.
11. Enter the functionName and parameterName in the API Call Form.
12. Click Invoke now to create the API to Report Parameter Mapping.
13. You must add the newly created attribute to the report. Modify the Query through the Query-Report Builder and add the field.

For more information, see [How to use Constants within API Calls](#), which includes an example to create and map a constant attribute through the GUI.

Note: If the Guardium report, with a constant added, is exported, the constant is not exported.

Note: When you use API mapping, table columns in a report appear in the report field whenever the table column is an attribute of an entity. Some of the columns, such as count column, are never displayed in the report field because it cannot be mapped.

## How to Generate API Call from Reports

Generate Guard API calls from a report either from a single row within a report or based on the whole report

Value-added: Through a GUI, by using existing data on the system that is displayed in reports as parameters for API calls, quickly and easily generate and populate API calls without having to perform system level commands or type lengthy API calls to quickly perform operations such as create datasources, define inspection engines, maintain user hierarchies, or maintain the Guardium features such as S-TAP.

Single Row API call

For this scenario, we will generate API function calls to populate the Data Security User Hierarchy.

1. To begin, let's show the current **Data Security User Hierarchy** for the user **scott**

The screenshot shows the 'Data Security User Hierarchy' window. On the left, there are dropdown menus for 'Roles' (set to 'All') and 'Users' (set to 'Knowitall, Scott (scott)'). Below these are two buttons: 'Refresh Cached Hierarchy' and 'Full Update Active User-DB Map'. On the right, a tree view displays a single node: 'User Knowitall, Scott (scott)'. A tooltip above the node says 'Parents : Click a node and right-click for options.' There is also a small icon of a person next to the node name.

2. To invoke an API function we must find a report that currently has the desired API functions linked to it. Since creating a user hierarchy is related to users, selection of a user report should yield good results. For this scenario we've selected the **User - Role** report.

The screenshot shows the 'User - Role' report interface. The title bar says 'User - Role'. The report table has columns: 'Login Name', 'Last Active', '# of Role', and '# of Users'. The data shows several users with their last active times, role counts, and user counts. At the bottom, there are navigation buttons and a toolbar with icons for print, copy, etc. A status bar at the bottom indicates 'Start Date: 2001-04-09 13:21:17 End Date: 2009-08-09 13:21:17' and 'REMOTE\_SOURCE'. The 'Aliases: OFF' option is checked.

3. Double-clicking on a row for drill-down will display an option to **Invoke...**

The screenshot shows the same 'User - Role' report interface. A context menu is open over the row for 'koopmann'. The menu items are 'Record Details' (disabled), 'Invoke...', and 'Delete'. The 'Invoke...' option is highlighted with a red box. The status bar at the bottom shows 'Start Date: 2001-04-09 13:21:17 End Date: 2009-08-09 13:21:17' and 'REMOTE\_SOURCE'. The 'Aliases: OFF' option is checked.

4. Click on the **Invoke...** option to display a list of API functions that are mapped to this report

The screenshot shows the same 'User - Role' report interface. The 'Invoke...' menu is open, displaying three API functions: 'create\_user\_hierarchy', 'delete\_user\_hierarchy\_by\_user', and 'list\_user\_hierarchy\_by\_parent\_user'. The 'create\_user\_hierarchy' option is highlighted with a red box. The status bar at the bottom shows 'Start Date: 2001-04-09 13:21:17 End Date: 2009-08-09 13:21:17' and 'REMOTE\_SOURCE'. The 'Aliases: OFF' option is checked.

5. Click on the **API** you'd like to invoke; bringing up the API Call Form for the Report and Invoked API Function.

6. Fill in the Required Parameters and any non-Required Parameters for the selected API call. Many of the parameters are pre-filled from the report but may be changed to build a unique API call. For specific help in filling out required or non-required parameters please see the individual API function calls within the GuardAPI Reference guide.

The screenshot shows the 'API Call Form' for the 'User - Role' report. The 'Report' field is set to 'User - Role' and the 'Api Function' field is set to 'create\_user\_hierarchy'. The form contains three input fields: 'userName' (set to 'jkoopmann'), 'parentUserName' (set to 'scott'), and 'api\_target\_host' (empty). Below these fields is a note: '\* Required parameter'. Underneath the fields are two dropdown menus: 'Log level' (set to '0') and 'Parameter to encrypt' (set to '-----'). At the bottom are two buttons: 'Generate script' and 'Invoke now'.

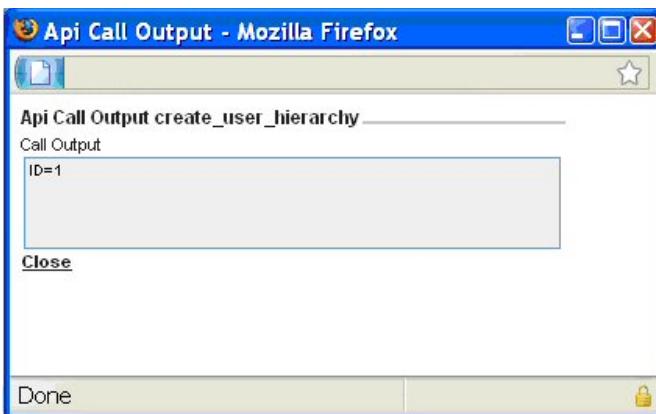

7. Use the drop-down list to select the **Log level**, where Log level represents the following (0 - returns ID=identifier and ERR=error\_code as defined in Return Codes, 1 - displays additional information to screen, 2 - puts information into the Guardium application debug logs, 3 - both 1 and 2).

8. Use the drop-down list to select a **Parameter to encrypt**.

Note: Parameter Encryption is enabled by setting the Shared Secret and is relevant only for invoking the API function through script generation.

9. Choose to **Invoke Now** or **Generate Script**.

- a. If **Invoke Now** is selected the API call will run immediately and display an API Call Output screen showing the status of the API call.

b. If **Generate Script** is selected: Open the generated script with your favorite editor or optionally save to disk to edit and execute at a later time -- replacing any of the empty parameter values (denoted by '< >') if contained within the script.

Note: Empty parameters may remain in the script as the API call will ignore them

Example Script

```
A template script for invoking guardAPI function create_user_hierarchy :

Usage: ssh cli@a1.corp.com<create_user_hierarchy_api_call.txt

replace any < > with the required value

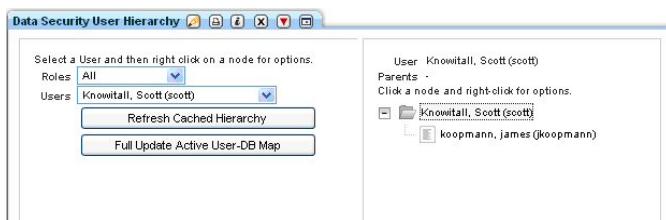

#
grdap create_user_hierarchy userName=jkoopmann parentUserName=scott
```

c. Execute the CLI function call.

Example Call

```
$ ssh cli@a1.corp.com<create_user_hierarchy_api_call.txt
```

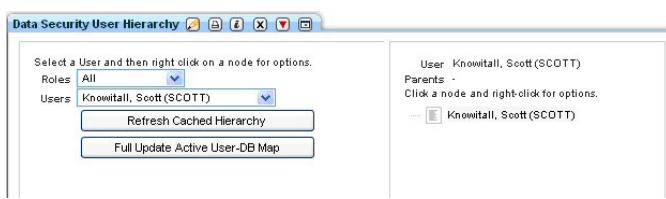

10. Validate. For this scenario it is a redisplay of the Data Security User Hierarchy.

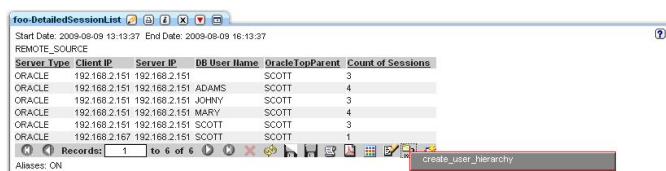

#### Multi Row API call

This scenario uses a custom report with mapped parameters to report fields. Please see additional scenarios further in this section for additional information.

1. To begin, let's show the current **Data Security User Hierarchy** for the user **scott**

2. Click on the **Invoke...** icon to display a list of APIs that are mapped to this report

3. Click on the **API** you'd like to invoke; bringing up the API Call Form for the Report and Invoked API Function. Invoking an API call from a report for multiple rows will produce an API Call Form that displays and enables the editing of all records displayed on the screen (dependent on the fetch size) to a maximum of 20 records.

Api Call Form - Mozilla Firefox

Report: foo-DetailedSessionList  
Api Function: create\_user\_hierarchy

| username *                                | parentUserName * |
|-------------------------------------------|------------------|
| <input checked="" type="checkbox"/> ADAMS | SCOTT            |
| <input checked="" type="checkbox"/> JOHNY | SCOTT            |
| <input checked="" type="checkbox"/> MARY  | SCOTT            |
| <input checked="" type="checkbox"/> SCOTT | SCOTT            |
| <input checked="" type="checkbox"/> SCOTT | SCOTT            |

\* Required parameter

Log level: 0 Parameter to encrypt: -----

Generate script    Invoke now

Done

4. Use the **check boxes** to select / de-select the rows that will be targeted for the API call.
5. Fill in the **Required Parameters** and any **non-Required Parameters** for the selected API call. Many of the parameters are pre-filled from the report but may be changed to build a unique API call. For specific help in filling out required or non-required parameters please see the individual API function calls within the GuardAPI Reference guide. Additionally, use the set of parameters for the API to enter a value for a parameter and then click the down arrow to populate that parameter for all records.
6. Use the drop-down list to select the **Log level**, where Log level represents the following (0 - returns ID=identifier and ERR=error\_code as defined in Return Codes, 1 - displays additional information to screen, 2 - puts information into the Guardium application debug logs, 3 - both 1 and 2).
7. Use the drop-down list to select a **Parameter to encrypt**.  
Note: Parameter Encryption is enabled by setting the Shared Secret and is relevant only for invoking the API function through script generation.

8. Choose to **Invoke Now** or **Generate Script**.

a. If **Invoke Now** is selected the API call runs immediately and displays an API Call Output screen showing the status of the API call. In this specific scenario the last two API calls would fail since we can not have a cyclical relationship in the hierarchy.

b. If **Generate Script** is selected: Open the generated script with your favorite editor or optionally save to disk to edit and execute at a later time. You can replace any of the empty parameter values (denoted by '< >') if contained within the script. With this scenario, we could easily delete the last two lines of the script -- knowing they would create cyclical errors.

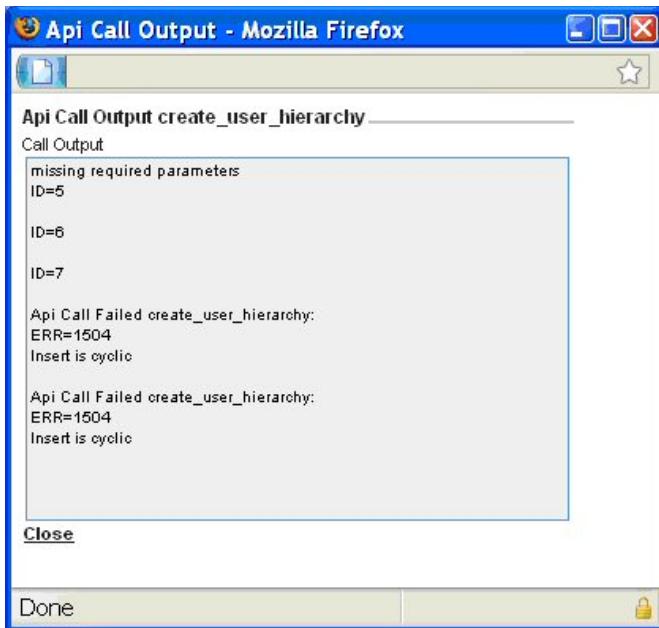

Note: Empty parameters are valid in the script since the API call ignores them.

Example Script

```
A template script for invoking guardAPI function create_user_hierarchy :
Usage: ssh cli@al.corp.com<create_user_hierarchy_api_call.txt
replace any < > with the required value
#
grdapi create_user_hierarchy userName=ADAMS parentUserName=SCOTT
grdapi create_user_hierarchy userName=JOHNY parentUserName=SCOTT
grdapi create_user_hierarchy userName=MARY parentUserName=SCOTT
grdapi create_user_hierarchy userName=SCOTT parentUserName=SCOTT
grdapi create_user_hierarchy userName=SCOTT parentUserName=SCOTT
```

Then Execute the CLI function call, for example:

```
$ ssh cli@al.corp.com<create_user_hierarchy_api_call.txt
```

9. Validate. For this scenario it is a re-display of the Data Security User Hierarchy.

## How to use Constants within API Calls

Create a new entity attribute to be used during an API function call.

Value-added: Through a GUI, create a user-defined constant that can be used for filling in a parameter in an API function call .

- From our report, we can modify it to have a field that we could use for parameter mappings.

| Server Type | Client IP     | Server IP     | DB User Name | Count of Sessions |
|-------------|---------------|---------------|--------------|-------------------|
| ORACLE      | 192.168.2.151 | 192.168.2.151 |              | 3                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | ADAMS        | 4                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | JOHNY        | 3                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | MARY         | 4                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | SCOTT        | 3                 |
| ORACLE      | 192.168.2.167 | 192.168.2.151 | SCOTT        | 1                 |

- Go to the Query Entities & Attributes report for the Client/Server entity within the ACCESS RULES VIOLATIONS domain. Double-click on a row and select the Invoke... option.

**Query Entities & Attributes**

DOMAIN\_LIKE LIKE % ENTITY\_LIKE LIKE Client/Server  
ATTRIBUTE\_LIKE LIKE %

| Domain Name             | Entity Label  | Attribute Label     |
|-------------------------|---------------|---------------------|

| ACCESS RULES VIOLATIONS | Client/Server | Source Program      |

Records: 1 to 20 of 150 Aliases: ON

4. Fill in the constant value to use ('SCOTT'), fill in the attributeLabel you like to name it ('OracleTopParent'), and then click on the Invoke now button to create the constant.

**Api Call Form - Mozilla Firefox**

Report: Query Entities & Attributes  
Api Function: create\_constant\_attribute

|                |                 |
|----------------|-----------------|
| constant       | SCOTT           |
| entityLabel    | Client/Server   |
| attributeLabel | OracleTopParent |

\* Required parameter

Log level: 0 Parameter to encrypt: -----

Generate script    **Invoke now**

Done

5. Clicking on the Invoke now button will produce a API Call Output status showing the constant was created.

**Api Call Output create\_constant\_attribute**

Call Output

```
ID=20000
Constant SCOTT Created
```

6. A re-display of the Query Entities & Attributes report will show the new attribute created.

| Domain Name             | Entity Label  | Attribute Label     |
|-------------------------|---------------|---------------------|
| ACCESS RULES VIOLATIONS | Client/Server | Access Id           |
| ACCESS RULES VIOLATIONS | Client/Server | Analyzed Client IP  |
| ACCESS RULES VIOLATIONS | Client/Server | Client Host Name    |
| ACCESS RULES VIOLATIONS | Client/Server | Client IP           |

| ACCESS RULES VIOLATIONS | Client/Server | Service Name                    |
| ACCESS RULES VIOLATIONS | Client/Server | Source Program                  |

9. Fill in the functionName and the parameterName and click on the Invoke now button.

Api Call Form - Mozilla Firefox:

Report: Query Entities & Attributes  
Api Function: create\_api\_parameter\_mapping

|                 |                        |
|-----------------|------------------------|
| functionName    | create_user_hierarchy  |
| parameterName   | parentUserName         |
| domain          | ACCESS RULES VIOLATION |
| entityLabel     | Client/Server          |
| attributeLabel  | OracleTopParent        |
| api_target_host |                        |

\*Required parameter

Log level: 0

Parameter Encryption not enabled - shared secret not set.

Generate script    Invoke now

Done

10. The newly created attribute must be added to the report. Edit the query through Query Builder and add the field.

The screenshot displays two instances of the Query Builder application window. Both windows show a hierarchical navigation pane on the left with categories like 'Session', 'Application Events', 'SQL', and 'Command'. The main area contains a 'foo-DetailedSessionList' report. In the first window (left), a context menu is open over the 'OracleTopParent' attribute in the 'Query Conditions' pane, with options like 'Add Field', 'Add Condition', 'Remove', 'Clone', 'Roles...', 'Save', and 'Back'. The second window (right) shows the same setup but without the context menu open.

11. Now when the report is displayed the new attribute is displayed.

| foo-DetailedSessionList                                                        |               |               |              |                 |                   |
|--------------------------------------------------------------------------------|---------------|---------------|--------------|-----------------|-------------------|
| Start Date: 2009-08-09 13:07:42 End Date: 2009-08-09 16:07:42<br>REMOTE_SOURCE |               |               |              |                 |                   |
| Server Type                                                                    | Client IP     | Server IP     | DB User Name | OracleTopParent | Count of Sessions |
| ORACLE                                                                         | 192.168.2.151 | 192.168.2.151 | SCOTT        | 3               |                   |
| ORACLE                                                                         | 192.168.2.151 | 192.168.2.151 | ADAMS        | SCOTT           | 4                 |
| ORACLE                                                                         | 192.168.2.151 | 192.168.2.151 | JOHNNY       | SCOTT           | 3                 |

A context menu is open over the 'JOHNNY' row in the table, listing various reporting options:

- Admin Users Sessions
- Client IP Activity Summary
- DB Predefined Users Sessions
- DB Server Throughput-Chart
- Detailed Sessions List
- Exceptions Type Distribution
- Full SQL By Client IP
- Full SQL By DB User
- Sessions By Client IP
- Sessions By Server IP
- Sessions By Source Program
- Sessions By User
- Sessions Details By Server
- Throughput-Chart
- User Activity Summary
- Alias Definition
- Invoke...

13. Select the API function

| Server Type | Client IP     | Server IP     | DB User Name | OracleTopParent | Count of Sessions |
|-------------|---------------|---------------|--------------|-----------------|-------------------|
| ORACLE      | 192.168.2.151 | 192.168.2.151 | ADAMS        | SCOTT           | 3                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | JOHNY        | SCOTT           | 3                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | MARY         | SCOTT           | 4                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | SCOTT        | SCOTT           | 3                 |
| ORACLE      | 192.168.2.151 | 192.168.2.151 | SCOTT        | SCOTT           | 1                 |

14. Now the parentUserName is populated from the newly added constant. Click the Invoke now button.

Report: foo-DetailedSessionList  
Api Function: create\_user\_hierarchy

userName: JOHNY \*  
parentUserName: SCOTT \*

\* Required parameter

Log level: 0 Parameter to encrypt: -----

Generate script    Invoke now

Done

15. Validate the new Data Security User Hierarchy.

Select a User and then right click on a node for options.

Roles: All  
Users: Knowitall, Scott (SCOTT)

Parents: Click a node and right-click for options.

- User: Knowitall, Scott (SCOTT)
  - Parents:
  - Click a node and right-click for options.
  - Nodes:
    - Knowitall, Scott (SCOTT)
    - Cat, Johny (JOHNY)
    - koopmann, james (koopmann)
    - Smith, Adams (ADAMS)

## How to use API Calls from Custom Reports

Link API functions to reports and map report fields to the API functional parameters.

Value-added: Through a GUI, quickly and easily map API parameters to custom report fields to be used in API function calls.

By default, a newly created custom report does not have any API functions linked to it. Linking API functions to reports is done through Guardium's Query-Report Builder

1. Open the Query-Report Builder, find your custom report, and then click on the API Assignment button.
2. The API Assignment panel shows all the API functions assigned to the selected report. Notice for our scenario the report selected has no API functions assigned to it.

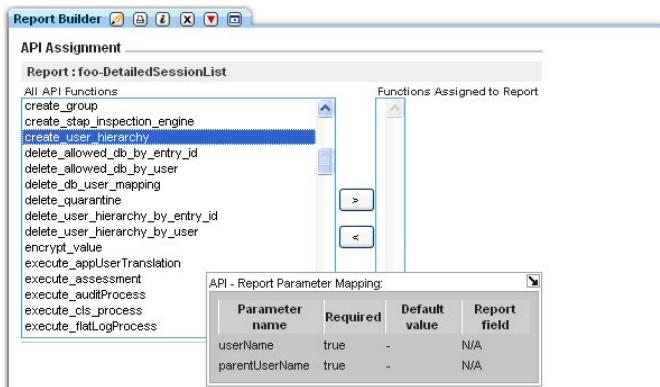

Report : foo-DetailedSessionList

All API Functions

Functions Assigned to Report

Back    Apply

3. To assign an API function to a report, find an API you'd like to link to the report, click the greater than arrow, and then click the apply button. For our scenario we selected create\_user\_hierarchy. When selected a pop-up window will appear that shows the report parameter mappings (which report fields will be used when calling the API function). Notice there are no mapped report fields to parameter names.

4. At this point, none of the report fields are mapped to the API parameters. Users can go to the Query Entities & Attributes report to create these mappings, otherwise when invoking the API call none of the parameters will have values. add the API parameter mappings. Open the Query Entities & Attributes report and create the mappings. Since our report for this scenario uses the Client/Server entity within the ACCESS RULES VIOLATIONS domain, filter the report by using the customize button; modifying the report to display only the Client/Server entity.

| Query Entities & Attributes                                           |               |                     |

## Working with external feeds

Use external feeds to send Guardium report data directly to an external database. Sending reporting data to an external database is useful in several scenarios, for example when combining or correlating Guardium data with non-Guardium data, when using Guardium data with external tools, or when machine-parsing records in especially large reports.

- [Mapping an External Feed](#)  
Learn how to map an external feed to send Guardium report data directly to an external database.
- [Creating an external feed](#)  
An external feed task defines the task and the target external database.

## Mapping an External Feed

Learn how to map an external feed to send Guardium report data directly to an external database.

### Before you begin

Verify the following prerequisites before mapping an external feed:

- Identify the external database that will receive data from the feed, and gather the connection information required for that database (ip address, port number, username, password, etc.). External feeds currently support relational databases and may not function with other database types.
- Identify the Guardium report that will provide data to the external feed.

## About this task

External feeds allow you to send Guardium report information directly to an external database. Anything that can be defined in a report can be sent via an external feed. These feeds depend on mapping DOMAIN\_ID and ATTRIBUTE\_ID from Guardium's reporting mechanism to table fields on the external database. Each mapping consists of the records in four tables (EF\_MAP\_TYPE\_HDR, EF\_MAP\_TABLE, EF\_MAP\_COLUMN, and EF\_MAP\_GDM\_TYPE). Use the `grdapicreate_ef_mapping` function to help create these tables and establish the mapping.

## Procedure

1. Generate a report with the data you would like to transfer using an external feed. You can do this from a central manager, aggregator, or stand-alone Guardium instance, provided that system can access the report data you require.
2. From the CLI, run `grdapicreate_ef_mapping reportName="My report"`. In addition to establishing the mapping, the `grdapicreate_ef_mapping` function also generates a sample `create table` statement to be used in subsequent steps.
3. On the Guardium system where your report is defined, search `/var/log/guard` for a filename like `ef_sample_[my_report].sql`. This file contains the example `create table` statements. You must modify the statements in this file to match the requirements of your external database. After modifying the file, run the statements against your external database to create the target tables.

## Results

The external feed should now be available for use in workflow processes defined through the audit process builder. Continue with [Creating an external feed](#).

## Creating an external feed

An external feed task defines the task and the target external database.

Before using external feeds, verify the following prerequisites:

- [Mapping an External Feed](#): Map a feed between Guardium and an external database. External feeds currently support relational databases and may not function with other database types.
- The External Data Feed is an optional component. It must be enabled (by product key), or else you cannot create an external feed.
- Create a report defining the data to send via the external feed. Predefined reports do not work with external feeds. If you want to use a predefined reports, make a copy with the report and use the copy for the external feed.

The first time that an optional external feed task runs, the necessary internal representation of the audit sources are created. One limitation is that data that is timestamped with a date earlier than the audit source creation date cannot be stored. This means that the first time the task runs, it only exports data for the current date. On subsequent executions of the task, following that date, any data from that date forward can be exported. (In other words, the next day, you can export that day's data plus the prior day's data.)

If you have not yet started to define a compliance workflow automation process, see [Create a Workflow Process](#) before performing this procedure.

1. Navigate to Comply > Tools and Views > Audit Process Builder and click . The Create New Audit Process window opens.
2. Type in the name of the process.
3. Open the Add Tasks row and click .
4. From the Task Type drop-down list, select External Feed. The New Task window refreshes with the External Feed parameters.
5. Fill in the parameters:
  - Name: a unique task name
  - Feed Type: (The controls that appear next depend on the feed type selected.)
  - External Feed Event:
  - Report: the report Depending on the report selected, a variable number of parameters appear in the Task Parameters pane.
  - In the Extract Lag box, enter the number of hours by which the feed is to lag, and mark the Continuous box to include data up to the time that the audit task runs. Extract Log only works when the Continuous box is marked.
  - Datasource: identify one or more datasources for the external feed, or create a new datasource by clicking .
  - Enter all parameter values in the Task Parameters pane. The parameters vary depending on the report selected. Count column is not supported in External Feed.
6. Click OK.

## Creating reports for z/OS

Learn how to create Guardium reports for z/OS data sources by customizing built-in reports and example queries.

While the process of creating reports for z/OS data sources is the same as for other databases, there is not always a direct mapping between mainframe concepts and Guardium's reporting entities and attributes. To ease communication between auditors and mainframe personnel, this section outlines the mapping of mainframe event data to Guardium entities and attributes. There are some built-in reports that can be customized, and this information describes additional queries that are useful for typical auditing scenarios.

## Built-in reports for Data Sets

### DATA SET Access

This report is based on a main entity of "object". This means that the report has one line for each object (data set). So if you have an access command (Verb) with multiple objects, the command will appear in the report multiple times, once for each object.

The extra rows can be skipped if you check 'add distinct' in the Query-Report Builder for the report.

Note: This report does have customized column names to make the report more readable. By editing the report query and comparing with the report headers, you can see the differences.

Example: Instead of SQL Verb, the column is Action. And instead of DB Protocol, the column is Event Type.

If you like the built-in query and want to further customize the report, you can go to Report Builder to clone the report definition and customize the column headers.

### DATA SET Access

This report is based on the Full SQL main entity and includes a pretty complete set of attributes for data set and record level access.

Recommendation: Clone this query and make the following modifications:

- Move the timestamp to the first column.
- Add the full SQL ID column to enable very detailed sorting if timestamp granularity is not fine enough.
- Review the query conditions in the query. If you want to use the same report for other databases, such as IMS, you may want to make the DB Protocol field a Parameter instead of a value.

## Report entities and attributes for Data Sets

Use this information to find reporting attributes for Data Sets.

Table 1. Attributes for Client/Server Entity (Data Sets)

| Attribute          | Description                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp          | All attributes in this session are static, so this timestamp is created only once, when Guardium observes a request on the defined connection for the first time. |
| Service Name       | LPAR.                                                                                                                                                             |
| Server Description | Not populated.                                                                                                                                                    |
| DB User Name       | Not populated. Use the following attributes from the Full SQL entity instead: IMS/DATA SET User ID or VSAM RLM CICS User ID (for RLM only)                        |
| Server Type        | DATA SET. IMS. If more than one type of database is writing events to the Guardium system, this field helps separate the events.                                  |
| Server IP          | IP Address of LPAR.                                                                                                                                               |
| Server Host Name   | Hostname of LPAR.                                                                                                                                                 |
| Client IP          | IP address of S-TAP. Usually the same as the Server IP.                                                                                                           |
| Network Protocol   | Type of access. <ul style="list-style-type: none"><li>• DATA SET</li><li>• DATA SET Record Level Monitoring (RLM)</li></ul>                                       |
| DB Protocol        | DATA SET                                                                                                                                                          |
| Source Program     | Job type:<br>STC – Started Task<br>TSU-Time sharing user<br>JOB-Batch job<br>APPC – Advanced Program-to-Program communication)<br>OMVS- Unix System Services      |

Table 2. Attributes for Session Entity (Data Sets)

| Attribute  | Description                                                                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp  | Initially, a timestamp created for the first request on a connection. Later, it is updated when it is marked inactive following an extended period of time with no observed activity. |
| Session ID | Unique identifier generated by Guardium. Because IMS does not have the concept of 'sessions', this is not particularly meaningful in IMS reporting.                                   |

| Attribute | Description                                                        |
|-----------|--------------------------------------------------------------------|
| Access ID | Uniquely identifies the access period for this line of the report. |

Table 3. Attributes for Access Period Entity (Data Sets). This entity provides no useful information for Data Sets monitoring.

| Attribute              | Description                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application User       | Not used for Data Sets                                                                                                                                                                                                      |
| Failed SQLs            | Not used for Data Sets                                                                                                                                                                                                      |
| Total Records Affected | Not used. You will see -1 in this field. If you are interested in seeing how many records are affected for VSAM data sets, see the Data Set Records Inserted, Updated, Deleted and Retrieved fields in the Full SQL entity. |
| Successful SQLs        | Not used.                                                                                                                                                                                                                   |

Table 4. Attributes for Full SQL Entity (Data Sets)

| Attribute                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Full SQL                             | Contains almost all information about an event. Computed attributes for other report fields are created from this data, which includes:<br>uid=; prog=; job=; step=; step#=; job#=; ugid=; rec_dlt=; rec_del=; rec_ins=; rec_upd=; rec_ret=; pre=; desc=; type=; dbd=; dsn=; smf_accs=; nvs_mmb=; vsm_ddn=; nrexctr=; evt_time=;<br><br>In general, you don't need to include this attribute in reports, since the data is available in a more consumable fashion using other attributes. |
| Timestamp                            | Timestamp of the event in the collector's timezone.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Records Affected                     | Not used. Instead, use the attributes DATA SETS Records Retrieved, Updated, Deleted, Inserted.                                                                                                                                                                                                                                                                                                                                                                                            |
| Returned Data                        | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Full SQL ID                          | Unique, sequenced identifier for this event. Can be helpful for sorting events in sequence.                                                                                                                                                                                                                                                                                                                                                                                               |
| Ack Response Time                    | Microsecond value from Timestamp of the event on the mainframe.<br>Example: 677032<br>It is not recommended to use this field for sorting as it does not include leading zeros. Use Full SQL ID instead.                                                                                                                                                                                                                                                                                  |
| Statement Type                       | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Blind Variables Values               | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IMS/DATA SET Program Name            | The name of the application program issuing the data set calls or other access.                                                                                                                                                                                                                                                                                                                                                                                                           |
| IMS/DATA SET Step Name               | JCL step name for the executing program.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| IMS/DATA SET Step Number             | JCL step number for the executing program.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| IMS/DATA SET Previous DSN            | Data Set name before the rename occurred.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IMS/DATA SET Name                    | The data set name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| IMS/DATA SET Context                 | Type of activity. Examples for Data Set level reporting: DATA SET OPEN, DATA SET CLOSE, Member Delete, Member update, Security facility READ violation, Security facility ALTER violation, etc. For record level monitoring: Record Insert, Record Read, Record Update, and Record Delete.                                                                                                                                                                                                |
| IMS SMF/DATA SET Expiration Days     | How many days until the data set expires.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IMS SMF/DATA SET Expiration IPL Time | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IMS SMF/DATA SET Type                | Possible values for Data set monitoring: VSAM, Non-VSAM.<br><br>Possible values for record level monitoring: RRDS, KSDS, VRRDS                                                                                                                                                                                                                                                                                                                                                            |

The possible function codes and their mappings are as follows:<br>1 – READ_INTO<br>2 – READ_SET<br>3 – READ_UPDATE_SET<br>4 - READ_UPDATE_INTO<br>5 – WRITE<br>6 – REWRITE<br>8 – REWRITE_DELETE<br>10 – DELETE<br>11 – UNLOCK<br>12 – START_BROWSE<br>13 – READ_NEXT_INTO<br>14 – READ_NEXT_SET<br>15 – READ_PREVIOUS_INTO<br>16 – READ_PREVIOUS_SET<br>17 – READ_NEXT_UPDATE_INTO<br>18 – READ_NEXT_UPDATE_SET<br>19 - READ_PREVIOUS_UPDATE_INTO<br>20 - READ_PREVIOUS_UPDATE_SET<br>21 – RESET_BROWSE<br>22 – END_BROWSE |
| VSAM SMF Access Type            | Possible values: IN, OUT Written only on CLOSE events. Distinguishes whether an access was "open for read" (IN) or "open for update" (OUT).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| IMS/DATA SET Event Time         | Timestamp of the event as recorded on the host in UTC format. The collector timezone is in the Timestamp field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DATA SET Non-VSAM Member        | If a PDS or PDSE member is allocated and opened, Member name is reported on event close. For programs that can access/update multiple members, such as IEBCOPY, member names are not reported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DATA SET DD Name                | The data definition (DDNAME) in the JCL or dynamically allocated by the started task.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Data SET Non-VSAM EXCP Count    | The execute channel program (EXCP) counts for non-VSAM data sets, which basically tells you the number of reads and writes against these non-VSAM data sets. This allows for more granular reporting of access to partitioned data sets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DATA SET RLM DD Name            | The data definition (DDNAME) in the JCL or dynamically allocated by the started task for RLM monitoring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Timestamp(microsec)             | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| More information                | Contains CICS Unit of Work ID. There is no reason to use this attribute in your report. Use the DB2 z/IMS/DATA SET attribute for a more consumable version of this information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DB2 z/IMS/DATA SET Unit of Work | CICS unit of work ID, in hex. Only available for record-level monitoring.<br>0x0000000000000000 if this activity is not part of a CICS transaction and RLM is not activated for a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DATA SET Non-VSAM New Member    | If a PDS or PDS/E member name is renamed, this is the new name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 5. Attributes for SQL Entity (Data Sets). The SQL Entity provides no added value for Data Sets reporting. Use the attributes you need from the Full SQL Entity instead

| Attribute     | Description                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------|
| SQL           | Contains a subset of fields from the FULL SQL entity. There is no reason to use this attribute in reporting. |
| Truncated SQL | Not used for data sets.                                                                                      |

Table 6. Attributes for Command Entity (Data Sets)

| Attribute | Description                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL Verb  | The event type. See Data Set Context Field in Full SQL for examples. If this field is added to a report built with Main Entity of Full SQL, this is reported as a count. |

Table 7. Attributes for Object Entity (Data Sets)

| Attribute                 | Description                                              |
|---------------------------|----------------------------------------------------------|
| Object Name               | Name of the data set.                                    |
| Object Type               | Format of the object such as KSDS, RRDS, VSAM, non-VSAM. |
| IMS Segment/DSN/PART/AREA | The data set name.                                       |

Table 8. Attributes for Field Entity (Data Sets)

| Attribute | Description |
|-----------|-------------|
| Field     | Not used.   |

#### Exception Domain

There is no useful information logged in exception domain for Data Sets.

## Built-in reports for DB2 for z/OS

For DB2, there are no built-in reports specifically for z/OS. In many cases, the existing Guardium built-in reports work fine, with perhaps some minor changes because of the way z-specific fields are mapped to the Guardium internal database.

Some of these mappings are shown in the following table.

Table 1. Key mappings of DB2 for z/OS concepts to Guardium report fields

| Concept                                                                                                          | Entity                           | Attribute                           |
|------------------------------------------------------------------------------------------------------------------|----------------------------------|-------------------------------------|
| Subsystem ID                                                                                                     | Client/Server                    | Service Name                        |
| Location Name                                                                                                    | Client/Server                    | Service Description                 |
| Database Name                                                                                                    | Access Period                    | DB2 i/z Database                    |
| Plan Name of originating request                                                                                 | App User Name (or Access Period) | App User Name (or Application User) |
| DBRM name for originating request (For example, SYSLH200 is used to execute JDBC distributed dynamic statements) | Access Period                    | DB2 i/z Program Name                |

Tip: You can rename report columns as you like by going to the Query-Report Builder, access the query, click the Display Options row and modify the column headings.

## Example reports for DB2 for z/OS

This section includes queries that you can use as a base for building your own DB2 for z/OS reports.

Start by looking at the following queries:

- DB2 z/OS Connection Report (Main Entity: Session Start). This report can help you get the “big picture” of what types of applications and users are connecting to your DB2 environment.
- DML on Sensitive Objects (Main Entity: Object) This report depends on two groups: One that contains your sensitive objects and one that contains DML commands. You can easily clone the beginning of this report from the System-defined report “DML Execution on Sensitive Objects” and add the additional columns such as Network Protocol and Service Name.

Table 1. DB2 z/OS Connection Report Query Fields (Main Entity: Session Start)

| Entity        | Attribute        | Field Mode                                                | Comments                                                                                                                                                                                                                                                |
|---------------|------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session       | Session Start    | Value (Check Order-by, Sort Rank 1 and check Dec end box) |                                                                                                                                                                                                                                                         |
| Client/Server | Service Name     | Value                                                     | This is the SSID                                                                                                                                                                                                                                        |
| Client/Server | DB User Name     | Value                                                     |                                                                                                                                                                                                                                                         |
| Client/Server | Network Protocol | Value                                                     | Concatenation of Connection Name and Connection Type. Example TSO:BATCH and DRDA:SERVER                                                                                                                                                                 |
| Client/Server | Client IP        |                                                           |                                                                                                                                                                                                                                                         |
| Client/Server | Server IP        |                                                           |                                                                                                                                                                                                                                                         |
| Client/Server | Source Program   |                                                           | Concatenation of server name with correlation name and ID. Could vary based on what the application sends. Example from distributed application (DB2JCC) could be: GUARDIUMZ4.SVL.I:DB2JCC_APPL A CICS transaction could be the transaction identifier. |

Table 2. DB2 z/OS Connection Report: Query Conditions

| Entity              | Attribute and Operator                  | Comments                                                             |
|---------------------|-----------------------------------------|----------------------------------------------------------------------|
| WHERE Client/Server | DB Protocol=Value DB2/Z                 | This narrows report to just DB2 z/OS traffic.                        |
| AND Client/Server   | Service Name LIKE Parameter ServiceName | Use % in your runtime parameters to display data from all SSID data. |
| AND Client/Server   | DB User Name LIKE Parameter DBUser      | Use % in your runtime parameters to display all data.                |

Table 3. DML on Sensitive Objects Query Fields (Main Entity: Object)

| Entity        | Attribute        | Field Mode                                                  | Comments                                                                                                                            |
|---------------|------------------|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| FULL SQL      | Timestamp        | Value                                                       |                                                                                                                                     |
| Client/Server | Service name     | Value                                                       | This is the SSID.                                                                                                                   |
| Client/Server | Network Protocol | Value                                                       | Concatenation of Connection Name and Connection Type. Example TSO:BATCH and DRDA:SERVER                                             |
| Client/Server | DB User Name     | Value                                                       |                                                                                                                                     |
| Object        | Object Name      | Value                                                       |                                                                                                                                     |
| Command       | SQL Verb         |                                                             |                                                                                                                                     |
| Client/Server | Client IP        |                                                             |                                                                                                                                     |
| FULL SQL      | Full SQL         |                                                             | This field is populated only with LOG FULL DETAILS policy rule.                                                                     |
| FULL SQL      | Full SQL ID      | Value with Order-by checked, Sort-by =1 and Descend checked | This can help order events within a second in the correct order.<br>This field is populated only with LOG FULL DETAILS policy rule. |

| Entity             | Attribute       | Field Mode | Comments                                                                                                                                                                                                                 |
|--------------------|-----------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| App User Name      | App User name   | Value      | Consists of PLAN, SQLID, PROG and DB_NAME Example: PLAN=DISTSERV ; SQLID=SYSADM ; PROG=SYSLH200 ; DB_NAME=DSN00006<br><br>Note: If AppEvents mechanism is used to collect 'real' end user, this field will display that. |
| Application Events | DB2 Client Info | Value      | Information in the DB2 Client Info depends on what the application assigns to these fields. None, some, or all values could be populated: WSUSER, APPL, WKSTN.                                                           |

Table 4. DML on Sensitive Objects Query Conditions

| Entity              | Attribute and Operator                                                                             | Comments                                                                                                                                                                                                         |
|---------------------|----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WHERE Client/Server | DB Protocol=Value DB2/Z                                                                            | This narrows report to just DB2 z/OS traffic.                                                                                                                                                                    |
| AND Client/Server   | Service Name LIKE Parameter Service Name                                                           | Use % in your runtime parameters to display data from all SSIDs.                                                                                                                                                 |
| AND Client/Server   | DB User Name LIKE Parameter DB User                                                                | Use % in your run time parameters to display all data                                                                                                                                                            |
| AND Object          | Object Name LIKE GROUP Sensitive Objects (or whatever you have named your sensitive objects group) | Objects could be views, aliases, package names, or plan names. If Quick Parse Native is used, the schema.base-table-name is used instead of view or aliases. Make sure your groups accommodate this flexibility. |
| AND Command         | SQL Verb IN GROUP DML Commands (or whatever you have named your DML group)                         |                                                                                                                                                                                                                  |

Tip: Reporting on **SELECT \* Users**: You can choose whichever query fields you like and include a query condition for Full SQL **LIKE Value %select%\***. Alternatively, you can specify this as a Parameter and specify it at run time (using the wrench icon to customize the run time parameters).

## Report entities and attributes for DB2 for z/OS

Use this information to find reporting attributes for DB2 for z/OS.

This is not meant to be a complete listing of all entities and attributes. See [Domains, Entities, and Attributes](#) for the complete list.

Table 1. Attributes for Client/Server Entity (DB2 for z/OS)

| Attribute          | Description                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp          | All attributes in this session are static, so this timestamp is created only once, when Guardium observes a request on the defined connection for the first time.                                                                                        |
| OS User            | OS USER, TSO logon ID, or Authid for batch job.<br>Example: SYSADM                                                                                                                                                                                       |
| DB User Name       | Authorization ID                                                                                                                                                                                                                                         |
| Service Name       | DB2 SSID                                                                                                                                                                                                                                                 |
| Server Description | DB2 Location name.<br>Example: STLEC1                                                                                                                                                                                                                    |
| Network Protocol   | Concatenation of connection type and name.<br>Example: TSO:BATCH and DRDA:SERVER                                                                                                                                                                         |
| DB Protocol        | DB2/Z.                                                                                                                                                                                                                                                   |
| Client IP          | This is the IP Address of the client workstation for distributed connections.                                                                                                                                                                            |
| Server Host Name   | LPAR name - example: LABEC247                                                                                                                                                                                                                            |
| Source Program     | Concatenation of Server name with correlation name and ID. Could vary based on what the application sends. Example from distributed application (DB2JCC) could be: GUARDIUMZ4.SVL.I:DB2JCC_APPL. A CICS transaction could be the transaction identifier. |
| Server Type        | DB2. If more than one type of database is writing events to the Guardium system, this field helps separate the events.                                                                                                                                   |

Table 2. Attributes for Session Entity

| Attribute     | Description                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session Start | Sessions in z/OS are not able to be specified the same way as in distributed platforms, which relies on logins and logouts to the database. A session identifier is based on a set of characteristics and the timestamp recorded for that "session." |
| Session End   | Timestamp recorded after a period of no activity on the associated session.                                                                                                                                                                          |
| UID Chain     | Contains the VTAM network ID. Example: NETWORK_ID=G91E7FCC                                                                                                                                                                                           |
| Terminal ID   | For distributed access, this is the outgoing client port or socket In hex.<br>Example: A314 (port 41748)                                                                                                                                             |
| Process ID    | This is a thread token identifier. You probably won't need this for normal reporting purposes.                                                                                                                                                       |

Table 3. Attributes for Client Server / Session Entity

| Attribute                                                     | Description                                                                                                                                            |
|---------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| Server IP/Port                                                | Server IP concatenate with zero. Server port is always 0.                                                                                              |
| Client IP/Src App/DB User/Server IP/Svc. Name/OS User/DB Name | A tuple containing the named fields. Note: DB Name is always blank. You must obtain DB Name from the Access Period Entity, DB2 i/z Database attribute. |
| UID Chain                                                     | Contains the VTAM network ID.<br>Example: NETWORK_ID=G91E7FCC                                                                                          |
| Terminal ID                                                   | For distributed access, this is the outgoing client port or socket In hex.<br>Example: A314 (port 41748)                                               |
| Process ID                                                    | This is a thread token identifier. You probably won't need this for normal reporting purposes.                                                         |

Table 4. Attributes for Access Period Entity (DB2 for z/OS)

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

| Attribute             | Description                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB2 i/z Program       | This is the name of the DBRM that contains the executable code within the bound plan.<br>Example: SYS1H200 is used to execute JDBC distributed dynamic statements. |
| DB2 i/z Database      | Database name<br>Example: DSN00006                                                                                                                                 |
| Application User Name | This consists of consists of PLAN, SQLID, PROG and DB_NAME Example: PLAN=DISTSERV ; SQLID=SADM ; PROG=SYS1H200 ; DB_NAME=DSN00006                                  |
| SQL                   | SQL text “template”; i.e., construct. Field values are replaced by question marks.<br>Example: INSERT INTO GDMC_LABEC247_VA1A VALUES (?, ?, ?, ?, ?, ?, ?)         |

Table 5. Attributes for Full SQL Entity (DB2 for z/OS)

| Attribute                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID                                        | A generated value for each statement. You can use this to put statements in order.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timestamp                                 | A timestamp from the DB2 server.<br>Example: 2012-04-25-11.51.40.005951                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Ack Response Time                         | Microsecond value from Timestamp.<br>Example: 677032<br>It is not recommended to use this field for sorting as it does not include leading zeros. Use FullSQL ID instead.                                                                                                                                                                                                                                                                                                                                                               |
| Records Affected                          | Number of rows, valid for SELECT, INSERT, or DELETE. -1 if not applicable or if number of rows is not available.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| More Information: TSSTOC=; stmttyp=; pds= | This contains a variety of information.<br><br>TSSTOC=. Store clock value. Example: TSSTOC=0x00D13309E22C45D8D4000000012F0001; May be useful to facilitate correlation of events within a commit or rollback.<br><br>Stmttyp= 'S' for Static and 'D' for Dynamic. If you want to sort by this field, then it's recommended that you use the DB2 z Statement Type attribute of this Entity instead, which pulls this value into a separate attribute.<br><br>pds- For a Bind Package command, this is the PDS Name for the DBRM members. |
| Bind Variables Values                     | The values of the host variables. To log masked data instead, use LOG MASKED DETAILS policy rule for the appliance.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Full SQL                                  | Full SQL statement logged for each occurrence. Example: INSERT INTO GDMC_LABEC247_VA1A VALUES ('/08/15/16 19:49:56.653', '/08/15/16 19:49:56.653'--, 1, 1, 1, 'guardiumz4 -count -update -server nulldn9seq -test_duration 7 -delay 999 -concurrent_connections 1')<br><br>This can also contain the full BIND PLAN and BIND PACKAGE commands.<br><br>Note: Values can be masked by using LOG MASKED DETAILS in the appliance policy.                                                                                                   |
| App User Name                             | Displays the user name from the App Event entity of an App Event exists; otherwise, displays Application User from Access Period Entity.                                                                                                                                                                                                                                                                                                                                                                                                |
| DB2 z/IMS/DATA SET Unit of Work           | Computed attribute containing the CICS Unit of Work ID that can be used to correlate CICS traffic across multiple S-TAP Entities (IMS, Data Sets, and DB2).                                                                                                                                                                                                                                                                                                                                                                             |
| DB2 z Statement Type                      | Computed attribute that contains either 'Static' or 'Dynamic'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DB2 z/IMS/DATA SET Unit of Work           | CICS unit of work ID, in hex. Can be used to correlate data access events across DB2, IMS and Data Sets within a CICS Transaction.<br><br>This field is blank if this activity is not part of a CICS transaction.                                                                                                                                                                                                                                                                                                                       |

Note: The appliance-side policy for DB2 for z/OS activities must include the logging action LOG FULL DETAILS to collect Full SQL data. Otherwise, you will only get data in the SQL Entity attributes.

Table 6. Attributes for Application Events Entity (DB2 for z/OS)

| Attribute       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DB2 Client Info | Information in the DB2 Client Info depends on what the application assigns to these fields. None, some, or all values could be populated:<br><br>WSUSER= The user ID of the client end user. Can be CICS original signon client, if used.<br><br>APPL= The application or transaction name of the end user's application.<br><br>WKSTN= The workstation name of the client end user.<br><br>The following two fields are populated only when z/OS Identity propagation is used: DN=X.500 distinguished name<br><br>REG=X.500 registry name<br><br>Example: WSUSER=SYSADM;WRKSTN=guardiumz4.svl.ibm;APPL=db2jcc_application;DN=;REG= |

Table 7. Attributes for SQL Entity (DB2 for z/OS)

| Attribute     | Description                                                                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL           | SQL text by construct. Constructs only reflect the SQL template text and will not log each instance that a matching statement is executed, only once per hour (reporting period).<br>Example: INSERT INTO GDMC_LABEC247_VA1A VALUES (?, ?, ?, ?, ?, ?, ?) |
| Truncated SQL | Yes or No. This is historical and is not used any more.                                                                                                                                                                                                   |

Table 8. Attributes for Command Entity

| Attribute | Description                                                                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL Verb  | This is the SQL verb, such as SELECT, INSERT, UPDATE, DELETE, BIND PLAN or BIND PACKAGE.<br><br>Prior to 10.1.3, the SQL Verb would be recorded differently when Quick Parse Native is used (TABLE READ or TABLE WRITE). With 10.1.3, the Verb will more closely match what is used when LOG FULL DETAILS or ALLOW is used. |

Note: SQL Verb will only be a count in a report created with a Full SQL main entity.

Table 9. Attributes for Object Entity (DB2 for z/OS)

| Attribute   | Description                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Object Name | This is the object used in the SQL, such as the table, view, alias name, plan name, package name, bind plan owner.<br><br>However, if the policy uses a Quick Parse Native action, then a data object will always be the base table in the format schema-name.table-name. |

Table 10. Attributes for Field Entity (DB2 for z/OS)

| Attribute  | Description                                                                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Field Name | This is the column name used in the SQL.<br>Note: You will get field names in other Entities (SQL or Full SQL); this Entity is used for reporting on lists of fields. Use of Quick Parse Native will not allow population of this field. |

Table 11. Attributes for the Exception Entity  
(Main entity: Exception) (DB2 for z/OS)

| Attribute             | Description                          |
|-----------------------|--------------------------------------|
| Exception Description | Contains the negative SQLCODE.       |
| Database Error Text   | The text associated with this error. |

Attention:

- With z/OS, you must specify on the Collection Profile policy rule that you want to collect negative SQLCODEs, and you must also specify which codes to collect. See the following table for a list of negative SQL codes that you might find useful. Refer to the Knowledge Center documentation for DB2 for z/OS to see the complete list of codes to tailor the list to your own needs.
- Some negative SQL codes support descriptions with real SQL values. Where available, these descriptions are included in the "SQL string that caused the exception" report column. Take for example the base description of SQLCODE -556:

```
revoke-target CANNOT HAVE THE privilege PRIVILEGE object-name REVOKED BY revoker-id
BECAUSE THE REVOKEE DOES NOT POSSESS THE PRIVILEGE OR THE REVOKER DID NOT MAKE THE GRANT
```

This description can be presented with real values:

```
ADMF002 CANNOT HAVE THE SELECT PRIVILEGE ON SYSADM.HOLLK REVOKED BY ADMF001
BECAUSE THE REVOKEE DOES NOT POSSESS THE PRIVILEGE OR THE REVOKER DID NOT MAKE THE GRANT
```

Table 12. Suggested list of negative SQL Codes to audit

|        | Description                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -164   | authorization-id DOES NOT HAVE THE PRIVILEGE TO CREATE A VIEW WITH QUALIFICATION qualifier-name                                                                                                                             |
| -204   | name IS AN UNDEFINED NAME                                                                                                                                                                                                   |
| -206   | object-name IS NOT VALID IN THE CONTEXT WHERE IT IS USED                                                                                                                                                                    |
| -551   | auth-id DOES NOT HAVE THE PRIVILEGE TO PERFORM OPERATION operation ON OBJECT object-name                                                                                                                                    |
| -552   | authorization-id DOES NOT HAVE THE PRIVILEGE TO PERFORM OPERATION operation                                                                                                                                                 |
| -553   | AUTHORIZATION ID OR SCHEMA NAME name SPECIFIED IS NOT VALID FOR REQUESTED OPERATION                                                                                                                                         |
| -554   | AN AUTHORIZATION ID OR ROLE CANNOT GRANT A PRIVILEGE TO ITSELF                                                                                                                                                              |
| -555   | AN AUTHORIZATION ID OR ROLE CANNOT REVOKE A PRIVILEGE FROM ITSELF                                                                                                                                                           |
| -556   | revoke-target CANNOT HAVE THE privilege PRIVILEGE object-name REVOKED BY revoker-id BECAUSE THE REVOKEE DOES NOT POSSESS THE PRIVILEGE OR THE REVOKER DID NOT MAKE THE GRANT                                                |
| -557   | INCONSISTENT GRANT/REVOKE KEYWORD keyword. PERMITTED KEYWORDS ARE keyword-list                                                                                                                                              |
| -559   | ALL AUTHORIZATION FUNCTIONS HAVE BEEN DISABLED                                                                                                                                                                              |
| -562   | THE SPECIFIED PRIVILEGES CANNOT BE GRANTED TO PUBLIC.                                                                                                                                                                       |

## Built-in reports for IMS

### IMS Checkpoint Results

This is not a report you would use for auditing. This IMS S-TAP report is used internally to track information. You cannot modify or clone this report.

### IMS Access

This report provides an overview of access (a profile) within the default 1 hour reporting periods. Note that you should change the runtime parameter of DB Protocol and/or Server Type to narrow results to IMS.

### IMS Data Access Details

Uses the full SQL Entity as the main entity and provides full details of each access to IMS.

Tip: When you clone this report, optionally add the DB Protocol attribute from Client/Server as a query condition to avoid mixing this report with other information that may be sent to this appliance.

#### IMS Event

A good report for summarizing the type of access (such as DLI), the psb\_name, and the command and object mapping.

Tip: When you clone the IMS Event report, remove DB User Name from both the column and query condition and replace it with the IMS/DATA SET User ID attribute under the Full SQL entity. In addition, add the Full SQL ID as the last column of the report so you use it for sorting and more clearly see a sequence of events for forensics, as the regular timestamp may not provide enough precision.

You can modify the column names to be more reflective of the content, such as changing Application User to PSB Name.

#### IMS Object

This report provides an object-level view of access.

Tip: When you clone this report, make the following modifications:

- Remove DB User Name from both the column and query condition and replace it with the IMS/DATA SET User ID attribute under the Full SQL entity.
- Remove the Object Type field as well, as this is not populated.
- Add the Full SQL ID as a column as the last column of the report to more clearly see a sequence of events for forensics

## Example reports for IMS

This section includes queries that you can use as a base for building your own IMS reports.

Note: Performance on the reports will be slower the more runtime parameters using 'LIKE' that you add. If you are sending out regularly scheduled batch reports, consider using more hard coded parameters for the query conditions.

The query in the following table is very similar to the IMS Data Detail built in report, but it narrows results to just DLI and also includes some additional fields such as IMS Terminal, IMS Segment, and the SSID (Service Name).

Table 1. IMS DLI Detail Report Query Fields (Main entity: FULL SQL)

| Entity        | Attribute            | Field Mode                                                       | Comments                                                                             |
|---------------|----------------------|------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| FULL SQL      | Timestamp            | Value                                                            |                                                                                      |
| Client/Server | Service Name         | Value                                                            | SSID as defined in the Guardium IMS Definitions panel.                               |
| Client/Server | Server Type          | Value                                                            | Example: IMS                                                                         |
| FULL SQL      | MS/DATA SET User ID  | Value                                                            |                                                                                      |
| Client/Server | Network Protocol     | Value                                                            |                                                                                      |
| FULL SQL      | Source Program       | Value                                                            |                                                                                      |
| FULL SQL      | IMS Transaction      | Value                                                            |                                                                                      |
| FULL SQL      | IMS Terminal         | Value                                                            |                                                                                      |
| FULL SQL      | IMS Segment          | Value                                                            |                                                                                      |
| FULL SQL      | Bind Variable Values | Value                                                            |                                                                                      |
| FULL SQL      | Full SQL             | Value                                                            |                                                                                      |
| FULL SQL      | Full SQL ID          | Value. Order by is checked, sort rank 1, and Descend is checked. | This helps to sequence events in a report when the timestamp is not granular enough. |

Table 2. IMS DLI Detail Report Query Conditions

| Entity            | Attribute and Operator                       | Comments                                                                                         |
|-------------------|----------------------------------------------|--------------------------------------------------------------------------------------------------|
| Client/Server     | Server Type LIKE Value IMS                   |                                                                                                  |
| AND Client/Server | Network Protocol LIKE Value DLI              |                                                                                                  |
| AND Client/Server | Service Name LIKE Parameter ServiceName      |                                                                                                  |
| AND FULL SQL      | IMS/DATASET User ID LIKE Parameter IMSUserID | At runtime, use % or specify a user ID or wildcarded user ID.                                    |
| AND FULL SQL      | Full SQL LIKE Parameter FULLSQL              | At runtime, use % or specify a wild card for a portion of the full SQL string.<br>Example: %GET% |

Table 3. Query for IMS Privileged User Report Query Fields (Main entity: FULL SQL)

| Entity        | Attribute                 | Field Mode | Comments                                               |
|---------------|---------------------------|------------|--------------------------------------------------------|
| FULL SQL      | Timestamp                 | Value      |                                                        |
| Client/Server | Service Name              | Value      | SSID as defined in the Guardium IMS Definitions panel. |
| Client/Server | Server Type               | Value      | Example: IMS                                           |
| Full SQL      | IMS/DATA SET User ID      | Value      |                                                        |
| Client/Server | Network Protocol          | Value      |                                                        |
| FULL SQL      | IMS/DATA SET Program Name | Value      |                                                        |
| FULL SQL      | DBD                       | Value      |                                                        |
| FULL SQL      | IMS/DATA SET Context      | Value      |                                                        |
| FULL SQL      | IMS/DATA SET Job Name     | Value      |                                                        |
| FULL SQL      | IMS/DATA SET Job Number   | Value      |                                                        |
| Access Period | IMS PSB NAME              | Value      |                                                        |
| FULL SQL      | IMS Segment               | Value      |                                                        |

| Entity        | Attribute           | Field Mode                                                       | Comments                                                                                                                                                                                 |
|---------------|---------------------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FULL SQL      | IMS PCB NAME        | Value                                                            |                                                                                                                                                                                          |
| FULL SQL      | IMS Transaction     | Value                                                            |                                                                                                                                                                                          |
| FULL SQL      | IMS Terminal        | Value                                                            |                                                                                                                                                                                          |
| FULL SQL      | IMS DLI Status Code | Value                                                            | If you collected audit events that have non-blank status codes, this field will contain those. Non-blank status codes can indicate that the DLI call failed or completed with a warning. |
| Client/Server | Client IP           | Value                                                            |                                                                                                                                                                                          |
| Client/Server | Server IP           | Value                                                            |                                                                                                                                                                                          |
| FULL SQL      | Full SQL ID         | Value. Order by is checked, sort rank 1, and Descend is checked. | This helps to sequence events in a report when the timestamp is not granular enough.                                                                                                     |
| FULL SQL      | Full SQL            | Value                                                            |                                                                                                                                                                                          |

Table 4. Query for IMS Privileged User Report Query Conditions

| Entity              | Attribute and Operator                       | Comments                                                                                                                                                                                                                                                                                     |
|---------------------|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WHERE Client/Server | Network Protocol LIKE Value DLI              | Make this a runtime parameter instead if you are concerned with privileged activity related to activities reported by SMF and IMS Log reporting.                                                                                                                                             |

| AND FULL SQL        | IMS/DATASET User ID LIKE Parameter IMSUserID |                                                                                                                                                                                                                                                                                              |
| AND FULL SQL        | Full SQL LIKE Parameter FULLSQL              | At runtime, use % or specify a wild card for a portion of the full SQL string.<br>Example: %GET%                                                                                                                                                                                             |
| AND FULL SQL        | IMS/DATA SET User ID IN GROUP AdminUserGroup | Use your own group here for where you keep privileged user IDs. This group can be maintained manually, but it more maintainable by regularly scheduling uploads from the external source that maintains these IDs.<br><br>Wild cards are not allowed in this field because of the use of IN. |

## Report entities and attributes for IMS

Use this information to find reporting attributes for IMS.

Table 1. Attributes for Client/Server Entity (IMS)

| Attribute           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp           | All attributes in this session are static, so this timestamp is created only once, when Guardium observes a request on the defined connection for the first time.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Service Description | IMS Subsystem ID                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Server Type         | IMS. If more than one type of database is writing events to the Guardium system, this field helps separate the events                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Client IP           | IP address of LPAR . Usually the same as the server IP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Server IP           | IP Address of LPAR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Network Protocol    | Reflects each type of IMS S-TAP Audit Event collection component: <ul style="list-style-type: none"> <li>DLI- online or batch DL/I activity</li> <li>SMF- data from SMF Data Collector activity monitor, which can collect events on data sets related to IMS.</li> <li>IMS_LOG – data from the IMS Archived Log Data Collector, used to collect events such as IMS user signon and signoff, changes to DBD and PSB status and IMS online region stops and starts</li> <li>IMS_MIS_LOG – data collected from the IMS Missing Log Utility, which analyzes IMS RECON data sets to confirm existence of log data sets.</li> </ul> |
| DB Protocol         | IMS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DB User Name        | Not populated here for IMS. Use IMS/DATA SET User ID from the FULL SQL entity instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Server Host Name    | Hostname of LPAR                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Source Program      | Region type of the access. For batch: 'DLI BTC' 'DBB BTC' . For online: MPP (Message processing region), JMP (Java Message Processing), BMP (Batch message processing-Transaction oriented) JBP (Java Batch Processing). Other possible values: AER (Application Execution Region), IFP (IMS Fast Path)                                                                                                                                                                                                                                                                                                                        |
| Service Name        | Subsystem name from IMS Definitions panel. If more than one IMS is being audited, Service Name sorting or filtering allows reporting by IMS system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| OS User             | Not used for IMS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

Table 2. Attributes for Session Entity (IMS)

| Attribute  | Description                                                                                                                                                                           |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Timestamp  | Initially, a timestamp created for the first request on a connection. Later, it is updated when it is marked inactive following an extended period of time with no observed activity. |
| Session ID | Unique identifier generated by Guardium. Because IMS does not have the concept of 'sessions', this is not particularly meaningful in IMS reporting.                                   |
| Access ID  | Uniquely identifies the access period                                                                                                                                                 |

Table 3. Attributes for Access Period Entity (IMS)

| Attribute              | Description                                                                                                                          |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Application User       | IMS Program Specification Block (PSB). Appears as psb_name=name. Use the IMS PSB Name attribute instead to report on the name alone. |
| Failed SQLs            | Not used.                                                                                                                            |
| Total records affected | Not used. -1                                                                                                                         |
| Successful SQLs        | Not applicable for IMS.                                                                                                              |
| IMS PSB Name           | IMS Program Specification Block (PSB)                                                                                                |

| Attribute             | Description                  |
|-----------------------|------------------------------|
| Timestamps (microsec) | Not used. Always contains 0. |

Table 4. Attributes for Full SQL Entity (IMS)

| Attribute                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Full SQL                             | Contains all information about an event. Computed attributes for other report fields are created from this data, which includes:<br>uid=; prog=; job=; step=; tran=; job#=; term=; pcb=; pcb#; dli_sts=; before=; desc=; dbd=; seg=;                                                                                                                                                                                                                             |
| Timestamp                            | Timestamp of the event in the collector's timezone.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Records Affected                     | Not used for IMS. Always -1.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Returned Data                        | Segment data, in hex, as returned to the application.<br>Enabling the return of this data requires the assistance of IBM support to enable the correct policy action. This option is almost never recommended because it means that potentially sensitive data is stored on the collector.                                                                                                                                                                       |
| Full SQL ID                          | Unique, sequenced identifier for this event. Can be helpful for sorting events in sequence.                                                                                                                                                                                                                                                                                                                                                                      |
| Ack Response Time                    | Microsecond value from Timestamp on the event from the mainframe.<br>Example: 677032<br>It is not recommended to use this field for sorting as it does not include leading zeros; use FullSQL ID instead.                                                                                                                                                                                                                                                        |
| Statement Type                       | Not used for IMS. Always contains 'SQL'                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Blind Variables Values               | This is the same as the fieldDB2 z/IMS/DATA SET Unit of Work, prefixed with the SSID. To correlate unit of work IDs across subsystems, it is recommended to use the DB2 z/IMS/DATA SET Unit of Work field instead of this one.                                                                                                                                                                                                                                   |
| IMS/DATA SET Program Name            | The name of the application program issuing the DLI calls or other access.                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS/DATA SET Step Name               | JCL step name for the executing program.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IMS/DATA SET Step Number             | JCL step number for the executing program.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS Transaction                      | IMS transaction identifier                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS Terminal                         | Terminal ID of the originating request.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| IMS PCB Name                         | The name of the IMS Program Communications Block (PCB)                                                                                                                                                                                                                                                                                                                                                                                                           |
| IMS PCB Number                       | The PCB in the PSB that the program used to access the database                                                                                                                                                                                                                                                                                                                                                                                                  |
| IMS/DATA SET                         | Data set name before an SMF rename.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Previous DSN                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| IMS Database                         | IMS database descriptor (DBD)                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| IMS Segment                          | IMS Segment name in the database.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| IMS/DATA SET Name                    | When SMF is used, the IMS Data Set name that was accessed.                                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS/DATA SET Context                 | Type of activity (such as IMS Segment level GET)                                                                                                                                                                                                                                                                                                                                                                                                                 |
| IMS SMF/DATA SET Expiration Days     | SMF data has expired due to data sitting in the spill file for this number of days. There could be incomplete data. This should be a rare event.                                                                                                                                                                                                                                                                                                                 |
| IMS SMF/DATA SET Expiration IPL Time | SMF data has expired due to an IPL occurring on the host. This could indicate incomplete data.                                                                                                                                                                                                                                                                                                                                                                   |
| IMS Segment Data Length              | The length of the IMS data segment.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| IMS/DATA SET Type                    | The type of data set such as database, image copy, log type, LDS type, recon, and unknown. Applicable only when SMF data collection is used.                                                                                                                                                                                                                                                                                                                     |
| IMS/DATA SET Job Name                | Job name                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| IMS/DATA SET Job Number              | Job number                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS/DATA SET User ID                 | ID of originating request, such as the TSO or RACF authid.                                                                                                                                                                                                                                                                                                                                                                                                       |
| IMS PART/AREA                        | The name of the partition or area. A DEDB can use multiple data sets, called areas, with each area containing the entire data structure. A partition is a subset of a high availability large database (HALDB).                                                                                                                                                                                                                                                  |
| IMS/DATA SET Event Time              | Timestamp of the event as recorded on the host in UTC format.<br><br>The collector timezone is in the Timestamp field.                                                                                                                                                                                                                                                                                                                                           |
| IMS DLI Status Code                  | Status code from DLI. 'bb' means blank (no status code). This is available only when status code collection is specified in the IMS Collection Profile policy as described in<br><a href="https://www.ibm.com/support/knowledgecenter/SSMPHH_10.1.0/com.ibm.guardium.doc.zos/db2_stap_ims/AUI/V1013_AUI/DITA/auuir009.html">https://www.ibm.com/support/knowledgecenter/SSMPHH_10.1.0/com.ibm.guardium.doc.zos/db2_stap_ims/AUI/V1013_AUI/DITA/auuir009.html</a> |
| Timestamp(microsec)                  | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DB2 z/IMS/DATA SET Unit of Work      | Unit of work ID (recovery token), in hex. When the token is from a CICS transaction, it can be used to correlate data access across DB2, IMS and Data Sets within a transaction. (Unlike Data Sets, this token is included even for non-CICS transactions).                                                                                                                                                                                                      |

Table 5. Attributes for SQL Entity (IMS)

| Attribute     | Description                                                  |
|---------------|--------------------------------------------------------------|
| SQL           | Event type (desc=), DBD name (dbd=), and segment name (seg=) |
| Truncated SQL | Not used for IMS.                                            |

Table 6. Attributes for Command Entity (IMS)

| Attribute | Description |
|-----------|-------------|
|-----------|-------------|

| Attribute | Description                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| SQL Verb  | The event type, which depends on what is collected from the policy.<br>Example: Segment Level GET, REPLACE, INSERT and DELETE |

Table 7. Attributes for Object Entity (IMS)

| Attribute                 | Description                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------------------|
| Object Name               | DBD name and segment name separated by a colon.                                                     |
| Object Type               | For SMF, the type of data set such as database, image copy, log type, LDS type, recon, and unknown. |
| IMS Segment/DSN/PART/AREA | Name of the segment, data set name (if SMF) partition name, or area.                                |

Table 8. Attribute for Field Entity (IMS)

| Attribute | Description      |
|-----------|------------------|
| Field     | Not used for IMS |

#### Exception Domain

There is no useful information logged in exception domain for IMS. You can collect events that receive particular status codes, but those are reported in the FULL SQL domain (IMS DLI Status Code attribute).

## Assess and harden

The Guardium® Vulnerability Assessment solution is the first step in the security and compliance lifecycle management for any IT environment. You can create a security assessment scan and workflow audits to identify and detect database vulnerabilities in an automated fashion—proactively improving configurations and hardening infrastructures.

- [\*\*Introducing Guardium Vulnerability Assessment\*\*](#)

Guardium Vulnerability Assessment enables you to identify and correct security vulnerabilities in your database infrastructure.

- [\*\*Set up your environment for Vulnerability Assessment\*\*](#)

Set up your central manager and managed units for Vulnerability Assessment.

- [\*\*Types of Vulnerability Assessments\*\*](#)

Guardium provides over two thousand predefined tests to check database configuration parameters, privileges, and other vulnerabilities. Some tests can also be customized to meet specific requirements.

- [\*\*Assessments\*\*](#)

Assessments are a group of tests that scan database infrastructures for vulnerabilities and provide an evaluation of database and data security health with real-time and historical measurements.

- [\*\*IBM Guardium Data Protection app in ServiceNow\*\*](#)

You can configure IBM Security Guardium to track incidents, problems, and tasks discovered by Guardium using the external ticketing system ServiceNow®.

- [\*\*Required schema change\*\*](#)

The schema used by vulnerability assessment tests on IBM Db2® for z/OS® changed in Guardium V9.1. If you upgrade from a release prior to 9.1, you must update your database in order to continue using these tests.

- [\*\*Assessing RACF vulnerabilities\*\*](#)

If you use IBM Db2 for z/OS, you can use vulnerability assessment tests to assess your RACF vulnerabilities. You must have at least version 9.1 of Guardium installed to use RACF assessments.

- [\*\*Configuration Auditing System \(CAS\)\*\*](#)

The Configuration Auditing System (CAS) tracks and reports changes to the server environment; for example, modified configuration files, environment or registry variables, or other database or operating system components. Auditing includes executable files or scripts that are used by the database management system or the operating system. The data is available on the Guardium system and can be used for reports and alerts.

- [\*\*License information for Guardium Vulnerability Assessment\*\*](#)

The license information describes the purchase options for Guardium Vulnerability Assessment. It also describes how to measure the license for Guardium Vulnerability Assessment and perform scans on nonproduction, failover, disaster recovery, and other environments.

## Introducing Guardium Vulnerability Assessment

Guardium Vulnerability Assessment enables you to identify and correct security vulnerabilities in your database infrastructure.

Database Vulnerability Assessment is used to scan the database infrastructure for vulnerabilities and provide evaluation of database and data security health, with real time and historical measurements.

Vulnerability Assessment uses three types of artifacts:

Test

A test checks the database environment for vulnerabilities for a particular threat or area of concern.

Assessment

An assessment is a job that includes a set of tests that are run together.

Data source

The source of data itself, such as a database or XML file, and the connection information necessary for accessing the data.

The Guardium® Vulnerability Assessment application enables organizations to identify and address database vulnerabilities in a consistent and automated fashion. Guardium's assessment process evaluates the health of your database environment and recommends improvement by:

- Assessing system configuration against best practices and finding vulnerabilities or potential threats to database resources, including configuration and behavioral risks. For example, identifying all default accounts that haven't been disabled; checking public privileges and authentication methods chosen, etc.
- Finding any inherent vulnerabilities present in the IT environment, like missing security patches.

- Recommending and prioritizing an action plan based on discovered areas of most critical risks and vulnerabilities. The generation of reports and recommendations provide guidelines on how to meet compliance changes and elevate security of the evaluated database environment.

Guardium's Database Vulnerability Assessment combines two essential testing methods to guarantee full depth and breadth of coverage. It leverages multiple sources of information to compile a full picture of the security health of the database and data environment.

1. Agent-based-Using software installed on each endpoint (e.g. database server). They can determine aspects of the endpoint that cannot be determined remotely, such as administrator's access to sensitive data directly from the database console.
2. Scanning-Interrogating an endpoint over the network through credentialled access.

Included in the Guardium Vulnerability and Threat Management solution are:

- Database Auto-Discovery performs a network auto-discovery of the database environment and creates graphical representation of interactions among database clients and servers.
- Database Content Classifier automatically discovers and classifies sensitive data, such as 16-digit credit card numbers and 9-digit Social Security numbers—helping organizations quickly identify faulty business or IT processes that store confidential data.
- Database Vulnerability Assessment scans the database infrastructure for vulnerabilities and provides evaluation of database and data security health, with real time and historical measurements.
- CAS (Configuration Auditing System) tracks all changes to items such as database structures, security and access controls, critical data values, and database configuration files.
- Compliance Workflow Automation automates the entire compliance process through starting with assessment and hardening, activity monitoring to audit reporting, report distribution, and sign-off by key stakeholders.

CAS (Configuration Auditing System) plays an important role in the identification of vulnerabilities and threats. Guardium pre-configured and user-defined CAS templates can be used in the Assessment test and bring a holistic view of the customer's database environment; With CAS, Guardium can identify vulnerabilities to the database in the OS level such as file permissions, ownership and environment variables. These tests can be seen through the CAS Template Set Definition panel and have the word Assessment in their name.

Note: Configuration Auditing System (CAS) is only supported in English.

Common Vulnerabilities and Exposures (CVE®) is a dictionary of common names (i.e., CVE Identifiers) for publicly known information security vulnerabilities. CVE's common identifiers makes it easier to share data across separate network security databases and tools, and provide a baseline for evaluating coverage such that, if a report incorporates CVE Identifiers, users may quickly and accurately access fix information in one or more separate CVE-compatible databases to remediate the problem.

Numerous organizations have made their information security products and services CVE compatible by incorporating CVE Identifiers. Guardium constantly monitors the common vulnerabilities and exposures (CVE) from the MITRE Corporation and adds these tests for the relevant database related vulnerabilities.

To aid in the finding of individual vulnerabilities while viewing the CVE names for specific databases, the user, when configuring tests through Security Assessment Builder, can select the CVE radio button for the desired database and then select and add the appropriate CVE identifier. Additional information can always be found on the master copy of the CVE list maintained by the MITRE Corporation.

To keep CVEs current within the Guardium solution, Guardium will download and use the most current CVE database to populate a database table with all current CVE entries and candidates. Guardium programmatically compares the downloaded CVE data with the CVE data already in the Guardium Vulnerability Assessment repository; producing a list of new CVEs for review. Guardium Database Security Team then manually reviews these candidates for the Guardium Vulnerability Knowledgebase, tests them and adds the relevant ones to the GA Guardium Vulnerability Assessment Knowledgebase. These tests are tagged with the appropriate CVE number, and once in the GA repository, these tests can automatically run using the Guardium Vulnerability Assessment application.

Note:

- For both Vulnerability Assessments and Entitlements Reporting, when looking for scripts to grant privileges for entitlement reporting, use scripts in the gdmonitor\_scripts directory. Do not use the entitlement\_monitor\_role folder, which is no longer updated.
- When using an expiring product license key, or license with a limited number of datasources, the following message may appear: Cannot add datasource. The maximum number of datasources allowed by license has been reached. The License valid until date and Number of datasources can be seen on the System Configuration panel of the Administrator Console. A Vulnerability or Classification process with N datasources are counted as N scans every time they run.
- Guardium Vulnerability Assessments requires access to the databases it evaluates. To do this, Guardium provides a set of SQL scripts (one script for each database type) that creates users and roles in the database to be used by Guardium.

The template scripts are available on the Guardium system once it is built and can be found and downloaded via fileserver at the following path: /log/debug-logs/gdmonitor\_scripts/. More information is available in the README.txt file.

## Guardium Vulnerability Assessment Test Exceptions

---

The Guardium vulnerability assessment test exception groups are prepopulated with the default members, schema, objects, or privileges created when a database is installed. Use these groups to avoid false-positives when running vulnerability assessments. If an assessment fails, link the appropriate exception group to the test to exclude the default members and run the test again: if the test now runs without violations, this indicates that the initial violations were due to the default members, schema, objects, or privileges created when the database was installed.

For more information, see [Test Exceptions](#).

## MongoDB

---

Developed in 2007, MongoDB is a NoSQL, document-oriented database. MongoDB uses JSON documents with dynamic schemas (this format is called BSON). In MongoDB, a collection is the equivalent of a RDBMS table while documents are equivalent to records in an RDBMS table.

MongoDB is the largest and fastest growing NoSQL database system. It tends to be used as an operational system and as a backend for web applications due to an ease of programming for non-relationally formatted data like JSON documents which are often found in web applications.

- First NoSQL database supported for Guardium Vulnerability Assessment (VA).
- First non-JDBC database connection. Connection uses a Java driver.
- MongoDB data sources support SSL server and client/server connections with SSL client certificates.
- Guardium's VA solution for MongoDB Clusters can be run on mongos, a primary node and all secondary nodes for replica sets.
- Entitlement reports and Query Based Builder are not supported for MongoDB.

## MongoDB Datasource with SSL

You can import server cert which we do behind the scene for self signed. Customer can also import their certificate. Certificates also work on central manager and push down to collectors.

## CAS for MongoDB

The Mongo CAS Assessment template allows you to specify multiple paths in the datasource to scan various components of the file system.

## Teradata Aster

### Aster Data

Acquired by Teradata in 2011, typically used for data warehousing and analytic applications (OLAP). Aster Data created a framework called SQL-MapReduce that allows the Structured Query Language (SQL) to be used with Map Reduce. Most often associated with clickstream kinds of applications.

A security assessment should be created to execute all tests on the queen node. All database connections for Aster Data go through the queen node only.

Testing on worker and loader nodes is only required when performing CAS tests (File permission and File ownership).

Privilege tests loop through all the databases in a given Aster's instance.

## SAP HANA

SAP HANA is an in-memory, column-oriented, relational database management system developed and marketed by SAP SE. HANA's architecture is designed to handle both high transaction rates and complex query processing on the same platform.

## Database privileges for vulnerability assessments and classification

Guardium provides a set of scripts to simplify the creation of groups or roles with minimum privileges required for running vulnerability assessments.

## Before you begin

This task requires downloading scripts from a Guardium system and running those scripts on a database server. You will need to identify the IP address of the machine used to access the Guardium system. This could be the IP address of an individual workstation where you will download the scripts before transferring them to a database server, or it could be the IP address of the database server itself.

## About this task

A user requires access to the database and specific database privileges to run Guardium vulnerability assessments and Guardium classifier. Guardium provides a set of scripts to simplify the creation of groups or roles with minimum privileges required for running vulnerability assessments. Once created, these groups or roles can be assigned to any database user who needs to run an assessment. You will create a Guardium datasource with this user to perform the VA scan.

Scripts are provided to support most database types and are designed to be run in the database tool itself. Each script includes detailed instructions in the script header. The privileges granted for each database type can be seen in the script looking at each grants.

Important: Before running any scripts, database administrators should read the instructions in the script headers and review the database actions that will be taken by the script.

## Procedure

1. On a Guardium system, enable the file server using the **fileserver** CLI command.  
For example, to enable the file server for one hour and download the scripts to a system with IP address **10.0.0.1**, use the following command:

```
fileserver 10.0.0.1 3600
```

When successfully initiated, the file server should display output similar to the following:

```
Starting the file server...
The file server is ready at https://guardium.host.com:8445
The timeout has been set to 3600 seconds and it may timeout during the uploading.

The upload will only be accessible from the IP you are logged in from: 10.0.0.1

Press ENTER to stop the file server.
```

2. On the machine where you will download the scripts, use a web browser to access the file server.

For example, for a Guardium system running at <https://guardium.host.com:8445>, access the scripts for vulnerability assessment and classification at the following URLs:

[https://guardium.host.com:8445/log/debug-logs/gdmonitor\\_scripts/](https://guardium.host.com:8445/log/debug-logs/gdmonitor_scripts/)  
[https://guardium.host.com:8445/log/debug-logs/classification\\_role/](https://guardium.host.com:8445/log/debug-logs/classification_role/)

Important: Discovery processes of the Guardium classifier require a higher level of database access than is required for vulnerability assessment tests. It is recommended to use the scripts in `gdmonitor_scripts` for vulnerability assessment and the scripts in `classification_role` for the classifier.

3. Download the required scripts using the web browser's Right-click  $\rightarrow$  Save link as... action or a similar function.

Review the README.txt files to identify the correct scripts to use for specific database types.

Tip: The following scripts are for Microsoft SQL Server:

- `gdmonitor-mss.sql` is for Microsoft SQL Server
- `gdmonitor-mss-SA.sql` provides administrative privileges required for six of the Microsoft SQL Server vulnerability assessment tests. If you do not allow these privileges, the tests will return errors indicating inadequate privileges. These six tests represent no more than 5% of the available tests.

## What to do next

Once you have downloaded the scripts required for your database servers, closely review and follow the instructions in the script headers.

## Deploying VA for Db2 for i

Enable a group of users to run vulnerability assessments, and configure and run the tests.

### About this task

#### Deployment Steps

1. Vulnerability Assessment is deployed from the Guardium system.
2. User runs a Guardium-supplied script against the target database to create a role with the appropriate privileges. User then creates a datasource connection to the database.
3. Create a security assessment, then select your datasources and desired tests to execute.
4. Once the execution is done, a report is created, showing what tests have passed and/or failed along with detailed hardening recommendations.

IBM for i version support:

- IBM for i 6.1, 7.1 and 7.2 partitions
- VA test Coverage (115 tests in total)
- Profiles with Special Authorities
- Profiles with access to Database Function Usage
- Password policies
- Database Objects privilege granted to PUBLIC
- Database Objects privilege granted to individual user
- Database Objects privilege granted with grant option
- Security APARS
- Entitlement Reports
- Profiles with Special Authorities
- Group granted to user
- Database Objects privilege granted to PUBLIC
- Database Executable Objects privileges granted to PUBLIC
- Database Objects privilege granted to individual user
- Database Objects privilege granted with grant option

## Procedure

1. Use the Group Builder to create a group of users that you want to use VA. Open the Group Builder by clicking Setup  $\rightarrow$  Tools and View  $\rightarrow$  Group Builder. The next step uses a script for a group named `gdmonitor`.
2. Run the following script on your Db2 for i system to grant privileges needed for executing VA to the group. This is done outside the Guardium system using a database native client.

```
grant select on SYSIBADM.FUNCTION_INFO to gdmonitor;
grant select on SYSIBADM.FUNCTION_USAGE to gdmonitor;
grant select on SYSIBADM.GROUP_PROFILE_ENTRIES to gdmonitor;
grant select on SYSIBADM.SYSTEM_VALUE_INFO to gdmonitor;
grant select on SYSIBADM.USER_STORAGE to gdmonitor;
grant select on Qsys2.Authorizations to gdmonitor;
grant select on SYSIBADM.USER_INFO to gdmonitor;
grant select on QSYS2.SYSSCHEMAAUTH to gdmonitor;
grant select on QSYS2.SYSTABAUTH to gdmonitor;
grant select on QSYS2.SYSPACKAGEAUTH to gdmonitor;
grant select on QSYS2.SYSROUTINEAUTH to gdmonitor;
grant select on QSYS2.SYSSEQUENCEAUTH to gdmonitor;
grant select on QSYS2.SYSCOLAUTH to gdmonitor;
```

For IBM Db2 for i v7.1 and higher, also include the scripts:

```
grant select on QSYS2.SYSVARIABLEAUTH to gdmonitor;
grant select on QSYS2.SYSXSROBJECTAUTH to gdmonitor;
```

3. Create a JDBC connection to your Db2 for i system. To open the Select datasource window, browse to Setup > Tools and Views > Datasource Definitions. Click **+** to create a new datasource, and select Security Assessment as the application type. For more information, see [Creating a datasource definition](#).
- a. Click New and enter the appropriate information. For Connection Property, enter "property1=com.ibm.access.AS400JDBCDriver;translate binary=true".
4. Create an assessment using the Assessment Builder. Open the Assessment Builder by clicking Harden > Vulnerability Assessment > Assessment Builder.
- a. Enter a description for the assessment.
  - b. To add the datasource created in the previous step, click Add Datasource, select the datasource from the Select datasource, and then click Save. Note: You must click Apply to save the assessment before you can configure tests.
5. Add tests to the assessment by clicking Configure Tests. Click the IBM for i tab, select the tests that you want to add, and click Add Selections.
6. Click Return to go back to the Security Assessment Finder. Run the test by clicking Run Once Now, or schedule the test using Audit Process Builder. Open the Audit Process Builder by clicking Discover > Classifications > Audit Process Builder.
7. Click View Results to view the details of all the executed tests, including recommendations for improving your score.

## Results

What to do when a test fails?

- You can patch your database if it is relating to patches.
- You can re-configure database parameters to best practice recommendation.
- You can revoke objects or system privileges that are not required by your applications.
- You can revoke objects granted directly to grantee and grant the object privileges to a role/group and assign the grantee to that role/group.
- You can change password policy setting or change users default password.
- If your application required specific grant, you can create exception group and link that to your failed test and re-execute.

## Using VA with Cloudera

Learn how to use Guardium vulnerability assessments with Cloudera distributions of Apache Hadoop.

Cloudera Manager  
Datasource Setup

The Cloudera Manager datasource uses the Cloudera Manager Java API for a connection. It does not use JDBC.

The Cluster Name must be defined in the datasource GUI. The Cluster name is the Cluster display name in the Cloudera manager GUI on the left-hand side.

To execute Vulnerability Assessment tests for Cloudera Manager, you need to define a datasource user with the Read-Only role for most the Vulnerability Assessment tests. Then, there are a small number of Vulnerability Assessment tests which require the datasource user have the Cluster Administrator role as the minimum privilege to run the tests.

The following Vulnerability Assessment tests require the datasource user to have the Cluster Administrator role:

1. Authentication Backend Order
2. HTTP port for Admin Console
3. HTTPS port for Admin Console
4. Use TLS Authentication of Agents to server
5. Use TLS Encryption for Admin Console
6. Use TLS Encryption for Agents

This information is also available in the Cloudera Manager gdmmonitor script (`/log/debug-logs/gdmmonitor_scripts/gdmmonitor-Cloudera-Manager.sql`).

If SSL is enabled, check Use SSL and check Import server ssl certificate.

CAS Database Instance setting

The Account should be root.

The Directory will need to be defined as the Cloudera manager install path. For example: `installpath=/opt/cloudera`

Example of Cloudera Manager datasource settings.

**Update datasource**

## Hive

### Datasource Setup

Use the Apache Hive JDBC driver 1.1.1.

Kerberos - The User Name and Password must be a valid Kerberos User ID and Password. It is also used for CA. Test to make sure your Kerberos User ID and Password can be used to login to the Hive beeline command line.

Make sure you have already created a Kerberos Configuration that defines your KDC and Realm for your appliance. On the Guardium GUI, go to Setup > Tools and Views > Kerberos Configuration. If no Kerberos Configuration has been created, then click on + icon to create a new Kerberos Configuration.

### Edit Kerberos Configuration

---

|                   |                                   |
|-------------------|-----------------------------------|
| * Name            | kerberos_hive                     |
| * KDC             | dbanetdc01.guard.swg.usma.ibm.com |
| * Realm           | DBANET.ROOT                       |
| * Encryption type | aes256-cts-hmac-sha1-96           |

---

**Save**

**Close**

After you have created a Kerberos Configuration, you can select it to configure your datasource setup.

If SSL is enabled, check "Use SSL" box and check the "Import server ssl certificate" box.

Note: Hive can only support either LDAP/SSL or Kerberos, not both.

#### CAS Database Instance setting

1. The Directory will need to be defined as the Cloudera manager install path. For example: installpath=/opt/cloudera
2. If HDFS is enabled for Kerberos, the Datasource User Name and Password must be a valid Kerberos User ID and Password. CAS scripts uses it for obtaining a Kerberos ticket.
3. The Account must be root. For certain parameter tests that require CAS, it is important that the CAS user is root in order to access the real-time configuration under the Cloudera agent process directory (/var/run/cloudera-scm-agent/process/).

Note: Guardium does not in any way modify or alter your configuration data.

For Hive

For the Privilege tests, the datasource account must be a member of the Sentry Admin group. See the Hive gdmonitor script for steps to check the Sentry Admin group.

When setting up Hive datasources, you can only perform a JDBC test connection when the datasource is pointing to your Hive server2. For all other Hive datasources, you can clone this specific datasource using nodename where the Cloudera service is installed. Make sure the cloned datasource has a valid Username and Password just like the Hive server2 datasource. For these datasources, you cannot perform a datasource test connection. However, Guardium relies on the accuracy of the Username and Password from the datasource to perform a Kerberos connection using CAS when Kerberos enabled.

#### Vulnerability Assessment Tests

The Hive Privilege tests require Sentry Services to be installed and configured. Without Sentry, there is no security. Everyone can connect to Hive and access data.

The Vulnerability Assessment CAS test for HDFS parameters are from configuration files under the Cloudera agent process directory (/var/run/cloudera-scm-agent/process/). The folder names inside these process directories change every time the Cloudera agent services are started.

Some of the HDFS parameter CAS tests require the datasource system to be a specific node configuration (for example, NameNode or DataNode). Some CAS tests require Yarn, Mapreduce or Hive Server to be installed on the datasource system. Please select the tests carefully for your assessment based upon your datasource system configuration. If the requirements are not met for the test, then the test will error with the recommendation to execute these tests on the correct Cloudera services. The requirements are also mentioned in the test description.

When creating a Hive datasource, it is recommended to have one datasource for each Cloudera service (NameNode, DataNode, HiveServer2, Hive metastore, Yarn NodeManager and Yarn ResourceManager).

Regardless of the number of nodes in your cluster, if you have Guardium Hive datasources that cover all of these services, you then have properly setup your environment to run Vulnerability Assessment.

For example

| dfs.namenode.name.dir Permissions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Not Applicable                                                                                 |

Severity: Major                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | (1/9/17 3:17 AM) Current datasource environment is not setup as a Hadoop NameNode.             |
| This test is to ensure the "dfs.namenode.name.dir" directory permissions are set to "u=rwx,g=rx,o=rx". The "dfs.namenode.name.dir" HDFS property specifies where the name node should store the name table (fileimage) on the local file system. Securing HDFS files and directories will reduce the probability of unauthorized modifications to those resources. Namenode directories may contain sensitive information that should not be accessible by other accounts on the system. The value of this property may be a single directory or a comma-delimited list of directories. When it is a comma-delimited list of directories, each will contain the same information. This test only works on the Hadoop namenode. | Recommendation: This test is not valid for this datasource environment. No action is required. |

| Datasource type: HIVE Severity: None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                |

## Troubleshooting Cassandra

Troubleshooting DataStax Enterprise (DSE) Cassandra for Vulnerability Assessment (VA).

### Troubleshooting data refresh issues

#### Issue

A new table or data is added or changed to the Cassandra database but is not reflected in the VA assessment results. You get an error in your test result or the datasource connection fails after the change is made.

Example: [DataDirect] [Cassandra JDBC Driver] [Cassandra]The server failed to respond to the connection request. Please verify the host and port specified. The non-thrift based Cassandra client port should be used, which on default Cassandra installs is 9042.

#### Possible cause

The local DataDirect Cassandra JDBC driver schema map file is corrupted or not up-to-date.

#### Description

To support SQL access to a noSQL Cassandra database, the DataDirect driver maps the Cassandra data model to a relational schema. The schema map files are saved in the location that is specified by the SchemaMap connection property. The driver looks for this file when it connects to the server. If the file does not exist, the driver creates one.

For Guardium, the SchemaMap is set to /var/log/guard/db\_driver/datastax/ <IP address>.config on the Guardium system.

#### Solution

1. In the Datasource Definition screen, set the Connection Property to CreateMap=forceNew.

When CreateMap is set to forceNew, the driver deletes the group of internal files that are specified by SchemaMap and creates a new group of these files at the same location. These internal files are required for a relational view of the native data, but they do not include schema map configuration file.

Guardium also runs the SQL extension refresh map when the CreateMap is set to forceNew. The refresh map statement adds newly discovered objects to your relational view of native data. It also incorporates configuration changes that are made to your relational view by reloading the schema map configuration file.

2. Test the connection to ensure that it is successful.

3. Remove the CreateMap=forceNew from your datasource connection property.

Note: This property forces the rebuild of internal files and involves the discovery of native data. If the size of your database is large, the schema maps can take time to build causing performance issues.

4. Save the datasource and run the assessment again.

### Troubleshooting consistency level issues

#### Issue

The error Cassandra code 4096 – Cannot achieve consistency level quorum appears in assessment report for some of the VA tests.

#### Possible causes

- Replication factors are not configured correctly for DSE security in production environments.
- Not all nodes in the cluster are up.

#### Solutions

##### Solution 1

1. Ensure that all nodes in the clusters are up and running.
2. Configure replication factors by changing the replication class to NetworkTopologyStrategy. Set the replication factor in the range 3 - 5 for the following security keyspaces. Do not set the replication factor greater than the number of nodes in the data center.
  - system\_auth
  - dse\_security
3. Run nodetool repair on the security keyspaces to repair the keyspace on all nodes to sync with each other. For more information, see the DSE administrator guide on the DataStax web page.
  - nodetool repair --full system\_auth
  - nodetool repair --full dse\_security
4. Run the assessment again.

##### Solution 2

1. In the Datasource Definition screen, set the Connection Property to ReadConsistency=one. When ReadConsistency is set to one, data is returned from the closest replica.

2. Save the datasource and run the assessment again.

## Set up your environment for Vulnerability Assessment

Set up your central manager and managed units for Vulnerability Assessment.

If you use Vulnerability Assessment (VA), it is recommended that your central manager is in the same data center as the managed units. Managed units that are running VA, access the central manager for definitions and content.

Note:

If a central manager is located in a different data center than the managed units, then environmental factors such as network latency, network congestion, and network traffic can impact performance when the centrally-managed definitions are retrieved.

For example, if your central manager and managed units are in different data centers, then you must set up your assessment and datasource definitions in your central manager, and run the assessment in the managed units. This set up might result in a significantly slower performance.

## Types of Vulnerability Assessments

Guardium® provides over two thousand predefined tests to check database configuration parameters, privileges, and other vulnerabilities. Some tests can also be customized to meet specific requirements.

### Vulnerability Assessment - Test types

A Vulnerability Assessment may contain one or more of the following types of tests: predefined or custom.

Predefined tests are designed to illustrate common vulnerability issues that may be encountered in database environments. However, due to the highly variable nature of database applications, some of these tests may be suitable for certain databases but totally inappropriate for others, even if they are within the same organization.

Guardium has enabled customization of some of the predefined tests to meet specific requirements of your organization. Additionally, to keep your assessments current with industry best practices and to protect against newly discovered vulnerabilities, Guardium distributes new assessment tests and updates on a quarterly basis as part of its Database Protection Subscription (DPS) Service. For more information, see [Installing IBM Security Guardium Database Protection Subscription \(DPS\) patches](#).

Predefined Tests include Privilege, Authentication, Configuration, Version, CVE, Security APAR, Query-based and CAS-based tests. Query-based and CAS-based tests may also be customized.

### Categories of Tests

The current categories with some high-level tests for security-related vulnerabilities include:

- Privilege
  - Object creation / usage rights
  - Privilege grants to DBA and individual users
  - System level rights
- Authentication
  - User account usage
  - Remote login usage
  - Password regulations
- Configuration
  - Database specific parameter settings
  - System level parameter settings
- Version
  - Database versions
  - Database patch levels
- Other
  - Installed sample databases
  - File ownership
  - File permissions

### CVE Tests

Guardium constantly monitors the Common Vulnerabilities and Exposures (CVE) from the MITRE Corporation and adds these tests for the relevant database related vulnerabilities.

### Security APAR Tests

Guardium adds predefined security Authorized Program Analysis Report (APAR) tests to monitor relevant database related vulnerabilities.

### Query-based Tests

A query-based test is either a predefined or custom test that can be quickly and easily created by defining your own test criteria. See [Defining a query-based test](#) for additional information on building a custom query-based test.

## CAS-based Tests

---

A CAS-based test is either a predefined or custom test that is based on a CAS template item of type OS Script command and uses CAS collected data.

Users can specify the template item and test it against the contents of the CAS results. See [Create a New Template Set](#) for assistance on creating an OS Script type CAS template.

Guardium is preconfigured with some CAS template items of type OS Script that can be used for creating a CAS-based test. These tests can be accessed through the CAS Template Set Definition panel and contain the word *Assessment*. For instance, the Unix/Oracle set for assessments is named Guardium Unix/Oracle Assessment. Additionally, any template added that involves file permissions will also be used for permission and ownership checking. See [Modify a Template Set](#) for viewing these template sets and seeing those items with type OS Script.

Both predefined and custom tests can be selected during the creation or modification of CAS-based tests. For more information, see [Defining a CAS-based test](#).

- [Defining a query-based test](#)

Create a test based on a query that runs an SQL statement.

- [Defining a CAS-based test](#)

Vulnerability Assessments use the CAS mechanism to run-OS level tests on the database server, and identify vulnerabilities.

---

## Defining a query-based test

Create a test based on a query that runs an SQL statement.

### About this task

---

You can create a new query-based test by using any of these approaches:

New

Start from the beginning and define all the fields.

Clone

Clone an existing query-based test.

Modify

Modify an existing query-based test.

## Procedure

---

1. Open the Assessment Builder by clicking Harden > Vulnerability Assessment > Assessment Builder.
2. From the User-defined tests, click Query-based Tests.
3. Click New, Clone or Modify to open the Query-based Test Builder.
4. Enter a unique Test Name.
5. Select a Database Type.
6. Select a Category.
7. Select a Severity.
8. Optional: Enter a Short Description for the test.
9. Optional: Enter an External Reference for the test.
10. Enter the Result text for pass that will be displayed when the test passes.
11. Enter the Result text for fail that will be displayed when the test fails.
12. Enter the SQL statement that will be run for the test.

Use the following convention to add and reference group members within a SQL statement:

For example:

To reference a group of users defined for the group MyUsersGroup and replace it with the actual members of the group use:

```
Select ... from DBA_GRANTS where ... AND USER in (~~G~MyUsersGroup~~) and ...
```

This will result in a SQL Statement such as the following where U1, U2, etc are the members of the MyUsersGroup group:

```
Select ... from DBA_GRANTS where ... AND USER in ('U1','U2','U3',...) and ...
```

If the group has no members, the database returns an error. In this case the reference is replaced with a single pair of quotation marks, like this:

```
Select ... from DBA_GRANTS where ... AND USER in ('') and ...
```

Use the following convention to replace a reference to a specific alias (of a specific group type) with the actual alias:

For example:

```
Select ... from USER_OBJECTS where ... AND OBJECT_TYPE = '~~A~GroupType~TYPE~~'
```

If there is an alias to TYPE of group type GroupType it will replace the string and the resulting SQL will look like:

```
Select ... from USER_OBJECTS where ... AND OBJECT_TYPE = 'TYPE'
```

where TYPE is the actual ALIAS

13. Optional: Enter a SQL Statement for Detail, a SQL statement that retrieves a list of strings to generate a detail string of Detail prefix + list of strings. See the example in Detail prefix.

Note: The detail generated is only displayed when the query-based test fails; allowing the user to enter a SQL statement that can retrieve the information that caused the test to fail and help identify the cause of failure.

- Note: Detail string can be seen within a Security Assessment Results by clicking on the Assessment Test Name and also queried through the Result Details attribute of the Test Result Entity.
14. Optional: Enter a Pre-test check SQL statement. This statement is run before running the test. If the statement returns 0, the test is not run. If the test returns 1 or an error, the test is run.
  15. Optional: Enter a Pre-test fail message. This message is inserted into the assessment results if the test is not run due to the SQL statement returning 0.
  16. Optional: In Loop databases, enter a list of databases through which the test should loop. The test returns the union or sum of the results returned from all the specified databases. You can use this function only when the test returns an integer value, and only with these database types: Informix, SQL Server, Sybase SE, PostgreSQL and MySQL. The looping is performed if the DB loop flag box is checked.  
One or more of the specified databases might be unavailable when the test is run. In that case the test will either skip that database and continue, or stop and issue a failure message, depending on whether the Skip on error box is checked.
  17. Optional: Enter a Detail prefix that will appear at the beginning of the detail string.

```
Example for SQL Statement for Detail & Detail prefix:
Test that checks for objects with certain grants.
Detail prefix: "Objects found with certain GRANT:"
SQL Statement for Detail: SELECT object FROM....--returning 4 records:
Obj1
Obj2
Obj3
Obj4
==> Details: Objects found with certain GRANT: Obj1, Obj2, Obj3, Obj4
```

18. Optional: Check the Bind output variable check box if the entered text in SQL statement is a procedural block of code that will return a value that should be bound to an internal Guardium® variable that will be used in the comparison to the Compare to value.

```
Example (Oracle):
declare
 retval integer := 0;
 strval varchar2(255) := '';
 nver number;
 sver varchar2(255) := '';
begin
 select VERSION
 into sver
 from V$INSTANCE;
 nver := to_number(substr(sver,1,(instr(sver,'.',1,2) - 1)));
 if nver >= 11.1 then
 select VALUE
 into strval
 from V$PARAMETER
 where NAME = 'sec_case_sensitive_logon';
 end if;
 if (nver < 11.1 or strval = 'TRUE') then
 retval := 0;
 else
 retval := 1;
 end if;
 ? := retval;
end;
```

19. Select the Return type that will be returned from the SQL statement.
20. Select the operator that will be used for the condition.
21. Enter in a Compare to value that will be used to compare against the return value from the SQL statement using the compare operator. It is this comparison that determines whether this test have passed or failed. You may also click on the RE (regex) to define a regular expression for the compare value.
22. Do one of the following:
  - Click Back to cancel changes and return to the previous screen.
  - Click Apply to save the query-based test.

## Results

---

You can add this newly created query-based test to an assessment.

## What to do next

---

### Defining a CAS-based test

Vulnerability Assessments use the CAS mechanism to run-OS level tests on the database server, and identify vulnerabilities.

### Before you begin

---

### About this task

---

You can create a new CAS-based test by modifying an existing CAS-based test or by starting from the beginning and defining all the fields.

### Procedure

---

1. Open the Assessment Builder by clicking Harden > Vulnerability Assessment > Assessment Builder.
2. From the User-defined tests, click CAS-based Tests to open the CAS-based Test Finder panel.
3. Click New or Modify to create a new test.
4. Enter a unique Test name.

5. Select a database from the Database Type menu.
6. Select a category from the Category menu.
7. Select a category from the Severity menu.
8. Optional: Enter a Short Description for the test.
9. Optional: Enter an External reference for the test.
10. Enter a Result text for pass that will be displayed when the test passes.
11. Enter a Result text for fail that will be displayed when the test fails.
12. Enter a Recommendation text for pass that will be displayed when the test passes.
13. Enter a Recommendation text for fail that will be displayed when the test fails. Recommendation text for fail - To prevent cross site hacking, any name from this list, used in the Recommendation text for fail text box, will be rewritten: expression; function; javascript; script; alert; eval; <img; ContentType
14. Select a template to use from the CAS Template menu.
15. Select an operator to use from the operator menu.
16. Enter a Search string that will be used with the operator to compare what is returned from the CAS template. This comparison that determines whether this test passes or fails. You may also click on the RE icon to define a regular expression for the search string.
17. Optional: Check the Fail if match check box if the test should fail when a match is made with the search string.
18. Click Apply to save the CAS-based test.

## Results

---

You can add this newly created CAS-based test to an assessment.

## Assessments

Assessments are a group of tests that scan database infrastructures for vulnerabilities and provide an evaluation of database and data security health with real-time and historical measurements.

- [\*\*Creating an assessment\*\*](#)  
Run security assessments against selected datasources to proactively identify and address vulnerabilities, improve configurations, and harden infrastructures.
- [\*\*Finding an assessment\*\*](#)  
Admins can find an existing vulnerability assessment by using the Security Assessment Finder screen.
- [\*\*Running an assessment\*\*](#)  
To get the results of an assessment, it must be run once it is created.
- [\*\*Viewing assessment results\*\*](#)  
You can take various actions while you view the results of an assessment.
- [\*\*Tuning a test\*\*](#)  
Tests can be optimized by adjusting parameters, applying group exceptions, and test detail exceptions.
- [\*\*Determining test severity\*\*](#)  
Considerations for determining and altering the severity of Vulnerability Assessment tests.
- [\*\*Deleting an assessment\*\*](#)  
You can delete an assessment and its dependencies.
- [\*\*Creating a test exception\*\*](#)  
When a test fails, you can apply an exception to the test. This exception allows the test to pass until a certain date, if specified, or indefinitely.
- [\*\*Group exceptions\*\*](#)  
Use a test exception to exclude specific members of a group from a security assessment. Run the security assessment against the exception group to see if a specific member of a group is affecting your assessment results. This is useful if you do not want to, or are not authorized to change group settings.
- [\*\*Test detail exceptions\*\*](#)  
A test exception can be fine-tuned by including an exception group, adding selected members to the exception group, and then adding test detail exceptions.
- [\*\*Adding custom comments to a test\*\*](#)  
Add custom comments to a vulnerability assessment test. These comments can be added to pre-defined or custom tests and can be exported or imported between Guardium systems.
- [\*\*Modifying the database version and patch level\*\*](#)  
Manually add the database version and patch level to override a failed vulnerability assessment.
- [\*\*VA summary\*\*](#)  
The following table list information per test and database key displayed in the VA summary table: test result by unique identifier; cumulative failed age; first failed date/ last failed date; last passed date; and, last scanned date. This information is tracked and users can create a report on this information.

## Creating an assessment

---

Run security assessments against selected datasources to proactively identify and address vulnerabilities, improve configurations, and harden infrastructures.

## About this task

---

The basic steps for creating a security assessment are:

1. Create the assessment
2. Add datasources to the assessment
3. Add tests to the assessment

## Procedure

---

1. Open the Assessment Builder by clicking Harden > Vulnerability Assessment > Assessment Builder.
2. To work with an existing assessment, click Clone or Edit to open the Security Assessment Builder window. Enter a new description, and modify only the fields that you want to change.

- If you are creating an entirely new assessment, complete all of the following steps.
3. In the Security Assessment Finder window, click New to create a new assessment.
  4. Enter a unique name for the assessment in Description.
  5. Optionally add an audit process that runs upon completion of the assessment.  
Note: Only audit processes with task types report or external feed can be assigned to a security assessment. You cannot run the audit process for a task that has the Remote Data Source parameter enabled.
  6. Click Add Datasource to open the Select datasource window. Select an existing datasource or click  to add a new datasource. For more information, see [Creating a datasource definition](#).
  7. To add a Datasource group, click Add Datasource Group.
  8. Add Roles to the Assessment, if applicable. You cannot assign roles to an assessment until you assign roles to the datasources it is based on.
  9. Click Apply to save the assessment.
  10. Add tests to the assessment by clicking Configure Tests.
    - a. From the Tests available for addition pane, select the appropriate tab for the datasource you added previously.
    - b. Select the tests that you want, and click Add Selections to add them to the assessment. Your selections appear in Assessment Test Selections.
    - c. Use the Assessment Test Selections to manage tests for your assessment. Delete any selected test, or click  to customize the test's parameters.
  11. Click Back to return to the Security Assessment Builder window. Click Return to return to the Security Assessment Finder.

## What to do next

---

From the Security Assessment Finder window, select the created assessment, and click Run Once Now to run your test.

---

## Finding an assessment

Admins can find an existing vulnerability assessment by using the Security Assessment Finder screen.

### Procedure

---

1. Access the Security Assessment Finder screen by clicking Harden > Vulnerability Assessment > Assessment Builder.
  2. Enter your search parameter in the search box.
  3. Click  to view the filtered assessments.
- 

## Running an assessment

To get the results of an assessment, it must be run once it is created.

Assessments can run in a serial or parallel mode. If more than one assessment is scheduled to run, the queue can be viewed through the Guardium Job Queue report. See [Viewing assessment results](#) for more information on the results of an assessment.

You can optionally define and schedule an automated process for running of an assessment definition. The Audit Process finder panel is the starting point for creating or modifying an audit process schedule. Create a schedule to automatically run your assessments by going to the Audit Process finder panel. See Compliance Workflow Automation for assistance in defining an audit process

## Multi-thread Assessment

---

Guardium can run multiple vulnerability assessments in parallel to optimize the performance and utilization of the CPU. The number of threads that can run in parallel can be identified by multiplying the number of CPU cores in the machine by 2.

As an example, if there are 4 CPU cores, then 8 would be the maximum number of processes that can be defined and run concurrently. The cap limit, irrespective of the number of CPU cores, is 100.

To retrieve or define the concurrency limit, see [Classification APIs](#).

---

## Viewing assessment results

You can take various actions while you view the results of an assessment.

### View Results of an Assessment

---

View the results of an assessment in the Query-Report Builder. Open the Query-Report Builder by clicking Investigate > Query-Report Builder, and use the filter to find the report you are looking for.

### Interpreting the Results of an Assessment

---

An assessment evaluates multiple tests based on multiple reports. The overall results are displayed in a separate browser window entitled Security Assessment Results and have the following sections:

## Assessment Identity

---

The Assessment results identifies:

- The assessment name
- The date and time the assessment was run
- The time period for the assessment
- The Client and Server IP addresses or subnets

## Assessment Selection

---

Use the drop-down menu to select and display past results for an assessment. The latest result is displayed by default.

## Assessment Results History

---

The Assessment Results History shows the percentage of tests passing over a period of time. Further recommendations to improve the percentage of passing tests are given under the Assessment Test Results section.

## View log

---

When clicked, the Execution Log will be displayed in a new window that shows the runtime execution of the assessment test. A timestamp, along with events, and messages can aid in the debugging of issues that might have caused certain tests to fail.

## Results Summary

---

A tabular graph summarizes all the tests that were executed within this assessment. The X-axis represents the test's severity (CRITICAL, MAJOR, MINOR, CAUTION, or INFO). The Y-axis represents the type of test (Privilege, Authentication, Configuration, Version, or Other). Within the grid is the representation of the number of tests that have either Passed, Failed, or had an Error when trying to execute. The tests that are not categorized as "Passed" or "Failed" are also listed as errors. As an example, if an error is displayed due to an unsupported database, you can see this detail when you filter on the error type. The number of tests represented in this grid are directly related to the detail for the assessment tests that is given under the Assessment Test Results section.

## Current filtering applied

---

If you would like to change the filtering from what is currently applied, use the following two options to filter the results as you would like:

Reset Filtering - Removes all filtering options selected through the Filter / Sort Controls options.

Filter / Sort Controls - Use this to open a filter/sort options for the report. Options allow you to filter by Severities, Datasource Severity Classification (DS sev. class), Scores (pass, fail, or error), and Test Types (Observed/Database type). The sort option allows you to sort across combinations of severity, score, and datasource. Click Apply when you would like the chosen filter/sort options to take effect.

## Assessment Test Results

---

The Assessment Test Results section provides a detailed description of the test taken, information about the target datasource and datasource severity classification, and the test's Pass/Fail status, severity, the external reference, and reason for the current status. Each test name is clickable and will filter all information off the report except for relevant information about that particular test. A hover-over feature on the Reason field will display the recommendation to help remedy failed or tests in error.

The assessment results include a count of the number of tests and the number of passed tests in each of these categories:

- CIS tests
- CVE tests
- STIG tests

These values are displayed in the assessment result viewer and available for reporting as part of the VA results domain.

## Datasource Details

---

When expanded, the Datasource Details section will show all of the datasources that were referenced within this assessment including the datasource's specific environmental information.

## CVE and CVSS information

---

CVE Records and CVSS information will be displayed in the Assessment test result viewer.

The reference links are clickable (opens new window). Either section will be absent when there is no corresponding record for a result.

The CVSS fields of interest are:

- CVSS Score
- Access Complexity
- Availability Impact
- Confidentiality Impact
- Integrity Impact
- Authentication
- Access Vendor
- Source

- Generated on Datetime

## Working with failed tests

---

If some of the tests in your assessment show a failed status, you might want to take one of these actions:

- Tune a test. For more information, see [Tuning a test](#).
- Create a test exception. For more information, see [Creating a test exception](#).
- Create an exception group. For more information, see [Group exceptions](#).
- Create a test detail exception. For more information, see [Test detail exceptions](#).

## Export to PDF or to SCAP or AXIS XML

---

You can generate a PDF version of Assessment result by clicking Download PDF.

Use the Download XML button to open two menu choices: Download as SCAP xml and Download as AXIS xml. Choose one of these selections in order to download to your workstation an XML file representing the displayed assessment results. The file can be formatted for Security Content Automation Protocol (SCAP) XML or Apache Extensible Interaction System (AXIS) XML, which is used by QRadar.

---

## Tuning a test

Tests can be optimized by adjusting parameters, applying group exceptions, and test detail exceptions.

### About this task

---

Use this procedure to add exceptions to a test by using the test tuning feature.

Note: Depending on the assessment, some tests are not designed to allow group exceptions and test detail exceptions.

### Procedure

---

1. Go to Harden > Vulnerability Assessment > Assessment Builder.
2. Select the assessment you want to edit, and click  . From the Security Assessment Builder screen, click Configure Tests to access the Assessment Test Selections.
3. From the tuning column, select the test you want to adjust and click  .
4. To customize your test's parameters, use the Tuning section.
5. Use the Exception Group section to add an exception group. Click on the Exception Group drop down box and select the exception group. You can optionally enter a start and end date for your selected exception, and include a justification.
6. Select Test Detail Exceptions to search for one or more assessments that use single or multiple datasources, or a group of datasources. For more information, see [List existing Test Detail Exceptions](#).
7. Click Save to save your adjustments.

### Related concepts

---

- [Determining test severity](#)

## Determining test severity

---

Considerations for determining and altering the severity of Vulnerability Assessment tests.

Guardium® Vulnerability Assessment is designed to help you to alter the severity for each vulnerability assessment (VA) test, including tests that are within different security assessments.

## Defining test severity

---

The Guardium Vulnerability Assessment research and development team determines the severity of specific benchmarks such as Security Technical Implementation Guides (STIG) or Center for Internet Security (CIS), by considering the following references along with Common Vulnerability Scoring System (CVSS) scoring for each specific Common Vulnerabilities and Exposures (CVE) test.

- Type of Vulnerability (CVEs)
- Configuration
- Privileges
- Authentication
- Database vendor's security guide (in collaboration with database vendor teams)
- Extensive industry research and expertise
- Compliance Benchmarks (STIGs and CIS)

A VA test can reference multiple benchmarks, vendors, and other security references in parallel.

## Determining the severity of CRITICAL and MAJOR tests

---

- Password default and password hardening policies are typically assigned with a CRITICAL severity as they are deemed to be important in making sure that database account authentication cannot be easily hacked.
- Default database ports can be vulnerable to a variety of security risks, including brute-force attacks, exposure of sensitive information, malware distribution, and DDoS attacks.
- Encryption protocols, encryption strengths, encryption at rest and various database defaults, which may have a negative impact to production databases.
- The highest concentration of configuration tests is in the severity: MAJOR, CRITICAL (highest in security impact), CAUTION, MINOR, and INFO. Severity is assigned based on the individual configuration and the database type.
- PUBLIC grants on objects are assigned the CRITICAL severity level based on CRITICAL system level roles, privileges, and authorities depending on the database types.
  - Most privilege tests are assigned with a CRITICAL or MAJOR severity. Some object types or privileges may be more sensitive than others and they are assigned with different severity levels (CRITICAL, MAJOR, MINOR, and CAUTION).

Guardium VA patch tests are recommendations to the DBA to patch their database server to the latest patch level when comparing to metadata derived from the quarterly DPS upload.

Beginning 2019 Q3 DPS (15 August 2019), changes to the CVE severity is made for new CVE tests. To be synced up based on CVE CVSS 3.0 scoring, each new CVE severity is defined based on the CVSS 3.0 score.

For more information on optimizing tests, see [Tuning a test](#).

## Deleting an assessment

You can delete an assessment and its dependencies.

You can delete a security assessment from the Security Assessment Finder UI or by running the GuardAPI command **grdapi delete\_assessment**. For more information, see [delete\\_assessment](#).

Note: When you force delete an assessment, all its dependencies are deleted even if the assessment has results or is used by an audit task. The assessment results are deleted when the system data is purged. For more information, see [store\\_purge\\_object](#).

## Creating a test exception

When a test fails, you can apply an exception to the test. This exception allows the test to pass until a certain date, if specified, or indefinitely.

### Procedure

1. In the Security Assessment Results screen, go the Assessment Test Results section.
2. Go to the Test/Datasource that failed and click on the Fail link. You can also click on the Add test exception link to pull up the same screen.
3. Select the Assessment scope. You can apply the exception to a specific security assessment, or to all assessments.
4. Select the Datasource scope. You can apply the exception to a single datasource, a datasource group, or all datasources. The Single datasource option applies to the current datasource.
5. The name of the Approver cannot be changed.
6. Add a Start date, End date, provide a Justification for the exception and click Save. If an end date is not specified, then the exception will never expire.
7. To add another exception, click on the View test exceptions link. This brings up a Confirmation screen that lists the existing test exceptions. You can create another test exception by clicking Create.

## Group exceptions

Use a test exception to exclude specific members of a group from a security assessment. Run the security assessment against the exception group to see if a specific member of a group is affecting your assessment results. This is useful if you do not want to, or are not authorized to change group settings.

### About this task

Use this procedure to add group exceptions to a test.

Note: Depending on the assessment, some tests are not designed to allow group exceptions and test detail exceptions.

### Procedure

1. Open the Group Builder by clicking **Setup > Tools and Views > Group Builder**.
  2. Select VA Tests Exception from the Group Type menu to view the list of predefined exception groups.
  3. Select a group from the Modify Existing Groups menu and click Modify.
  4. Add the group members that you want to exclude from the VA test.
  5. Open the Assessment Builder by clicking **Harden > Vulnerability Assessment > Assessment Builder**. Select an assessment from the Security Assessment Finder and click Configure Tests.
  6. Find the test you want add the exception to, and click the test's Adjust this test's tuning button from the Tuning column.
  7. Select your exception group from the menu, and click Save. Run your assessment again to see if the exception group affects the outcome of the test.
  8. You can also add a group exception when a test is tuned. For more information, see [Tuning a test](#).
- Note: By default, Guardium includes an exception group called IBM iSeries Profile User Exclusions. You can clone and modify this group to suit your needs. All the Database Objects privilege tests exclude default system schemas from Guardium groups.

## Test detail exceptions

A test exception can be fine-tuned by including an exception group, adding selected members to the exception group, and then adding test detail exceptions.

A test detail exception is highly customizable. It can be added to one test in one single assessment, or to all assessments. Within the assessment, it can be applied to one datasource only, or one group of datasources, or all datasources. You can also apply a start and end date, and provide a justification for the exception.

A test detail ID is generated for each test detail exception. This ID can be referenced by using guardAPI.

### Create a Test Detail Exception

To create a test detail exception, click the Create Test Detail Exception link from the Security Assessment Results screen.

1. Click  to create a new test detail exception.
2. Select the appropriate element type. Selecting Regular Expression returns all the test detail values that match with the string that is entered in Step 3. The matching values are highlighted with a green check mark in the test detail exception list. Expired exceptions are highlighted in red.
3. Enter the Regular Expression that can match a test detail.
4. Select the Assessment scope and Datasource scope, if applicable.
5. Enter the start and end date, if applicable. Provide a justification for the exception and click Save.

You can also edit an existing test detail exception, add it to a group, or create a new datasource group and merge it with an existing group.

Note: A test detail exception will exist indefinitely if an end date is not applied.

### List existing Test Detail Exceptions

Access the Test Detail Exceptions search from the Security Assessment Finder screen, the Assessment Test Selections screen, or the Assessment Test Tuning screen.

Use the following procedure to search for test detail exceptions.

1. In the Assessments drop down box, select one of the following options:
  - a. All assessments: This search option returns records that have a scope set to "All assessments".
  - b. Any assessment: This search option returns records where the scope is set to any single assessment. It also returns records that have the scope set to "all assessments".
  - c. To search for test detail exceptions in a single assessment, select the name of the assessment in which you want to run your search query.
2. Use the Datasource scope radio button to search for test detail exceptions within a Single datasource, Group of datasources, or extend your search to records that have the scope set to All datasources.
3. From the Datasource drop down box, select the name of your datasource. To extend the scope of your search across datasource groups, check the Included in datasource group check box.
4. Use the Datasource type drop down box to select the type of the datasource.
5. Select the relevant test from the Test drop down box.
6. Click Search to access the Test Detail Exceptions results. Use the results section to view the results, add, or modify exceptions.

## Adding custom comments to a test

Add custom comments to a vulnerability assessment test. These comments can be added to pre-defined or custom tests and can be exported or imported between Guardium systems.

### About this task

User-defined fields can be used to add custom descriptions to vulnerability assessment test results. As an example, add a custom risk score for your test to a user-defined field. Then, use the Query-Report builder to add the custom field to your custom report. You can then view the custom risk score when you generate the custom report.

When you export your vulnerability assessment test to another Guardium system, your custom comments are also exported.

The following procedure describes the method to add custom comments to a vulnerability assessment test by using the Guardium UI.

### Procedure

1. Browse to Harden > Vulnerability Assessment > Available Test Notes.
2. Select the Datasource type.
3. Select the Test name or Test ID.
4. Under the User-defined Comments section, add up to three custom references and comments to the selected test.
5. Click Save.

### What to do next

Add the user-defined fields to your custom report by using the Query-Report builder. Generate the report and view your custom description in the test results.

## Modifying the database version and patch level

Manually add the database version and patch level to override a failed vulnerability assessment.

## About this task

When the database version and patch level is lower than the defined levels, the security assessment is designed to fail. To override this, the recommended patch level and database version can be manually added to the Group Builder.

Note: For Netezza users, the database version and patch level must match the defined level for the security assessment to pass.

## Procedure

1. Open the Group Builder by navigating to Setup > Tools and Views > Group Builder.
2. Select your Database version+Patches.  
For example: Oracle Database Version+Patches.  
Tip: Filter the Group Builder by typing `patch` into the table filter.
3. Click  to modify.  
This opens the Edit Group window.
4. Open the Members tab and click  to add member.
  - a. Use the DB Ver. and Patches fields to enter the database version and patch level.
  - b. Click OK to add the group member.

Tip: Use an existing record to determine the syntax for DB Ver. and Patches fields.
5. Click Save.

## VA summary

The following table lists information per test and database key displayed in the VA summary table: test result by unique identifier; cumulative failed age; first failed date/last failed date; last passed date; and, last scanned date. This information is tracked and users can create a report on this information.

## VA Summary

The default summary key for ISO installations includes the datasource name, host, and port.

Use VA Summary Tracking in Query Builder to define queries and reports.

This table can be exported/imported. Import Data will override existing data on the Guardium system (per key).

Table 1. VA Summary

| Table Column        | Type        | Description                                                  |
|---------------------|-------------|--------------------------------------------------------------|
| VA_SUMMARY_ID       | Int         | Auto-increment – primary key                                 |
| DATA_SOURCE_HASH    | Varchar(40) | Hash for the Key                                             |
| DB_TYPE             | Varchar     | Database Type                                                |
| SERVICE_NAME        | Varchar     | Database instance Name (if part of the key, "N/A" otherwise) |
| DB_PORT             | Varchar     | Database Port (if part of the key, "N/A" otherwise)          |
| DB_HOST             | Varchar     | Host / IP (if part of the key, "N/A" otherwise)              |
| TEST_ID             | Int         | Id of the Test                                               |
| FIRST_EXECUTION     | DateTime    | First time the test was executed                             |
| LAST_EXECUTION      | DateTime    | Last time the test was executed                              |
| FIRST_FAIL          | DateTime    | First time the test failed on this DB                        |
| LAST_FAIL           | DateTime    | Last time the Test failed on this DB                         |
| FIRST_PASS          | DateTime    | First time the Test passed on this DB                        |
| LAST_PASS           | DateTime    | Last time the Test passed on this DB                         |
| CURRENT_SCORE       | varchar     | Pass / Fail / Error                                          |
| CURRENT_SCORE_SINCE | Datetime    | Date Since the test is in the current status                 |
| CUMULATIVE_FAIL_AGE | Int         | Cumulative fail age (in days)                                |
| CUMULATIVE_PASS_AGE | Int         | Cumulative pass age (in days)                                |

The CLI commands are: store va\_test\_show\_query and show va\_test\_show\_query. Use export va\_summary to export this information.

The GuardAPI commands to change or display the key are: grdapi modify\_va\_summary\_key and grdapi reset\_va\_summary\_by\_key. The GuardAPI command to reset cumulative ages, both pass and fail, is grdapi reset\_va\_summary\_by\_id. Use grdapi export\_va\_summary to export this information.

An additional parameter, datasourceName, has been added to grdapi reset\_va\_summary\_by\_key and grdapi modify\_va\_summary\_key.

The VA Summary entity has an additional attribute, Datasource Name, that is populated ONLY if the datasource name is part of the key.

Note: The GrdAPI command, modify\_va\_summary\_key, will allow the key to be empty by calling the GrdAPI with all four parameters: useHost, usePort, useServiceName, useDatasourceName, equal to false. In this case, when the key is empty, the VA Summary calculation is disabled (no summary data will be calculated, updated or saved).

## IBM Guardium Data Protection app in ServiceNow

You can configure IBM Security Guardium to track incidents, problems, and tasks discovered by Guardium using the external ticketing system ServiceNow®.

A certified ServiceNow application is available if you prefer to use ServiceNow as your response control center. The IBM Guardium Data Protection integration is available on the ServiceNow site and can "pull" data from IBM Guardium Vulnerability Assessment (VA) via REST-API. The app synchronizes VA test definitions, data-source definitions, database group definitions, and VA test result entries for tighter integration with ServiceNow modules such as: Configuration Management Database (CMDB), Vulnerability Response, and Configuration Compliance. You can start scanning jobs right from the ServiceNow user interface. Once the VA results are in ServiceNow, your ServiceNow assignment rules automatically assign tickets to the designated group.

If you do not want to use the ServiceNow app, VA also provides more traditional integration with ServiceNow using ServiceNow's Table API. This out-of-the-box integration can send failed vulnerability scan results from the Guardium to ServiceNow as Incidents. In addition, you can integrate ServiceNow into your Guardium system. For more information, see [Configuring an external ticketing system](#).

Note: This feature is available for Guardium® Data Protection 11.4 with bundle 11.0p441, 11.5 with bundle 11.0p525, and later releases.

For more information about the ServiceNow Guardium Data Protection app, see: <https://github.com/IBM/ServiceNow-Guardium-Vulnerability-Assessment#readme>

## Required schema change

The schema used by vulnerability assessment tests on IBM Db2® for z/OS® changed in Guardium V9.1. If you upgrade from a release prior to 9.1, you must update your database in order to continue using these tests.

## About this task

When you upgrade your Guardium® system to version 10.x, you must create new database tables on your database server. These tables add support for a new set of tests, but you must create them whether you want to use the new tests or not.

In prior releases you created and populated tables in the gdmonitor schema:

- GDMMONITOR.OS\_GROUP
- GDMMONITOR.OS\_USER

These tables are replaced by tables in the CKADBVA schema:

- CKADBVA.CKA\_OS\_GROUP
- CKADBVA.CKA\_OS\_USER

## Procedure

1. Install Guardium 10.x
2. Copy `create_CKADBVA-schema_tables_zOS.sql` from the `/var/log/guard/gdmonitor_scripts` directory on your Guardium system to your database server. Run the `fileserver` command on your database server to retrieve the file.
3. The script contains instructions that describe steps to be performed before and after running the script. Read these instructions and run the script.
4. Populate the new tables with data similar to the data that was stored in the old tables.

## Results

Your system is now configured to use current vulnerability assessment tests.

## What to do next

## Assessing RACF vulnerabilities

If you use IBM Db2® for z/OS®, you can use vulnerability assessment tests to assess your RACF vulnerabilities. You must have at least version 9.1 of Guardium installed to use RACF assessments.

## About this task

Assess your Resource Access Control Facility (RACF) privileges whether they are granted within the database or external to the database. The tests, that comprise the RACF vulnerability assessments, identify the access control for object privileges, database privileges, and system privileges.

In order to use these tests, you must obtain and install IBM Security zSecure Audit, Version 2.1. This product enables the commands that are used in these tests to interact with RACF.

Tests that examine entitlements do not return a pass/fail grade; they return a list of entitled users. Examples of these reports include table and view privileges granted to grantees and package privileges granted to grantees. In a large environment that includes very large numbers of users and applications, these reports generate an overwhelming amount of data. When you run these reports in such a large environment, the process can run for a long time and consume large amounts of resources, and it might eventually time out.

## Procedure

1. Upgrade the database schema used to support vulnerability assessment on your database server.
2. Install zSecure Audit on your database server.  
Use the instructions and tools that are provided with zSecure Audit to learn how to populate approximately 24 tables in the CKADBVA schema to support the new zSecure tests.
3. The zSecure team will issue a PTF that enables zSecure Audit to work with Guardium vulnerability assessment. Obtain this PTF and apply it according to the accompanying instructions.

## Results

---

Your system is now configured to take advantage of the new zSecure tests.

## What to do next

---

Choose the new tests that you want to run to assess your RACF vulnerabilities. Configure and run the tests.

## Configuration Auditing System (CAS)

---

The Configuration Auditing System (CAS) tracks and reports changes to the server environment; for example, modified configuration files, environment or registry variables, or other database or operating system components. Auditing includes executable files or scripts that are used by the database management system or the operating system. The data is available on the Guardium® system and can be used for reports and alerts.

Note: The Configuration Auditing System is supported only in English.

### CAS Agent

---

CAS is an agent that is installed on the database server and reports to the Guardium system whenever a monitored entity changes, either in content or in ownership or permissions. CAS shares configuration information with S-TAP, though each component runs independently of the other. After you install the CAS client on the host, configure the actual change auditing functions from the Guardium portal. For more information about installing CAS, see either [Prerequisites, installing, and running CAS on a Windows server](#) or [Prerequisites, installing and running CAS on a Linux, UNIX server](#), depending on your operating system.

### CAS Server

---

The CAS server is a component of Guardium and runs on the Guardium system. It runs as a stand-alone process, independent of the Tomcat application server. It is controlled through systemd.

The CAS server is configured to use only a few of the available processors on the Guardium system. The number of processors that CAS uses is determined by the *divide\_num\_of\_processors\_by* parameter, which is stored in the cas.server.config.properties file. The default value of *divide\_num\_of\_processors\_by* is 2. The number of available processors on the Guardium system is divided by this value. Therefore, even when CAS uses 100% of the CPU on the allocated processors, the remaining processors are available for use by other applications.

### Template Set

---

A CAS template set contains a list of item templates, bundled together, that share a common purpose such as monitoring a particular type of database (Oracle on UNIX, for example). Two types of CAS templates are available:

- Operating System Only (UNIX or Windows)
- Database (UNIX-Oracle, Windows-Oracle, UNIX-Db2, Windows-Db2, and so on.)

A database template set is always specific to both the database type and the operating system type.

### CAS Template Item

---

The definition or set of attributes of a monitoring task over a single Monitored Entity. Users can define new CAS tests by creating new CAS templates or users can use predefined CAS templates that can be modified.

A template item is a specific file or file pattern, an environment or registry variable, the output of an OS or SQL script, or the list of logged-in users. The state of any of these items is reflected by raw data, that is, the contents of a file or the value of a registry variable. CAS detects changes by checking the size of the raw data, or computing a checksum of the raw data. For files, CAS can also check for system level changes such as ownership, access permission, and path for a file.

In a federated environment where all units (collectors and aggregators) are managed by one manager, all templates are shared by both collectors and aggregators and you can use CAS data in reporting or vulnerability assessments. When the collector and aggregator (or host where archived data is restored) are not part of the same management cluster the templates are not shared. Therefore, you cannot use CAS data with vulnerability assessments (VA) even when the data is present. To use CAS with VA, export or import definitions to copy the templates from the collector to the aggregator (or restore target).

Note: It is recommended that you do not use CAS to monitor more than 10,000 files per client.

### Monitored Entity

---

The actual entity being monitored, can be A File (its content and properties), Value of an Environment Variable or Windows Registry, Output of an OS command or Script or SQL statement

### CAS Instance

---

Application of a CAS Template Set on a specific Host (creating an Instance of that Template Set and applying it on a specific host)

### CAS Configuration

---

A CAS configuration defines one or more CAS instances, each of which identifies a template set to be used to monitor a set of items on that host.

## Default Template Sets

---

For each operating system and database type supported, Guardium provides a preconfigured, default template sets for monitoring a variety of databases on either Unix or Windows platforms. A default template set is one used as a starting point for any new template set defined for that template-set type. A template-set type is either an operating system alone (Unix or Windows), or a database management system (DB2®, Informix®, Oracle, and so on.), which is always qualified by an operating system type - for example, UNIX-Oracle, or Windows-Oracle. Many of the preconfigured, default template sets are used within Guardium's Vulnerability Assessments where, for example, known parameters, file locations, and file permissions can be checked.

You cannot modify a Guardium default template set, but you can clone it and modify the cloned version. Each of the Guardium default template sets defines a set of items to be monitored. Make sure that you understand the function and use of each of the items monitored by that default template set and use the ones that are relevant to your environment. After defining a template set of your own, you can designate that template set as the default template set for that template-set type. After that, any new template sets defined for that operating system and database type are defined with your new default template set as a starting point. The Guardium default template set for that type is removed; it remains defined, but is not marked as the default.

## Rationale for creating template sets to meet specific database configurations

---

Although Guardium supplies predefined CAS template sets for each database type, the wide variety of possible database configurations means that you might need to tweak the predefined template sets or create new ones to meet all of your needs in a production environment -- particularly concerning database software and data file locations. Plan on creating additional templates if you want CAS to monitor ownership of, permissions on, and changes to your database files.

For example, the predefined CAS template set for Oracle contains these templates, among others:

- \$ORACLE\_HOME/oradata/../\*.dbf
- \$ORACLE\_HOME/oradata/../\*.ctl
- \$ORACLE\_HOME/oradata/../\*.log
- \$ORACLE\_HOME/../init\*.ora

As you can see, these file-pattern templates all start with the same root, \$ORACLE\_HOME (NOTE: This is not necessarily the \$ORACLE\_HOME environment variable that is defined on your database server. By preference, CAS uses the data source field *Database Instance Directory* as the value for \$ORACLE\_HOME).

It is possible that in a production environment your Oracle data files are not in the same directory tree, or even on the same device, as your log files. Furthermore, the Oracle configuration files might be in yet another location.

You might create additional CAS templates using absolute paths to allow CAS to find and monitor all of your Oracle files, for example:

- /u01/oradata/mydb/\*.dbf
- /u02/oradata/mydb/\*.dbf
- /u03/oradata/mydb/\*.dbf
- /u01/oradata/mydb/\*.ctl
- /u02/oradata/mydb/\*.ctl
- /u03/oradata/mydb/\*.ctl
- /home/oracle11/admin/mydb/bdump/\*.log
- /home/oracle11/product/11.1/db\_1/dbs/init\*.ora

You can even use additional environment variables that are defined in your Oracle instance account. As an example, if you have variables defined as \$ORA\_DATA1, \$ORA\_DATA2 and \$ORA\_SOFT you can use:

- \$ORA\_DATA1/mydb/\*.dbf
- \$ORA\_DATA2/mydb/\*.dbf
- \$ORA\_DATA1/mydb/\*.ctl
- \$ORA\_DATA2/mydb/\*.ctl
- \$ORA\_SOFT/admin/mydb/bdump/\*.log
- \$ORA\_SOFT/product/11.1/db\_1/dbs/init\*.ora

## Sourcing files from different locations

---

CAS templates assume that certain files, such as user profiles, are in specific locations. You can configure CAS to look for these files in other locations that you specify by using a regular expression. To use this feature, add the user\_profile\_files parameter to the cas.client.config.properties file in the config directory. The format for each entry is

*identifying\_string=comma-separated list of files*

For example, suppose that you want to find .profile files in any Db2 user's home directory. For this example we assume that the names of all of these home directories include the string "db2." Add this line to the properties file:

**user\_profile\_files=.\*db2.\*=.profile**

If you need to specify more than one pattern, use the bar symbol (|) to separate patterns. If you want to add the profiles of your mysql users to the previous entry, replace the previous example with this:

**user\_profile\_files=.\*db2.\*=.profile|.\*mysql.\*=.profile**

## CAS server authentication with SSL

You can provide different levels of CAS server authentication support, from a non-secure connection to a secure connection with a signed certificate.

In addition to the basic security SSL provides, Guardium® provides CAS Server authentication support on the CAS client that runs on the database server. Authentication guarantees that CAS client communicates only with Guardium's CAS server. Unauthenticated connections and Common Name (CN) mismatches are reported in the CAS log file.

After the CAS client is configured, when the CAS server starts it loads a signed certificate as well as a private key. The server assigns the certificate and the key to a server socket on which it accepts connections. You can choose to provide authentication from either the CAS client side or server side.

The CAS client supports authentication with the following connection modes. Depending on your requirements, set the following parameters in the guard\_tap.ini file.

Non-secure connection

Set use\_tls='0'.

Secure connection without authentication (without FIPS mode)

Set use\_tls='1' and guardium\_ca\_path=NULL.

These settings force CAS to use SSL to communicate with the CAS server (that is, CAS uses SSL without server authentication) and disables FIPS mode.

Secure connection with server authentication (FIPS mode)

Set use\_tls='1' and guardium\_ca\_path=<public key location>.

The CAS client uses the public key in a certificate to authenticate the CAS server.

To prepare the custom certificate,

1. Create a custom certificate by using the **create csr alias** CLI command and have it signed by a certificate authority (CA) such as Verisign as described in [Certificate CLI commands](#).

Note: When you create the certificate, enter cas as the response to Please enter a one-word alias to uniquely identify this certificate.

2. Add the custom certificate to tomcat keystore: After you have the signed certificate (or certificates), use the **store certificate keystore alias console** CLI command to store the certificates starting from the last certificate to the root certificate in the chain.

Note: Enter cas as the response to Please enter a one-word alias to uniquely identify this certificate.

3. Copy the certificate in PEM format (for example, ca.cert.pem) to the CAS client machine, in the <public key location> described in the guardium\_ca\_path parameter of the guard\_tap.ini file.

On the CAS client machine, you can either set guardium\_ca\_path in guard\_tap.ini to,

- The full path, including the actual public key file name.
- A directory name, where all of the public keys within this directory are used to authenticate the server.

If guardium\_ca\_path is set to a file or directory that doesn't contain the public key, the connection attempt fails.

The CAS server supports secure connection with server authentication and common name verification. The common name (CN) verification provides an additional check-in which the certificate CN from the server is compared with the certificate CN set in the sqguard\_cert\_cn parameter in guard\_tap.ini. If sqguard\_cert\_cn is NULL or empty, this check is disabled. Otherwise, the value of sqguard\_cert\_cn must be the same as the CN of the custom certificate stored in CAS server tomcat keystore.

## Prerequisites, installing, and running CAS on a Windows server

Learn about the Configuration Auditing System (CAS) prerequisites, and how to install the CAS agent on your database server.

## Prerequisites on Windows

---

Before you install CAS, make sure that Microsoft .NET 4.5 or later is installed. After .NET is installed, approximately 2 GB of disk space is required for CAS.

Note: If .NET is not already installed, Guardium automatically installs it. In this case, .NET requires an additional 5 GB of disk space.

To run in FIPS mode, the CAS client requires IBM Java 8 SR7 or later. For more information, see [Managing the TLS version](#).

Table 1. Port Requirements for Windows servers

| Port  | Protocol | Guardium® connection to ... |
|-------|----------|-----------------------------|
| 16017 | TCP      | Clear (open the port) CAS   |
| 16019 | TLS      | Encrypted CAS               |

## Installing CAS

---

Use one of the following methods to install CAS:

- From the Windows installer wizard. To install CAS directly from Windows, browse to the directory where you download the .zip file, extract the file contents, double-click Setup.exe and follow the instructions.
- From the command line interface, as described in [Installing CAS from the CLI](#).
- From the Guardium Installation Manager (GIM) as described in [Installing CAS with GIM](#).

## Reconfiguring JAVA\_HOME (JVM) location for CAS

---

In most cases, the installation program takes care of finding the JAVA\_HOME value. This value is placed in the CAS configuration file.

If for any reason (for example, you install a new Java™ version after the Guardium CAS product is installed), you need to change the location of JAVA\_HOME (JVM), use the following procedure.

- Locate and open the CAS configuration file for editing. The full path name of the configuration file is <installation directory>/cas/conf/casclient.cfg.
- Within the configuration file, locate the [RUNTIMELIB] section, and change the value of the JVM directory (JVM=C:\Java\jre\bin\classic\jvm.dll).
- Save the file and restart the CAS service (service name: casclient or display name: IBM Security Guardium Change Audit System).

- [Installing CAS from the CLI](#)

Use the command line interface (CLI) to create scripts that are useful for managing large Configuration Auditing System (CAS) deployments.

- [Installing CAS with GIM](#)

When you install the Configuration Auditing System (CAS) on your database servers with the Guardium Installation Manager (GIM) client, you can install, upgrade, and manage agents on individual servers or groups of servers. Available actions include monitoring processes that are installed under GIM control, modifying CAS parameters, and performing other management tasks.

## Related reference

## Installing CAS from the CLI

---

Use the command line interface (CLI) to create scripts that are useful for managing large Configuration Auditing System (CAS) deployments.

To install CAS from the command line, call **setup.exe** with the appropriate parameters, as follows:

**Setup.exe -PARAMETER value**

Note: Use a space between each parameter and value pair. Do not use an equal sign (=).

The following parameters are available:

Table 1. Parameters that require an input value.

| Parameter        | Description                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------|
| -INSTALLPATH     | The installation directory. The default installation path is "C:\Program Files (x86)\IBM\CAS" |
| -APPLIANCE       | Required. Set the appliance address to which CAS connects.                                    |
| -LOCALIP         | Required. The IP address of the server where you are installing CAS.                          |
| -CUSTOMER        | Sets the customer name in the registry.                                                       |
| -COMPANY         | Sets the company name in registry.                                                            |
| -SERVICEUSER     | Specifies a user to run the service under.                                                    |
| -SERVICEPASSWORD | The password for the service user.                                                            |

Table 2. Parameters that do not require a value

| Parameter         | Description                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -INSTALLEDLOGPATH | Specifies the location for storing the CAS installer log files. Use this parameter if you want don't want to use the default location (C:\Program Files\IBM\Windows CAS).                   |
| -UNATTENDED       | Required. Install silently.                                                                                                                                                                 |
| -UNINSTALL        | Uninstall the CAS.                                                                                                                                                                          |
| -JVM              | Specifies the directory where jvm.dll can be found. If no value is provided, then the installer tries to find jvm.dll automatically. Check the installation log for file detection results. |

For example, to install CAS in unattended mode, create a command similar to the following command:

```
setup.exe -UNATTENDED -INSTALLPATH "C:\Program Files (x86)\IBM\CAS" -APPLIANCE 10.0.148.160 -LOCALIP 10.0.146.161
```

## Installing CAS with GIM

---

When you install the Configuration Auditing System (CAS) on your database servers with the Guardium® Installation Manager (GIM) client, you can install, upgrade, and manage agents on individual servers or groups of servers. Available actions include monitoring processes that are installed under GIM control, modifying CAS parameters, and performing other management tasks.

## About this task

Verify the following before you begin:

- Review the Windows CAS installation requirements in [Prerequisites, installing, and running CAS on a Windows server](#).
- The database server and operating system are supported.
- The intended CAS installation directory is empty or does not exist.
- The GIM client is installed on the database server where you plan to install a CAS.
- The GIM client on the database server is communicating with the Guardium system.
- Obtain the CAS module from either [Fix Central](#) or your Guardium representative.

After you install a GIM client on the database server, installation of the CAS for Windows is scheduled from the Guardium system.

Note: You cannot modify the CAS\_INSTALL\_DIR parameter after the installation. All other parameters can be modified after installation.

## Procedure

1. Upload the Windows CAS module for installation.
  - a. On the Guardium system, browse to **Manage > Module Installation > Upload Modules**.
  - b. Click **Browse** and select the CAS module that you want to install.
  - c. Click **Upload** to upload the module to the Guardium system.  
After you upload the module, it is listed in the Import Uploaded Modules table.
  - d. In the Import Uploaded Modules table, click the check box next to the CAS module to install.  
The module is imported and made available for installation. After the module is imported, Guardium resets the Upload Modules page and clears the Import Uploaded Modules table.
2. Install the uploaded CAS modules:
  - a. Under **Choose Clients** select the GIM client where you want to install CAS and click **Next**.
  - b. On the **Choose Bundle** page, clear the **Show only bundles** checkbox and select the CAS build from the drop-down list. Then, click **Next**.
  - c. On the **Choose parameters** page, the CAS\_INSTALL\_DIR and CAS\_JVM\_PATH parameters display. Values for these parameters are required before you can proceed. The default CAS install directory is C:\Program Files (x86)\IBM\CAS. Supply these values and then click **Next**.
  - d. Confirm your installation parameters and client name and click **Install**. To install the CAS immediately, you can simply click **OK**.  
If you want to change the location of the CAS installer log files from the default (C:\Program Files\IBM\Windows CAS), use the parameter CAS\_INSTALLER\_LOG\_DIR.

## What to do next

In the Success window, click **Show Status** to open the Status window to monitor the software install or upgrade. Click  to refresh the results. If an installation or upgrade has a failed status, click **Uninstall** if the button is available. Otherwise, click **Reset connection**. You can also view the status of the module installation by reviewing the report at **Manage > Reports > Install Management > GIM Clients Status**.

To verify that the CAS is communicating with the Guardium system, browse to **Manage > Activity Monitoring > CAS Control** and reviewing the CAS status and configuration.

## Prerequisites, installing and running CAS on a Linux, UNIX server

Learn about the Configuration Auditing System (CAS) prerequisites for Linux® and UNIX servers, and how to install the CAS agent on your database server.

### Prerequisites for Linux or UNIX servers

- CAS works with the following Java™ distributions: IBM®, OpenJDK, or Sun.
- The CAS server must be a Guardium® collector. The CAS server parameter (CAS\_SQLGUARD\_IP to install CAS with GIM, or sqlguard\_ip if you install CAS from the command line) is required.
- To run in FIPS mode, the CAS client requires IBM Java 8 SR7 or later. For more information, see [Managing the TLS version](#).

Table 1. Disk Space Requirements for Linux or UNIX servers

| Disk Space                        | Description                                                                                                                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAS Program files, including Java | AIX® - 309 MB, HP-UX - 630 MB, Linux - 405 MB, Solaris - 390 MB<br>Java runtime environment (JRE) 1.8 or later is required for CAS. You must obtain and install a JRE yourself (due to licensing constraints). |

Table 2. Port Requirements for Linux, UNIX servers

| Port  | Protocol | Guardium connection to ... |
|-------|----------|----------------------------|
| 16017 | TCP      | Clear CAS                  |
| 16019 | TLS      | Encrypted CAS              |

## Installing CAS with GIM

You can install CAS as a bundle with the Guardium Installation Manager (GIM), in the same way you install any other module. Use the following process, which is described in detail in [Set up by client](#), to install CAS with GIM:

1. Browse to Manage...>Module Installation,>Set up by Client.
2. Select the server where you want to install CAS and then click Next.
3. Select the CAS bundle and click Next.
4. Enter the Java home parameter for CAS. For more information, see [Locating the Java home directory and version](#).
5. Click Install to install the CAS bundle.

Note: If your site installed CAS using GIM in v10.6 or earlier, and then you upgrade CAS using GIM, delete and then re-create the Template/Datasource mapping after you upgrade. For more information, see [CAS hosts](#).

## Installing CAS client from the command line

---

Take the following steps to install the CAS client from the CLI:

1. Log on to the database server system with the root account.
2. Run the **install** command:

```
<guard-cas-setup>.sh -- install --java-home <JAVA_HOME> [--install-path <INSTALL_PATH>]
{--stap-conf <FULL_PATH_TO_GUARD_TAP_INI> | --sqlguard_ip <IP_OF_GUARDIUM_COLLECTOR>}
```

Where:

- <guard-cas-setup> - Identifies the name of the script file.
- -- install - Indicates an installation of CAS.
- --java-home - Identifies the JAVA\_HOME directory.
- --install-path - Identifies the installation path. You can specify the directory where you want to install the CAS client. Create the directory from root (make sure that the permissions are set to 755). If you do not include a directory in the installation path, Guardium automatically creates the directory for you.  
Note: If you install CAS on an AIX server, make sure that enough space is available to process the data segments (as defined in the data parameter of the AIX /etc/security/limits file). The default, and recommended value, for the data parameter is -1 (*unlimited*). However, if your site requires an actual value, Guardium suggests that you set this limit to at least 1 GB.  
If you modify /etc/security/limits, you might need to restart your server.
- You must include one of the following parameters:
  - --stap-conf - Use when the guard\_tap.ini file is located in the specified **stap-conf** directory. The installer uses the guard\_tap.ini file as-is.
  - --sqlguard\_ip - Use the default .ini file provided by the installer. In this case, the installer modifies the sqlguard\_ip key inside the .ini file with the value that is provided by the **--sqlguard\_ip** parameter.

Note: You must specify either **--stap-conf** or **--sqlguard\_ip**.

Note: For more information about modifying the guard\_tap.ini file, see [Editing the S-TAP configuration parameters](#)

## Uninstall a CAS client

---

Enter the following command to uninstall a CAS client.

Note: To ensure that the CAS client is completely uninstalled, call **uninstall** from a directory that is above the <INSTALL\_PATH>. The CAS files are not removed if you run the command from the <INSTALL\_PATH> or any directory underneath it.

```
<INSTALL_PATH>/bin/guard-cas-setup uninstall
```

## Start and stop CAS from the command line

---

Depending on your install or uninstall scenario, you might need to start and stop CAS from the command line.

To start or stop CAS, log on to the database server system with the root account. Depending on your operating system, use one of the following methods.

- For Red Hat® Enterprise Linux 6: Stop or start CAS with the **stop cas** or **start cas** commands.
- For Red Hat Enterprise Linux 7: Stop or start CAS with the **systemctl stop guard\_cas** or **systemctl start guard\_cas** commands.
- For other operating systems:
  1. Comment out (to stop CAS) or undo the comment (to start CAS) for the CAS agent entry in the /etc/inittab file. By default, the statement is as follows:

```
cas:<nnnn>::respawn:/usr/local/guardium/guard_stap/cas/bin/run_wrapper.sh /usr/local/guardium/guard_stap/cas/bin
```

2. Save the /etc/inittab file.
3. Run the **init q** command

- To validate whether CAS is running, enter the **ps -fe | grep cas** command.
- [Locating the Java home directory and version](#)

Locate the home directory and check the Java version before you install CAS.

## Related reference

- [Configuration Auditing System \(CAS\) parameters](#)

## Locating the Java home directory and version

---

Locate the home directory and check the Java™ version before you install CAS.

## About this task

---

When you install CAS on a UNIX system, you need the following information about Java on your system:

- Identify the JAVA\_HOME directory. You are prompted for its location during the CAS installation.
  - Verify that a supported version of Java is installed. If a supported version is not installed, you must install it before you install CAS.
- Note: To use CAS over SSL in a FIPS-compliant environment, you must install IBM® Java on the server where the CAS agent runs.

The **java** command contains the JAVA\_HOME directory. For example, if the JAVA\_HOME directory is:

```
/usr/local/j2sdk1.4.2_03
```

Then, the **java** command is:

```
/usr/local/j2sdk1.4.2_03/bin/java
```

## Procedure

---

1. To determine your location and version of Java, use the **which java** command. For example,

```
[root@yourserver ~]# which java
/usr/local/j2sdk1.4.2_03/bin/java
```

The JAVA\_HOME directory is `/usr/local/j2sdk1.4.2_03`.

2. If the **which java** command returns a symbolic link, use the **ls -ld <symbolic\_link>** command to determine the real Java directory name.
3. If the **which java** command returns the message `command not found`, then Java might be installed, but is not included in the PATH variable. In this case, use the **find** command to locate the Java directory; for example,

```
[root@yourserver ~]# find . -name java
./usr/bin/
```

4. To check the version number, from the java directory, run the **java -version** command. For example,

```
[root@yourserver ~]# /usr/local/j2sdk1.4.2_03/bin/java -version
java version "1.4.2_03"
Java(TM) 2 Runtime Environment, Standard Edition (build 1.4.2_03-b02)
Java HotSpot(TM) Client VM (build 1.4.2_03-b02, mixed mode)
```

5. Note the Java version that is returned. You are not prompted for this information, but if an issue arises later, you can eliminate the possibility of an unsupported Java version.

---

## CAS start-up and failover

Various failover and connect parameters can be modified through S-TAP Control Change Auditing.

When the CAS client starts on the host, it looks for a checkpoint file that it may have written to the system. This file tells CAS what it was doing the last time it was running. CAS then connects to its Guardium® system. If it has found a checkpoint file, CAS will ask the Guardium system to verify its version of its monitoring assignment against what is stored in the Guardium database. While the CAS client and the Guardium system have been disconnected, there may have been changes to the assignment. When any differences are resolved, CAS will resume monitoring. If CAS does not find a checkpoint file, it will ask the Guardium system what it should do. If the Guardium system finds the CAS host in its database, then the associated template sets will be sent to the CAS client, expanded into monitored items, and monitoring will begin. If the Guardium system cannot find the CAS host in its database, it will add it to the database and send the default template set for the CAS host operating system.

When connectivity is lost between the CAS client and Guardium system, it may take the CAS client and Guardium system up to five minutes (the wait time for a CAS client to expect a message from the Guardium system) to discover that it has lost contact with the primary Guardium system, but may happen sooner if the communication error is detected.

If the CAS client loses its connection to the Guardium system or cannot make an initial connection, it opens a failover file and begins writing the messages that it would have sent to the Guardium system, to the failover file. The path to this fail over file is stored in `guard_tap.ini` with the name `cas_fail_over_file`. When communication is reestablished the CAS client shuts down and restarts, sends all messages stored in the failover file to the Guardium system, and deletes the file. If the CAS client was unable to make the initial connection, it will use the checkpoint file to determine what to monitor, and continues doing what it was doing before communication failed.

When communication is lost, the client also starts a thread which periodically tries to reconnect with the primary Guardium system. The number of times CAS will attempt to reconnect, and the average time interval between reconnect attempts, are configurable parameters. It will try to reconnect for a period of time set in `guard_tap.ini` with the name `cas_server_failover_delay`. After that time has passed, the client will also try to connect to any secondary servers identified in `guard_tap.ini`. The secondaries will be tried in the order of the value of the `primary` attribute listed in the `SQL_Guard` sections of `guard_tap.ini`. When `primary` is not 1, it is a secondary. While the client is connected to a secondary server it will continue to try to reconnect to the primary server.

If the reconnect attempt limit is met, the CAS client stops trying to reconnect, but continues to write data to a failover file. To cap disk space requirements on the database server, there are actually two failover files. CAS writes to one file until it reaches its maximum failover file size (which is configurable), and then switches to the other, overwriting any previous data on that file. The default failover file size is 50MB (for each of the files).

You can specify one or more secondary Guardium systems when configuring the CAS client. In failover mode, CAS only tries to reconnect to its primary server until the time specified by `cas_server_failover_delay` in `guard_tap.ini` is exceeded. At that time, CAS begins trying to connect to any of the secondary servers, as well as its primary server (which is always the first server it tries to connect with during any reconnect attempt). While it is connected to a secondary server, CAS continues to try to reconnect to its primary server.

Changes to the CAS client configuration can only be made from the primary server and only while the host is online. Whenever the configuration of the CAS client is changed on the primary server and Guardium system is in standalone configuration, an export file is saved on the host. If the CAS client connects to a secondary server, the saved export file is imported from the host to the secondary server.

There is no need to separately maintain configurations on both primary and secondary servers. However, if on the primary server, the parameters for an individual monitored item have been changed from those defined in the template, then these changes will not be transferred to the secondary server. For example, even if the test interval on a particular file was changed from the template default of 1 hr to 10 min, the test interval on the secondary server will again be 1 hr. Essentially, monitored items are regenerated from the templates of the imported configuration. The delay before searching for secondary servers is based directly on time rather than failover file size. The delay is set with the `cas_server_failover_delay` parameter in `guard_tap.ini` and has a default of 60 minutes.

Various failover and connect parameters can be modified through S-TAP Control Change Auditing.

As with S-TAP, CAS connectivity outages create exceptions on the Guardium system, so alerts can be issued within moments of detecting the outage.

## Setting Up and Maintaining Secondary Servers

In the S-TAP/CAS configuration file on the database server system, one or more secondary Guardium servers can be defined. If the primary Guardium server becomes unavailable, CAS on that database server system will connect to a secondary Guardium system (as described previously, see Start Up and Failover).

### Rules of Failover

| Rule # | Guardium system | Fails over to               | Valid |
|--------|-----------------|-----------------------------|-------|
| 1      | stand alone     | stand alone                 | Yes   |
| 2      | managed         | managed (same manager)      | Yes   |
| 3      | managed         | managed (different manager) | No    |
| 4      | managed         | stand alone                 | No    |
| 5      | stand alone     | managed                     | No    |

### CAS Failover Limitations

1. CAS instances will not be relocated to the failed-over Guardium system when the source Guardium system is a managed unit and the target Guardium system is either:
  - a stand-alone Guardium system
  - a managed unit which is being managed by a different manager
2. CAS import/export option will be limited to manager and stand-alone machines only.

### Exporting CAS Hosts

1. Click **Manage > Aggregation & Archive > Export** to open the Definitions Export panel. Select CAS Hosts from the Type menu, select the to-be exported definitions from the Definitions to Export menu, and click .in the Export
2. A file named `exp_<date>_<time>.sql` is saved on your system. This file will contain the definitions of all CAS hosts selected, and the definitions of any template sets used by those CAS hosts.

### Importing CAS Hosts

1. Click **Manage > Aggregation & Archive > Import** to open the Definitions Import panel.
2. Use the Browse and Upload buttons to select files and upload them, then select the definition from the Import Uploaded Definitions pane.
3. Click **Import this set of definitions**  to import the definition.
4. Confirm the selected action (or not).  
Note: An import operation does not overwrite an existing definition. If you attempt to import a definition with the same name as an existing definition, you are notified that the item was not replaced. If you want to overwrite an existing definition with an imported one, you must delete the existing definition before performing the import operation.

### Maintaining Secondary Servers for a CAS Host

CAS configurations can also be maintained through the use of export and import operations. Since the import operation will not replace an existing definition, on each secondary server you must delete the old CAS host definition before importing the new one.

Be sure to perform this procedure only while the selected CAS host is connected to its primary server.

1. Export the definition of the CAS host (see the previous section).
2. On each secondary server:
  - Delete the old CAS host definition that you want to replace.
  - Import the definitions that were exported from the primary server (see Importing CAS Hosts, previous).

### CAS Client Ignore Change Alerts

The CAS client agent can avoid sending change notifications to the CAS server based on a predefined settings.

The CAS client agent will now look for a new parameter `ignore_change_alerts` in the CAS client agent's `cas.client.config.properties` configuration file.

If the parameter is not found or not set, the CAS client will work without any changes and the Ignore change alerts functionality will not be enabled (for example, the CAS client will alert on any file change).

If the new parameter is set, CAS client agent will ignore sending change notifications based on the change-types specified in the parameter value.

The possible change-types are:

`PERMISSION, SIZE, OWNER, GROUP, TIMESTAMP`

Ignoring multiple change-types can be set by + delimited concatenation of any of the specified change-type.

For example:

In order to avoid sending change notification on OWNER and GROUP changes, set up the parameter as follows:

`ignore_change_alerts=OWNER+GROUP`

Note: In the initial installation or when defining a new template, the FIRST scan of the files will be performed and these files will appear in the CAS changes report regardless to settings of Ignore change alerts.

## Correcting an invalid non-IP hostname

---

In case the user installs CAS agent with a bogus tap\_ip, guard\_tap.ini param, or CAS\_TAP\_IP (GIM param), Windows datasources defined for that host might be useless (if used for activity that requires accessing the remote database).

If the scenario happens, the user will have to delete the datasource and change the tap\_ip parameter to the correct database server hostname/ip.

---

## CAS templates

Guardium provides a set of CAS templates, one for each type of data repository.

### CAS templates - Db2

---

#### OS Script

Designates an OS script to run. Must begin with the variable \$SCRIPTS, which refers to the scripts directory beneath the CAS home directory, and identify the script to run, e.g., \$HOME/ db2\_spm\_log\_path\_group\_test.sh". The script itself must, of course, reside in the CAS \$SCRIPTS directory. Output from the script is stored in the Guardium® database to be used by security assessments. This can be either a shell or batch script to run, or a set of commands to enter on the command line. Because of the fickle nature of Java's parsing, it is suggested that you put all but the simplest commands into a script rather than run directly. On UNIX the script is run in the environment of the OS user entered. Three environment variables will be defined for the run environment which the user could use in writing scripts: \$UCAS is the DB username, \$PCAS is the DB password, and \$ICAS is the DB instance name. For Windows these three values will be appended as the last three arguments to the batch file execution. For example, if you had an OS Script template %SCRIPTS%\MyScript.bat my-arg1 my-arg2, then %3, %4 and %5 would be the DB username, password, and instance name respectively.

#### File

Designates a file to be tracked and monitored by security assessments. The path to the file can be absolute, or relative to the \$INSTHOME variable. Set the value of the \$INSTHOME variable in Database Instance Directory on the Datasource Definition panel. This is assumed to name a single file. Environment variables from the OS user environment can be used in the file name and will be expanded. For example, \$HOME/START.sh will name the startup script in the DB2® user's home directory.

#### File Pattern

Designates a group of files to be tracked and monitored by security assessments. The path to the files can be absolute, or relative to the \$INSTHOME variable. Set the value of the \$INSTHOME variable in Database Instance Directory on the Datasource Definition panel. A.. in the path indicates one or more directories between the portion of the path before it and the portion of the path after it. A.+ in the path indicates exactly one directory between the portion of the path before it and the portion of the path after it. For example: \$INSTHOME/sql11ib/../\* is just a short-hand for creating many single file identifications from a single identification string, a file pattern which will match all files in the directory. A file pattern can be viewed as a series of regular expressions separated by '/'. A file is matched if each element of its full path can be matched by one of the regular expressions in order. If an element of the pattern is an environment variable, it is expanded before the match begins. If .. is one of the elements of the pattern, it will match zero or more directory levels. For example, /usr/local/..foo will match /usr/local/foo and /usr/local/gunk/junk/bunk/foo. Using more than one .. element in a file pattern should not be necessary and is discouraged because it makes the pattern very slow to expand. Because of the confusion with its use in regular expressions | cannot be used as a separator as it might be in Windows.

Additionally, the Guardium UNIX/Db2 Assessment: UNIX - Db2 for UNIX set includes the following templates:

#### Db2govd Setuid Bits Is Not Set

This test monitors that the SETUID bit on Db2GOVD has been disabled

#### Db2start Setuid Bits Is Not Set

This test monitors that the SETUID bit on Db2START has been disabled

#### Db2stop Setuid Bits Is Not Set

This test monitors that the SETUID bit on Db2STOP has been disabled

#### File ownership

This test monitors file ownership, and changes thereto, of Db2 files.

#### File permissions

This test monitors file permissions, and changes thereto, of Db2 files.

### CAS templates - Informix

---

#### OS Script

Designates an OS script to run. Must begin with the variable \$SCRIPTS, which refers to the scripts directory beneath the CAS home directory, and identify the script to run, e.g., \$HOME/ informix\_rootpath\_owner.sh". The script itself must, of course, reside in the CAS \$SCRIPTS directory. Output from the script is stored in the Guardium database to be used by security assessments. This can be either a shell/batch script to be run, or a set of commands that could be entered on the command line. Because of the fickle nature of Java's parsing it is suggested that any but the simplest commands be put into a script rather than run directly. On UNIX the script is run in the environment of the OS user entered. Three environment variables will be defined for the run environment which the user could use in writing scripts: \$UCAS is the DB username, \$PCAS is the DB password, and \$ICAS is the DB instance name. For Windows these three values will be appended as the last three arguments to the batch file execution. For example, if you had an OS Script template %SCRIPTS%\MyScript.bat my-arg1 my-arg2, then %3, %4 and %5 would be the DB username, password, and instance name respectively.

## File

Designates a file to be tracked and monitored by security assessments. The path to the file can be absolute, or relative to the \$INFORMIXDIR variable. Set the value of the \$INFORMIXDIR variable in Database Instance Directory on the Datasource Definition panel. This is assumed to name a single file. Environment variables from the OS user environment can be used in the file name and will be expanded. For example, \$HOME/START.sh will name the startup script in the Informix® user's home directory.

Additionally, the Guardium UNIX/Informix Assessment for UNIX set includes the following templates:

Scan log files for errors

This test monitors for error in the online.log file

File ownership

This test monitors file ownership, and changes thereto, of Informix files.

File permissions

This test monitors file permissions, and changes thereto, of Informix files.

## CAS templates - Oracle

---

### OS Script

Designates an OS script to run. Must begin with the variable \$SCRIPTS, which refers to the scripts directory beneath the CAS home directory, and identify the script to run, e.g., \$SCRIPTS/oracle\_user.sh. The script itself must, of course, reside in the CAS \$SCRIPTS directory. Output from the script is stored in the Guardium database to be used by security assessments. (This can be either a shell/batch script to be run, or a set of commands that could be entered on the command line. Because of the fickle nature of Java's parsing it is suggested that any but the simplest commands be put into a script rather than run directly. On UNIX the script is run in the environment of the OS user entered. Three environment variables will be defined for the run environment which the user could use in writing scripts: \$UCAS is the DB username, \$PCAS is the DB password, and \$ICAS is the DB instance name. For Windows these three values will be appended as the last three arguments to the batch file execution. For example, if you had an OS Script template \$SCRIPTS/mysql\_mysqld\_user.sh, then %3, %4 and %5 would be the DB username, password, and instance name respectively.)

### File

Designates a file to be tracked and monitored. The path to the file can be absolute, or relative to the \$ORACLE\_HOME variable. The value of the \$ORACLE\_HOME variable is the value you set in the Database Instance Directory field of the Datasource Definition panel. (This is assumed to name a single file. Environment variables from the OS user environment can be used in the file name and will be expanded. For example, \$HOME/START.sh will name the startup script in the Oracle user's home directory.)

### File Pattern

Designates a group of files to be tracked and monitored. The path to the files can be absolute, or relative to the \$ORACLE\_HOME variable. Set the value of the \$ORACLE\_HOME variable in Database Instance Directory on the Datasource Definition panel. A .. in the path indicates one or more directories between the portion of the path before it and the portion of the path after it. A .+ in the path indicates exactly one directory between the portion of the path before it and the portion of the path after it. For example: \$ORACLE\_HOME/oradata/../\*.dbf (This is just a short-hand for creating many single file identifications from a single identification string, a file pattern. A file pattern can be viewed as a series of regular expressions separated by /'s. A file is matched if each element of its full path can be matched by one of the regular expressions in order. If an element of the pattern is an environment variable, it is expanded before the match begins. If .. is one of the elements of the pattern, it will match zero or more directory levels. For example, /usr/local/..foo will match /usr/local/foo and /usr/local/gunk/junk/bunk/foo. Using more than one .. element in a file pattern should not be necessary and is discouraged because it makes the pattern very slow to expand. Because of the confusion with its use in regular expressions | cannot be used as a separator as it might be in Windows. The file pattern shown previously is not correct because \*.dbf is not a valid regular expression. It should be \*.dbf.

Additionally, the default Guardium UNIX/Oracle template set includes the following templates:

### ADMIN\_RESTRICTIONS Is On

This test monitors that the listener.ora parameter ADMIN\_RESTRICTIONS is set properly.

### File ownership

This test monitors file ownership, and changes thereto, of the Oracle data files, logs, executables, etc.

### File permissions

This test monitors file permissions, and changes thereto, on the Oracle data files, logs, executables, etc.

### Scan log files for errors

This test scans the Oracle log files for occurrences of error strings.

### SPOOLMAIN.LOG Does Not Exist

This test checks the existence of the Oracle SPOOLMAIN.LOG.

## CAS templates - MongoDB

---

MongoDB is typically used as an operational system and as a backend for web applications due to ease of programming for non-relational formatted data like JSON documents.

Use the UNIX/MongoDB template to specify multiple paths and multiple directories in the datasource to scan various components as specified in the MongoDB datasource definition.

Scan a file pattern by selecting template items beginning with a "\$".

Do not select the \$SCRIPTS/mongodb\_unmask\_value.sh item - it is a Guardium reserve item.

If the template item is not specified as part of the Database Instance Directory in the MongoDB datasource definition, the item will be skipped over and not scanned.

Note: For CAS scripts to work, you must enable log in for the MongoDB account on the Mongo DB server. To enable log in, log in as root, run the command **chsh mongod**, and when prompted for new shell, enter /bin/bash.

Note: You can create your own template with multiple file paths for any type of datasource. When creating your own template, we recommend that you use the UNIX/MongoDB as a reference. To create a new template for a MongoDB datasource, you can clone and modify the UNIX/MongoDB template.

Note: MongoDB datasources support SSL server and client/server connections with SSL client certificates. MongoDB connections use a Java driver, instead of a JDBC database connection.

Note: The VA solution for MongoDB clusters can be run on mongos, a primary node and all secondary nodes for replica sets.

## CAS templates - Netezza®

---

### File Ownership

This test checks whether the files are owned and belongs to the correct group according to the definition within the CAS template.

### File Permission

This test checks whether the file permission is properly set according to the definition within the CAS template.

### Scan Log files for errors

This test checks for these events (FATAL, ERROR, DEBUG, ABORT and PANIC) in these two log files. /nz/kit/log/postgres/pg.log and /nz/kit/log/startupsrv/startupsrv.log

## Configuration for Oracle RAC systems

---

This is the required configuration for Oracle RAC systems.

Change guard\_tap.ini on each node installed with S-TAP:

unix\_domain\_socket\_marker=<key>

where <key> value can be found in listener.ora in the IPC protocol definition

Example 1:

If the following is a description in the listener.ora

LISTENER=(DESCRIPTION=(ADDRESS\_LIST=(ADDRESS=(PROTOCOL=IPC)(KEY=ORCL)))

Then change the following parameter accordingly

unix\_domain\_socket\_marker=ORCL

Example 2:

In the case where there is more than one IPC line in listener.ora, use a common denominator of all the key LISTENER=(DESCRIPTION=(ADDRESS\_LIST=(ADDRESS=(PROTOCOL=IPC)(KEY=LISTENER)))) LISTENER\_SCAN1=(DESCRIPTION=(ADDRESS\_LIST=(ADDRESS=(PROTOCOL=IPC)(KEY=LISTENER\_SCAN1)))) LISTENER\_SCAN2=(DESCRIPTION=(ADDRESS\_LIST=(ADDRESS=(PROTOCOL=IPC)(KEY=LISTENER\_SCAN2)))) LISTENER\_SCAN3=(DESCRIPTION=(ADDRESS\_LIST=(ADDRESS=(PROTOCOL=IPC)(KEY=LISTENER\_SCAN3))))

Guardium uses a string search in the path so LISTENER will work for all four and should be used in this case:

unix\_domain\_socket\_marker=LISTENER

## CAS templates - PostgreSQL

---

Note: It is very important that PostgreSQL\_BIN and PostgreSQL\_DATA environment variables are defined correctly. An invalid setting causes other CAS assessment tests not to work properly or at all.

### File Ownership

This test checks whether the files are owned and belongs to the correct group according to the definition within the CAS template.

### File Permission

This test checks whether the file permission is properly set according to the definition within the CAS template.

### PostgreSQL\_BIN environment variable defined

This test check if the \$PostgreSQL\_BIN environment variable is defined in your database server. This variable need to be defined under the root account for UNIX/Linux or you can add to .profile for root login. For Windows OS, it needed to be defined for the Administrator login. For Red Hat Linux®, PostgreSQL BIN folder is usually in /usr/bin. For Solaris, it is usually something like /data/postgres/postgres/8.3-community/bin/64. Setting this environment variable is very important as other assessment tests relied on the location of this folder.

### PostgreSQL\_DATA environment variable defined

This test check if the \$PostgreSQL\_DATA environment variable is defined in your database server. This variable need to be defined under the root account for UNIX/Linux or you can add to .profile for root login. For Windows OS, it needed to be defined for the Administrator login. For Red Hat Linux, the default for DATA folder is usually in /var/lib/pgsql/data. For Solaris, there is no consistent location. Setting this environment variable is very important as other assessment tests relied on the location of this folder to find the correct configuration files.

## CAS templates - SQL Server

---

### OS Script

Designates an OS script to run. Output from the script is stored in the Guardium database. This can be either a shell/batch script to be run, or a set of commands that could be entered on the command.

### Registry Variable

Search Windows registry for specific key value that are required by security assessments test.

## CAS templates - Sybase

---

#### OS Script

Designates an OS script to run. Must begin with the variable \$SCRIPTS, which refers to the scripts directory beneath the CAS home directory, and identify the script to run, e.g., \$HOME/sybase\_sysdevice\_type\_test.sh. The script itself must, of course, reside in the CAS \$SCRIPTS directory. Output from the script is stored in the Guardium database to be used by security assessments. This can be either a shell/batch script to be run, or a set of commands that could be entered on the command line. Because of the fickle nature of Java's parsing it is suggested that any but the simplest commands be put into a script rather than run directly. On UNIX the script is run in the environment of the OS user entered. Three environment variables will be defined for the run environment which the user could use in writing scripts: \$UCAS is the DB username, \$PCAS is the DB password, and \$ICAS is the DB instance name. For Windows these three values will be appended as the last three arguments to the batch file execution. For example, if you had an OS Script template %SCRIPTS%\MyScript.bat my-arg1 my-arg2, then %3, %4 and %5 would be the DB username, password, and instance name respectively.

#### File

Designates a file to be tracked and monitored by security assessments. The path to the file can be absolute, or relative to the \$SYBASE variable. The value of the \$SYBASE variable is the value you set in the Database Instance Directory field of the Datasource Definition panel. This is assumed to name a single file. Environment variables from the OS user environment can be used in the file name and will be expanded. For example, \$HOME/START.sh will name the startup script in the Sybase user's home directory.

#### File Pattern

Designates a group of files to be tracked and monitored by security assessments. The path to the files can be absolute, or relative to the \$SYBASE variable. The value of the \$SYBASE variable is the value you set in the Database Instance Directory field of the Datasource Definition panel. A .. in the path indicates one or more directories between the portion of the path before it and the portion of the path after it. A .+ in the path indicates exactly one directory between the portion of the path before it and the portion of the path after it. For example: \$SYBASE/../\*dat" This is just a short-hand for creating many single file identifications from a single identification string, a file pattern. A file pattern can be viewed as a series of regular expressions separated by /'s. A file is matched if each element of its full path can be matched by one of the regular expressions in order. If an element of the pattern is an environment variable, it is expanded before the match begins. If .. is one of the elements of the pattern, it will match zero or more directory levels. For example, /usr/local/..foo will match /usr/local/foo and /usr/local/gunk/junk/bunk/foo. Using more than one .. element in a file pattern should not be necessary and is discouraged because it makes the pattern very slow to expand. Because of the confusion with its use in regular expressions |cannot be used as a separator as it might be in Windows.

Additionally, the Guardium UNIX/Sybase Assessment : UNX - SYBASE set includes the following templates :

#### Scan log files for errors

This test monitors for errors in Sybase log files.

#### sysdevice Owner is sysbase

This test monitors for ownership of sysdevice.

#### File ownership

This test monitors file ownership, and changes thereto, of Sybase files.

#### File permissions

This test monitors file permissions, and changes thereto, of Sybase files.

## CAS templates - Teradata

---

#### File ownership

This test checks whether the files are owned and belongs to the correct group according to the definition within the CAS template.

#### File permission

This test checks whether the file permission is properly set according to the definition within the CAS template.

#### Aster Data

Aster Data was acquired by Teradata in 2011, typically used for data warehousing and analytic application (OLAP). Aster Data created a framework called SQL-MapReduce that allows the Structured Query Language (SQL) to be used with Map Reduce. Aster Data is most often associated with clickstream kinds of applications.

An Aster nCluster includes a Queen Node Group, a Worker Node Group, and a Loader Node Group. A CAS agent is installed on all three node groups.

A security assessment should be created to execute all tests on the queen node. All database connections for Aster Data go through the queen node only.

Testing on worker and loader nodes are only required when performing CAS tests (File permission and File ownership).

Privilege tests loop through all the databases in a given instance.

When running VA tests that require CAS access, and filling in the CAS datasource configuration choices, specify the username that Aster is installed under for Database Instance Account. This username typically is called beehive.

For Database Instance Directory, this is the home directory of the beehive user. The default typically is /home/beehive.

When running VA tests that are do not use CAS, the customer should create their datasource, pointing to the QUEEN node within the cluster.

When running VA tests that are CAS dependent, if the node you are testing is one of the worker, then you would have to setup "Custom URL" in the datasource to point to the Queen node as that is how it is listening.

#### Example

Host Name/IP = Worker.guard.xxx.xxx..com or 1xx.1xx.111.111 (This is the actual worker host even though worker is not listening to this. CAS needs this so it can send and receive data from the Worker's node)

Port = 2046 or whatever the port used.

Database = beehive

Custom URL= jdbc:ncluster://aster6q:2406/beehive (This JDBC example shows that we are actually connecting to the aster6q which is the queen node on port 2406 and beehive database)

Database instance account = beehive

Database instance directory = /home/beehive

## Working with CAS templates

This section describes how to maintain CAS templates and template sets.

### Define a Template/Template Set

- Create a New Template Set
- Modify a Template Set
- Clone a Template Set
- Delete a Template Set

### Create a New Template Set

1. Open the CAS Configuration Navigator by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Click New to open the Monitored Item Template Definitions panel.
3. Select OS Type.
4. Select DB Type. If the template set does not require any specific DB type then select N\_A as the DB Type.
5. Enter a unique name for Template Set Name.  
Note: Template Set Names over 128 characters will be truncated
6. Click Apply to save the CAS Template Set Definition.
7. To add items to the new template set, click Add to Set and see [Define a Template Set Item](#).

### Finding the Guardium CAS Panel

Access to CAS Configuration Functions, by default, is restricted to the admin user and to users who have been assigned the CAS role.

Click Harden. The list of CAS functions is listed within the Configuration Change Control (CAS Application) header.

### Opening the CAS Configuration Navigator

The CAS Configuration Navigator panel is the starting point for creating or modifying CAS Template Sets.

Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.

The list can be filtered by OS type and DB type.

### Modify a Template Set

Use the CAS Configuration Navigator panel to modify an existing CAS template set. Once a template set is in use on any CAS host, the modifications that you can make to that template set are limited. You will be able to make minor changes to various elements of the definition, but you will not be able to add or remove templates.

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Filter the template set list by OS Type or DB Type.
3. Select the Template Set that you want to modify and click Modify to open the CAS Template Set Definition pane.
4. Make your changes and click Apply to save them.

### Clone a Template Set

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Filter the template set list by OS Type or DB Type.
3. Select the Template Set that you want to clone and click Clone to open the CAS Template Set Definition panel.
4. Once cloned, modify the clone to suit your needs.

Note: Predefined templates cannot be edited. They have the same restrictions as those that are in use by a CAS host. To make changes, clone it, then edit the cloned copy as needed.

### Delete a Template Set

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Filter the template set list by OS Type or DB Type.
3. Select the Template Set that you want to delete and click Delete.

### Define a Template Set Item

Once a template set is in use on any CAS host, the modifications that you can make to that template set are limited. You will be able to make minor changes to various elements of the definition, but you will not be able to add or remove templates.

- Create a New Template Set Item
- Modify a Template Set Item
- Delete a Template Set Item

## Create a New Template Set Item

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Click New to open the Monitored Item Template Definitions panel.
3. Enter in a Template Set Name, select an OS Type and DB Type, and click Apply.
4. Click Add To Set to create a new item.

## Modify a Template Set Item

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Filter the template set list by OS Type or DB Type.
3. Select the Template Set that you want to modify and click Modify to open the CAS Template Set Definition panel.
4. Select the items you want to modify, and click Edit Selected.... Make your desired changes and click Apply to save them.

## Delete a Template Set Item

1. Open the CAS Configuration Navigator panel by clicking Harden > Configuration Change Control (CAS Application) > CAS Template Set Configuration.
2. Filter the template set list by OS Type or DB Type.
3. Select the Template Set that you want to modify and click Modify to open the CAS Template Set Definition panel.
4. Select the items you want to delete, and click Delete Selected.

## CAS Item Template Definition Pane

| Component        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OS Type          | The operating system type: Windows or UNIX. You can change this selection when the template set is empty, but you cannot change it if the template set contains one or more items.                                                                                                                                                                                                                                                                                                         |
| DB Type          | The database type (Oracle, MS-Sql, DB2®, Sybase, Informix®, etc.) or N/A for an operating system template set. You can change this selection when the template set is empty but you cannot change it if the template set contains one or more items.                                                                                                                                                                                                                                       |
| Description      | An optional name for the item used in reports and to identify the item in other CAS panels (the CAS Template Set Definition for example). If omitted, the item name defaults to the file name or pattern, variable name, or script (as appropriate for the type).                                                                                                                                                                                                                          |
| Type             | One of the following: SQL Query, OS Script, Environment Variable, Registry Variable, Registry Variable Pattern, File, and File Pattern.<br><br>See Template and Audit Types for further information.<br><br>Note: If being used with CAS-based assessment tests this must be of type OS Script.                                                                                                                                                                                            |
| Content          | Type dependent text defining the specific item to monitor, or how to generate it.<br><br>See Template and Audit Types for further information.<br><br>Note: For an OS script CAS will wait for a script to complete. To limit the time allowed for an OS script to run and allowing CAS to terminate the script, use the <b>cas_command_wait</b> guard_tap.ini parameter. The default wait time is 300 seconds or 5 minutes. When changing this parameter there is no need to restart CAS. |
| Permission Limit | For File and File Pattern Type only.<br><br>Used for UNIX only - the permissions that this file should not exceed.                                                                                                                                                                                                                                                                                                                                                                         |
| File Owner       | For File and File Pattern Type only. The owner of the file(s).                                                                                                                                                                                                                                                                                                                                                                                                                             |
| File Group       | For File and File Pattern Type only. The group owner of the file(s).                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Period           | The maximum interval between tests, specified as a number of minutes(m), hours(h), or days(d). Data becomes available after the initial period is realized and up to and before the next period begins.                                                                                                                                                                                                                                                                                    |
| Keep Data        | If selected, a copy of the actual data is saved with each change. For example: for a file item, a copy of the file is saved. If selected, but the size of the raw data for the item is greater than the Raw Data Limit configured for this CAS host, no data will be saved.                                                                                                                                                                                                                |
| Use MD5          | Indicates whether or not an additional comparison is done by calculating a checksum of the raw data using the MD5 algorithm. Computing the MD5 checksum is time consuming for large character objects. However, it is a better indicator of change than just the size. The default is not to use MD5. If MD5 is used, but the size of the raw data is greater than the MD5 Size Limit configured for the CAS host, the MD5 calculation and comparison will be skipped.                     |
| Enabled          | Selected by default; indicates whether or not the item will be checked for changes.                                                                                                                                                                                                                                                                                                                                                                                                        |

## Template and Audit Types

| Type                 | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SQL Query            | The content should be a valid SQL statement. The result returned by the statement will be compared to the result returned the last time the query was run. The query will be run with the parameters specified in the datasource that is being used: username, password, DB port, and so forth. Care should be taken when filling out these parameters in the datasource or the query will fail to return a result. |
| OS Script            | The content can be a valid command line entry, or the name of a file containing an OS executable script. The script is executed in the environment of the OS user specified in the Database Instance Account field of the datasource definition.                                                                                                                                                                    |
| Environment Variable | The content should name an environment variable that is defined in the context of the OS user specified in the Database Instance Account field of the datasource definition.                                                                                                                                                                                                                                        |

| Type                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Registry Variable         | The content is interpreted as the path to a variable in the Windows Registry of the host. The value found on that path is compared to the value found the last time the path was traced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Registry Variable Pattern | <p>The content is a sequence of regular expressions that is used to match the components of paths in the Windows Registry. The pattern is used to develop registry variable type monitored items which will be treated as described previously.</p> <p>The regular expressions are joined by / so that the pattern resembles a registry path. The more familiar   character cannot be used, since that is a special character in the syntax of Java™ regular expressions. If a / is needed in one of the regular expressions, it must be escaped with a \ . (e.g. U/235 would be used to match U/235).</p> <p>The pattern .. can be used to match zero or more components within a path. For example, HKLM\Software/../buzz will match HKLM\Software\buzz, or HKLM\Software\one\two\three\buzz. This type of pattern can lead to a computationally expensive registry search, so use it carefully.</p> <p>Other than these exceptions, the regular expressions follow the syntax of Java regular expressions.</p> |
| File                      | The content is interpreted as an absolute file path on the host. The characteristics of the file found on the path will be compared to the characteristic found the last time the path was traced. The path may include environment variables which will be expanded in the context of the OS user specified in the datasource. The path may also begin with a substitution variable, like "\$SYBASE_HOME", which will be replaced by the value entered in the Database Instance Directory field of the datasource definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| File Pattern              | The content is a sequence of regular expressions that is used to match the components of file paths and to generate File type monitored items. The regular expressions are joined by / so that the pattern resembles an actual file path. As with registry patterns, the   cannot be used for Windows files because of the regular expression syntax. If the pattern begins with ?: on a Windows machine, the pattern match will be started on each of the drives of a multi-drive machine. The ... construction described with registry patterns can also be carefully used in a file pattern. Environment variables from the context of the OS user can be used in a file pattern and will be expanded before the expansion of the regular expressions.                                                                                                                                                                                                                                                         |

## Configuration Auditing System APIs

CAS includes a robust set of GuardAPIs and REST APIs that you can use to manage hosts, template items, and template sets outside of the Guardium UI. For more information about the APIs, see [Configuration Auditing System APIs](#).

## CAS hosts

A Configuration Auditing System (CAS) host configuration defines one or more CAS instances.

After you define one or more CAS template sets, and install CAS on a database server, you are ready to configure CAS on that host. A CAS host configuration defines one or more CAS instances. Each CAS instance specifies a CAS template set, and defines any parameters that are needed to connect to the database. Each database server on which CAS is installed has a single CAS host configuration, which typically contains multiple CAS instances. For example, one CAS instance to monitor operating system items, and additional CAS instances to monitor individual database instances.

- Define a CAS Instance
- Modify a CAS Instance
- Delete a CAS Instance
- Disable a CAS Instance

## Define a CAS Instance

1. Open the CAS Configuration Navigator by clicking Harden > Configuration Change Control (CAS Application) > CAS Host Configuration. The menu lists all database servers where CAS is installed and this host is connected to the Guardium® system.

2. Filter by the OS Type or DB Type to find the host that you want to work with.
  3. Highlight the host that you want to modify and click Modify.
  4. Select a Template Set from the menu.
- Note: You cannot define a CAS Instance if the host is offline or on a secondary Guardium system for the host.

5. Click Add Datasource to open the Select datasource window.

Note: If no compatible datasource is available for this template set on this host, click  to open the Create datasource window and add a datasource.

6. Select the data source that you want to add to the template set, and click Save to add it to the template set.

## Finding the Guardium CAS Pane

Access to CAS Configuration Functions is restricted to the admin and users who are assigned the CAS role.

Click Harden. All of the CAS functions are listed within the Configuration Change Control (CAS Application) header.

## Open the CAS Configuration Navigator

The CAS Configuration Navigator page is the starting point for creating or modifying CAS Hosts.

Open the CAS Configuration Navigator page by clicking Harden > Configuration Change Control (CAS Application) > CAS Host Configuration.

## Modify a CAS Instance

1. Open the CAS Configuration Navigator.
2. Filter by the OS Type or DB Type to find the instance that you want to work with.
3. Highlight the host to modify and click Modify.

A list of defined CAS instances that are associated with the selected host displays with the following information and editing options:

Table 1. Modify a CAS Instance

| Component                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Disable/Enable Instance Icon | Click the Disable Instance icon to disable or enable the CAS instance                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Delete Instance Icon         | Click the Delete Instance icon to delete the CAS instance                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Datasource                   | Identifies the data source that is used by the instance. To edit the data source definition, click Datasource to open the Datasource Definition pane.                                                                                                                                                                                                                                                                                                                                                    |
| Template Set                 | Identifies the CAS template set used by the instance. To view or modify the template set definition, click the link to open the Monitored Item Template Definitions pane.<br><br>For more information, see <a href="#">Working with CAS templates</a> .                                                                                                                                                                                                                                                  |
| Monitored Items              | A count of items currently monitored by the instance. Click this link to open the Monitored Items Definitions pane, which displays the list of all items that are currently monitored.<br><br>For more information, see <a href="#">View Monitored Item Lists</a> .<br>Note: Up to 10,000 monitored items are viewable for reports regardless of the number of monitored items that are defined. To view more items when the number of monitored items approaches this limit, define multiple instances. |

## Delete a CAS Instance

1. Open the CAS Configuration Navigator
2. Filter by the OS Type or DB Type to find the instance that you want to work with.
3. Click Delete Instance to delete a CAS instance. All collected change data is also deleted.

## Disable a CAS Instance

1. Open the CAS Configuration Navigator.
2. Filter by OS Type or DB Type to find the instance that you want to work with.
3. Highlight the host that you want to modify and click Modify, or double-click to open the Host Instance Definitions pane.
4. Click Disable Instance to disable a CAS Instance. Change data is not collected until the instance is enabled again when you click the icon.

## View Monitored Item Lists

In the Host Instance Definitions pane, click a Monitored Items link to view the complete list of items monitored in the Monitored Items Definitions pane. The following table describes the components in the Monitored Items Definitions pane for this Host Configuration.

All the monitored items refer to raw data, a character object on the host, the result of an SQL query, the output of an OS script, or the contents of a file. The size of that character object is computed. If the item is a file, then the permissions, owner, group, and last modified time are also checked. If any of the objects changed since the last time the item was checked, the change is noted.

Table 2. View Monitored Item Lists

| Component  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select Box | Check the Select Box if you'd like to edit a monitored item individually or as a group. Double-click any monitored item to edit that item.                                                                                                                                                                                                                                                                                                                              |
| Item       | The name of the monitored item from the description in the CAS Item Template Definition pane.                                                                                                                                                                                                                                                                                                                                                                           |
| Type       | One of the following types: <ul style="list-style-type: none"> <li>• OS Script or SQL Script: The actual text or the path to an operating system or SQL script, whose output will be compared with the output produced the next time that it runs.</li> <li>• File or File Pattern: A specific file or a pattern to identify a set of files.</li> <li>• Environment Variable or Registry Variable: An environment variable or a (Windows) registry variable.</li> </ul> |
| Period     | The average interval between tests, which are specified as a number of seconds (s), minutes (m), hours (h), or days (d).                                                                                                                                                                                                                                                                                                                                                |
| Keep Data  | If marked, a copy of the actual data is saved with each change. For example, for a file item, a copy of the file is saved. If marked, but the size of the raw data for the item is greater than the Raw Data Limit configured for this CAS host, no data is saved.                                                                                                                                                                                                      |
| Use MD5    | Indicates whether the comparison is done by calculating a checksum of the raw data by using the MD5 algorithm. Computing the MD5 checksum is time-consuming for large character objects. However, it is a better indicator of change than just the size. The default is not to use MD5. If MD5 is used, but the size of the raw data is greater than the MD5 Size Limit configured for the CAS host, the MD5 calculation and comparison is skipped.                     |

## Configuration Auditing System APIs

CAS includes a robust set of GuardAPIs and REST APIs that you can use to manage hosts, template items, and template sets outside of the Guardium UI. For more information about the APIs, see [Configuration Auditing System APIs](#).

## CAS reporting

This section describes Configuration Auditing System (CAS) reporting.

The admin user has access to all query builders and default reports. The admin role allows access to the default CAS reports, but not to the CAS query builders. The CAS role allows access to both the default CAS reports and the query builders.

## Accessing the Query-Report Builder

See [Using the Query-Report Builder](#).

CAS domains are described in [Domains, Entities, and Attributes](#).

CAS predefined reports are described in [Predefined admin reports](#).

## Accessing Default CAS Reports

View the default reports related to CAS by clicking Harden > Reports.

## CAS status

To open the Configuration Auditing System Status page, browse to Harden > Reports > CAS Status

Displays the CAS status, and the status of each CAS instance for each database server that is configured as the active Guardium® host and where CAS is installed and running.

Hover your mouse over the status lights to display the status text.

| Component                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAS System Status indicator light | Indicates whether CAS is actively running on the Guardium system.<br>Red - CAS is not running on this Guardium system.<br>Green - CAS is active on this Guardium system.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CAS agent status indicator lights | Indicate whether the individual CAS agent is connected to a Guardium system. Identify each CAS agent by referencing the IP address that appears before the row of status indicator lights.<br>Red - Either the host, the CAS agent, or both are offline or unreachable.<br>Green - Host and CAS agent are online.<br>Yellow - The Guardium system is a secondary for the CAS host.                                                                                                                                                                                                                               |
| Reset                             | Reset the CAS agent on this monitored system, which stops and restarts the CAS agent on the database server.<br>Note: Reset also resets checkpoint files; allowing for a fresh start and rescan of files from scratch.                                                                                                                                                                                                                                                                                                                                                                                           |
| Delete (X)                        | Remove this monitored system from CAS and delete the data on the Guardium system that is associated with the CAS client.<br>Delete is unavailable if the CAS agent is running on this system. To delete the monitored system, stop the CAS agent first. For more information, see <a href="#">Stopping and starting the CAS agent</a> .                                                                                                                                                                                                                                                                          |
| Red/Yellow/Green light            | Indicates the status of a CAS instance on the monitored system. If the owning monitored system status is red (indicating that the CAS agent is offline), ignore this set of status lights.<br>Red - The instance is disabled.<br>Green - The instance is enabled and online, and its configuration is synchronized with the Guardium system configuration.<br>Yellow - The instance is enabled, but the instance configuration on the Guardium system does not match the instance configuration on the monitored system (that is, the instance is updated in Guardium, but the monitored system is not updated). |
| Refresh                           | Update the status of all servers in the list. Refresh does not stop or restart CAS on a database server. Refresh checks only the connection between CAS on the Guardium system and CAS on each database server.                                                                                                                                                                                                                                                                                                                                                                                                  |

Note: The TAP\_IP entry in the guard\_tap.ini file is required. If TAP\_IP is missing CAS does not start, and an error message is logged in the log file on the CAS client.

## Stopping and starting the CAS agent

Several situations exist where you might need to stop or start the CAS agent on a monitored system.

Stopping CAS on a UNIX host

1. Edit the file /etc/inittab.
2. Find the CAS respawn line:

```
, cas:2345:respawn:/usr/local/guardium/guard_stap/cas/bin/run_wrapper.sh /usr/local/guardium/guard_stap/cas/bin
```

3. Insert a number sign (#) in the first character position to comment out the line.
4. Save the file.
5. Enter the following commands and note the PID of each listed process.

```
init -q
ps -er | grep cas
```

6. For each process, issue the following command,

```
kill -9 <pid>
```

7. In the Configuration Auditing System Status window, make sure that the status light for this CAS host is red, and that the Remove button is enabled. If needed, click Remove to remove data from this CAS host from the Guardium system internal database.

Starting CAS on a UNIX host

Restart the CAS agent only if it was stopped by editing the /etc/inittab file as described in [Stopping CAS on a UNIX host](#).

1. Edit the file /etc/inittab.

2. Find the respawn line:

```
, #cas:2345:respawn:/usr/local/guardium/guard_stap/cas/bin/run_wrapper.sh /usr/local/guardium/guard_stap/cas/bin
```

3. Remove the # in the first character position to uncomment the line.

Note: Depending on your operating system, the comment character might be different.

4. Save the file.

5. Enter the following command to restart the CAS agent, **init -q**.

Starting and Stopping CAS on a Windows Host

On Windows, CAS runs as a system service.

1. In the Windows Services window, highlight the Configuration Auditing System Client item.

2. Select either Start or Stop from the Action menu.

## License information for Guardium Vulnerability Assessment

The license information describes the purchase options for Guardium Vulnerability Assessment. It also describes how to measure the license for Guardium Vulnerability Assessment and perform scans on nonproduction, failover, disaster recovery, and other environments.

Note: This License Guide is intended to provide only supplementary information to assist you in deploying the Programs you have licensed from IBM within your purchased entitlement. Your license agreement (such as the IBM International Program License Agreement (IPLA) or equivalent and its transaction documents, including the License Information for IBM Security Guardium Vulnerability Assessment is the sole and complete agreement between you and IBM regarding use of the Program.

## Purchasing options for Guardium Vulnerability Assessment

Guardium Vulnerability Assessment can be purchased by using the stand-alone part numbers or as part of the Guardium Package Software.

This licensing guide is specific to Guardium Vulnerability Assessment stand-alone parts. For more information about Guardium Package Software, see [Guardium Package Software License Guide](#).

## Measuring licensing for Guardium Vulnerability Assessment

Resource entitlements convert to managed virtual servers (MVS). You must obtain sufficient entitlements based on the quantity of managed virtual server (MVS) scanned by the program.

The entitlements apply no matter where client data resides, provided the users account for the correct number of MVS to cover the servers, where the Guardium Vulnerability Assessment is scanning your data sources.

A managed virtual Server (MVS) can be one of two types of servers:

- A physical computer composed of processing units, memory, and input/output capabilities that execute requested procedures, commands, or applications for one or more users or client devices. If racks, blade enclosures, or other similar equipments are used, each separable physical device (for example, a blade or a rack-mounted device) that has the required components is considered a separate server.
- A virtual server that is either a virtual machine created by partitioning the resources of a physical server or an unpartitioned physical server.

For on-prem (noncloud) data sources, any server with a unique IP address or hostname is counted as an MVS. The unique IP address can be a physical IP address or a virtual IP address based on the database type and deployment architecture.

The following scenarios explain the behavior of Guardium Vulnerability Assessment. When Guardium Vulnerability Assessment runs an assessment scan against:

- A multinode or high availability data source (for example, Oracle RAC and Teradata), each node that is associated with a unique IP address (physical or virtual) or a unique host must be counted as a separate MVS for entitlement. See [Example 2: Counting multinode systems](#) for more information.
- A Database Management System (DBMS) comprising multiple databases, each node or an instance associated with a unique IP address (physical or virtual) or a unique host must be counted as a separate MVS for entitlement. See [Example 4: Counting multiple databases across multiple instances \(non z/OS\)](#) for more information.
- A cloud database or cloud warehouse, each node, instance, and a database must be counted as a separate MVS for entitlement. See [Example 6: Counting databases on cloud DBaaS](#) and [Example 7: Counting databases on Snowflake environment](#) for more information.

## Performing Guardium Vulnerability Assessment scans on nonproduction, failover, disaster recovery, and other environments

Nonproduction activities for Guardium Vulnerability Assessment are activities other than running scans to harden the environment, and these activities are independent of the environment type.

When you run scans on nonproduction environments such as development and testing, these environments are considered as production use for Guardium Vulnerability Assessment, and need sufficient entitlements.

Similarly, when you run scans on other types of environments, such as failover and disaster recovery, these environments are also considered as production use, and need sufficient entitlements.

In high availability (HA) and disaster recovery (DR) scenarios; for example, Oracle DataGuard, if the standby databases are not scanned by Guardium Vulnerability Assessment, no entitlement is needed. However, if the standby databases are scanned by Guardium Vulnerability Assessment, even if they are cold" or "warm" standby, entitlement is needed to cover these databases.

The database systems that are sharing the workload and IP address for scaling compute and storage purposes; for example, Veritas InfoScale or VMWare VMotion capabilities do not require a separate scan for hardening purposes. So, these databases do not need additional entitlements.

- [Example scenarios](#)

The following section lists the example scenarios for calculating entitlements.

## Example scenarios

The following section lists the example scenarios for calculating entitlements.

Note: These examples are not exhaustive in terms of different database deployment architectures.

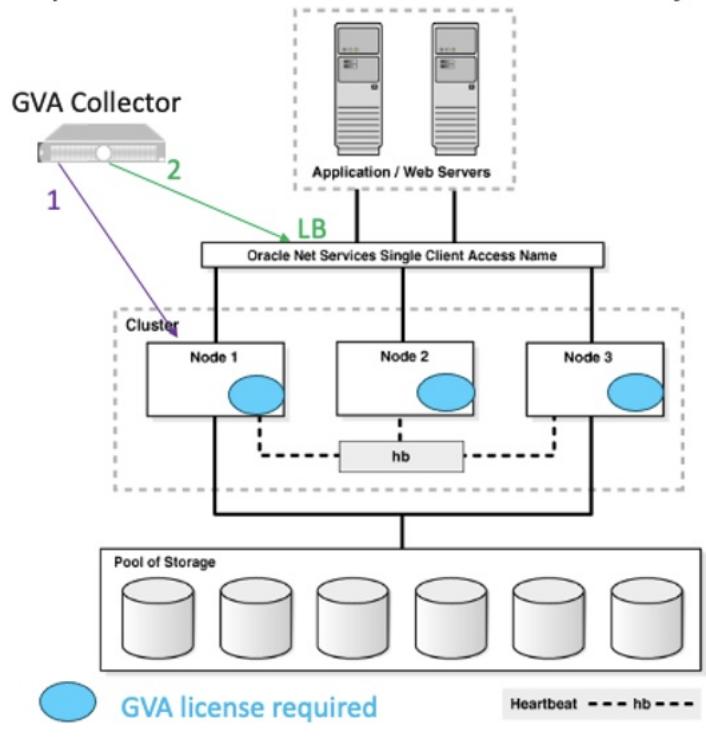

### Example 1: Counting MVS (Managed Virtual Server) by hostname/IP

If you use Guardium Vulnerability Assessment to scan 100 database servers, each with a unique IP address or hostname, you need entitlements that support 100 MVS.

If you use Guardium Vulnerability Assessment to scan more than 100 database servers with unique IP address or hostname, you need an additional entitlements that support 100 MVS.

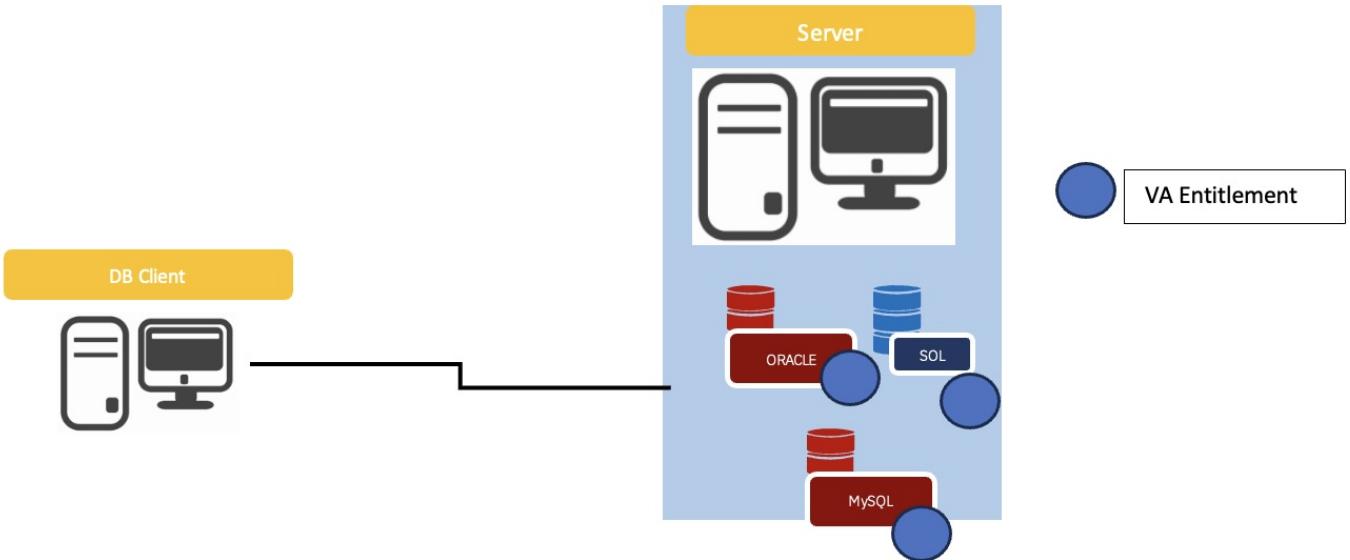

### Example 2: Counting multinode systems

If you have an on-prem database system with 3 nodes for high availability as shown in the following figure, you require 3 MVS of Guardium Vulnerability Assessment.

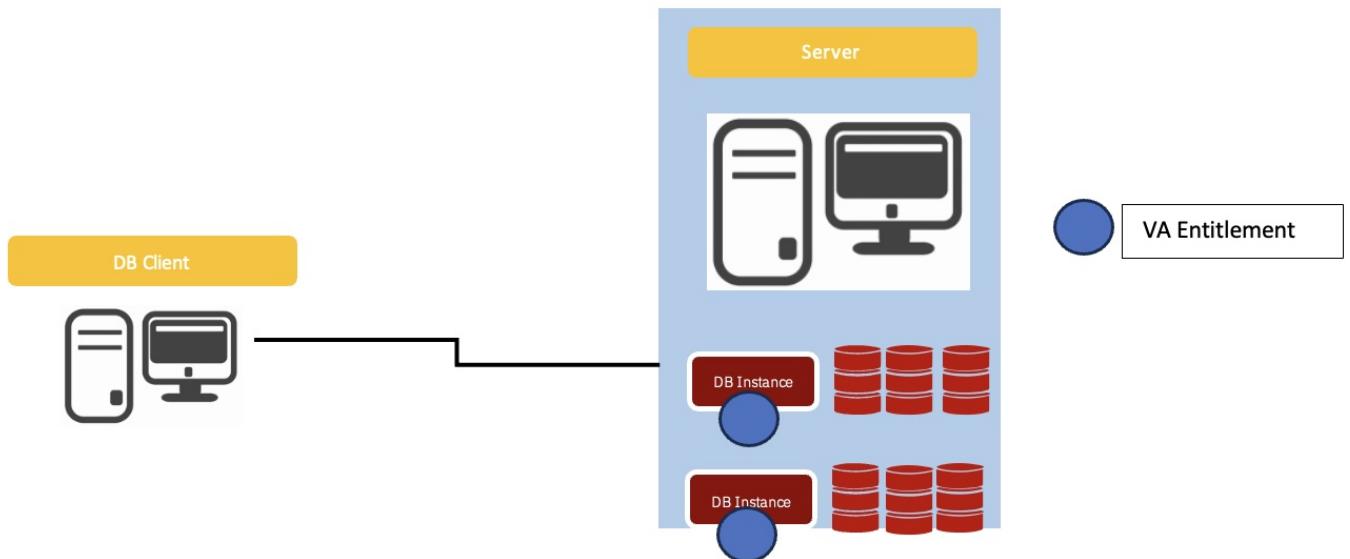

### Example 3: Counting DB systems deployed by different DB vendors

If you have an on-prem server with 3 different DBs deployed, you require 3 MVS of Guardium Vulnerability Assessment regardless of the IP configuration of these database instances.

#### Example 4: Counting multiple databases across multiple instances (non z/OS)

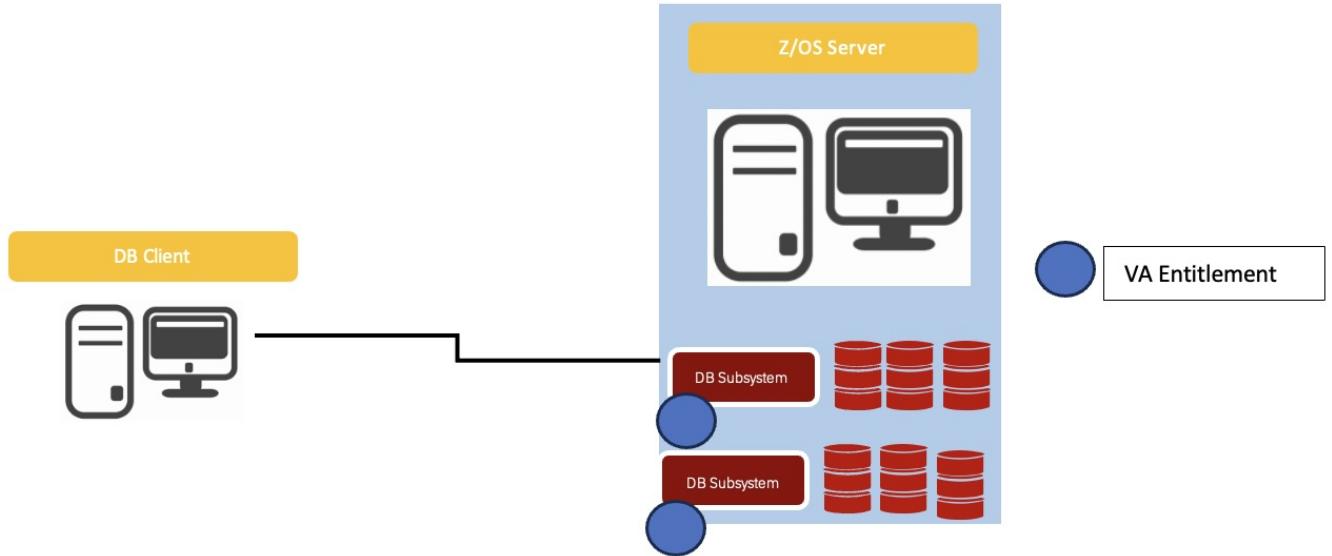

If you have an on-prem DBMS with 2 instances deployed and each of the DB instance has 3 databases, you need 2 MVS of Guardium Vulnerability Assessment.

#### Example 5: Counting Db2 running on z/OS

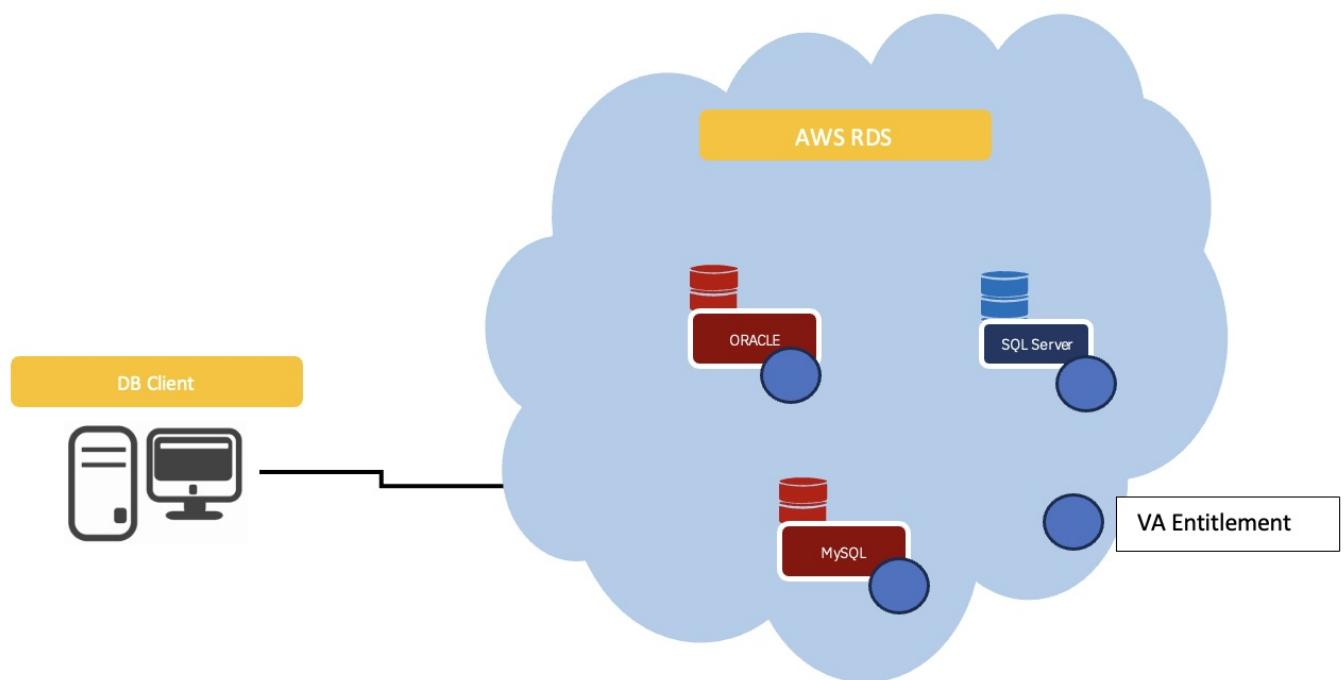

If you use Guardium Vulnerability Assessment to scan 2 Db2 for z/OS subsystems, you need an entitlement that supports 2 MVS.

Note: A subsystem on Db2 z/OS is similar to an instance of Db2 running on Linux, UNIX, and Windows systems. The subsystem provides a separate Db2 environment and configuration. Guardium Vulnerability Assessment has two separate part numbers; one for Linux, UNIX, and Windows (LUW) and another for Db2 for z/OS. So, ensure that you use the correct part number for scanning these systems.

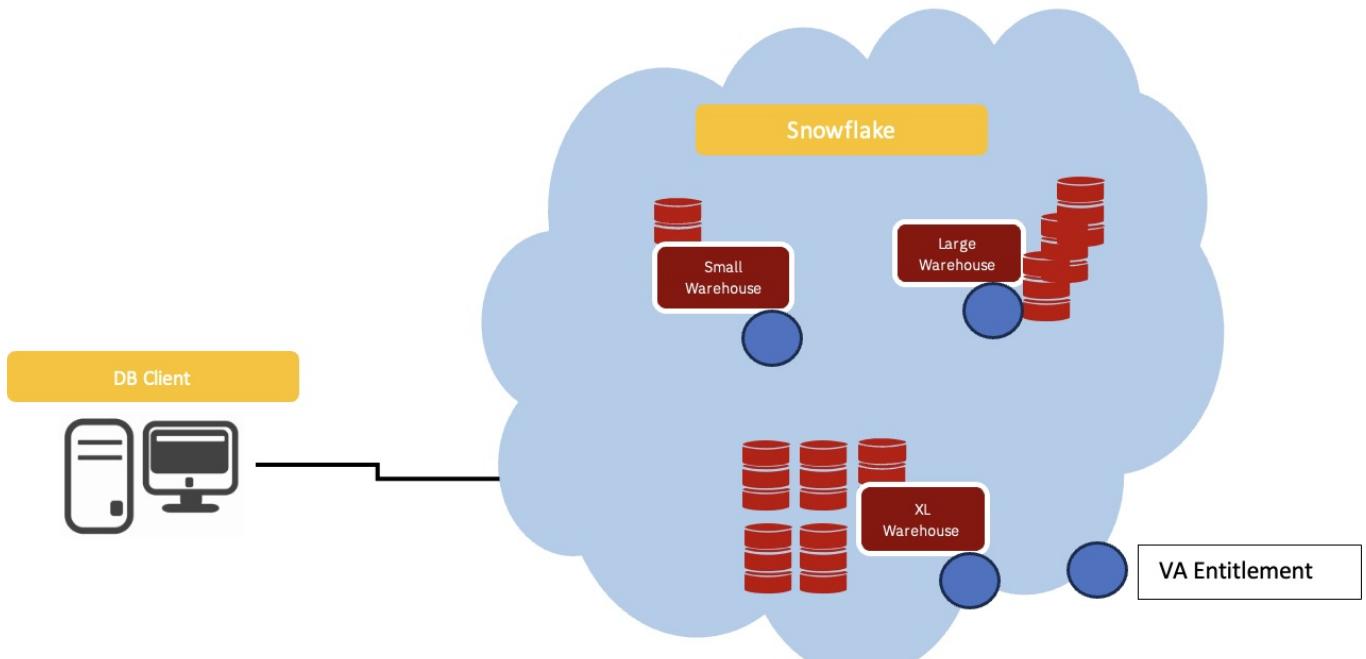

### Example 6: Counting databases on cloud DBaaS

If you use Guardium Vulnerability Assessment to scan 3 databases in your AWS Relational Database Service (RDS) environment, each with a unique IP address or hostname, you need 3 MVS of Guardium Vulnerability Assessment regardless of the compute power allocated to each of these databases.

### Example 7: Counting databases on Snowflake environment

If you are use Guardium Vulnerability Assessment to scan 3 instances in your Snowflake environment, you need 3 MVS of Guardium Vulnerability Assessment regardless of the instance size.

The exact number of Resource Value Units (RVUs) for all these scenarios can be calculated by using the VUE Table 103A mentioned in [License Information](#).

## Configuring your Guardium system

You can configure several aspects of your Guardium system to enable you to meet your business goals effectively and efficiently.

- [\*\*System Configuration\*\*](#)  
Most of the information on the System Configuration panel is set by using the CLI at installation time.
- [\*\*Managing data: archive, restore, aggregation, and system backup\*\*](#)  
Establish data retention practices; control activity volume; manage scheduling of data archive and purge, and monthly backups.
- [\*\*Internet Protocol modes\*\*](#)  
Configure Guardium® to run in a traditional IPv4-only environment, an IPv6-only environment, or in *dual mode* where the system supports both IPv4 and IPv6 addresses.
- [\*\*Network mirroring methods \(SPAN, N-TAP\) and related inspection engines\*\*](#)  
This configuration is used in cases where an S-TAP cannot be installed in the host where the database instances to be monitored are run. Instead, you can direct a copy of the network traffic that goes to the host running the database servers, to a Guardium collector. This method only captures network traffic, not local traffic within the database server host. The limitations are listed further on in this section. IBM strongly encourages you to use an S-TAP instead.
- [\*\*Configuring inspection engines\*\*](#)  
An inspection engine extracts SQL from network packets; compiles parse trees that identify sentences, requests, commands, objects, and fields; and logs detailed information about that traffic to an internal database.
- [\*\*Configuring the Guardium portal\*\*](#)  
From the Guardium Portal page, you can reset the port for the Guardium appliance web server, import SSL certificates, and configure authentication for your Guardium system users.
- [\*\*Managing the TLS version\*\*](#)  
Use APIs to manage TLS 1.2 and TLS 1.3 protocols for your appliances, S-TAP agents, CAS and GIM clients. As you update your Guardium system to Guardium 12.0, you can enable TLS 1.3 and disable TLS 1.2.
- [\*\*Global profile\*\*](#)  
The Global Profile page defines defaults that apply to all users.
- [\*\*Configuring the alerter\*\*](#)  
Configure and activate the alerter to send email messages, SNMP traps, and alert-related Syslog messages.
- [\*\*Facility and priority of syslog messages\*\*](#)  
The facility and priority of messages configured in the Guardium syslog can impact how they are consumed by the Security Incident Event Manager (SIEM).
- [\*\*Anomaly Detection\*\*](#)  
The Anomaly Detection process runs every polling interval to create and save, but not send, correlation alert notifications that are based on an alert's query.
- [\*\*Session Inference\*\*](#)  
Session Inference checks for open sessions that have not been active for a specified period of time, and marks them as closed.
- [\*\*Allow \(approve\) S-TAP connection to Guardium \(S-TAP certification\)\*\*](#)  
Use this function to control the specific S-TAP hosts whose clients are allowed ("approved") to access the Guardium system.
- [\*\*IP to Hostname Aliasing\*\*](#)  
The IP-to-Hostname Aliasing function accesses the Domain Name System (DNS) server to define hostname aliases for client and server IP addresses.
- [\*\*Configure Permission to Socket connection\*\*](#)  
This topic applies to Custom Alerting Classes.

## System Configuration

Most of the information on the System Configuration panel is set by using the CLI at installation time.

For instructions on how to configure the system, or to modify any other System Configuration settings, see [Modify the System Configuration](#).

There must be a valid license to use various functions within the appliance. When a license is entered after the system starts, a restart of the GUI is needed.

## About System Shared Secret

The Guardium® administrator defines the system shared secret in the System Configuration window. The system shared secret is used for two general purposes:

- To sign and encrypt files for export or archive, and for importing or restoring data exports and data archives.
- To establish secure communications between Central Managers and managed units.

If you are using Central Management and/or aggregation, you must set the System Shared Secret for all related systems to the same value.

The system shared secret value is null at installation time. Depending on a company's security practices, it may be necessary to change the system shared secret on a periodic basis. Each appliance maintains a shared secret keys file, containing an historical record of all shared secrets defined on that appliance. The same system thus will have no problem at a later date decrypting information that has been encrypted on that system.

When information is exported or archived from one system, and imported or restored on another, the latter must have access to the shared secret used by the former. For these cases, there are CLI commands that can be used to export the system shared secrets from one Guardium system, and import them on another.

See the following commands in the CLI appendix:

- **aggregator backup keys file**
- **aggregator restore keys file**

## Modifying the System Configuration

1. Click **Setup > Tools and Views > System** to open System Configuration.
2. Make your changes.
3. Click **Apply** to save the updated system configuration.

Note: The applied changes do not take effect until the Guardium system is restarted. After you apply configuration changes, click **Restart** to stop and restart the system.

Table 1. System Configuration Panel Reference

| Field or Control         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unique Global Identifier | This value is used for collation and aggregation of data. The default value is a unique value that is derived from the MAC address of the machine. Do not change this value after the system begins monitoring operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| System Shared Secret     | <p>Any value that you enter here is not displayed. Each character you type is masked.</p> <p>The system shared secret is used for archive/restore operations, and for Central Management and aggregation operations. When used, its value must be the same for all units that will communicate. This value is null at installation time, and can change over time.</p> <p>The system shared secret is used:</p> <ul style="list-style-type: none"><li>• When secure connections are being established between a Central Manager and a managed unit.</li><li>• When an aggregated unit signs and encrypts data for export to the aggregator.</li><li>• When any unit signs and encrypts data for archiving.</li><li>• When an aggregator imports data from an aggregated unit.</li><li>• When any unit restores archived data.</li></ul> <p>Depending on your company's security practices, you might be required to change the system shared secret from time to time. Because the shared secret can change, each system maintains a shared secret keys file, containing an historical record of all shared secrets defined on that system. This allows an exported (or archived) file from a system with an older shared secret to be imported (or restored) by a system on which that same shared secret has been replaced with a newer one.</p> <p><b>Caution:</b> When used, be sure to save the shared secret value in a safe location. If you lose the value, you will not be able to access archived data.</p> |
| Retype Secret            | When you enter or change the system shared secret, retype the new value a second time. Any value that you enter here is not displayed. Each character you type is displayed as an asterisk.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| License Key              | <p>The license key is inserted in the configuration during installation. Do not modify this field unless you are instructed to do so by Technical Support. You might need to paste a new product key here if optional components are being added.</p> <p>If you install a new product key on the central management unit, when you click <b>Apply</b>, you will receive a warning message that reads: <b>Warning: changing the license on a Central Management Unit requires refreshing all managed units.</b> After you click <b>OK</b> to close the message window, you must click <b>Apply</b> a second time to install the new product key. You will know that the new license has been installed when you receive the message: <b>Data successfully saved.</b></p> <p>If you install a new product key on a Central Management Unit, you might get a warning that states the license applied to the CM must be refreshed on the managed unit. This requires a refresh done from the Central Manager and is done by pressing the refresh icon from the Central Manager to each of the collectors listed.</p> <p>License entitles user to access products and the corresponding features.</p> <p>License can be appended or overridden.</p> <p>Active license is stored in <b>LICENSE_KEY</b> in <b>ADMINCONSOLE_PARAMETER</b></p> <p>Product types DAM; FAM; VA</p> <p>Edition for product types: Express; Standard; Advanced</p>                                                                                 |
| Number of Datasources    | If a limited license is applied, the maximum number of datasources permitted per datasource license is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Metered Scans Left       | If a limited license is applied, the number of vulnerability assessment scans permitted (datasource metering) per metering license is displayed. Each time a vulnerability assessment is triggered, the scan counter decreases by one.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| License valid until      | If a limited license is applied, a fixed date when the license will be disabled is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| System IP Address (Secondary)                                                                      | <p>Optional: A port can also be configured to team with the primary interface in order to provide high-availability failover IP teaming. Alternatively, a port on the device can be configured as a secondary management interface with a different IP address, network mask, and gateway from the primary.</p> <p>These two options are mutually exclusive.</p> <p>There are two different, and mutually exclusive, kinds of secondary management connections, both controlled by options to the same CLI command:</p> <p>Bonding or teaming</p> <p>Turns the primary interface and another specified network interface card (NIC) into a bonded pair with standby failover. To implement this option, use the CLI command <b>store network interface high-availability on &lt;nic&gt;</b>, where nic is an available NIC.</p> <p>Secondary interface</p> <p>Allows the GUI and CLI to be accessible from another NIC in the Guardium system. To implement this option, use the CLI command <b>store network interface secondary on &lt;nic&gt; &lt;ip&gt; &lt;mask&gt; &lt;gateway&gt;</b> to specify the secondary NIC, its IP address and network mask, and optionally a gateway.</p> <p>BOTH physical and VM systems have the same capabilities. Dependent on the number of NICs installed on the Guardium system or VM.</p> <p>To display the network interfaces installed on the unit, use the <b>show network interface inventory</b> CLI command. For example:</p> <pre>show network interface inventory Current network card configuration: Device   Mac Address   Member of ----- eno3    08:94:EF:28:AA:F9   br2 eno1    08:94:EF:28:AA:F7   eno2    08:94:EF:28:AA:F8   br1 eno4    08:94:EF:28:AA:FA   br3 ens2f0   00:21:5E:E2:9F:0C   br7 ens2f1   00:21:5E:E2:9F:0E   br8 ens1f1   40:F2:E9:1E:40:18   br6 ens1f0   40:F2:E9:1E:40:19   br5 ens3f1   90:E2:BA:D8:50:3D   br10 ens3f0   90:E2:BA:D8:50:3C   br9</pre> <p>Note: The "Member of" will show which NICs are in a bond pair, if a bonding exists.<br/>To locate the eth connectors on your appliance, use the <b>show network interface port</b> CLI command, which will blink the orange light on that port, 20 times. For example:</p> <pre>guard14.xyz.com&gt; sho net int port 3</pre> <p>The orange light on port eth5 now blinks 20 times.</p> <p><b>Note:</b> The secondary IP address and its associated port are NOT related to the high availability feature, which provides fail-over support via IP Teaming for the primary connection. For more information about the high-availability option, see the <b>store network interface</b> commands in the CLI Appendix.</p> |
| SubNet Mask (Secondary)                                                                            | Optional. The subnet mask for the secondary System IP Address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Default Route/ Secondary Route                                                                     | The IP address of the default router for the system./ The IP address of the Secondary Router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Primary Resolver Secondary Resolver Tertiary Resolver                                              | The IP address for the Primary Resolver (DNS) is required. The secondary and tertiary are optional.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Test Connection                                                                                    | Click Test Connection to test the connection to the corresponding DNS (Domain Name System) server. This only tests that there is access to port 53 (DNS) on the specified host. It does not verify that this is a working DNS server. You will receive a message box indicating if the DNS server responded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Restart                                                                                            | Click Restart to stop and then restart the system. You will be prompted to confirm the action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Apply                                                                                              | Click Apply to save the changes. The changes are applied the next time the system restarts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Managing data: archive, restore, aggregation, and system backup

Establish data retention practices; control activity volume; manage scheduling of data archive and purge, and monthly backups.

- [Planning archiving, storage capacity, and scheduling](#)

Learn about archiving and purging, and capacity and scheduling planning, so you can configure archiving and purging on your system.

- [Managing stored data](#)  
Typically, no more than one or two months worth of audit data is stored on an appliance (or as little as a few days), to save disk space and maintain performance. However, auditors might require to keep audit data available for a few years. Guardium® provides the mechanism to archive audit data in chunks of one day and store them on a remote location. Configure the archive process during implementation to run daily. Configure archive and purge as part of your overall data management policy. Learn how to archive, and export and import data from collectors to aggregators.
- [Exporting \(files\) results](#)  
CSV, CEF, and PDF files can be created by workflow processes. This function exports all such files that are on the Guardium system to the target system you specify.
- [Viewing days whose data was not archived or exported](#)  
The predefined report **Days that are not archived or exported** shows the days whose data remains on the appliance, and will not be purged based on the Guardium system settings.
- [Data and Result catalogs](#)  
Each Guardium system can have both a Data catalog and a Result catalog. The catalogs list all archive files that were created on the server. Each time the system archives data or results, one entry is added to the relevant catalog. Each archive file is tracked, so that it can be retrieved and restored.
- [Data aggregation](#)  
Collect and merge information from multiple Guardium units into a single Guardium Aggregation appliance to offload the reporting and analysis function from the collectors, while also providing a consolidated view of the data from multiple collectors.
- [Purging data](#)  
Data that has been successfully archived should be purged from the Guardium appliance to maintain the disk space. Configure and schedule the purge mechanism during the implementation stage to run nightly: to purge data that is older than a specified number of days.
- [Configuring system backup](#)  
System backups store all the necessary data and configuration values to restore a Guardium Server. Configure and schedule regular system backups during the implementation stage.
- [Restoring a Guardium system](#)  
Each type of guardium system (collectors, aggregators, and central manager) have different purposes and store data in different ways. Use the appropriate recovery strategies for each system type. The recovery strategy that is used also depends on whether the system that must be recovered is a stand-alone appliance or is used with other systems.
- [Enabling SSH key pairs for data archive, data export, data mart](#)  
You can use SSH key pairs for authentication, instead of passwords, for archiving and exporting results, archiving data, and exporting data marts.
- [Transferring data to a remote host by using SSH key pairs for authentication](#)  
You can archive and export results, archive data, and export data marts with SSH key pairs for authentication, instead of usernames and passwords.
- [Configuring external storage](#)  
Archive files can be sent using SCP or FTP protocol, or to a configured external storage system (Amazon S3, EMC Centera, Tivoli Storage Manager, IBM COS, and IBM Cloud). You can define a single archiving configuration for each Guardium system.

## Planning archiving, storage capacity, and scheduling

Learn about archiving and purging, and capacity and scheduling planning, so you can configure archiving and purging on your system.

### Archiving and Purging

Archiving and purging data on a regular basis is essential for the health of your Guardium® system. Archive preserves information for future use. Purge frees up space and speeds up access operations on the internal database. For the best performance, archive and purge all data that is not needed. For example, if you only need three months of data on the Guardium appliance, archive and purge all data that is older than 90 days.

The Guardium archive function creates signed, encrypted files that cannot be tampered with. Archive files are transferred and stored on external systems such as file servers or storage systems. For more information about the encryption used for archives, see the *File backup cipher* section of [Cipher suites](#).

If both archive and purge are scheduled, purge runs after archive.

Data that was archived on a collector can be restored either on another collector or an aggregator server. Data that was archived on an aggregator cannot be restored on a collector.

The export, archive, and purge functions can work on the same data, but not the same date ranges. For example, you may want to export and archive all information older than one day and purge all information older than one month, thereby always leaving one month of data on the sending unit.

### Data retention

Data retention policies vary widely from depending on your system and your needs. Factors to consider include:

- Required retention time
- Amount of stored data/day
- Disk size

You could decide to keep seven days of data on the collectors, and to maintain the data on the aggregators for a much longer period.

For disaster recovery: keep a rolling two-weeks worth of daily archives from the managed collectors.

Note: If you have stand-alone collectors, maintain daily archives according to your data retention policy.

For historical investigation or auditing purposes, maintain daily archives from the collectors for the period that is required by your auditing or corporate data-retention policies.

### Archiving from collectors versus aggregators

Archive is required if you need to store more data than your disk allows. You can archive from either collectors or aggregators. There are advantages and disadvantages to both. It comes down to what works best for you. After data is successfully archived, it can be purged from the Guardium appliance.

Audit data is stored in normalized form in an internal database of a Guardium system. The audit data that changes constantly is referred as dynamic data. The audit data that stays relatively constant is referred as static data. The user login time is a good example of dynamic data. It is unique for every user, for each login. Username is an example of static data. It stays the same for every login of this user to the database.

Archives from an aggregator are full archives: static and dynamic data, which simplifies the archive restore process.

Archives from collectors use an incremental archive strategy. The dynamic audit data is archived when it is observed. Static audit data is archived only when the data is observed for the first time. This incremental approach reduces the size of archive files dramatically. The tradeoff is that a single archive file might not contain all of the audit data that you want to restore. To compensate for this tradeoff, the archive process generates a full (not incremental) archive file the first time the archive process runs, and then the first day of every month. For example, to restore 28 June, either restore 1 June through 28 June, or restore 28 June and 1 July.

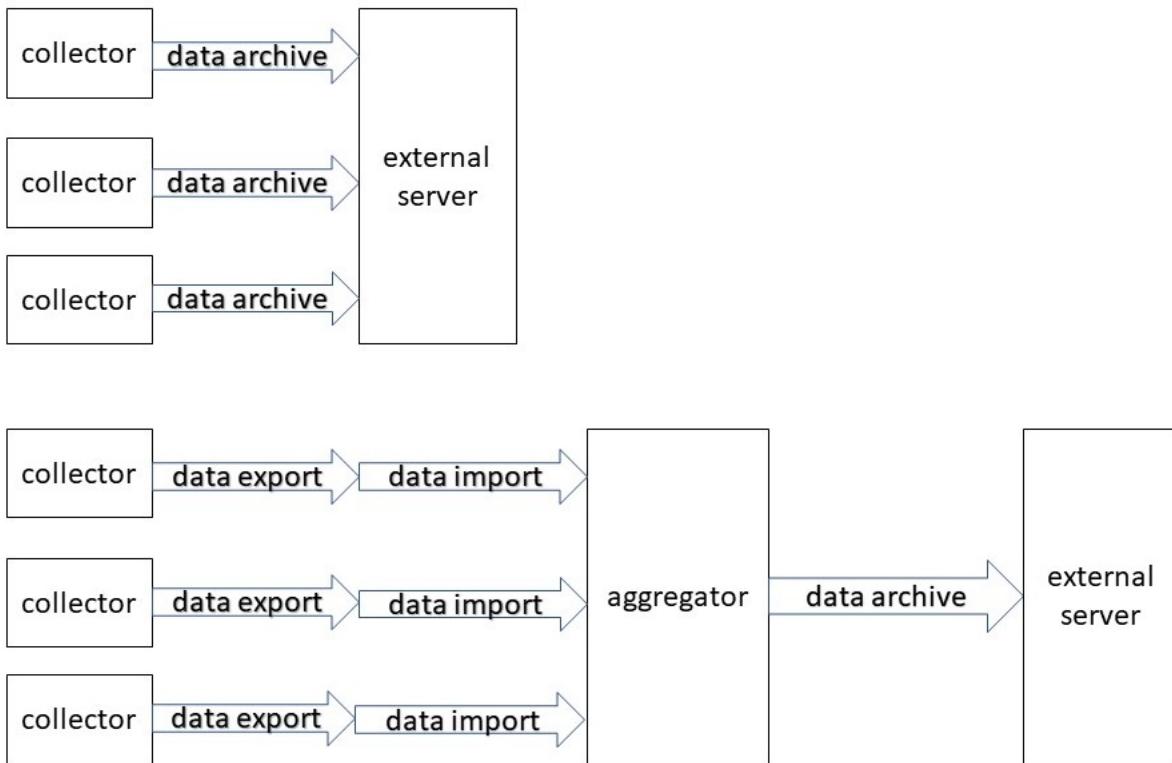

Archiving on the collectors:

- Incremental daily information for both static and dynamic data.
- Static data is archived in full during the archive on the first day of each month.
- Archiving data from the original source.
- Less usage of long-term storage.
- To restore data for specific day: restore data for all days of that month up to the target day.
- Collector's archive file can be restored directly into aggregator.

Archiving on the aggregators:

- Incremental daily information for dynamic data.
- Static data is archived in full daily.
- Verify that imports are complete before starting the archive; otherwise, some data can be missing in the archive.
- More usage of long-term storage (static data is included every day).
- Faster restore: need to restore only one file for the specific target day.

Figure 1. Archiving from collectors to an external server, or exporting to an aggregator and archiving from the aggregator

## Storage capacity

The following are only estimates of backup and archive file sizes for auxiliary storage capacity planning purposes. The actual sizes vary depending on the volume and granularity of the database activity that is logged on the Guardium collectors, and the retention period of the backup files.

Daily Archives:

- Collector: approximately 40 MB (privileged user monitoring) to 1 GB (Comprehensive monitoring with full details logged on all traffic).
- Aggregator: a rough multiple of the number of collectors, for example, Number of collectors multiplied by 40 MB.

Monthly System backups, assuming a 50% full database on 600 GB disk size:

Note: The backup gets roughly a 1:8 compression for the backup file.

- Collector: 7 – 10 GB
- Aggregator: 16 – 20 GB
- Central Manager (no aggregation): < 1 GB

Results Archives: Depends on the number and frequency of audit processes implemented.

The amount of data kept online is constrained by the size of the database on each Guardium system. The Purge process helps to manage how much data is kept online. Purge is coordinated with the Daily Archive so that all data is retained as required. Keep the minimum amount of data necessary on your Guardium system to avoid filling up the database and to maintain database performance.

Guardium recommends 15 days for the collector and 30 days for the aggregator. The actual length depends on how much data is recorded (for example, numbers of S-TAPs, policy rules, and collectors).

## Control activity volume

Controlling the volume of activity monitored (on the database server) and logged (on the collector) helps to:

- Reduce network usage.
- Reduce the Guardium system's database disk consumption.
- Improves the overall capacity and performance of the system.

This control is primarily achieved in the policy rules, and in the inspection engine configuration, by using these guidelines:

- Avoid specifying port ranges in inspection engines.
- Identify all trusted applications and batch programs (these programs generally generate the bulk of the database activity). If possible, ignore, or skip their activity by using the Ignore S-TAP Session or Skip Logging actions.
- Unless necessary, avoid the Log Full Details action in your policies.
- If possible, use the Selective Audit policy (with the Ignore S-TAP session rules) to minimize network traffic.
- If no extrusion rules are used, for example, result sets are not examined. Consider using the Ignore Responses per Session action to eliminate result sets being sent to the Guardium system.
- Establish a process to periodically review and update policy rules, including groups to accommodate new databases and applications.
- Establish a process to periodically monitor SQL Errors and provide to the DBA and Application development teams for remediation.

## Scheduling

Default schedule times are supplied when the unit is built and these can be amended accordingly. The Data Management tasks should be scheduled at less busy times, for example, overnight. They should be spaced out so as not to overlap (for example, one task should complete before the next one starts.)

In a typical scenario, data older than one day is archived, and data older than two days is ignored. It's critical that the data import completes before the data archive starts, to capture the data that is one day old.

If the Data Archive runs BEFORE the Data Imports from other Collector(s)/Aggregator(s), then the Archive does NOT contain the imported data that should be archived. For example: Data Archive runs at 00:30 and Data Import runs at 06:00. In this scenario, when the Archive runs, yesterday's data is not yet present in the system because the Import of yesterday's data has not occurred. By scheduling Data Archive AFTER the Data Import(s) have finished, the Archive contains yesterday's data.

Another issue that can arise if the archive is scheduled too early in the day: suppose the export on one of your collectors failed, and you successfully rerun the export in the morning. You would need to manually rerun all processes related to this data: import to process the file, possibly rerun your audit processes, rerun the archive since the archive file didn't have data from one of the collectors. But when the archive is scheduled for 7PM, you don't need to rerun any tasks.

The timing of the archive is flexible as long as it is later in the day, and it finishes on the same day.

It's recommended to run import and audit tasks early in the morning, so that you have current reports available at the start of the workday.

The following tables provide a summary of the key schedules to be configured on your Guardium systems.

Use the Aggregation/Archive log to record the time and status of these processes to assist with adjusting your scheduling times.

Table 1. Typical collector schedule

| Function                                   | Schedule                                                                            |
|--------------------------------------------|-------------------------------------------------------------------------------------|
| Data export (to the Aggregators) and purge | Daily: 12:30 AM<br>Purge is initially set to 15 days.                               |

| Data Import (from the Collectors)    | Daily 2:30 AM                                                                                                                                                                                                                                                                                                                                                                                        |
| Audit/Workflow jobs                  | Daily: 03:30 AM                                                                                                                                                                                                                                                                                                                                                                                      |
| CSV/CEF export to the SCP/FTP Server | Daily: 05:15 AM, if configured in the Audit jobs, and after the audit jobs complete.                                                                                                                                                                                                                                                                                                                 |
| IP-to-Hostname Aliasing              | Daily: 06:00 AM                                                                                                                                                                                                                                                                                                                                                                                      |
| System backups                       | Monthly: First Sunday of each month at 7:00 AM                                                                                                                                                                                                                                                                                                                                                       |

Note: Avoid scheduling before 12:15 AM to avoid any conflicts with the internal start-of-day processing on each Guardium system.

## Managing stored data

Typically, no more than one or two months worth of audit data is stored on an appliance (or as little as a few days), to save disk space and maintain performance. However, auditors might require to keep audit data available for a few years. Guardium® provides the mechanism to archive audit data in chunks of one day and store them on a remote location. Configure the archive process during implementation to run daily. Configure archive and purge as part of your overall data management policy. Learn how to archive, and export and import data from collectors to aggregators.

- [Configure data archive](#)

*Data Archive* backs up the audit data that Guardium captured, for a specified date, to another location. Typically, data is archived for the previous day, which ensures that if there is a catastrophe, only the data of that day is lost. This practice also saves disk space and boosts appliance performance. Configure and schedule the archive mechanism during the implementation stage to run nightly: to archive the last day's data.

- [Archiving \(audit\) results](#)

The results archive includes: reports, assessment tests, entity audit trail, privacy sets, classification processes, and the view and sign-off trails and the accumulated comments from workflow processes. Use Archived results for compliance purposes.

- [Restoring archived data](#)

You can restore archived data files to review historical data, and run reports or investigations.

## Configure data archive

*Data Archive* backs up the audit data that Guardium captured, for a specified date, to another location. Typically, data is archived for the previous day, which ensures that if there is a catastrophe, only the data of that day is lost. This practice also saves disk space and boosts appliance performance. Configure and schedule the archive mechanism during the implementation stage to run nightly: to archive the last day's data.

### About this task

Archive and purge are enabled independently of each other, and the ages at which data is archived and purged are configured independently.

*Data Archive* files can be used for data restoration for forensic purposes when data for a limited number of days needs to be restored. Restoring archive data does not override the existing data: you can restore data on an appliance that already has data, but you can't restore data on the same unit if data for that day still exists.

In an aggregated environment, data can be archived from the collector, from the aggregator, or from both locations. Most commonly, the data is archived only once, and the location from where it is archived varies depending on your requirements.

The audit data is stored in a normalized way in an internal database of an appliance. The audit data that changes constantly is referred as dynamic data, and the audit data that stays relatively constant is referred as static data. For example, profile data is static and audit data is dynamic.

To save space on storage servers, Guardium uses an incremental archive strategy. The dynamic audit data is archived when it is observed. Static audit data is archived only when the data is observed for the first time. This incremental approach reduces the size of archive files dramatically. The tradeoff is that a single archive file might not contain all of the audit data that is needed to be restored back to the appliance. To compensate for this tradeoff, the archive process generates a full (not incremental) archive file the first time the archive process runs, and then again the first day of every month. If you want to have a full archive for the next archive run, use this CLI command: **store archive\_static\_table=on**. After that run, the parameter switches back to be **off**. To check if the static data will be archived in the next run, run the CLI command: **show archive\_static\_table**.

The data archive is usually set to archive data older than one day and ignore data older than two days. In this scenario, each run archives only the data from the previous day.

Guardium's archive function creates signed, encrypted files that cannot be tampered with. DO NOT change the names of the generated archive files. The archive and restore operations depend on the file names that are created during the archiving process.

Archive uses the system shared secret to create encrypted data files. Before information encrypted on one system can be restored on another, the target restore system must have the shared secret that was used on the archiving system when the file was created. Data can be restored on the same unit type it was archived from: collector data on a collector, aggregator data on an aggregator.

The archive data file name format is one of:

- <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.dbdump.enc
- <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.agg.<sql ver>tar.gc.enc

Note: The archive and restore operations depend on the file names generated during the archiving process. DO NOT change the names of archived files.

## Procedure

1. Go to [Manage](#) > [Data Management](#) > [Data Archive](#).
2. To archive, check the Archive checkbox. More fields display in the Configuration page.
3. For Archive data older than, enter a value and select a unit of time from the menu. For example, to archive data from yesterday, enter the value 1, and select Day(s) from the menu.
4. In Ignore data older than enter the time interval to archive. For example, to archive one day's data, enter 2. Any value that is specified here must be greater than the Archive data older than value. If you leave this field blank, you archive data for **all days** older than the value specified in Archive data older than. If you archive daily and purge data older than 30 days, you archive each day of data 30 times (before it is purged on the 31st day).
5. Check the Archive Values checkbox to include values from SQL strings in the archived data. If this box is cleared, values are replaced with question mark characters on the archive (and hence the values are not available following a restore operation).
6. Select a Protocols option, and enter the appropriate information. Depending on how your Guardium system is configured, one or more of these buttons might not be available. For a description of how to configure the archive and backup storage methods, see [Configuring external storage](#) or [File Handling CLI Commands](#).
7. Optional: Use the Scheduling section to define a schedule for running this operation regularly.
8. Click Test connection The system attempts to verify the configuration by sending a test data file to that location. If the operation fails, an error message displays and the configuration is not saved.

9. Click Save to save the configuration changes. The system attempts to verify the configuration by sending a test data file to that location. If the operation fails, an error message is displayed and the configuration is not saved.

10. Optional: Click Run Once Now to run the operation now.

## What to do next

---

- Verify that the operation completed successfully. Go to Manage > Reports > Data Management > Aggregation/Archive Log. Each archive operation shows multiple activities. Check that the status of each activity is Succeeded.
- AWS archives only. Check that the files were uploaded:
  - Log in to the AWS Management Console: <http://aws.amazon.com/console/> with your email address and password.
  - Click S3.
  - Click the bucket that you specified in Guardium UI. Verify that the files are there.
- EMC Centera archives only. Check that the files were uploaded to the EMC Centera. You need the name of the files and a ClipID.

## Related concepts

---

- [Viewing days whose data was not archived or exported](#)

## Archiving (audit) results

---

The results archive includes: reports, assessment tests, entity audit trail, privacy sets, classification processes, and the view and sign-off trails and the accumulated comments from workflow processes. Use Archived results for compliance purposes.

## About this task

---

Archiving results is optional: archive results if you need to store more than your disk allows.

An alternative to using the results archive is to save a PDF file from the Audit Process after all users complete the review process.

Guardium's archive function creates signed, encrypted files that cannot be tampered with. DO NOT change the names of the generated archive files. The archive and restore operations depend on the file names that are created during the archiving process. Archive and export activities use the system shared secret to create encrypted data files. Before information encrypted on one system can be restored on another, the restoring system must have the shared secret that was used on the archiving system when the file was created.

The audit process results that must be signed **are not archived** until they are reviewed and signed. Only the Audit Processes configured to be archived are archived. To archive an audit process, select Archive in the Advanced options of the Name and archive section of the Create New Audit Process page.

The results sets can be restored only into an investigation center. You can set up an investigation center by creating a special investigation user account on a Guardium® appliance. See [Investigation center](#).

## Procedure

---

- Go to Manage > Data Management > Results Archive.
- For Archive data older than, enter a value and select a unit of time from the menu. To archive data older than today's data, enter the value 1, and select Day(s) from the menu.
- Use Ignore data older than to control how many days of data are archived. Any value that is specified here must be greater than the Archive data older than value. If you leave this field blank, you archive data for all days older than the value specified in Archive data older than. For example, if you archive daily and purge data older than 30 days, you archive each day of data 30 times (before it is purged on the 31st day).
- Select a Protocols option, and enter the appropriate information. Depending on how your Guardium system is configured, one or more of these buttons might not be available. For a description of how to configure the archive and backup storage methods, see [Configuring external storage](#) or [File Handling CLI Commands](#).
- Optional: Use the Scheduling section to define a schedule for running this operation regularly.
- Click Test connection. The system attempts to verify the configuration by sending a test data file to that location. If the operation fails, an error message appears and the configuration is not saved.
- Optional: Click Run Once Now to run the operation now.

## What to do next

---

- Verify that the operation completed successfully. Go to Manage > Reports > Data Management > Aggregation/Archive Log. Each archive operation shows multiple activities. Check that the status of each activity is Succeeded.

## Restoring archived data

---

You can restore archived data files to review historical data, and run reports or investigations.

## Before you begin

---

Restore archived data from a collector only to the same collector, an aggregator, or a different collector that is dedicated to investigation that is not part of an aggregation cluster. Data that was archived on an aggregator cannot be restored on a collector.

## About this task

---

Archives are written to an SCP or an FTP host, or to another external storage system. Archived files are restored by retrieving them through the archive catalog. The [Data and Result catalogs](#), on each Guardium system, track archived files. A new record is added to the catalog whenever the appliance archives data or results. The catalog tracks where every archive file is sent so that the archive files can be retrieved and restored with minimal effort at any point in the future. To restore archives, you must copy one or more archive files to the Guardium system on which the data is to be restored.

Each day's data is in a separate file. Depending on how your archive and purge operations are configured, you might have multiple copies of archived data for the same day. For example, you schedule archive to run more than once per day; you click Run Once Now a couple of times; or the archive is scheduled to run and you also click Run Once Now.

Unless you are restoring data from the first archive that was created during the month, you need to restore multiple days of data because of the incremental archive strategy. All information that is needed for a restore operation is archived automatically, the first time that data is archived each month. Use one of these two methods to restore data:

- Restore the first day of the month and all the following days until the target date.
- Restore the target date and then the first day of the following month.

For example, to restore 28 June, either restore 1 June through 28 June, or restore 28 June and 1 July.

Restoring archive files from older versions into newer version appliance is supported for both collector and aggregator archive files. Restoring archive files into different or newly built appliances is supported. However, the "shared secret" used to archive on the original appliance must be the same as on the target appliance.

Restored audit data can be viewed as the regular audit data by using interactive or audit process reports.

- [Restoring archived data on an empty appliance](#)

You can restore archived data to a stand-alone system that has no other audit data on it, and is designated for restoring and reviewing historical data. Use a stand-alone system to avoid interference with current data that is operating.

- [Restoring a few days of recent data](#)

Use this procedure to restore a few days worth of data that was archived from the Guardium system that you are restoring it to.

- [Restoring and viewing audit results in the investigation center](#)

The investigation center is an extension of the aggregators. Investigation users (when defined) can restore results of selected historic dates and perform forensic investigation. After the data is restored, the investigation users can define and view reports by using the standard Guardium UI, only in the scope of the investigated dates.

---

## Restoring archived data on an empty appliance

You can restore archived data to a stand-alone system that has no other audit data on it, and is designated for restoring and reviewing historical data. Use a stand-alone system to avoid interference with current data that is operating.

## Before you begin

---

- Restoring from Tivoli Storage Manager only: A dsm.sys configuration file must be uploaded to the Guardium® system. Use the CLI command: **import tsm config**.
- Restoring from EMC Centera only: a .pea file must be uploaded to the Guardium system, in the Data Archive page.
- If the target restore system is not the system that generated the archive, you must create a location entry in the catalog. Create the entry either with the Catalog Archive ([Data and Result catalogs](#)) or with the GuardAPI ([create\\_entry\\_location](#)). This entry enables the file transfer to the target restore system.
- If the file was encrypted by a different Guardium system, make sure that the system shared secret used by the Guardium system that encrypted the file is available on this system. Otherwise, it cannot decrypt the file. See [About System Shared Secret](#).

## About this task

---

This procedure describes one method of adding a file record to a catalog. You can also move the file entry to the catalog by one of:

- Run [Export catalog entries](#) on the Guardium system where the archive files were created, then run [Import catalog entries](#) on the target Guardium restore system.
- Run [create\\_entry\\_location](#) on the target Guardium restore system, then run [delete\\_entry\\_location](#) on the Guardium system where the archive files were created.

## Procedure

---

1. Go to Manage > Data Management > Catalog Archive.
2. Enter the start and end dates, optionally enter the hostname, and click Search.
3. If the archive files that you want are not in the list, add the entries manually:
  - a. Click Add. The Add Location pane opens.
  - b. Select the Storage System: the type of server that the files are saved on. The fields update accord to the server type. Some might be unavailable.
  - c. Enter values for:
    - File Name: name of archive file that you want to restore, in one of these formats:
      - <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.dbdump.enc
      - <day of data>-<Guardium system name>-w<time of zip>-d<execution date>.agg.<sql ver>tar.gc.enc
    - Host Name: server on which the archive file is located
    - Path: full path to the archive file:
      - Amazon S3: bucket name
      - IBM COS: bucket name
      - EMC Centera: Centera clipID
      - SFTP (Formerly FTP): directory relative to the SFTP account home directory.

- SCP: directory as an absolute path.
  - IBM Cloud: Container
  - Tivoli Storage Manager: path
  - User Name: user with read access to retrieve the archive file.
    - Amazon S3, IBM COS: Access Key ID
    - IBM Cloud: X-Auth-User
  - Password: password for the user.
    - Amazon S3: Secret Access Key
    - IBM COS: Secret Access Key
    - IBM Cloud: X-Auth-Key
  - Retention: number of days to store the data on the target restore system.
4. Click Save.  
 The entry is added to the catalog.
5. Go to [Manage > Data Management > Data Restore](#).  
 The Data Restore Search Criteria window opens.
6. Select From and To dates to specify the time range for which you want data.  
 The Data Restore Search Results pane opens.
7. Optional: To filter the search results, enter the Host Name of the Guardium system from which the archive originated.
8. Click Search.  
 The Data Restore Search Results page opens, showing the records for all archive files from this Guardium system.
9. Optional: To prevent purging of restored data even though it meets the purge requirements on the target restore Guardium system: enter the number of days that you want to retain the restored data on the system in the Don't purge restored data for at least field, and click Apply.
10. Check the Select checkbox for each archive you want to restore.
11. Click Restore.
12. Click Done when you are finished.

## What to do next

Verify that the restore operation status in [Manage > Reports > Data Management > Restored Data](#) is Succeeded.

## Restoring a few days of recent data

Use this procedure to restore a few days worth of data that was archived from the Guardium® system that you are restoring it to.

### Before you begin

- On a Guardium collector, stop the inspection-core process by running CLI command **stop inspection-core**.
- To restore from a TSM (Tivoli Storage Manager) server, upload a dsm.sys configuration to the Guardium system. Use the CLI command: **import tsm config**.
- To restore from an EMC Centera, upload a .pea file to the Guardium system, in the Data Archive page.
- If the target restore system is not the system that generated the archive to be restored, create a location entry in the Catalog Archive ([Data and Result catalogs](#)) or by running the GuardAPI ([create\\_entry\\_location](#)). This information is used to transfer the file to the target restore system.
- If the archive file was created on a different Guardium system, verify that the system shared secret used by the Guardium system that encrypted the file is available on this system. Otherwise, it cannot decrypt the file. See [About System Shared Secret](#).

### About this task

Restoring archived data from a collector to: the same collector; an aggregator; or a different collector that is dedicated to investigation that is not part of an aggregation cluster.

Data cannot be captured during the restore process.

### Procedure

1. Go to [Manage > Data Management > Data Restore](#).  
 The Data Restore Search Criteria window opens.
2. Select From and To dates to specify the time range for which you want data.  
 The Data Restore Search Results pane opens.
3. Optional: To filter the search results, enter the Host Name of the Guardium system from which the archive originated.
4. Click Search.  
 The Data Restore Search Results page opens, showing the records for all archive files from this Guardium system.
5. Optional: To prevent purging of restored data even though it meets the purge requirements on the target restore Guardium system: enter the number of days that you want to retain the restored data on the system in the Don't purge restored data for at least field, and click Apply.
6. Check the Select checkbox for each archive you want to restore.
7. Click Restore.
8. Click Done when you are finished.

## What to do next

Verify that the restore operation status in [Manage > Reports > Data Management > Restored Data](#) is Succeeded.

## Restoring and viewing audit results in the investigation center

The investigation center is an extension of the aggregators. Investigation users (when defined) can restore results of selected historic dates and perform forensic investigation. After the data is restored, the investigation users can define and view reports by using the standard Guardium® UI, only in the scope of the investigated dates.

Each Guardium appliance maintains a catalog of all the data and results archived. The catalog contains information about the archive, its location, and credentials to access them. The catalog is exported from the collectors and merged into a complete catalog on the aggregator as part of the aggregation process. As an investigation user, you select the dates for restore. The results for these dates are uploaded to the investigation center and merged into that investigation user's view. In addition to merging collectors' catalogs through the aggregator, you can export and import catalogs from Manage > Data Management.

## Users and Roles

---

The special investigation role (`inv`) is available in an aggregator. Users with the `inv` role can perform forensic investigations on historic data. Only `inv` users can access the investigation center.

The role `inv` is a special role that connects the user to a separate, investigation-only internal database. It is usually combined with the role user, and in general it is incompatible with all other roles. The Run an Ad-Hoc Audit Process button is available on all report screens for all users except investigation (INV) user.

**Important:** The Last Name of the `inv` user must be one of the three investigation databases: INV\_1, INV\_2, or INV\_3 (case-sensitive). An investigation user uses the same query and report definitions as any other user would. The biggest difference is that the investigation user sees only the data that is uploaded for the investigation database. Multiple investigators can be configured to share an investigation database. Selected data can be restored from archive or viewed from the current database if the data was not purged yet. An investigation user can also restore archived audit process results and view them.

## Investigation context

---

The investigation center supports three concurrent investigation periods, named INV\_1, INV\_2 and INV\_3. Each can hold separate historic data, and provide the means of forensic investigation of that period. When logged in to the investigation center, the last name of the user indicates which investigation database you are viewing.

## Restore audit results

---

In the Audit Process builder, you can specify whether the results of a process are archived or not. Only results of processes marked for archive, and for which all sign-offs are complete, are archived. Results of specific runs are packed, compressed, and stored. The location is recorded in the catalog. These results contain the results, the view, and sign-off trails, and the comments associated with these results. Archived results can be restored to an investigation center.

1. Log in to the Guardium GUI as a user with the `inv` role.
2. Go to Manage > Data Management > Audit Results Restore to open the Restored Data page. Any previously restored results are listed. You can click Discard Data to unmount all previously mounted results.
3. Click Audit Results Restore to open the Results Restore Search Criteria page.
4. Enter the From: date and the To: date for the time period that you want to search.
5. Optionally, enter a Host name, Audit Process, or Run Number to further filter the result set.
6. Click Search to view the result set.
7. From the result set produced, check the Select box of those results you want to restore.
8. Click Restore to restore the selected results. Depending on the number of results to restore, and whether the data sets are local to the system, the restore process can take a long time.
9. You can monitor the progress of the restore process in View Restore Log.

## View Restore Log

---

The restore log provides a view of the Restore of past and current restore attempts that are filtered for the current user.

Go to Manage > Reports > Data Management > My Restore Log to open My Restore Log.

## Viewing Restored Audit Results

---

1. Log in to the Guardium GUI as a user with the `inv` role.
2. Go to Comply > Tools and Views > Audit Results Navigation to open the Audit Process Finder page.
3. From the drop-down list, select a process.
4. Click View to open another window and view the available reports for the audit results.

## Exporting (files) results

---

CSV, CEF, and PDF files can be created by workflow processes. This function exports all such files that are on the Guardium system to the target system you specify.

## About this task

---

Export data file names have the format: <daysequence>-<hostname.domain>-w<run> datestamp>-d<data\_date>.dbdump/TAR

CEF and CSV files that are created by workflow processes can also be written to syslog. When that happens, those files are not available to be exported by the method described here. Access those files in the syslog or by other means.

## Procedure

---

1. Go to Manage > Data Management > Results Export (files)
2. Select the protocol, one of: SCP or SFTP (Formerly FTP).
3. Enter the parameters:

- Host - The IP address or DNS hostname of the host to receive the files.
  - Directory - The target directory on the target destination server. The format depends on the protocol you selected.
    - For SCP - Specify the directory as an absolute path.
    - For SFTP - Specify the directory relative to the SFTP account home directory.
  - Port - Port on the target destination server. The default port for SSH, FTP, and SFTP is 22.
  - User Name - Username for the target destination server. This user must have write or execute permissions for the specified directory.
  - Password - Password for Username on the target destination host.
4. Click Save to save the configuration. The system attempts to verify the configuration by sending a test data file to that location. If the operation fails, it displays an error message. If the test file is transmitted successfully, the Scheduling section becomes active.
5. Optional: Use Scheduling to define a schedule for running this operation regularly.
6. Optional: To export the files now, click Run Once Now.

## What to do next

---

- Verify that the operation completed successfully. Go to [Manage > Reports > Data Management > Aggregation/Archive Log](#). Check that the status of each export activity is Succeeded.

## Viewing days whose data was not archived or exported

---

The predefined report **Days that are not archived or exported** shows the days whose data remains on the appliance, and will not be purged based on the Guardium system settings.

The Data archive and Data export pages have an option Allow purge without exporting or archiving that prevents purge from running before export or archive are complete. To ensure that no data is lost (before it is exported or archived), this option is not selected. However, the Guardium system can end up storing older days of data, due to an export or archive process that failed or was paused. This data can cause or contribute to a long running purge process or too much data on appliances. To maintain a well-running appliance, consider archiving or exporting, and purging the older days.

The report shows the days whose data was not archived or exported and would not be purged based on the current settings of purge process. You can archive or export days on a one-off basis, by using the Archive data older than and Ignore data older than values in the Data archive or Data export pages.

Using the report:

- Archive or export must be scheduled daily on the appliance for the report to work as expected.
- Set the runtime parameters back as far as possible, for example, NOW -48 Month, to identify all older days.
- The report shows days that would not be purged based on the current purge setting and if those days were older than the purge period. This means:
  - Today's date appears in the report even though it is too soon to archive it. You can ignore this date.
  - If Allow purge without exporting or archiving is selected, no data shows in the report because all the data would be purged.

## Data and Result catalogs

---

Each Guardium® system can have both a Data catalog and a Result catalog. The catalogs list all archive files that were created on the server. Each time the system archives data or results, one entry is added to the relevant catalog. Each archive file is tracked, so that it can be retrieved and restored.

## About this task

---

Catalog entries can be transferred between appliances by the following methods:

- Aggregation: Catalog tables are aggregated, which means that the aggregator has the merged catalog of all of its collectors.
- Export Catalog: Use the export function to transfer catalog entries between collectors, or to export a catalog to an external storage.
- Import Catalog: Use the import function to import one or more archive file records that were exported using Export Catalog.
- Data Restore: Each data restore operation contains the data of the archived day, reflected in the catalog entries of that day. When you restore data, the catalog is also updated.
- **[Import catalog entries](#)**  
Perform this task on a target restore server, to import one or more archive files that were created and saved to a backup location.
- **[Export catalog entries](#)**  
Use this task to export catalog entries from the catalog on the Guardium system that created the archive file. The resulting generated file can be imported to the Guardium system on which you want to restore the archives.
- **[Adding, removing, and modifying catalog entries](#)**  
Catalog entries are created each time that the system archives results or data. In time, you might want to modify the records.

## Related reference

---

- [Catalog entry APIs](#)

## Import catalog entries

Perform this task on a target restore server, to import one or more archive files that were created and saved to a backup location.

### About this task

When catalog entries are imported from another system, those entries point to files that have been encrypted by the original system. Before you restore or import any such file, the system shared secret of the originating system (that encrypted the file) must be available on the target import system. You can use the **aggregator backup keys file** and **aggregator restore keys file** CLI commands to copy the shared secrets from one Guardium® system to another.

### Procedure

1. Go to **Manage > Data Management > Catalog Import**.
2. Click **Browse** to locate and select the file.
3. Click **Upload**. You are notified when the operation completes and the definitions that are contained in the file are displayed. Repeat to upload more files.
4. Click the green arrow for each file you want to import, or click **Remove** without **Importing** to remove the uploaded files without importing the contents.

### Related reference

- [Catalog entry APIs](#)

## Export catalog entries

Use this task to export catalog entries from the catalog on the Guardium® system that created the archive file. The resulting generated file can be imported to the Guardium system on which you want to restore the archives.

### Procedure

1. Go to **Manage > Data Management > Catalog Export**.
2. Select a definition type from the Type dropdown list: Data Catalog or Result Catalog.  
The Definitions to Export list is populated with entries of the selected type.
3. Select each entry that you want to export and click **Export**.  
Depending on your browser security settings, you might see a message that asks whether you want to save the file or open it.
4. Choose a target location to save the exported file.

### Related reference

- [Catalog entry APIs](#)

## Adding, removing, and modifying catalog entries

Catalog entries are created each time that the system archives results or data. In time, you might want to modify the records.

### About this task

Take the scenario where the archives were moved to another external server due to disk space limitations. In this case, you would modify the hostname and path, and probably the username and password for the catalog entry. Another scenario is that you want to restore archives but not to the Guardium® system that initiated the archive. In this case, you need to add the entries to the catalog on the target restore Guardium system; and delete them from their original catalog. Delete all archive files that you no longer need, for any reason, from the catalog.

An alternative method of moving catalog entries from one set to another is to [Export catalog entries](#) on the Guardium system where the archive files were taken, then [Import catalog entries](#) on the target restore server. In this scenario, you do not need to remove the entries, they are removed when you export them.

### Procedure

1. Click **Manage > Data Management > Catalog Archive**.
2. To add a catalog entry:
  - a. Click **Add**.  
The Add Location pane opens.
  - b. Select an option from the Storage System drop-down.
  - c. Enter a File Name.
  - d. Enter all other details, according to the Storage System you selected. The value for Path depends on the server or protocol type:
    - For SCP - Specify the directory as an absolute path.
    - For SFTP - Specify the directory relative to the SFTP account home directory.
    - For TSM: Specify the directory as an absolute path of the original location.
  - e. Click **Save**.

3. To modify one or more entries:
  - a. Enter a From and To date.
  - b. Optional: Enter a host name or IP of an external server, to filter results for archives stored on that server only.
  - c. Click Search. The page refreshes with the relevant catalog entries.
  - d. Select an entry and modify as relevant.
  - e. Click Save.
4. To remove a catalog entry:
  - a. Enter a From and To date.
  - b. Optional: Enter a host name or IP of an external server, to filter results for archives stored on that server only.
  - c. Click Search. The page refreshes with the relevant catalog entries.
  - d. Select one or more entries and click Remove Selected.
5. Click Done when you are finished.

## Data aggregation

Collect and merge information from multiple Guardium® units into a single Guardium Aggregation appliance to offload the reporting and analysis function from the collectors, while also providing a consolidated view of the data from multiple collectors.

### Aggregation Process

---

- Accomplished by exporting data on a daily basis from the collectors to the aggregator (importing daily export files to the aggregator).
- Aggregator then goes over the uploaded files, extracts each file and merges it into the internal repository on the aggregator.

For example, if you are running Guardium in an enterprise deployment, you may have multiple Guardium servers monitoring different environments (different geographic locations or business units, for example). It may be useful to collect all data in a central location to facilitate an enterprise view of database usage. You can accomplish this by exporting data from a number of servers to another server that has been configured (during the initial installation procedures) as an aggregation appliance. In such a deployment, you typically run all reports, assessments, audit processes, and so forth, on the aggregation appliance to achieve a wider view, not always an enterprise view. The Aggregator does not collect data; it presents the data from the collectors.

Aggregation does not summarize or roll-up the data. It merges the records.

See pre-defined aggregation reports at: [Manage > Reports > Data Management > Aggregation/Archive Log and Reports > Guardium Operational Reports > Aggregation/Archive Log - Distributed](#), for example.

By default, all static tables on an aggregator are archived daily. Adding the static tables to the normal purge process eliminates the existence of orphans, freeing up disk space and improving report performance.

Archive and export of static tables on an aggregator includes full static data only on the first day of the month (archive) or when the export configuration changes (export). Use the CLI commands **store archive\_table\_by\_date [enable | disable]** or **show archive\_table\_by\_date**. Other relevant CLI commands are **store aggregator clean orphans** or **show aggregator clean orphans**.

## Hierarchical Aggregation

---

Guardium supports hierarchical aggregation, where multiple aggregators merge upwards to a higher-level, central aggregator. This is useful for multi-level views. For example, you may need to deploy one aggregator for North America aggregating multiple units, and another aggregator for Asia aggregating multiple units, and a central, global aggregator merging the contents of the North America and Asia aggregators into a single corporate view. To consolidate data, all aggregators export data to the global aggregator on a scheduled basis. The global aggregator combines that data into a single database (in the global aggregator), so that reports run on the global aggregator use the consolidated data from all of the lower level aggregators.

## Aggregating, Archiving, and Purging Operations

---

The data is transferred through daily batch files by using SCP. A daily data export is scheduled on the source and a corresponding data import is scheduled on the aggregator. There is an option to use a secondary aggregator in case the primary aggregator is unreachable. On either or both units, archive and purge operations are scheduled to back up and purge data on a regular basis (both to free up space and to speed up access operations on the internal database).

CAS data is also aggregated and archived.

**Important:** When setting the schedule of import on an aggregator, set it to run after export is completed on all collectors.

**Note:** The alert for no traffic is inactive for aggregator servers.

## Orphan cleanup on aggregators

---

When the aggregator includes restored data, orphans cleanup related to the restored data are set to run according to the expiration date set when data was first restored.

If any changes are done through API commands related to the expiration date, this does not affect the date restored data that is available for Orphans cleanup.

For example: The user restores data and wants to keep this data for 7 days. This means the expiration date of this data is 7 days from today and this data is available for orphan cleanup after 7 days.

If the expiration date is changed, for example, set to keep the data for shorter/longer period - it does not affect the date this data is available for orphan cleanup. Pay attention for this especially if you change the expiration period to be longer - in order not to lose data. The rest of the data on the managed unit is available for orphan cleanup as first designed.

## Calculating maximum number of Collectors per Aggregator

---

When a Guardium system is built from an .ISO, a default value of 10 for the maximum number of collectors per aggregator is set.

When a customer upgrades the Guardium system, the system calculates the maximum number of collectors using the following logic:

1. Get number of collectors according to data in internal Guardium table. The default value is 10.
2. If results of step 1 is 0 (no collectors are found), the system sets this value to 10.
3. If a different number of collectors is found, the system will add 20 percent more to the number determined in step 2.
4. For example, if Step 1 did not find any collectors, then Step 2 will set a value of 10, and then Step 3 will add 20% to it and will make it 12.
5. Another example, in Step 1 the system found five collectors exporting to an aggregator. In this case, the value is set to 5. Step 2 is not relevant as result was 5 and not 0. Step 3 will add 20% to 5 and will set this value to 6.

- **[Exporting data](#)**

Export compresses the data of the one day, midnight to midnight, into an encrypted file and sends it from a Guardium collector to a Guardium aggregator, daily. The aggregator has its own schedule to import the encrypted export file. Archive and purge operations can be scheduled on both collectors and aggregators to speed up access operations on the internal database. Purge also frees up space.

- **[Importing data](#)**

After data files are exported from the collector, they reside in a special location on the aggregator until the aggregator appliance executes an import operation to decrypt and merge all data to its own internal database. The Data Import process is scheduled only on an aggregator, or a central manager in a smaller system.

## Related concepts

---

- [Aggregator CLI commands](#)
- 

## Exporting data

---

Export compresses the data of the one day, midnight to midnight, into an encrypted file and sends it from a Guardium® collector to a Guardium aggregator, daily. The aggregator has its own schedule to import the encrypted export file. Archive and purge operations can be scheduled on both collectors and aggregators to speed up access operations on the internal database. Purge also frees up space.

## Before you begin

---

The collector that sends the data and the aggregator to which it is sending data must have the identical System Shared Secret. If not, the export operation works, but the aggregator that receives the data is not able to decrypt the exported file and the import fails. For more information, see [About System Shared Secret](#).

## About this task

---

You can define one export configuration for each Guardium system.

To stop a scheduled export, clear the Export checkbox. You cannot stop an export after clicking Run once now.

## Procedure

---

1. Go to [Manage > Data Management > Data Export](#)
2. Check Export.
3. Specify the data to be exported:
  - Export data older than (required): specify a starting day for the export operation as a number of days, weeks, or months before the current day, which is day zero. Time is measured in calendar days. For example, if today is 24 April, all data that was captured on 23 April is one day old. To archive data yesterday's data and data older than yesterday, specify 1 Day.
  - Ignore data older than: specifies how many days of data are archived. Guardium recommends always specifying Ignore data older than. Ignore data older than must always be greater than Export data older than. When left blank, you export data for all days previous to the date specified by Export data older than. The result is exporting the exact same days of data over and over again, overloading the network and the aggregator with redundant data.  
For example, to export daily data only: Export data older than=1 Day, and Ignore data older than=2 Day
4. The Export Values box is checked by default, meaning all fields that contain sensitive fields are included in the exported data. Clear this option to mask all sensitive fields in the exported data, and replace the fields with **Value~Removed**.
5. In the Host box, enter the IP address or DNS hostname of the aggregator to which this system's encrypted data files are sent. You can optionally specify a second aggregator to export data to more than one aggregator. If you specify two aggregators, Guardium exports to both of them.
6. Click Save to save the export configuration for this unit.
7. Use Scheduling to define a schedule for running this operation.
8. Click Apply: the system attempts to verify that the specified aggregator host accepts data from this unit. If the operation fails, the configuration is not saved, and system responds: A test data file could not be sent to this host. Please confirm the hostname or IP address is entered correctly and the host is online.
9. Optional: Click Run Once Now to run the operation one time.

## What to do next

---

Verify that the export operation succeeded. Go to [Manage > Reports > Data Management > Aggregation/Archive Log](#). Each archive operation shows multiple activities. Check that the status of each activity is Succeeded.

## Related concepts

---

- [Viewing days whose data was not archived or exported](#)

## Importing data

After data files are exported from the collector, they reside in a special location on the aggregator until the aggregator appliance executes an import operation to decrypt and merge all data to its own internal database. The Data Import process is scheduled only on an aggregator, or a central manager in a smaller system.

### Before you begin

The collector that sends the data and the aggregator to which it is sending data must have the identical System Shared Secret. If not, the aggregator that receives the data cannot decrypt the exported file and the import fails. For more information, see [About System Shared Secret](#).

### About this task

Import has no default schedule. Schedule it to start after export is complete. To avoid the possibility of importing files that have not completely arrived, the aggregator does not import files that have changed in the last two minutes. You can define one import configuration for each Guardium unit. Purge can be configured on either the Archive or Export GUI pages.

Do not run more than once a day unless you have a good reason for doing so. For example, data from one or more collectors arrived after an import run. In this case, click Run Once Now to import the additional data.

To stop a scheduled import, clear the Import data checkbox. You cannot stop an import after clicking Run once now.

### Procedure

1. Go to [Manage > Data Management > Import](#)
2. Define the import frequency, by day or by month.
3. Define the Repeat schedule

## Purging data

Data that has been successfully archived should be purged from the Guardium appliance to maintain the disk space. Configure and schedule the purge mechanism during the implementation stage to run nightly: to purge data that is older than a specified number of days.

- [Configuring data purge](#)  
Configure purge in one or both of the Data Archive page or the Data Export page. Although the purge configuration is on the same page, purge is enabled independently of Archive and Export.
- [Purging data to resolve a full disk when the GUI is down](#)  
Learn how to identify a full disk, and what to do about it.

## Configuring data purge

Configure purge in one or both of the Data Archive page or the Data Export page. Although the purge configuration is on the same page, purge is enabled independently of Archive and Export.

### About this task

Important: The Purge configuration is used by both Data Archive and Data Export. The Purge that is configured in the Data Archive page applies to archived data, and in the Data Export page to exported data.

The amount of data that can be stored on the appliance depends on many criteria, including appliance type, disk space, and policy. The data storage period must be adjusted to reflect the optimal balance between data accessibility and quick response time of the system process. Data purge configuration depends on the application and is highly variable, depending on business and auditing requirements.

- The default value for purge is 60 days.
- The purge schedule is not affected during an upgrade.
- To purge many records (10 million or higher), a large batch size setting (500k to 1 million) is the most effective. Using a smaller batch size or NULL results in a much slower purge time for large purges. Smaller purges finish quickly. Specify a large batch size for large purges only. Set the purge size with the GuardAPI [set\\_purge\\_batch\\_size](#).
- When a unit type is changed from managed unit to standalone or vice versa, the default purge schedule is applied.
- Purge does not delete records that are still "in use" (for example: open sessions).

Schedule purge on collectors, after the export or archive. Schedule purge on aggregators after the import.

Important: If purging is activated, and Allow purge without exporting or archiving checkbox is selected, and both Data export and Data Archive are run on the same day, then the first operation that runs probably purges any old data before the second operation's execution. When Data export and Data Archive are both configured, the purge age must be greater than the export age and the archive age. For example, data that is older than one day and younger than two days is archived; data that is older than seven days and younger than eight days is purged.

CAUTION:

There is no warning when you purge data that is not archived or exported by a previous operation.

The purge operation does not purge restored data whose age is within the Don't purge restored data for at least timeframe that is specified by a restore operation.

### Procedure

1. Check the Purge checkbox.
2. Use the Purge data older than field to specify a starting day for the purge operation as a number of days, weeks, or months before the current day, which is day zero. All data from the specified day and all older days is purged, except as noted. The starting purge date must be greater than the Export data older than and Archive data older than values, if export or archive are configured.
3. If the data is exported to a non-Guardium system, check Allow purge without exporting or archiving.
4. Clear Allow purge without exporting or archiving to prevent purge from running before both export and archive are completed. If archive and export are both configured and this checkbox is selected, the purge process runs with the overall process, meaning it runs after the first of export or archive that completes its run. For example, archive is scheduled to run at 01:00 and export is scheduled to run at 03:00. Purge runs immediately after archive, and probably before the export, and therefore there won't be a file to export. If this checkbox is cleared, then purge runs after both archive and export are complete.

## What to do next

Verify that the operation completed successfully. Go to Manage > Reports > Data Management > Aggregation/Archive Log. Each archive operation shows multiple activities. Check that the status of each activity is Succeeded.

## Related concepts

- [Viewing days whose data was not archived or exported](#)

## Purging data to resolve a full disk when the GUI is down

Learn how to identify a full disk, and what to do about it.

## About this task

Two areas can get full on a Guardium appliance which can then cause the GUI to stop:

- The internal database
- The filesystem itself (usually the /var partition)

One or both can become full. Usually it is the database that fills up, which then causes the filesystem to fill up, since the database files are held in the /var partition. If either gets to 90% full, the system automatically stops services, including the GUI.

Auto stop services: By default the appliance stops services including GUI and sniffer when the database or the filesystem reaches 90% full. An internal 'nanny' process checks the status every 5 minutes and takes actions. You can check the current setting in the CLI:

```
xxx.xxx.xxx.com> show auto_stop_services_when_full
```

See [Configuration and control CLI commands](#)

Important notes for auto stop services:

- If the auto\_stop\_services\_when\_full is switched **off**, the system might be filled to 100% preventing all access to the system
- Never set the auto\_stop\_services\_when\_full to **off** unless used temporarily in the specific circumstance described in the answer section
- You must **stop inspection-core** before setting auto\_stop\_services\_when\_full to **off**. This prevents the system filling any further.
- If you attempt to restart stopped services before the space issue is resolved, then the services stop again after 5 minutes. The filesystem and database usage keep increasing in that time. Command to restart stopped services:

```
restart stopped_services
```

Warning: Do not use this command until you are sure that space has been recovered.

### Diagnosing the problem

Internal database: As user cli, check whether the internal database is full with this command:

```
support show db-status used %
```

If the result is 90% or more the GUI should be stopped automatically by auto stop services. It is possible for the database to show over 100% used. It happens when the database files consume more than the set size defined on the system (50% of disk space for collectors, 75% for aggregators). This can happen if system services are not stopped when database reaches 90% or they are restarted manually.

Internal filesystem: To check if /var partition (filesystem) is 90% full or more, run a must gather from cli:

```
support must_gather system_db_info
```

Use fileserver to check the **df -k** output within the **system\_output.txt** file that can be seen in fileserver: **must\_gather/system\_logs/system\_output.txt**, or extracted from the **system.<datetime>.tgz** file once you have downloaded it

Inside the **system\_output.txt** file you can find the detail. In this example the /var is only 65% full:

```
=====2016-11-30 08:36:09 ... Output of df command=====
Filesystem 1024-blocks Used Available Capacity Mounted on
/dev/sda3 10154020 2272668 7357232 24% /
/dev/sda2 28571320 17384504 9712052 65% /var
/dev/sd1 505604 33476 446024 7% /boot
tmpfs 6169768 0 6169768 0% /dev/shm
```

Before the database or the filesystem fills to the "auto stop" level you should receive warnings in the system log (messages file). You can run a **must\_gather** command and look inside the compressed file that gets created to check the latest messages file within

```
support must_gather system_db_info
```

Sample message filesystem space problem errors.

In this example the messages file shows the filesystem is full (DB space may also be full)

```
Nov 23 12:00:13 xxx nanny:[2986]: Nanny is awake.
Nov 23 12:00:13 xxx nanny:[2986]: DB parameters - status 2 db warn level 75 db critical level 90 db auto stop 1.
Nov 23 12:00:13 xxx nanny:[2986]: It is in critical ..Used space on your system is almost full(currently at 93%). Please use
CLI command 'show filesystem usage' to see which directories take too much space to target your clean up.
Nov 23 12:00:13 xxx nanny:[2986]: Email has been sent to admin (admin@admin.com) on the out-of-space issue.
Nov 23 12:00:13 xxx nanny:[2986]: Stopping Guardium Services until used space on your system has been cleaned up.
```

This example shows both the DB and the filesystem (/var partition) NEARLY full (before the auto stop of services)

```
Nov 23 14:13:12 xxx nanny:[10070]: TURBINE DB is configured after nap
Nov 23 14:13:12 xxx nanny:[10070]: Nanny is awake.

Nov 23 14:13:13 xxx nanny:[15110]: Nanny set memory limit to 12277180
Nov 23 14:13:13 xxx nanny:[15110]: TURBINE DB Already configured before nap
Nov 23 14:13:13 xxx nanny:[15110]: Going for my initial nap.
```

## Procedure

1. If the database is 90% or more full but the filesystem is not 90% full yet:

If the auto stop has been triggered then this stops services such as the GUI, which stops you from making an emergency purge of data via the "Run Once Now" purge option. However, purge from the GUI is still the best way to reduce data in emergency, provided these steps and considerations are followed.

- a. Make sure that the inspection-core is switched **off** on collectors to stop more data flooding into the appliance. Check that NO database commands are running except the show process list. If needed let any running commands finish before the next step.

```
stop inspection-core
xxx.xxx.xxx.com> support show db-processlist running

Id	User	Host	db	Command	Time	State	Info
141791	enchantedg	localhost	TURBINE	Query	0	init	show processlist

Total of running processes: 1
Total of sleep processes: 44
```

- b. Run **restart gui** to gain access to the GUI to perform the once now purge.

- Before starting purge ensure that both Archive and Export are **not selected**, so the system does not first create archive or export files.
- If there is a problem where the GUI keeps going down every five minutes, then consider switching the **auto\_stop\_services\_when\_full** to **off**, only **temporarily**, to allow you to restart the GUI and purge some data. By restarting the GUI on its own, it might only stay running for 5 minutes, and the nanny process might stop the services again before enough data is purged or before you have had time to start the purge.
- If the **auto\_stop\_services\_when\_full** is switched off, the appliance might go on to fill the system to 100%, preventing you from accessing the system at all. Never set the **auto\_stop\_services\_when\_full** to OFF unless you are using it temporarily in the specific circumstance described here. As soon as you have resolved the the space problem, switch it back to ON.

- c. Keep checking the DB full percentage and the Aggregation Archive log to know when the purge process is finished.

- d. When the purge is finished, set the **auto\_stop\_services\_when\_full** back on and then restart the stopped services.

```
store auto_stop_services_when_full on
restart stopped_services
```

- e. Data should start to be collected again. Monitor the system carefully.

- f. Investigate the root cause to ensure the problem does not recur.

- Purging the data does not resolve any root cause of a full database. Check the policy configuration or level of incoming traffic from S-TAPs.

2. If the database size is fine but the filesystem (/var) is full then some system files might be left on the appliance for example:

- If daily exports or archives are failing a temporary file might be left in the system for each day.
- Some old large patch files might be left in the /var/log/guard/patches directory.
- Tomcat service running on the system might be crashing and creating dump files.

The following CLI commands can be used to identify large files.

- - **show filesystem usage**: Shows types of files (database, log, gim) and how much space is used by them. Log files usually can be deleted.
  - **support show large\_files 10 0**: Shows files larger than 10MB older than 0 days. Consider the largest ones for removal first.

You might need to work with IBM Technical Support to carefully check for large files and consider ones for deletion.

3. Use of these two options to delete files.

- support clean log\_files, for example:

```
support clean log_files <file to delete, full path>
```

- diag-> 4) Perform Maintenance Actions -> 3) Clean Disk Space
  - Pick the directory where the large files reside.
  - Carefully enter a filter term to isolate the specific files that will be removed. Work with IBM Support if needed.
  - Check the list that is returned
  - Confirm you want the files to be removed

## Configuring system backup

System backups store all the necessary data and configuration values to restore a Guardium Server. Configure and schedule regular system backups during the implementation stage.

### About this task

---

A system backup is a full backup of the Guardium database and selected configuration files, such as groups, queries, reports, audit processes, alerts, and policies. In virtualized environments, you can create a backup by making an actual snapshot of the Guardium® system. Use the snapshot to restore a failed system. In this case, it is not necessary to keep more than three rolling copies. It is important to back up the aggregators. A weekly backup is recommended, especially for the central manager. However, some users might opt for a slightly longer cycle. Tip: In a managed environment with aggregation, you might choose not to back up managed collectors. Always back up stand-alone collectors.

Suggested data retention for disaster recovery

- Keep a rolling three months full backup from each unit (minimum one month).
- Keep a rolling 2-weeks worth of daily archives from the managed collectors.
- Full or system backups
  - Weekly or daily full backups of the central manager unit (assuming a stand-alone central manager).
  - Monthly for aggregators and collectors during a quiet off-hour period.

Data and configuration values are stored in separate encrypted files and sent to the specified destination by using the transfer method that is configured for backups on the system. For more information about the encryption used for backup files, see the [File backup cipher](#) section of [Cipher suites](#)

Note: You cannot make new buckets nor delete any buckets from the Guardium UI/CLI.

Note: During a file transfer, if the backup file transfer fails, the last file in each set of backup or archive files (for example, backup, configuration backup, archive, CSV archive) is saved in the diag/current folder. When the backup file destination is again online, you can manually transfer the backup files from the diag/current folder to the destination. The set of backup or archive files is saved in the diag/current folder only if the file transfer fails. If a file transfer fails during another backup file transfer, the set of backup or archive files is saved in the diag/current folder. However, to avoid saving too many files and running out of disk space, only the latest file of each type are saved. The earlier backup files are overwritten.

To prevent backup scripts from filling up /var:

- Before it starts, the backup process checks for room in /var. This process also warns the user if the space is insufficient for backup.
- The archive process checks the size of the static tables and verifies that /var has space to create the archive.
- An error is logged in the log file and GUI if the backup is over 50%. For example:

```
ERROR: /var backup space is at 60% used. Insufficient disk space for backup.
```

## Procedure

---

1. Go to [Manage > Data Management > System Backup](#).
2. Select a storage method and enter the configuration details. Depending on how the Guardium system is configured, only some of the options are available. For more information about configuring the archive and backup storage methods, see [Configuring external storage](#), and [store storage-system](#) and [show storage-system](#) commands ([store storage-system](#)).
3. Select one or both of the backup options:
  - Configuration: to back up important definitions.
  - Data: to back up all data. (Not needed if you are archiving data regularly.)
4. Use the Scheduling section to define a schedule for backup.
5. Click Save to verify and save the configuration changes. The system attempts to verify the configuration by sending a test data file to that location. If the operation fails, an error message displays and the configuration is not saved.
6. Optional: Click Run Once Now to run the operation once.

## What to do next

---

Verify that the operation completed successfully. Go to [Manage > Reports > Data Management > Aggregation/Archive Log](#). Each backup operation shows multiple activities. Check that the status of each activity is Succeeded.

## Restoring a Guardium system

Each type of guardium system (collectors, aggregators, and central manager) have different purposes and store data in different ways. Use the appropriate recovery strategies for each system type. The recovery strategy that is used also depends on whether the system that must be recovered is a stand-alone appliance or is used with other systems.

- [Before you restore your Guardium system](#)  
Review the prerequisites to restoring, and understand the restore flow.

- [Restoring a standalone collector](#)  
Follow these steps to restore a standalone collector.

Restore a centrally managed aggregator.
- [Restoring a dedicated central manager \(no data aggregation\)](#)  
Take the following steps to restore a dedicated central manager that does not aggregate data.
- [Restoring default and custom certificates](#)  
12.1 and later Backup and restore process restores only certificates that are not expired rather than restoring all certificates.

## Before you restore your Guardium system

Review the prerequisites to restoring, and understand the restore flow.

### Before you begin

Before you start the appliance recovery process, verify that you have the following information:

- New physical or virtual appliance.
- ISO image of Guardium software.
- The same patches that were installed on the appliance when the last system backup was taken.
- Latest system backup files.
- Daily archive files.
- License, SSL certificates, and any settings that must be set manually.

For information about what data is restored during a backup restore, see [restore backup](#).

### About this task

The following items are not backed up and must be installed or configured manually to complete the disaster recovery process:

- License - Reinstall the license manually.
- SSL Certificate: SSL certificates are not backed up. You need to reinstall them manually.
- Language: Use the CLI command [store language](#) to change from English (default).
- Network Time Protocol (NTP) settings: Use the CLI commands [store system time server](#) with the **hostnames** and **state** options to complete NTP server configuration.
- Time zone: Use the CLI command [store system clock timezone](#) to configure the system time zone.
- Enterprise search data: Data is not saved in the backup, and is not available in dashboards on a restored system.
- If you are using Tivoli Storage Manager or Centera as a storage location, configure the appliance to support it before you attempt to restore the backup files.

**Tip:** If you restore a configuration system backup from an appliance where SAML was configured, and then restore the system on a different appliance with different hostname or IP address, you must reconfigure SAML on the new appliance after you restore. Most identity providers (IdPs) require each hostname or IP to have its own registration. Therefore, the original registration of the appliance where the backup was taken is not valid on the second appliance where it is restored.

**Note:** As part of the **restore backup** dialog, you can choose to either override or restore configuration details for risk spotter and for central manager and managed units registration, as follows.

- Enter Y to maintain the current configuration of the central manager and managed units in your Guardium system.
- Enter N to restore the managed configuration of your Guardium environment from your system back up.

**Limitation:** Restored data does not include quick search data.

### Procedure

To start the restore, enter the CLI command [restore backup](#).

The script has a few options, depending on what you want to do. The following example shows many of the options, but your system might differ.

```
restore backup

This procedure will restore a DATA or CONFIG backup file or both onto a v11.0 system.

Continue (y/n)?

## Restoring a standalone collector

---

Follow these steps to restore a standalone collector.

### Procedure

---

1. Use an ISO that is appropriate for your appliance.  
For example, to restore a collector, use a collector ISO; for an aggregator, use an aggregator ISO.
2. Apply the license.
3. Make sure that your newly built appliance is at an equal or later version than the source appliance from which the backup was taken. If the appliance is at an earlier version, then apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
For example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or later and sniffer patch version 11.0p4020 or later.  
Or,
  - Install GPU version 11.5 or later.
4. Use the [restore backup](#) CLI command to restore the data and configuration backups.  
For more information, see [Before you restore your Guardium system](#).
5. If needed, restore the archive files for any missing days.

## Restoring a collector with an aggregator that is not centrally managed

Follow these steps to restore a collector associated with an aggregator, but not in a centralized environment.

### Procedure

1. Use an ISO that is appropriate for your appliance.  
For example, to restore a collector, use a collector ISO; for an aggregator, use an aggregator ISO.
2. Apply the license.
3. Make sure that your newly built appliance is at an equal or later version than the source appliance from which the backup was taken. If the appliance is at an earlier version, then apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
For example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or later and sniffer patch version 11.0p4020 or later.
  - Or,
  - Install GPU version 11.5 or later.
4. Use the [restore backup](#) CLI command to restore the data and configuration backups.  
For more information, see [Before you restore your Guardium system](#).
5. Restoring the archive files is optional because the data already exists on an aggregator.

### Related concepts

- [File handling CLI commands](#)

## Restoring an aggregator that is not centrally managed

Follow these steps to restore an aggregator that is not centrally managed.

### About this task

Alternatively, to restore data backup, consider aggregating data again from collectors, depending on the number of collectors and the retention period requirements on the collectors and aggregator.

### Procedure

1. Use an ISO that is appropriate for your appliance.  
For example, to restore a collector, use a collector ISO; for an aggregator, use an aggregator ISO.
2. Apply the license.
3. Make sure that your newly built appliance is at an equal or later version than the source appliance from which the backup was taken. If the appliance is at an earlier version, then apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
For example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or later and sniffer patch version 11.0p4020 or later.
  - Or,
  - Install GPU version 11.5 or later.
4. Use the [restore backup](#) CLI command to restore the data and configuration backups.  
For more information, see [Before you restore your Guardium system](#).
5. If needed, restore the archive files for any missing days.

### What to do next

When restoring data from an aggregator to a new system with a different hostname, the new system shows collectors from the source aggregator, and the collectors on the new system. After completing the restore:

1. On each of the old collectors define a data export to the new aggregator and click Save.
2. Clear the Export checkbox in the data export (that you just defined) and click Save.

### Related concepts

- [File handling CLI commands](#)

## Restoring a centrally managed collector

Follow these steps to restore a centrally managed collector.

## About this task

---

A centrally managed collector stores its configuration data on the central manager; restore data is not required.

## Procedure

---

1. Use an ISO that is appropriate for your appliance.  
For example, to restore a collector, use a collector ISO; for an aggregator, use an aggregator ISO.
2. Register the newly built collector with central manager (licenses are pooled from central manager).
3. Make sure that your newly built appliance is at an equal or later version than the source appliance from which the backup was taken. If the appliance is at an earlier version, then apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
For example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or later and sniffer patch version 11.0p4020 or later.  
Or,
  - Install GPU version 11.5 or later.
4. Use the [restore backup](#) CLI command to restore the data backup.  
This step might be optional if the environment includes an aggregator and data from the collector also exists on the aggregator. (You do not need to restore the configuration backup because the definitions are pooled from the central manager.)  
For more information, see [Before you restore your Guardium system](#).
5. Use the [store system shared secret](#) CLI command to set the shared secret to enable communication with central manager. The shared secret encrypts communication of the appliance with central manager.
6. Optional: Restore archive files for missing days, as needed. This step is not required if you are not restoring data backup.

## Related concepts

---

- [File handling CLI commands](#)

## Restoring a centrally managed aggregator

---

Restore a centrally managed aggregator.

## About this task

---

The configuration data of a centrally managed aggregator is stored on the central manager. It is not necessary to restore the data on the aggregator during disaster recovery.

## Procedure

---

1. Use the appropriate ISO image to build an appliance.
2. The newly built appliance must be of an equal or higher version than the source appliance from which the backup was taken. If the version is lower, apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
As an example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or up and sniffer patch version 11.0p4020 or up.
  - Install GPU version 11.5 or up.
3. Enable all required network settings.
4. If the source appliance was a managed unit, you must register your newly built appliance with the central manager (licenses are pooled from central manager).
5. Shared secret must be set to enable communication with central manager. Shared secret is used to encrypt communication of the appliance with central manager.  
Use CLI command store system shared secret to complete this step.
6. Restore the data backup. It is not necessary to restore the configuration backup because the definitions are pooled from central manager.
7. Restore archive files for missing days, as needed.

## What to do next

---

When you restore data from an aggregator to a new system with a different hostname, the new system shows collectors from the source aggregator, and the collectors on the new system. After completing the restore:

1. On each of the old collectors, define a data export to the new aggregator and Save.
2. Clear the Export checkbox in the data export (that you just defined) and Save.

## Related concepts

---

- [File handling CLI commands](#)

## Restoring a dedicated central manager (no data aggregation)

---

Take the following steps to restore a dedicated central manager that does not aggregate data.

## About this task

When you restore a unit from the backup taken from the different environment that contains appliances that are not registered to the new restored system, go to the Managed Unit Groups page in the new environment and modify the groups accordingly. If there are distributed reports based on these groups, they are corrected automatically when you save the changes in the Managed Unit groups page.

## Procedure

1. Use an ISO that is appropriate for your appliance.  
For example, to restore a collector, use a collector ISO; for an aggregator, use an aggregator ISO.
2. Apply the license.
3. Make sure that your newly built appliance is at an equal or later version than the source appliance from which the backup was taken. If the appliance is at an earlier version, then apply the required GPU, bundle, and sniffer patches to bring the appliance to the same patch level as it was when the last backup was taken.  
For example, if the source appliance is a version 11.4 Guardium system that was patched with bundle 11.0p450 and sniffer patch 11.0p4020 and the new appliance was built from ISO 11.3, choose one of the following options:
  - Install 11.4 GPU. Then, apply appliance bundle version 11.0p450 or later and sniffer patch version 11.0p4020 or later.
  - Or,
  - Install GPU version 11.5 or later.
4. Use the [restore backup](#) CLI command to restore the configuration backup.  
For more information, see [Before you restore your Guardium system](#).

## Related concepts

- [File handling CLI commands](#)

## Restoring default and custom certificates

12.1 and later Backup and restore process restores only certificates that are not expired rather than restoring all certificates.

During config system backup, certificates are automatically backed up.

For custom certificates, restore it from the backup file always.

For default certificates, check the expiration date of the certificate in the backup file and the current target system. If the certificate in the backup file is newer than the current certificate on the system, restore it. If the certificate in the backup file is earlier than the current certificate on the system, don't restore it.

The following table lists the scenarios to show the behavior for default and custom certificates when they are backed up from the source version and restored to the target version.

Table 1. Scenarios for restoring default and custom certificates

| Type of certificate                                                         | Source version                      | Target version                                                                                                             | Restore process                                                         |
|-----------------------------------------------------------------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Default certificate, custom certificate, or default and custom certificates | Certificate is expired.             | Certificate is expired or not expired.                                                                                     | No changes in target.                                                   |
| Default certificates                                                        | Certificate is not expired.         | The expiration date of a certificate in target is later than the expiration date of the certificate in source.             | No changes in target.                                                   |
|                                                                             | Certificate is not expired.         | The expiration date of certificate in target is earlier than the expiration date of certificate in source.                 | Certificate in target replaces the certificate in source.               |
|                                                                             | Certificate is not expired.         | Certificate is expired.                                                                                                    | Certificate in source replaces the certificate in target.               |
|                                                                             | Certificate is not present.         | Certificate is present.                                                                                                    | No changes in target.                                                   |
|                                                                             | Certificate is not expired.         | Certificate is not present.                                                                                                | Certificate in source is added to the keystore in target.               |
| Custom certificates                                                         | Custom certificate is not expired.  | The expiration date of a custom certificate in target is later than the expiration date of custom certificate in source.   | No changes in target.                                                   |
|                                                                             | Custom certificate is not expired.  | The expiration date of a custom certificate in target is earlier than the expiration date of custom certificate in source. | Custom certificate in target replaces the custom certificate in source. |
|                                                                             | Custom certificate is not expired.  | Custom certificate is expired.                                                                                             | Custom certificate in source replaces the certificate in target.        |
|                                                                             | Custom certificate is not present.  | Custom certificate is present.                                                                                             | No changes in target.                                                   |
|                                                                             | Custom certificate is not expired.  | Custom certificate is not present.                                                                                         | Custom certificate in source is added to the keystore in target.        |
| Default and custom certificates                                             | Custom certificate is not expired.  | Default Guardium certificate is not expired.                                                                               | Custom certificate overwrites default.                                  |
|                                                                             | Default certificate is not expired. | Custom Guardium certificate is expired.                                                                                    | Default Guardium certificate is added to the keystore in target.        |

## Enabling SSH key pairs for data archive, data export, data mart

You can use SSH key pairs for authentication, instead of passwords, for archiving and exporting results, archiving data, and exporting data marts.

## About this task

The Guardium system generates SSH keys specific to the type of transfer (archive, export, data mart), and propagates them to remote hosts that support SCP connections. At the central manager level, you can generate SSH keys across the deployment and propagate them to remote hosts. The remote host gets a copy of the public-transfer-key, and the Guardium appliance retains the private part of the SSH key pair, allowing the data transfer without a password.

The two directories that contain the SSH key details (/opt/IBM/Guardium/etc/ssh/ssh-keys/tomcat/ and /opt/IBM/Guardium/etc/ssh/ssh-keys/transfer/) are backed up into the CONFIG backup file when you run the CLI command **backup system**. When you restore with the CLI command **restore backup**, the files from these two directories are restored into the current appliance. The restore process does not overwrite any existing files in the current appliance that are newer (last modified timestamp).

## Procedure

1. Log in to the Guardium system CLI as admin cli.
2. Enable the feature by entering `store system scp-ssh-key-mode on`
3. Verify that the feature is enabled by entering `show system scp-ssh-key-mode`.  
The response is `scp-ssh-key-mode is enabled`
4. Create the SSH key pair, which can be used for data transfer, by entering  
`store system public-transfer-key create`.  
(Alternatively, use the API command `grdapi generate_transfer_key`.)
5. Verify that the key was made and display the public portion of the key, by entering  
`show system public-transfer-key`
6. Install the public part of the SSH key on the remote host and users account for data transfer, by using one of these methods:
  - Copy the public part of the key and add it into the .ssh/authorized\_keys of the user on the remote host.
  - Run the command `export-public-transfer-key`.

```
...>export-public-transfer-key
This operation will force a new set of ssh keys onto the remote host specified. The keys will be put into the .ssh/author
Continuing ...
Please enter a valid host which will adopt the public transfer-key.
10.12.12.45
Please enter a valid user for the host.
admin
/usr/bin/ssh-copy-id: INFO: Source of key(s) to be installed: "/opt/IBM/Guardium/etc/ssh/ssh-keys/transfer/id_rsa.pub"
```

  - `grdapi export_transfer_key`
    - On the central manager, copy the unique public-transfer-key of each managed unit to the remote host, by entering:  
`grdapi export_transfer_key host="remote_host_1" user="user1" password="password" api_target_host=all`
    - On a managed unit, copy the specific, unique, public-transfer-key of the managed unit to the remote host, by entering:  
`grdapi export_transfer_key host="remote_host_1" user="user1" password="password"`

The key is imported, and you can run data archive, data export, and system backup to the remote host and user without needing a password.

## What to do next

It is good practice, and required in many environments, to periodically refresh the keys.

1. In the CLI, run the command `system public-transfer-key regenerate` to refresh the keys.
2. Delete the old keys from one or more remote hosts by entering **system public-transfer-key delete**.
3. Import the new keys into the host as described in step 6.

To archive and export results, archive data, and export data marts, see [Transferring data to a remote host by using SSH key pairs for authentication](#).

## Related reference

- [API command: generate\\_transfer\\_key](#)
- [API command: export\\_transfer\\_key](#)

## Transferring data to a remote host by using SSH key pairs for authentication

You can archive and export results, archive data, and export data marts with SSH key pairs for authentication, instead of usernames and passwords.

## Before you begin

Ensure that:

- If you are adding an SSH key pair to a data mart, the data mart is defined.
- The SSH key feature is enabled.
- The SSH key pairs were generated.
- The public part of the key, `public-transfer-key`, was copied to the remote host.

For more information, see [Enabling SSH key pairs for data archive, data export, data mart](#).

## About this task

These grdapi commands have a new parameter, ssh\_keys\_active. When ssh\_keys\_active=1, the system transfers data with the SSH key pairs, instead of a username and password. You can update an existing archive, export, or data mart by using these APIs.

- **grdapi configure\_archive**
- **grdapi datamart\_update\_copy\_file\_info**
- **grdapi datamart\_validate\_copy\_file\_info**
- **grdapi configure\_results\_archive**
- **grdapi configure\_results\_export**

You can also configure a new results archive, results export, and data archive, by using the relevant APIs.

The user and password details that are defined in the Data Archive, Results Archive, and Results Export pages are still valid after you define SSH key pairs. They function as a backup to the SSH key authentication. The UI does not show that you defined SSH key pairs.

## Procedure

---

Run any of the APIs with the parameter ssh\_keys\_active. For example,

- `grdapi configure_archive archiveOlderThan=1 archiveValues=1 destHost="n.n.n.n" ignoreOlderThan=30 protocol="scp" targetDir="/var/tmp" userName="root" ssh_keys_active=1`
- `grdapi datamart_update_copy_file_info destinationHost="n.n.n.n" destinationPath="/var/tmp/" destinationUser="root" transferMethod="SCP" Name="Export:Full SQL" ssh_keys_active=1`
- `grdapi datamart_validate_copy_file_info destinationHost="n.n.n.n" destinationPath="/var/tmp/" destinationUser="root" transferMethod="SCP" ssh_keys_active=1`
- `grdapi configure_results_archive archiveOlderThan=1 archiveValues=1 destHost="n.n.n.n" ignoreOlderThan=30 protocol="scp" targetDir="/var/tmp" userName="root" ssh_keys_active=1`
- `grdapi configure_results_export destHost="n.n.n.n" protocol="scp" targetDir="/var/tmp" userName="root" port=22 ssh_keys_active=1`

## Configuring external storage

---

Archive files can be sent using SCP or FTP protocol, or to a configured external storage system (Amazon S3, EMC Centera, Tivoli Storage Manager, IBM COS, and IBM Cloud). You can define a single archiving configuration for each Guardium® system.

- [Configure an Amazon S3 \(Amazon Simple Storage Service\) target for archive or backup](#)  
Export to Amazon S3 is not enabled by default. After you enable Amazon S3, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters that are used in the archive and backup pages.
- [Configuring an IBM COS \(formerly Cleversafe\) target for archive or backup](#)  
Export to IBM COS is not enabled by default. After you enable IBM COS, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters used in the archive and backup pages.
- [Configure an EMC Centera target for archive or backup](#)  
Export to EMC Centera is not enabled by default. After you enable EMC Centera, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters that are used in the archive and backup pages.
- [Configuring an SCP or SFTP target for archive or backup](#)  
Export by secure copy (SCP) or SFTP (secure file transfer protocol, formerly FTP) are used to archive and backup to the local database server. These options are enabled by default.
- [Configure a Tivoli Storage Manager \(TSM\) archive or backup](#)  
Export to TSM (Tivoli Storage Manager) is not enabled by default. After you enable TSM, you can configure it for backups. Learn how to enable the service, and understand the configuration parameters that are used in the backup page.

## Configure an Amazon S3 (Amazon Simple Storage Service) target for archive or backup

---

Export to Amazon S3 is not enabled by default. After you enable Amazon S3, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters that are used in the archive and backup pages.

### Before you begin

---

- An Amazon account and registration for the S3 service.
- Amazon S3 credentials:
  - Access Key ID: identifies user as the party responsible for service requests. It needs to be included in each request. It is not confidential and does not need to be encrypted. (20-character, alphanumeric sequence).
  - Secret Access Key: The Secret Access Key (40-character sequence) is associated with Access Key ID calculating a digital signature that is included in the request. The Secret Access Key is a secret, for use only by AWS and the user. This key is just a long string of characters (and not a file) that is used to calculate the digital signature that needs to be included in the request. The Secret Access Key is encrypted when saved into the database.
- S3 Bucket Name: Every object that is stored in Amazon S3 is contained in a bucket. Buckets partition the namespace of objects that are stored in Amazon S3. Within a bucket, you can use any names for your objects, but bucket names must be unique across all of Amazon S3.
- The clock time of Guardium system must be correct (within 15 minutes). Otherwise, requests are not accepted. If the Guardium system time is not correct, set the correct time by using the following CLI commands:

```
show system time_server hostnames
store system time_server hostnames (for example, ntp.xxx.yyy.example.com)
store system time_server state on
```

## Procedure

---

1. Enable Amazon S3 archive or backup from the Guardium CLI by entering one or both of these commands:

```
store storage-system amazon_s3 archive on
store storage-system amazon_s3 backup on
```

2. In Manage > Data Management > System Backup or Data Archive pages, select Amazon S3.

3. Enter the Bucket Name.

4. Select the Authentication Type, and its parameters:

- Security Credentials

This is the legacy authentication type. It requires the following parameters:

- Access Key ID
- Secret Access Key

- IAM Role

This authentication type allows the assumption of an *IAM Instance Profile* by specifying the following parameters:

- Access Key ID
- Secret Access Key
- Role ARN

Unlike the legacy *Security Credentials*, *IAM Role* uses temporary credentials to connect to S3. To configure *IAM Role* authentication:

- Create a user in AWS IAM. Make a note of the *Access Key ID* and *Secret Access Key*.
- Create the following policy and associate it with the user:

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
 "Action": [
 "iam>ListRoles",
 "sts:AssumeRole"
],
 "Resource": "*"
 }
]
}
```

- Create a new role and set a trust relationship for the user. For example:

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
 "Principal": {
 "Service": "ec2.amazonaws.com",
 "AWS": "arn:aws:iam::123456789012:user/guarduser"
 },
 "Action": "sts:AssumeRole"
 }
]
}
```

- Create the following policy and associate it with the role:

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": [
 "s3:GetObject",
 "s3>ListAllMyBuckets",
 "s3>ListBucket",
 "iamGetInstanceProfile",
 "sts:AssumeRole"
],
 "Resource": "*"
 }
]
}
```

- To authenticate with Guardium, use the *Access Key ID* and *Secret Access Key* of the user and the *Role ARN* of the instance profile role. Find the *Role ARN* by viewing the role in AWS IAM.

- IAM instance Profile

This authentication type only works when using a Guardium instance deployed on AWS EC2. To configure *IAM instance Profile* authentication, create the following AWS policy and associate it with an IAM role:

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "VisualEditor0",
 "Effect": "Allow",
 "Action": [
 "s3:PutObject",
 "s3:GetObject",
 "s3>ListAllMyBuckets",
 "s3>ListBucket",
 "iamGetInstanceProfile",
 "s3:DeleteObject"
],
 "Resource": "*"
 }
]
}
```

```

 "iam>ListInstanceProfilesForRole",
 "sts_ASSUMERole"
],
 "Resource": "*"
}
}

```

Authentication works once the role has been associated with the instance.

Important: For the latest information about AWS security credentials and IAM roles for Amazon EC2, read the Amazon AWS documentation.

- Enter or select values for these definitions use in all types of Amazon S3 backups:

- Region
- Port
- Storage class
- Backup: Configuration or Data

- Optional: Schedule the backup in the lower part of the page. For more details, see [Scheduling](#).

- Click Save.

## Configuring an IBM COS (formerly Cleversafe) target for archive or backup

Export to IBM COS is not enabled by default. After you enable IBM COS, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters used in the archive and backup pages.

## Before you begin

---

Note: Cleversafe is now IBM Cloud Object Storage (COS) on IBM Cloud.

Restriction: External storage on IBM COS is not supported for IPV6.

Prepare these details before you begin:

- Authentication endpoint URL
- IBM COS credentials:
  - Access Key ID: identifies user as the party responsible for service requests. It needs to be included in each request. It is not confidential and does not need to be encrypted. (20-character, alphanumeric sequence).
  - Secret Access Key: The Secret Access Key (40-character sequence) is associated with Access Key ID calculating a digital signature that is included in the request. It is a secret, for use only by IBM COS and the user. This key is just a long string of characters (and not a file) that is used to calculate the digital signature that needs to be included in the request. Secret Access Key is encrypted when saved into the database.
- Bucket Name: Buckets partition the namespace of objects in the storage. Within a bucket, you can use any names for your objects.
- The clock time of Guardium® system must be set to the correct local time. Otherwise, requests are not accepted. If the Guardium system time is not correct, set the correct time by using the following CLI commands:

```

show system time_server hostnames
store system time_server hostnames (for example, ntp.xxx.yyy.example.com)
store system time_server state on

```

## Procedure

---

- Enable IBM COS archive or backup from the Guardium CLI by entering the relevant command:

```

store storage-system IBMCOS archive on
store storage-system IBMCOS backup on

```

- In Manage > Data Management > System Backup or Data Archive pages, select IBM COS (Formerly Cleversafe).
- Enter the Authentication endpoint URL.
- Enter the Access Key ID.
- Enter the Secret Access Key.
- Select the Bucket Name.
- Optional: Schedule the backup in the lower part of the page. For more details, see [Scheduling](#).
- Click Save.
- If you are archiving or backing up by using the HTTPS protocol, you must store the rootca and intermediate certificate, if applicable, into the Tomcat keystore by running the CLI command **store certificate keystore trusted console**. For more information, see [store certificate keystore](#).

## Configure an EMC Centera target for archive or backup

Export to EMC Centera is not enabled by default. After you enable EMC Centera, you can configure it for archives and backup. Learn how to enable the service, and understand the configuration parameters that are used in the archive and backup pages.

### Before you begin

---

- License with username and password from EMC.
- Establish an account with EMC Centera on the network (requires an IP address and a ClipID)

Note: This procedure also supports Dell EMC ECS 3.5.x for Guardium 11.1 and later.

### Procedure

---

1. Enable Centera storage on Guardium® by entering the CLI command:

```
store storage-system centera backup ON
show storage-system
```

2. In Manage > Data Management > System Backup or Data Archive pages, select EMC Centera.
3. Enter Retention: the number of days to retain the data. The maximum is 24855 (68 years). If you want to save it for longer, you can restore the data later and save it again.
4. Enter Centera Pool Address: the Centera Pool Connection String; for example: 10.2.3.4,10.6.7.8?/var/centera/us1\_profile1\_rwe.pea.txt. This IP address and the .pea file come from EMC Centera. The question mark is required in the path. The .../var/centera/... path name is important as the backup might fail if the path name is not followed. The .pea file gives permissions, username, and password authentication per Centera backup request.
5. Click Upload PEA File to upload a Centera .pea file to be used for the connection string. If the message Cannot open the pool at this address.. appears, check the size of the Guardium system hostname.
6. Optional: Schedule the backup in the lower part of the page. For more details, see [Scheduling](#).
7. Click Save.

## Configuring an SCP or SFTP target for archive or backup

Export by secure copy (SCP) or SFTP (secure file transfer protocol, formerly FTP) are used to archive and backup to the local database server. These options are enabled by default.

### Procedure

---

1. In Manage > Data Management > System Backup or Data Archive pages, select SCP or SFTP (Formerly FTP).
2. Enter the Host - The IP address or hostname of the host to receive the archived data.
3. Enter the Directory where the data will be stored:
  - For SCP - Specify the directory as an absolute path.
  - For SFTP - Specify the directory relative to the SFTP account home directory.
4. Enter the Port to use to send files over SCP or SFTP. The default port for SCP, SFTP, or SSH is 22. If the port is set to 0 (zero), the default port is in use (and you do not need to change it).
5. Enter the Username and Password - Credentials for the user that logs on to the SCP or SFTP server. This user must have write and execute permissions for the directory that is specified in Directory. For Windows, a domain user is accepted with the format of domain\user.  
Attention: For SFTP, the Username value cannot include any of the following characters: ! " \$ & ' () ; \ |
6. Optional: Schedule the backup in the lower part of the page. For more details, see [Scheduling](#).
7. Click Save.

# Configure a Tivoli Storage Manager (TSM) archive or backup

Export to TSM (Tivoli Storage Manager) is not enabled by default. After you enable TSM, you can configure it for backups. Learn how to enable the service, and understand the configuration parameters that are used in the backup page.

## Before you begin

- Define a dsm.sys or dsm.opt configuration file on your server.
- For Tivoli Storage Manager (TSM) v7.1.8 or newer, you need a cert256.arm file. For more information, see [Configuring the server to use the cert256.arm certificate](#).

Note: The dsm.sys or dsm.opt file and cert256.arm file must be located in the same directory.

## About this task

Certificates are unique and cannot be reused on other Guardium servers.

## Procedure

1. Enable TSM backup from the Guardium CLI by entering:

```
store storage-system TSM backup on
```

2. Import the dsm.sys or dsm.opt configuration file by using the CLI command **import tsm config**.  
Guardium verifies the TSM version.

```
Is this Tivoli Storage Manager server <tsm server name> v7.1.8 or newer (y/n)?
```

If you are using TSM v7.1.8 or newer, type **y**. You are prompted to upload the cert256.arm file.

```
This appliance requires certificate authentication with <tsm server name>.
Is server certificate file ~/cert256.arm available now? (y/n)?
```

Type **y** to upload the certificate.

3. In **Manage > Data Management > System Backup**, select TSM.
4. Enter the Password, and reenter:
5. Select the Server:
6. Enter As host:
7. Optional: Schedule the backup in the lower part of the page. For more details, see [Scheduling](#).
8. Click Save.

## Internet Protocol modes

Configure Guardium® to run in a traditional IPv4-only environment, an IPv6-only environment, or in *dual mode* where the system supports both IPv4 and IPv6 addresses.

### IPv4 mode

IPv4 is the default mode of the Guardium system. This mode allows the system to communicate with devices that run over IPv4 only.

### IPv6 mode

If the IP mode is set to IPv6, Guardium supports only the databases, appliances, and other devices that are connected over IPv6.

### Dual mode

IPv4 and IPv6 are independent protocols and cannot communicate with each other.

The dual mode allows the Guardium system to communicate with devices that are running on IPv4, IPv6, or both.

#### Note:

The following Guardium features are not compatible with IPv6 mode and dual mode:

- Cloud database protection services
- IBM COS (Formerly Cleversafe) for archiving on external storage

The following third-party features and applications might not be compatible with IPv6 mode and dual mode. For more information, see the official website of the third-party.

- CyberArk
- Centera
- ECS 3.x or later
- ServiceNow
- z/OS versions earlier than 2.2

For information about using IPv6 with QRadar, see [IPv6 addressing in QRadar deployments](#).

- [Enable IPv4](#)

## Enable IPv4

Configure your Guardium® deployment to use IPv4 addresses exclusively.

### Before you begin

IPv4 is the default IP mode for new Guardium installations and most existing deployments. Follow this procedure to configure IPv4 on systems that have been previously set to IPv6 or *dual mode*.

Warning: If you set the IP mode to IPv4, Guardium cannot communicate with systems running on other network protocols and any previous network settings are wiped out.

Ensure that you meet these prerequisites:

- All devices in your environment use IPv4 addresses. For example, the Guardium system and all Guardium agents, such as S-TAPs, are assigned IPv4 addresses.
- The Domain Name System (DNS) of your network is configured for IPv4.

### Procedure

1. On the central manager, set the IP mode to IPv4 by running the CLI command **store system ipmode ipv4**.

Important: Do not restart the network until you complete step 2.

2. Set up IPv4 by running the following CLI commands.

- a. **store system hostname <hostname>**

Where <hostname> can be resolved by the DNS for IPv4 addresses.

- b. **store system domain <domain name>**

Where <domain> is the domain name of your network.

- c. **store network interface ip <IP address>**

Where <IP address> is the primary IPv4 address of your Guardium system in Classless Inter-Domain Routing (CIDR) notation. For example, **store network interface ip 9.70.145.77/24**.

- d. **store network routes defaultroute <IP address>**

Where <IP address> is the IPv4 address of the default router.

- e. **store network resolvers <IP address>**

Where <IP address> is one or more IPv4 addresses for your DNS servers.

3. Restart the network configuration by running the CLI command **restart network**.

4. Verify that you can ping your Guardium system's IPv4 address.

5. Repeat steps 1 - 4 on each managed unit.

6. Register managed units to the central manager using the CLI command **register management <central manager IP> <port>** from each managed unit.

Where <central manager IP> is the IPv4 address of the central manager and <port> is the port number. For example, **register management 9.70.145.07 8443**. Repeat this step for each managed unit.

Important: To avoid connectivity issues during registration, use the IP address and not the hostname. To unregister a managed unit from a central manager, use the same IP mode and IP address that was used during registration.

7. After the central manager and managed units are configured, the environment is ready to register databases, devices, and other agents to the Guardium system using IPv4 addresses.

# Enable dual IP mode in an existing IPv4 deployment

Configure your Guardium® deployment to use both IPv4 and IPv6 addresses.

## Before you begin

**Dual mode** allows Guardium to communicate with devices using IPv4, IPv6, or both network protocols. Follow this procedure to enable *dual mode* on your central manager and register managed units using either IPv4 or IPv6.  
Attention: If your Domain Name System (DNS) supports multiple protocols, it can return either an IPv4 or IPv6 address for a specific hostname. If the returned IP address does not match the IP mode of the Guardium system, this can result in network connectivity issues. To avoid this scenario, use the IP address and not the hostname to connect a database, host, or device to the Guardium system.

Ensure that you meet these prerequisites:

- Your central manager and managed units are running Guardium V11.1 or later.
- Your network is configured to use Guardium over both IPv4 and IPv6.
- All devices in your environment use the appropriate protocol. For example, if you are using IPv6, the Guardium system and all Guardium agents, such as S-TAPs, are assigned IPv6 addresses. If you are using IPv4, the Guardium system and all Guardium agents, such as S-TAPs, are assigned IPv4 addresses.
- Each device is assigned a distinct hostname for each protocol. For example, a device that is running both IPv4 and IPv6 is configured with hostnames `devicename-IPv4` and `devicename-IPv6`.
- The DNS of your network is configured for IPv4 and IPv6.

## Procedure

1. On the central manager, set the IP mode to *dual mode* by running the CLI command `store system ipmode dual`.

Important: Do not restart the network until you complete step 2.

2. Set up IPv6 by running the following CLI commands.

This assumes that the central manager had a functioning IPv4 configuration before enabling *dual mode*. The following commands leave the existing IPv4 configuration intact while configuring the central manager for IPv6 connections.

- a. **store network interface ip <IP address>**

Where `<IP address>` is the primary IPv6 address of your Guardium system in Classless Inter-Domain Routing (CIDR) notation. For example, `store network interface ip 2002:0920:c000:3145:0000:0000:0000:0013/96`.

- b. **store network routes defaultroute <IP address>**

Where `<IP address>` is the IPv6 address of the default router.

- c. **store network resolvers <IPv4 address> <IPv6 address>**

Where `IPv4 address` is one or more IPv4 DNS addresses and `IPv6 address` is one or more IPv6 DNS addresses. When migrating an existing IPv4 deployment to *dual mode*, specify the same `IPv4 address` values used for the original IPv4 configuration.

3. Restart the network configuration by running the CLI command `restart network`.

4. Verify that you can ping your Guardium system's IPv4 and IPv6 addresses.

5. Enable IPv4 or IPv6 on each managed unit.

Follow the procedures to [Enable IPv4](#), [Enable IPv6 in a new deployment](#), or [Migrate to IPv6 in an existing IPv4 deployment](#).

6. After the managed units are set up in either IPv4 or IPv6 mode, register each managed unit to the central manager using the CLI command `register management <central manager IP> <port>` from each managed unit.

Where `<central manager IP>` is the IPv4 or IPv6 address of the central manager and `<port>` is the port number. For example, `register management 9.70.145.07 8443` for an IPv4 managed unit or `register management 2620:1f7:807:a000:920:8400:0:182 8443` for an IPv6 managed unit.

Important: To avoid connectivity issues during registration, use the IP address and not the hostname. To unregister a managed unit from a central manager, use the same IP mode and IP address that was used during registration.

7. After the central manager and managed units are configured, the environment is ready to register databases, devices, and other agents to the Guardium system using either IPv4 or IPv6 addresses.

# Migrate to IPv6 in an existing IPv4 deployment

Configure your existing Guardium® deployment to use IPv6 addresses exclusively.

## Before you begin

Ensure that you meet these prerequisites:

- Your central manager and managed units are running on V11.1 or later.
- Your network is configured to use Guardium over IPv6.
- All devices in your environment use IPv6 addresses. For example, the Guardium system and all Guardium agents, such as S-TAPs, are assigned IPv6 addresses.

- The Domain Name System (DNS) of your network is configured for IPv6.

## About this task

---

Use this procedure to enable IPv6 on a central manager in an existing IPv4 environment.

Attention: If you set the IP mode to IPv6, Guardium cannot communicate with the systems that are running in IPv4 mode. Any previous network settings, including all IPv4 configurations, are wiped out.

## Procedure

---

- On the central manager, set the IP mode to *dual mode* by running the CLI command **store system ipmode dual**.

Important: Do not restart the network until you complete step [2](#).

- Set up IPv6 by running the following CLI commands.

- store network interface ip <IP address>**

Where <IP address> is the primary IPv6 address of your Guardium system in Classless Inter-Domain Routing (CIDR) notation. For example, **store network interface ip 2002:0920:c000:3145:0000:0000:0000:0013/96**.

- store network routes defaultroute <IP address>**

Where <IP address> is the IPv6 address of the default router.

- store network resolvers <IP address>**

Where IP address is one or more IPv6 addresses for your DNS servers.

- Unregister managed units by running the CLI command **unregister management** on each managed unit.

- Migrate each managed unit to *dual mode*.

- Set the IP mode to *dual mode* by running the CLI command **store system ipmode dual**.

Important: Do not restart the network until you complete step [4.b](#).

- Set up IPv6 by running the following CLI commands.

- store network interface ip <IP address>**

Where <IP address> is the primary IPv6 address of your Guardium system in Classless Inter-Domain Routing (CIDR) notation. For example, **store network interface ip 2002:0920:c000:3145:0000:0000:0000:0013/96**.

- store network routes defaultroute <IP address>**

Where <IP address> is the IPv6 address of the default router.

- store network resolvers <IP address>**

Where IP address is one or more IPv6 addresses for your DNS servers.

- Restart the network configuration by running the CLI command **restart network** on the central manager.

- Register managed units to the central manager using the CLI command **register management <central manager IP> <port>** from each managed unit.

Where <central manager IP> is the IPv6 address of the central manager and <port> is the port number. For example, **register management 2620:1f7:807:a000:920:8400:0:182 8443**. Repeat this step for each managed unit.

Important: To avoid connectivity issues during registration, use the IP address and not the hostname.

To unregister a managed unit from a central manager, use the same IP mode and IP address that was used during registration.

- After the central manager and managed units are configured, the environment is ready to register databases, devices, and other agents to the Guardium system using IPv6 addresses.

## Enable IPv6 in a new deployment

---

Configure your new Guardium® deployment to use IPv6 addresses exclusively.

## Before you begin

---

Warning: If you set the IP mode to IPv6, Guardium cannot communicate with systems running on other network protocols and any previous network settings are wiped out.

Ensure that you meet these prerequisites:

- Your central manager and managed units are running on V11.1 or later.
- Your network is configured to use Guardium over IPv6.
- All devices in your environment use IPv6 addresses. For example, the Guardium system and all Guardium agents, such as S-TAPs, are assigned IPv6 addresses.
- The Domain Name System (DNS) of your network is configured for IPv6.

## About this task

---

## Procedure

---

1. On the central manager, set the IP mode to IPv6 by running the CLI command **store system ipmode ipv6**.  
Important: Do not restart the network until you complete step 2.
2. Set up IPv6 by running the following CLI commands.
  - a. **store system hostname <hostname>**  
Where <hostname> can be resolved by the DNS for IPv6 addresses.
  - b. **store system domain <domain name>**  
Where <domain> is the domain name of your network.
  - c. **store network interface ip <IP address>**  
Where <IP address> is the primary IPv6 address of your Guardium system in Classless Inter-Domain Routing (CIDR) notation. For example, **store network interface ip 2002:0920:c000:3145:0000:0000:0000:0013/96**.
  - d. **store network routes defaultroute <IP address>**  
Where <IP address> is the IPv6 address of the default router.
  - e. **store network resolvers <IP address>**  
Where IP address is one or more IPv6 addresses for your DNS servers.
3. Restart the network configuration by running the CLI command **restart network**.
4. Verify that you can ping your Guardium system's IPv6 address.
5. Repeat steps 1 - 4 on each managed unit.
6. Register managed units to the central manager using the CLI command **register management <central manager IP> <port>** from each managed unit.  
Where <central manager IP> is the IPv6 address of the central manager and <port> is the port number. For example, **register management 2620:1f7:807:a000:920:8400:0:182 8443**. Repeat this step for each managed unit.  
Important: To avoid connectivity issues during registration, use the IP address and not the hostname. To unregister a managed unit from a central manager, use the same IP mode and IP address that was used during registration.
7. After the central manager and managed units are configured, the environment is ready to register databases, devices, and other agents to the Guardium system using IPv6 addresses.

## Assign IPv6 addresses to your devices

---

After you enable IPv6 in your central manager and managed units, assign the IPv6 protocol to all devices in your environment such as databases, and your Guardium® agents, such as S-TAPs.

## Databases

---

In the Datasource Definitions UI, update the datasource IP address in the Host Name/IP field.

## S-TAPs

---

1. If S-TAPs use numeric addresses for tap\_ip and sqlguard\_port, switch them to IPv6 format. Edit guard\_tap.ini, or use guard-config-update, for example.
2. These parameters might need modification, depending on the configuration:
  - Networks
  - exclude\_networks
  - connect\_to\_ip
  - alternate\_ips
  - load\_balancer\_ip
  - log4j\_listen\_address
3. Restart the S-TAPs.
4. Check connectivity to all databases and Guardium host systems.

## IPv6 limitations, best practices, FAQ, and troubleshooting

---

## Best practices

---

- Use a unique DNS name for every device and protocol on your network. For example, if you have a database server that supports both IPv4 and IPv6, it should have both an IPv4 DNS name and an IPv6 DNS name. For example, database-ip4.yourcompany.com and database-ipv6.yourcompany.com. This provides deterministic DNS lookups and prevents connectivity issues.
- Guardium systems only support one host name. When in *dual mode*, the system is registered to the DNS with the same host name for both IPv4 and IPv6. This can cause connectivity issues as the IP returned by the DNS could be IPv4 or IPv6. For example, if the central manager is in dual mode and you want to register a managed unit using IPv6, specify the IPv6 address of the central manager: **register management 2620:1f7:807:a000:920:8400:0:182 8443**.

To change the protocol used for registering a managed unit to the central manager, unregister the managed unit from the central manager, change its IP mode, then re-register it using the new IP format. For example, with a central manager in *dual mode* and a managed unit in IPv4, unregister the managed unit while it is in IPv4 mode, change its IP mode to IPv6, then re-register it to the central manager using an IPv6 address.

- Use Guardium host name aliasing to make reports easier to read. This feature works for both IPv4 and IPv6 protocols and uses DNS lookups for IP address aliasing.
- Configure infrastructure services like FTP to support IPv6.
- Use network tools and utilities that support IPv6. For example, the **ping** utility on some Linux and Windows system requires specifying the **-6** switch for IPv6 addresses (**ping -6 2620:1f7:807:a000:920:8400:0:182**), the **nslookup** utility requires specifying **-type=AAA** to resolve IPv6 host names (**nslookup -type=AAAA database-ipv6.yourcompany.com**), etc.

## Known limitations

---

### Changing to IPv4 or IPv6 mode from *dual mode*

If you are operating in *dual mode* and migrate to IPv4-only or IPv6-only mode, the network configuration for the IP protocol you did not migrate to is lost.

### Enterprise load balancing and *dual mode*

When using enterprise load balancing, a managed unit only supports the IP mode that was used for registering that managed unit to the central manager. This is true even if the collector is configured for *dual mode*. For example, if a managed unit in *dual mode* is registered to a central manager using IPv6, that managed unit cannot utilize IPv4. This limitation applies only to load balancing contexts with systems configured for *dual mode*.

### GDBI configuration

When migrating from IPv4 to IPv6 with an existing GDBI instance configured for IPv4, update the GDBI instance for IPv6 using the following GuardAPI command:

```
grdapic datamart_update_copy_file_info destinationHost=[<IPv6 address>] destinationPassword=<password>
destinationPath="/var/lib/sonargd/incoming" destinationUser="sonargd" transferMethod="SCP" Name=<datamart name>"
```

Issue this command on a central manager for each active datamart and allow the settings to sync to managed units.

### LDAP authentication configuration

When using LDAP for authentication configuration on the **Setup > Tools and Views > Portal** page, an IPv6 host address must be entered using brackets. For example: [2620:1f7:807:a000:920:8400:0:182].

### S-TAP `sqlguard_ip` parameter

If a Guardium collector has different networking information in DNS than what is configured on the system, S-TAP installations may have issues using a hostname for the `sqlguard_ip` parameter. To resolve this issue, align the DNS information and collector networking configuration. Otherwise, a numeric IP address can be specified for `sqlguard_ip`.

### S-TAP diagnostics

When the central manager is not on the same internet protocol as a Windows S-TAP, then the S-TAP diagnostics are not communicated to the central manager.

## Frequently asked questions

---

### How do you access a Guardium system using an IPv6 address?

Use square brackets for the IPv6 address in the URL. For example, [https://\[2620:1f7:807:a000:920:8400:0:182\]:8443](https://[2620:1f7:807:a000:920:8400:0:182]:8443)

### Why is it important to have unique names in DNS for the devices in my network?

Having unique DNS names makes DNS lookups deterministic. For example, if you have a database server that has the same name in DNS for IPv4 and IPv6, a lookup for that name may return either protocol. If that protocol is not used by the Guardium system, the connection will fail.

### The Guardium CLI only allows one hostname when configuring the system, but the IPv6 best practices indicate using unique host names for each IP protocol. Which hostname should I use when setting up a Guardium system in *dual mode*?

The name provided during host name setup is an internal configuration and is not used for networking configuration: it is used to help identify the system from the CLI and in reports. Any name can be used for this setting. For example, if you have a system configured with an IPv4 DNS name and an IPv6 DNS name, you can use either one.

### Why do you recommend using an IP address instead of a host name when registering managed units to a central manager?

In some environments, DNS is set up to have only one host name for both IPv4 and IPv6 addresses on the same device. In this case, using a host name does not guarantee which IP address is used and can lead to connection issues if one protocol is not supported. Therefore, when performing tasks such as registering managed units to a central manager, use the IP address of the protocol you want to use for the connection.

### I have both IPv4 and IPv6 databases on the same database server. How do I configure inspection engines on a collector running in *dual mode*?

Each internet protocol requires its own inspection engine. For a dual mode system, create both an IPv4 inspection engine and an IPv6 inspection engine.

### How do I determine which IP mode was used to register managed units to a central manager?

Use the **Reports > Guardium Operational Reports > Managed Units** report. The Managed Units report shows the host name and IP address of managed units: the IP address will be in either IPv4 or IPv6 format, depending on how the managed unit is registered to the central manager.

### I converted my collector to *dual mode*. Why is my S-TAP status red in the S-TAP monitor?

Verify that the S-TAP and collector are both communicating in the correct IP protocol. Use the **Manage > Activity Monitoring > S-TAP Control** page to confirm that the IP formats are the same. Expand the **Guardium Hosts** information for a specific S-TAP to review the collector information. If the S-TAP and collector are using different protocols, change the protocols to match.

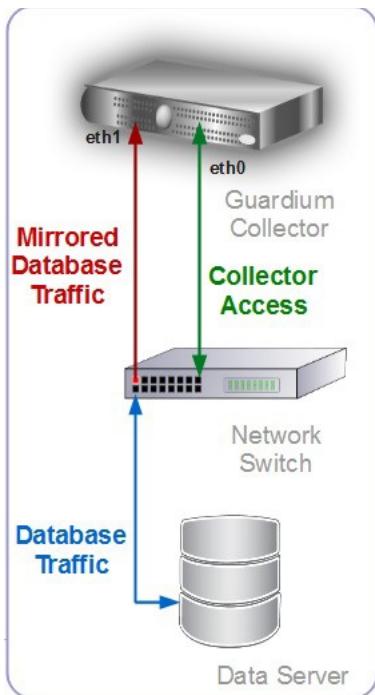

## Network mirroring methods (SPAN , N-TAP) and related inspection engines

---

This configuration is used in cases where an S-TAP cannot be installed in the host where the database instances to be monitored are run. Instead, you can direct a copy of the network traffic that goes to the host running the database servers, to a Guardium collector. This method only captures network traffic, not local traffic within the database server host. The limitations are listed further on in this section. IBM strongly encourages you to use an S-TAP instead.

**Port Mirroring:** For network traffic, you can use port mirroring, which is mirroring through SPAN (Switched Port Analyzer) ports. This requires a network switch with port mirroring capability. Physical setup and configuration of the inspection engine is required for port mirroring.

**Physical Setup:** The LAN containing the desktop used for connecting to the Guardium collector GUI should be connected to the eth0 port on the Guardium collector appliance. The SPAN port from the network switch should be connected to the eth1 port of the Guardium collector appliance. You can also connect additional SPAN ports to the remaining ethernet ports of the Guardium appliance, in order. The network switch must then be configured to mirror all traffic to and from the databases to be monitored, to a port on which the appliance is connected. A network administrator should be able to perform this configuration. You may need to consult the switch vendor's documentation for the exact process for setting up this configuration.

Since all network traffic from the host is sent to the collector, there can be potentially a high amount of useless (non-DB related) traffic the collector has to check before deciding to ignore it.

The collector needs to have a separate port for the incoming traffic from SPAN/NTAP. The actual setup is beyond the scope of Guardium (and Guardium support). Your network administrators are responsible for configuring this solution. Once the mirrored traffic is directed to the collector, you need to define inspection engines for each of the databases for which the traffic has been mirrored. Note that these inspection engine definitions are different from the definitions with the same name under S-TAP control.

For more information about creating and managing inspection engines, see [Configuring inspection engines](#).

## Related reference

- [update\\_engine\\_config](#)

## Configuring inspection engines

An inspection engine extracts SQL from network packets; compiles parse trees that identify sentences, requests, commands, objects, and fields; and logs detailed information about that traffic to an internal database.

You can configure, start, and stop multiple inspection engines on the Guardium® Data Protection appliance. You cannot create or run inspection engines on a central manager unit. However, you can start and stop inspection engines on managed units from the central manager control panel. After the inspection engine is configured, you can use the [update\\_engine\\_config](#) API to change the parameters.

You can define up to 50 inspection engines per Guardium appliance.

## Creating an inspection engine

1. Browse to [Manage > Activity Monitoring > Inspection Engines](#) to open the Inspection Engine Configuration page.
2. Click Add Inspection Engine to expand the panel.
3. Type a name in the Name box. It must be unique on the appliance. Guardium recommends that you use only letters and numbers in the name, as the use of any special characters prevents working with this inspection engine via the CLI.
4. From the Protocol box, select the protocol that you want to monitor from the list. Protocols are: Db2®, Informix, MSSQL, Mysql, Oracle, Sybase.
5. In the DB Client IP/Mask boxes, enter a list of clients (a client host from which the database connection was initiated) to be monitored (or excluded if the Exclude DB Client IP box is marked). The clients are identified by IP addresses and subnet masks. There are detailed instructions on how to use these fields in the overview.
  - Click the plus sign to add additional IP address and subnet mask.
  - Click the minus sign to remove the last IP address and subnet mask.
6. In the DB Server IP/Mask boxes, enter a list of database servers (where a database sits) to be monitored. The servers are identified by IP addresses and subnet masks. For information about identifying the IP addresses and subnet masks, see [Selecting IP addresses](#).
  - Click the plus sign to add additional IP address and subnet mask.
  - Click the minus sign to remove the last IP address and subnet mask.
7. In the Port box, enter a single port or a range of ports over which traffic between the specified clients and database servers will be monitored. Most often, this should be a single port.  
Warning: Do not enter a wide range of ports, just to be certain that you have included the correct one! You may cause the inspection engine to bog down attempting to analyze traffic on ports that carry no database traffic or traffic that is of no interest for your environment.
8. Mark the Active on startup box if this inspection engine should be started automatically on start-up.
9. Mark the Exclude DB Client IP box if you want the inspection engine to monitor traffic from all clients except for those listed in the DB Client IP/Mask list. Be sure that you understand the difference between this and the Ignore protocol selection. This includes all traffic except for the from IP addresses. To ignore a specific set of clients without including all other clients, define a separate inspection engine for those clients and use the Ignore protocol.

10. Click Add to save the definition.
11. Reposition the inspection engine in the list of inspection engines. Filtering mechanisms defined in the inspection engines are executed in the order. If necessary, reposition the new inspection engine configuration, or any existing configurations, using the Up and/or Down buttons in the border of the definition.
12. Click Start to start the inspection engine that you just configured. After the inspection engine starts, the Start button changes to Stop.

## Selecting IP addresses

---

Each inspection engine monitors traffic between one or more client and server IP addresses. In an inspection engine definition these are defined using an IP address and a mask. You can think of an IP address as a single location and a mask as a wild-card mechanism that allows you to define a range of IP addresses.

IP addresses have the format: n.n.n.n, where each n is an eight-bit number (called an octet) in the range 0-255.

For example, an IP address for your PC might be: 192.168.1.3. This address is used in the examples. Since these are binary numbers, the last octet (3) can be represented as: 00000011.

The mask is specified in the same format as the IP address: n.n.n.n. A zero in any bit position of the mask serves as a wildcard. Thus, the mask 255.255.255.240 combined with the IP address 192.168.1.3 matches all values from 0-15 in the last octet, since the value 240 in binary is 11110000. But it only matches the values 192.168.1 in the first three octets, since 255 is all 1s in binary (in other words, no wildcards apply for the first three octets).

Specifying binary masks can be a little confusing. However, for the sake of convenience, IP addresses are usually grouped in a hierarchical fashion, with all of the addresses in one category (desktop computers, for example) grouped together in one of the last two octets. Therefore, in practice, the numbers you see most often in masks are either 255 (no wildcard) or 0 (all).

Thus a mask 255.255.255.255 (which has no zero bits) identifies only the single address specified by IP address (192.168.1.3 in the example).

Alternatively, the mask 255.255.255.0, combined with the same IP address matches all IP addresses beginning with 192.168.1.

## Selecting all addresses

---

The IP address 0.0.0.0, which is sometimes used to indicate all IP addresses, is not allowed by Guardium. To select all IP addresses when using an IP address/mask combination, use any non-zero IP address followed by a mask containing all zeroes (for example: 1.1.1.1/0.0.0.0). However, 0.0.0.0/0.0.0.0 is a valid combination.

## Configure Settings that apply to all Inspection Engines

---

1. Go to Manage > Activity Monitoring > Inspection Engines to open the Inspection Engine Configuration.
2. Use the information in [Table 1](#) to make any needed changes.
3. Click Apply to save the updated system configuration when you are done making changes.  
Note: Any global changes made (and saved by using Apply) do not take effect until you restart the inspection engines. However, individual inspection engine attributes, such as exclude, sequence order, etc., take effect immediately.
4. Optionally add comments to the configuration.
5. Click Restart Inspection Engines to stop and restart all inspection engines.

You can also update the inspection engines by using the [update\\_engine\\_config API](#).

Note: The applied changes do not take effect until the inspection engines are restarted. After applying inspection engine configuration changes, click Restart to stop and restart the system (using the new configuration settings).

Note: The following inspection engine settings are not supported for HTTP: Default Capture Value; Default Mark Auto Commit; Log Sequencing; Log Exception Sql String; Log Records Affected; Compute Avg. Response Time; Inspect Returned Data; Record Empty Sessions.

Table 1. Settings that apply to all inspection engines

| Control                  | Description                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Capture Value    | Used by Replay function to distinguish between transactions and capture values, meaning that if you have a prepared statement, assigned values will be captured and replayed. If you want to replay your captured prepared statements as prepared statements the check box should be checked for the captured data.<br>Default value = false.         |
| Default Mark Auto Commit | Default value is true. Due to various auto-commit models for different databases, this value is used by Replay function to explicitly mark up the transactions and auto commit after each command.<br>Note: If the check box is checked then commits and rollbacks will be ignored. Databases currently supported include Db2, Informix®, and Oracle. |
| Log Sequencing           | If selected, a record is made of the immediately previous SQL statement, as well as the current SQL statement, provided that the previous construct occurs within a short enough time period.                                                                                                                                                         |
| Log Exception Sql String | If selected, when exceptions are logged, the entire SQL statement is logged.                                                                                                                                                                                                                                                                          |

| Control                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Log Records Affected        | <p>Records affected - Result set of the number of records which are affected by each execution of SQL statements.</p> <p>The records affected feature is not supported in:</p> <ul style="list-style-type: none"> <li>• Db2 when streaming is used to send the results.</li> <li>• AWS</li> <li>• Couchbase</li> <li>• Hadoop integration</li> </ul> <p>If selected, the number of records affected is recorded for each SQL statement (when applicable). Default value for log records affected is FALSE (0).</p> <p>Note: The records affected option is a sniffer operation which requires sniffer to process additional response packets and postpone logging of impacted data which increases the buffer size and might potentially have a adverse effect on overall sniffer performance. Significant impact comes from really large responses. To prevent large amount of overhead associated with this operation, Guardium uses a set of default thresholds that allows sniffer to decide to skip processing operation when exceeded.</p> <p>Note: Usually, Records Affected is set correctly when the user turns on Log Records Affected via Inspection Engines &gt; Log Records Affected. However using MS-SQL via stored procedure will set Records Affected as -1.</p> <p>Refer to <a href="#">Configuration and Control CLI Commands</a> <code>store max_results_set_size</code>, <code>store max_result_set_packet_size</code> and <code>store max_tds_response_packets</code>, to set levels of granularity.</p> <p>Example of result set values:</p> <ul style="list-style-type: none"> <li>• Case 1, record affected value, positive number. This represents correct size of the result set.</li> <li>• Case 2, record affected value, -2. This means number of records exceeded configurable limit (This can be tuned through CLI commands).</li> <li>• Case 3, record affected value, -1. This shows any unsupported cases of packets configurations by Guardium.</li> <li>• Case 4, record affected value, -2. If the result set is sent by streaming mode.</li> <li>• Case 5, record affected value, less than -2. Intermediate result during record count to update user about current value, ends up with positive number of total records. For example, the server returns 1000 records in 4 packets: <ul style="list-style-type: none"> <li>◦ Packet #1 250</li> <li>◦ Packet #2 200</li> <li>◦ Packet #3 250</li> <li>◦ Packet #4 200</li> </ul> </li> </ul> <p>Then records affected are reported as</p> <ul style="list-style-type: none"> <li>◦ Packet #1 -250</li> <li>◦ Packet #2 -500</li> <li>◦ Packet #3 -750</li> <li>◦ Packet #4 1000</li> </ul> |
| Compute Avg Response Time   | When selected, for each SQL construct logged, the average response time is computed. 12.1 and later If the response time is longer than about 35 minutes (2 million milliseconds), the response time displays as -1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Inspect Returned Data       | Select to inspect data returned by SQL requests as well as update the ingress and egress counts.<br>If rules are used in the security policy, this checkbox must be selected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Record Empty Sessions       | When selected, sessions containing no SQL statements are logged. When cleared, these sessions are ignored.<br>Note: This configuration works for other protocols, but not for Oracle Unified Auditing (OUA).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Parse XML                   | The Inspection Engine does not normally parse XML traffic. Mark this checkbox to parse XML traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Logging Granularity         | The number of minutes (1, 2, 5, 10, 15, 30, or 60) in a logging unit. If requested in a report, Guardium summarizes request data at this granularity. For example, if the logging granularity is 60, a certain request occurred n times in a given hour. If the check box is not selected, exactly when the command occurred within the hour is not recorded. But, if a rule in a policy is triggered by a request, a real time alert can indicate the exact time. When you define exception rules for a policy, those rules can also apply to the logging unit. For example, you might want to ignore 5 login failures per hour, but send an alert on the sixth login failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Max. Hits per Returned Data | When returned data is being inspected, indicate how many hits (policy rule violations) are to be recorded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Ignored Ports List          | A list of ports to be ignored. Add values to this list if you know your database servers are processing non-database protocols, and you want Guardium to not waste cycles analyzing non-database traffic. For example, if you know the host on which your database resides also runs an HTTP server on port 80, you can add 80 to the ignored ports list, ensuring that Guardium does not process these streams. Separate multiple values with commas, and use a hyphen to specify an inclusive range of ports. For example: 101,105,110-223                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Buffer Free: n %            | Display only. n is the percent of free buffer space available for the inspection engine process. This value is updated each time the window is refreshed. There is a single inspection engine process that drives all inspection engines. This is the buffer used by that process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Starting or stop an inspection engine

Browse to Manage > Activity Monitoring > Inspection Engines to open the Inspection Engine Configuration page.

- To start an inspection engine, click Start.
- To stop an inspection engine, click Stop.

## Removing an inspection engine

If you are no longer using an inspection engine, remove the definition, so that it is not accidentally restarted.

1. Click Manage > Activity Monitoring > Inspection Engines to open the Inspection Engines.
2. If the inspection engine you want to remove is still running, click Stop.
3. To remove an inspection engine, click Delete.

## Configuring the Guardium portal

From the Guardium Portal page, you can reset the port for the Guardium® appliance web server, import SSL certificates, and configure authentication for your Guardium system users.

To open the Guardium Portal page, click **Setup > Tools and Views > Portal**.

### Setting the port number

You can keep the Guardium appliance web server on its default port (8443) or reset the portal. Guardium recommends that you use the default port.

1. If not selected, select the Active on Startup checkbox (make sure that Active on Startup is always enabled).
2. Set the HTTPS Port to an integer value 1025 - 65535.
3. Click **Apply** to save the value. (The Guardium security portal does not start listening on this port until it is restarted.) Or click **Revert** to restore the value that is stored by the last **Apply** operation.
4. Click **Restart** to restart the Guardium web server if you made and saved any changes. You can now connect to the unit on the newly assigned port.

Note: To reconnect to the unit after it restarts with the new port number, change the URL that opens the Guardium Login page on your browser.

For more information about Guardium ports, see [Guardium port requirements](#)

### Importing SSL certificates

Use Import Certificate to import self-signed certificates with private keys.

Before you begin, generate certificates for each Guardium system, and store them locally.

Certificates can be generated in two formats:

- PKCS 12
- PEM

Note: After the certificates are imported, the GUI must be restarted for the changes to take effect.

- To import a PKCS 12 certificate:
  1. Select Import PKCS 12 certificate.
  2. Select Browse, and then browse to the certificate stored on your local system.
  3. In the **Password** field, enter your PKCS 12 file's password.
  4. In the **Certificate alias** field, enter the certificate's alias.
  5. Click **Import**. In the confirmation dialog, click Yes to restart the GUI. To restart the GUI later, click No.

Note: PKCS 12 certificates can be imported only through the GUI.

- To import a PEM certificate:
  1. Select Import PEM certificate.
  2. In the **PEM certificate** field, paste your certificate. Include the markers "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----".
  3. In the **PEM private key** field, paste your certificate's key. Include the markers "-----BEGIN RSA PRIVATE KEY-----" and "-----END RSA PRIVATE KEY-----".
  4. Click **Import**. In the confirmation dialog, click Yes to restart the GUI. To restart the GUI later, click No.

Note: You can also import PEM certificates from the CLI. For more information, see [Store certificates with private key](#).

### Configuring authentication

Authentication defines the way user passwords are authenticated when users log in to the Guardium appliance. From the Portal page, select one of the following authentication configurations:

- Local (the default) - A login and password for a specific user is defined from the accessmgr role on the Guardium accessmgr account.
- RADIUS - Allow login authentication through a Radius server. The Radius/RSA server is defined by using both a password and a SecurID token number. The SecurID token numeric password is displayed on a hardware token.
- LDAP - Allow login authentication when the password is defined and stored on a specified lightweight directory access protocol (LDAP) server.
- Smart Card - Require login to the Guardium UI using a smart card.
- Single sign-on SAML - Allows access to multiple web-based applications using one set of login credentials.

For more information about user authentication, see [Configuring authentication](#). For more information about smart card authentication, see [Enabling smart card authentication](#).

### Configuring multi-factor (two-factor) authentication

Multi-factor (or two-factor) authentication (MFA) adds an extra layer of security to your Guardium user accounts. Guardium supports DUO and RSA SecurID authentication engines. For more information about configuring your system for multi-factor authentication, see [Configuring multi-factor authentication](#).

- [Configuring authentication](#)  
By default, Guardium user logins are authenticated by Guardium, independent of any other application.
- [Enabling smart card authentication](#)  
Guardium smart card support meets the United States government mandate that all vendors must support multi-factor authentication for user access. Smart card authentication is supported only for access to the web-based Guardium user interface (UI).

- [Configuring multi-factor authentication](#)

Multi-factor (or two-factor) authentication (MFA) adds an extra layer of security to your Guardium user accounts.

## Configuring authentication

By default, Guardium® user logins are authenticated by Guardium, independent of any other application.

For the Guardium admin user account, login is always authenticated by Guardium alone. For all other Guardium user accounts, authentication can be configured to use RADIUS, LDAP, a smart card or Single sign-on SAML. Extra configuration information is required for connecting with the authentication server.

When using RADIUS or LDAP, all Guardium users must still be defined as users on the Guardium appliance. It is only the authentication that is performed by another application.

While user accounts and roles are managed by the accessmgr user, the authentication method used is managed by the admin user, which is a standard separation-of duties best practice.

In addition, you can also authenticate users with a smart card and for any authentication method, add a level of security with multi-factor authentication. For more information, see [Enabling smart card authentication](#) and [Configuring multi-factor authentication](#).

To set up user authentication from the Portal:

1. Browse to Setup > Tools and Views > Portal.
2. From Authentication Configuration, select the type of authentication you want to use.  
Note: Local is the default.
3. Configure the authentication type as required.

## Configuring Guardium local authentication

Select Local (the default) to define logins and passwords for specific users from the access manager (that is, the accessmgr role on the Guardium accessmgr account). For more information about accessmgr, see [Managing users](#).

When you define a username and password from the accessmgr role, the defined password per user is used to log in to the Guardium system.

To configure Guardium for local authentication, select Local and click Apply.

## Configuring RADIUS authentication

Select RADIUS to allow login authentication through a Radius server. The Radius/RSA server is defined by using both a password and a SecurID token number. The SecurID token numeric password is displayed on a hardware token.

You can define the Radius/RSA server on either a Windows or UNIX server. The security RSA SecurID token is defined and stored on the Radius server. You do not need to download it for the Radius portal to work.

Guardium supports FreeRADIUS client software. To use FreeRADIUS, the client (Guardium server), username, and passwords are defined on the FreeRADIUS UNIX servers and used when the Radius Portal connection is defined.

1. Select RADIUS in the Authentication Configuration page to display the RADIUS-specific fields. Enter the following information for RADIUS:
  - a. Primary Server - The hostname or IP address of the primary RADIUS server.
  - b. Secondary Server and Tertiary Server - Optionally enter the hostname or IP address of the secondary and tertiary RADIUS servers.
  - c. Port The UDP port used (1812 or 1645) by RADIUS.
  - d. Shared Secret - Enter the RADIUS server Shared Secret, twice.
  - e. Timeout Seconds - The number of seconds before the server times out (the default is 120).
  - f. Auth Type - Select an authentication type:
    - PAP - Password authentication protocol
    - CHAP - Challenge-handshake authentication protocol
    - MS-CHAPv2 - Microsoft version 2 of the challenge-handshake authentication protocol
2. Click Test to verify the configuration. You are informed of the results of the test. The configuration is also tested whenever you click Apply to save changes.
3. Click Apply. Guardium attempts to authenticate a test user, and informs you of the results.

## Configuring LDAP authentication

LDAP authentication allows login authentication when the password is defined and stored on a specified lightweight directory access protocol (LDAP) server. A user account name must be imported from the LDAP server to allow a user to use the LDAP portal and to log in.

Guardium supports multiple LDAP servers. The access manager defines the LDAP configurations, which display in the LDAP servers table under Authentication Configuration. For more information about defining the LDAP configurations, see [Importing users from LDAP](#).

Note: Default User RDN Type defines the default value of User RDN Type. If you add a new LDAP server for user import, the User RDN Type attribute is populated with the value defined here.

If you configure Default User RDN Type with the <LDAP Attribute>=search, Guardium applies an additional filter (<LDAP Attribute>=<username>). Guardium searches for the user DN and then authenticates the user with the resultant DN.

For example, let's say that you configure User RDN Type as uid=search, when a user logs in (Hadrian Wall for example), Guardium applies the additional filter (uid="home\_markdown\_jenkins\_workspace\_Transform\_in\_SSMPHH\_12.x\_com.ibm.guardium.doc.admin\_config\_configuring\_authentication\_HadrianWall") and searches for the user DN in LDAP. If Guardium finds "HadrianWall," then Guardium uses the DN and the supplied password to authenticate with the LDAP server.

Note: If the user RDN type for your site is not uid, then work with your access manager to establish the user RDN. The access manager imports LDAP users and can tell you which RDN to use as the default.

After the access manager configures LDAP authentication, you can optionally choose to add or view trusted certificates or test the authentication. When you are done, click Apply to finish the set up, as described in step 4.

1. Optional. To inspect one or more trusted certificates, click Trusted Certificates and follow the instructions in that window.
2. Optional. To add a trusted certificate, click Add Trusted Certificates and follow the instructions in that window.  
Note: If multiple LDAP servers use SSL, you need to add an SSL certificate for each server. However, if the certificates are signed by the same certificate authority, you can add only the root certificate.
3. Optional. Click Test to verify the configuration and return the results. The configuration is also tested whenever you click Apply to save changes.
4. Click Apply. Guardium attempts to authenticate a test user, and informs you of the results.

## Enabling smart card authentication

---

You can configure Guardium smart card support that meets the United States government mandate that all vendors must support multi-factor authentication for user access. Smart card authentication is supported for access to the web-based Guardium user interface (UI). For more information about smart card authentication, see [Enabling smart card authentication](#).

## Single sign-on SAML authentication

---

Single sign-on SAML is an authentication process that allows access to multiple web-based applications that use one set of login credentials.

Before you set up SAML authorization on the Guardium appliance, you need to have your identity provider (IDP) metadata file that is provided by your company. This file contains a public certificate that communicates with the Guardium appliance. More information on the IDP can be found of your companies help page.

1. Click Single sign-on (SAML) and then click Configure. The Configure SAML authentication window is displayed.
2. Enter the following information in the Configure SAML authentication window:

### Browse

Select an XML-format file that contains an IDP certificate.

### Request binding protocol

Depending on your IDP, select the correct protocol:

- HTTP-Redirect - Communicates through URL parameters given.
- HTTP- Post - Communicates through messages based on Base64 encoding.

### Request signed assertion

Select Yes if you want the IDP to sign the SAML assertion that is sent back to the Guardium Appliance. An assertion contains a package of information about a user and their authentication status and XML attributes.

### Request encrypted assertion

Select Yes to encrypt the assertion that is given to the Guardium appliance.

### Sign authentication requests

Select Yes to have Guardium sign the SAML request sent to the IDP.

### Enable service provider initiated single logout

Select Yes to be signed out of the IDP whenever logout is initiated. Your response depends on whether this feature is supported by your IDP.

### Certificate for signing and encryption

Select guardium\_default or click  to add your own PEM-formatted certificate.

### How to authorize

Select one of the following parameters:

- Local - Allows authorization for local users on the Guardium appliance. These local users are manually created and added into the Guardium appliance.
- User attribute - Allows authorization for users from the LDAP in the IDP. Searches for specific attributes that are returned from the SAML assertion.

You can choose one or more of the following attributes:

- Role attribute - Assigns permissions to the user based on the Guardium role
- First name attribute
- Last name attribute
- Email attribute

3. Click Generate SP metadata to generate a metadata file using the given data.

4. Click Save to save your changes and close the Configure SAML Authentication window. After saving, the metadata file is automatically downloaded and can then be uploaded to your IDP. You are now back to the Authentication Configuration screen.

5. Click Apply to save your changes. Reconfiguration of SSO can happen without needing to click again.

Tip: Admin and accessmgr users can log into the Guardium system without using SAML authentication. For more information, see the CLI command [store system admin-only](#).

## Enabling smart card authentication

---

Guardium smart card support meets the United States government mandate that all vendors must support multi-factor authentication for user access. Smart card authentication is supported only for access to the web-based Guardium user interface (UI).

## Before you begin

---

Details of the multi-factor authentication requirement are found in the Identification and Authentication (Organizational Users) (IA-2) section the Security and Privacy Controls for Federal Information Systems and Organizations (NIST Special Publication 800-53) document. NIST 800-53 is available through the NIST website: <https://www.nist.gov>.

Government applications refer to Personal Identification and Verification Cards (PIV). Civilian applications refer to Common Access Cards (CAC). PIV and CAC cards have different certificate authorities, but the cards are otherwise the same.

Guardium smart card support meets the HIGH confidence PIV assurance level. PIV assurance is described in the PIV Cardholder Authentication (6) section of the Personal Identity Verification (PIV) of Federal Employees and Contractors (FIPS Publication 201-2) document. FIPS 201-2 is available through the NIST website: <https://www.nist.gov>.

In addition to the configuration steps described here, users require,

- Access to the Guardium UI from a web browser that can access the smart card certificate.
- A valid PIV or CAC card.
- A smart card reader.

Tip: Admin and accessmgr users can log into the Guardium® system without using a smart card. For more information, see the CLI command [store system admin-only](#).

You can either associate existing Guardium users or create users to associate with smart cards. You can also import user definitions from an LDAP server and edit the smart card user name field without losing any related settings. After you configure your site to use smart card for authentication, Guardium uses the smart card credential only to establish SSL/TLS communication (Guardium uses HTTPS). For more information about creating users and access management, see [Managing access to Guardium](#). Note: While smart card authentication is used to authenticate, you still need to set user access control (that is, which Guardium modules a user can access) through access management.

## About this task

This task describes how to associate the information on a smart card with a Guardium user.

## Procedure

1. Log in as Admin from a central manager or standalone machine.
2. Browse to Setup > Tools and Views > Portal.
3. From Authentication Configuration, select Smart Card.
4. In Regex Match Pattern, use a regular expression (regex) to match the user information on the smart card, for example,

```
CN ?= ?(.*)?, ?OU ?= ?Test Agency, ?OU ?= ?Test Department, ?O ?= ?Test Government, ?C ?= ?US
```

In this example, both patterns match the mapping for the client certificate. Pattern 1 is more exact, but with pattern 2, you can edit the pattern to match your needs. If you are not familiar with the data on the smart card, work with someone who can write efficient mapping patterns.

- Pattern 1:

```
CN ?= ?(.*)?, ?OU ?= ?Test Agency, ?OU ?= ?Test Department, ?O ?= ?Test Government, ?C ?= ?US
```

- Pattern 2:

```
CN ?= ?.*?
```

Both of the examples get the value for CN attribute in the certificate subject (which you can see by examining the certificate details in the browser). Configuring this pattern correctly is probably the most important step in making sure that smart card authentication is successful.

Note: The Guardium regex validation tool cannot validate the regex for smart card.

Tip: You can update the regex values for smart card authentication with the SMART\_CARD\_MAPPING\_REGEX parameter of the **modify\_guard\_param** API command. For more information, see [Smart card parameter](#).

5. Upload or add a trusted certificate from a certificate authority (CA) to your web server truststore.

You can obtain a certificate either directly from a customer or by exporting it from a smart card by using a certificate management tool such as certMgr.exe or OpenSSL.

Note: If you do not have the root certificate of the CA that signed the certificates on the smart cards, export a root certificate from a CA-signed user certificate or a smart card that contains one.

Important: If you enable Online Certificate Status Protocol (OCSP) validation, you must upload valid OCSP client certificates. If the client certificates are not OCSP-enabled, you cannot access the Guardium system and the admin user cannot revert the setting. Valid OCSP certificates indicate Method #1: Online Certificate Status Protocol and include a valid URI

- a. If trusted certificates are available, click Trusted Certificates.

Select a certificate to use for smart card authentication. The signing chain lists a series of signing authorities. The best certificate to select is usually the intermediate authority above the user certificate.

- b. If you do not have a certificate available, click Add Trusted Certificates and then browse to the certificate location and click Upload to import the certificate.

In general, you want to import the public root certificate of a trusted CA. This is the most common source of a root certificate in environments that already have a smart card infrastructure and a standardized approach to smart card distribution and authentication.

6. If needed, select Enable OCSP check to enable OCSP validation.

When the OCSP check is enabled, Guardium communicates with the OCSP responder ensures that the certificate in the truststore is valid. If the certificate is unknown or revoked, a user receives an error message when they attempt to log in to Guardium.

Note: Upload the OCSP-enabled certificates before you select Enable OCSP check.

7. Click Save to save your work. However, you aren't finished yet. You still need to distribute the authentication configuration to managed units on your network and then enable smart card authentication from the CLI.

8. On a central manager, browse to Manage > Central Management > Central Management.

- a. On the Central Management page, select the managed units that you want to include for smart card authentication.

- b. Click Distribute Authentication Config and then check the results to make sure that the selected managed units were updated successfully.

- c. Distributing the authentication configuration to the managed units can take up to an hour. To distribute the authentication configuration immediately, click Refresh.

9. Next, turn on smart card authentication from the Guardium CLI.

To turn smart card authentication on or off, use the following CLI command,

```
store system websmartcard [on | off]
```

Note: Whenever you run this CLI command, the GUI automatically restarts. When you disable smart card authentication, the GUI restarts with the system that uses local authentication.

To check the status of smart card authentication, use the following CLI command,

```
show system websmartcard
```

For more information, see [store websmartcard](#) in [System CLI commands](#).

10. Optional: The admin or accessmgr can log into the Guardium system without a smart card by using a separate login page.

Run the CLI command **store system admin-only on**. Then, access the login page by appending /admin to the URL of your Guardium system. Example: *https://www.[your\_guardium\_system's\_domain\_name].com:[port\_number]/admin*. Log in using your credentials.

For more information, see [store system admin-only](#) in [System CLI commands](#).

## What to do next

---

After smart card authentication is enabled, you can access the site with a valid smart card (such as PIV or CAC). Enter the card into the card reader. Depending on how your smart card is configured, you might be asked to enter the PIN associated with the smart card.

After you swipe the smart card:

1. A list of certificates displays. Select a certificate from the list.
2. If requested, enter your PIN.
3. If Guardium recognizes the smart card certificate, the Guardium dashboard opens. If the certificate is invalid (or revoked), the user receives an authentication error.

### Troubleshooting

- After you enable smart card authentication, you get an error from the Guardium URL.

Diagnosis: Most likely, your configuration of the matching regular expression is incorrect or you don't have a valid certificate on the card.

- You created a matching regex and it does not seem to be working. You know that Guardium has a regex validation tool and use it, thinking that if it works in the tool, it's a good regex pattern. Unfortunately, while the test is successful in the tool, the regex pattern doesn't work for smart card configuration.

Diagnosis: The regex tool determines if regex can find an expression inside a text paragraph. When configuring a smart card, regex extracts a piece of text from the certificate (displayed in the subject as shown in certificate details), and therefore does not work in this situation.

- You didn't get prompt from the browser to select a certificate.

Diagnosis: Your computer is able to install the card reader and the smart card. A copy of the certificate in the smart card is copied to the certmgr in Windows OS. However, the browser (such as Firefox or Chrome) cannot read the certificate. In other words, browsers on Windows are unable to read the certificate and there is no prompt to choose the certificate.

This is a rare, but known, situation on all browsers on some laptops that were tested. In this case, the issue is with your smart card configuration and not Guardium.

Solution: Contact your smart card administrator.

## Configuring multi-factor authentication

---

Multi-factor (or two-factor) authentication (MFA) adds an extra layer of security to your Guardium user accounts.

## Multi-factor (two-factor) authentication configuration

---

Guardium supports DUO and RSA SecurID authentication engines.

To start configuring an authentication service, click Configure to open the Configure multi-factor authentication window. Select an authentication service, and click Save to view the settings for the selected service.

For more information about using DUO, see [Configuring multi-factor authentication with DUO](#).

For more information about using RSA SecurID, see [Configuring multi-factor authentication with RSA SecurID](#).

## Configuring multi-factor authentication with DUO

---

To enable multi-factor authentication for DUO on Guardium, your site needs a DUO administrator. For more information, see <https://duo.com/product/multi-factor-authentication-mfa>. After you install DUO, you can enable MFA for your GUI, your CLI, or both. In addition, you can create a list of users who are exempt from additional authentication.

Note: To use MFA, the user's web browser (for GUI) or gmachine (for CLI and SSH) must have access to the DUO cloud service for MFA. If the DUO cloud service is not reachable (via the internet), then the user cannot be authenticated (and cannot log in).

To use MFA with DUO in a centrally managed environment, you must set up MFA on the central manager. The MFA configuration is automatically synchronized to all of its managed units.

Note: Even though you can set or change MFA authentication only from the central manager, you can query the configuration from any associated machine.

Note: If you unregister a managed unit in a centrally managed environment, the MFA settings for the unregistered unit are disabled.

1. Determine which users require MFA. You can configure MFA for GUI users, regular CLI users (that is, CLI users that are created by the accessmgr), or administrative OS users (cli and guardcli1 - guardcli9 users). Before you configure Guardium®, you need to protect the application with DUO:
  - For the GUI, protect the Web SDK.
  - For the CLI, protect the DUO Auth API.
  - For SSH, protect the UNIX application. You can configure each DUO application as needed. For more information, see the DUO documentation.
2. Within DUO, configure your users for authentication.

After you set up protection in DUO, you can configure multi-factor authentication in Guardium.

1. From the Guardium UI, click Configure next to Multi-factor Authentication.
2. From the Configure multi-factor authentication window, select DUO as the service.
3. To configure the GUI for MFA,
  - a. From the GUI login tab, select Enable multi-factor authentication for GUI logins.
  - b. Copy the Integration key, Secret key, and API hostname from DUO Web SDK application.
  - c. Click Save.
4. To configure the CLI for MFA,
  - a. From the CLI login tab, select Enable multi-factor authentication for CLI logins.
  - b. Copy the Integration key, Secret key, and API hostname from DUO Auth API application.
  - c. Click Save.

For more information about logging in to the CLI with multi-factor authentication, see [Using GuardAPI commands](#).
5. To configure SSH users for MFA,
  - a. From the SSH login tab, select Enable multi-factor authentication for SSH logins.
  - b. Copy the Integration key, Secret key, and API hostname from the UNIX application.
  - c. Click Save.

Note: SSH login supports only password-based authentication with MFA. If your site uses certificate-based authentication, the MFA settings are ignored.
6. To add exempt users,
  - a. On the Exemptions tab, all of the users on your system display (including disabled users and users imported from the LDAP server).
  - b. Select the users who you want to exempt from MFA. Exempt users might include accessmgr, admin, and selected trusted users.
  - c. Click Save to add the users to the exempt list.

Note: You cannot exempt administrative OS users (cli and guardcli1 - guardcli9).

When non-exempt users next login, they are asked to authenticate based on your configuration selections in DUO.

Note: You can use GuardAPIs or REST APIs to manage multi-factor authentication. For more information, see [Multi-factor authentication APIs](#).

## Configuring multi-factor authentication with RSA SecurID

Your site can use MFA with RSA SecurID for Guardium GUI users, regular CLI users (that is, CLI users who are created by the accessmgr), or SSH users (cli and guardcli1 - guardcli9 users). Before you can use RSA SecurID for multi-factor authentication, you need to install and configure the RSA Authentication Manager on a central manager or stand-alone machine.

Note: When you install RSA Configuration Manager, you must enable the RSA SecurIDAuthentication API. When you enable the API, RSA SecurID generates and displays the Access Key. Copy the Access Key value to a secure location where you can access it when you configure the authentication agents later.

For more information, see the RSA SecurID documentation about configuring the RSA SecurID Authentication API.

RSA SecurID uses token-based authentication. The token is either generated on a hardware key fob or as a software token. You can use either token type for MFA with Guardium.

For more information about RSA SecurID and the RSA Authentication Manager, see "Getting Started with RSA Authentication Manager" from the RSA website.

Note: If you plan to require MFA for SSH users, you need a signed SSL certificate from a trusted certificate authority (CA). The certificates are not required for GUI and CLI users. The certificate must be in PEM format, for example, `rsa_cert.pem`.

When you configure Guardium, you can upload the certificate either by using the `store certificate rsa_securid` CLI command or from the Configure multi-factor authentication page.

To configure RSA SecurID on a Guardium central manager, log in to the RSA security console, and then take the following steps,

1. Add users to RSA SecurID. From the RSA security console, select Identity->Users->Add New.
2. If your site uses software tokens, determine the authentication type that you want to use, and add a software token profile. Select Authentication->Software Token Profiles->Add New. For more information about managing software tokens, see the RSA SecurID documentation.

Note: If your site uses hardware tokens, do not create a software token profile.
3. Assign tokens to users,
  - a. From the RSA security console, select Identity->Users->Manage Existing.
  - b. Click Search to display all of the available users. Leave the search criteria empty to display all users.
  - c. Click a username and then select SecurID Tokens from the drop-down list.
  - d. Select a token from the available tokens list and click Assign. A message displays when a token is assigned.
  - e. Click Cancel to return to the Manage Existing page and assign tokens to other users.
4. Set up the authentication agent,
  - a. From the RSA security console, browse to Access->Authentication Agents->Add New.
  - b. Add a new, unique, hostname for the Guardium machine to which you want to authenticate. The Guardium host can be either a central manager or a managed unit. After you enter the hostname, click Resolve Hostname; the IP address is automatically entered.
  - c. Copy and save the hostname. You will need to enter it in Guardium as the Client ID.
  - d. You can keep the default settings or change the settings as needed and then click Save.
5. If you did not save the Access Key earlier, you can find the value from the RSA security console System Settings window,
  - a. Browse to Setup->System Settings. Under Authentication Settings, click RSA SecurID Authentication API.
  - b. Copy the value of the Access Key to a secure location.

## Configuring RSA SecurID authentication on Guardium

After the RSA SecurID console is configured, you can configure RSA SecurID on Guardium. Each user requires their own client ID and access key (or token). In addition, you can create a list of users who are exempt from additional authentication.

To enable MFA, you need the following information from the RSA SecurID Authentication Manager:

- Hostname: The hostname of the RSA SecurID Authentication Manager. The hostname is usually a fully qualified domain name.
- Port: The port that RSA SecurID Authentication Manager uses for the authentication service. The default is 5555.
- Client ID: The hostname of the authentication agent that you added to the RSA SecurID security console in Step 4 of [Configuring multi-factor authentication with RSA SecurID](#).
- Access key: The access key that is generated from the RSA SecurID Authentication API. You can find the value of the Access key in the RSA SecurID Security Settings, as described in Step 5 of [Configuring multi-factor authentication with RSA SecurID](#).

In addition, you can include a signed SSL server certificate. Select Validate server certificate and then click Upload certificate. Browse to the location of the certificate and click Open.

Note: A signed certificate, in PEM format, is required for SSH logins only.

To add exempt users,

1. On the Exemptions tab, all of the users on your system display (including disabled users and users imported from the LDAP server).
2. Select the users who you want to exempt from MFA. Exempt users might include accessmgr, admin, and selected trusted users.
3. Click Save to add the users to the exempt list.

Note: You cannot exempt administrative OS users (*cli* and *guardcli1 - guardcli9*).

When non-exempt users log in to Guardium, they need to provide a passcode from RSA SecurID. The passcode is either generated on the user's RSA SecurID hardware fob (token) or from the RSA SecurID software token on the users computer or phone.

## Logging in to Guardium with RSA SecurID MFA

---

To log in to Guardium as a user in an environment with RSA SecurID MFA, you need to either acquire a hardware token from your RSA SecurID or download the RSA SecurID software token.

Follow your administrator's instructions for installing the RSA SecurID token. After you have a token (either software or hardware) and MFA is configured for Guardium, you will need to provide a token passcode whenever you log in.

When a passcode is requested, copy the passcode and paste (or type) it into the Passcode box (for the UI) or at the Enter passcode prompt (for the CLI).

Depending on how your environment is configured, you might need to provide a passcode to log in to the GUI, the Guardium CLI, or both.

---

## Managing the TLS version

Use APIs to manage TLS 1.2 and TLS 1.3 protocols for your appliances, S-TAP agents, CAS and GIM clients. As you update your Guardium system to Guardium 12.0, you can enable TLS 1.3 and disable TLS 1.2.

## Before you begin

---

Updating your Guardium configuration to transport layer security (TLS), 1.3 provides a faster and more secure encryption protocol. However, TLS 1.3 runs only on Guardium 12.0 or later. For systems in transition, where you have appliances and S-TAPs that use different versions of Guardium, you can use both TLS 1.2 and TLS 1.3. When you install or upgrade to Guardium 12.0 or later, TLS 1.2 and TLS 1.3 are enabled by default.

Note: You can enable TLS 1.3 only on appliances, the GIM client, and S-TAPs that are at Guardium 12.0 or later. While you can, for example, use a Guardium 12.0 central manager (with TLS 1.3 enabled) along with earlier versions of Guardium for the managed units and S-TAPs (with TLS 1.2 enabled), Guardium recommends that you bring all of your appliances to Guardium 12.0 or later so that you can enable TLS 1.3 across your entire Guardium system.

Note: As you prepare to upgrade to Guardium 12.0, all of the appliances, agents, and so on that you plan to upgrade must have TLS 1.2 enabled. Make sure that all of the systems that you plan to upgrade have TLS 1.2 enabled. For information about upgrading to TLS 1.2 on a pre-12.0 system, see [Managing the TLS version](#) in IBM Docs for your (pre-12.0) version of Guardium.

Important: While Guardium supports TLS 1.3, not all add-ons and features currently provide TLS 1.3 support. Until you know that every part of your Guardium system supports TLS 1.3, do not disable TLS 1.2 (that is, do not run the [enable\\_latest\\_tls](#) API on your central manager). The following add-ons and features support only TLS 1.2:

- External ticketing with IBM Resilient. For more information about IBM Resilient, see [Configuring an external ticketing system](#).
- External ticketing with ServiceNow. For more information about ServiceNow, see [Configuring an external ticketing system](#).
- Running CAS in FIPS mode. To run in FIPS mode, the CAS client requires IBM Java 8 SR7 or later. For more information about configuring CAS, see [Prerequisites, installing and running CAS on a Linux, UNIX server](#) or [Prerequisites, installing, and running CAS on a Windows server](#).
- In most cases, both TLS 1.2 and 1.3 support FIPS 140 mode. However, under some circumstances, you must disable TLS 1.3 before you can enable FIPS 140 mode. For more information, see [enable\\_fips\\_tls](#).
- Guardium® Data Protection does not support TLS 1.3 on Solaris operating system from version 12.0 and later.
- Guardium Data Protection does not support FIPS 140-3 on Solaris operating system from version 12.1.

## Procedure

---

1. Access the CLI as admin.
2. Determine the versions of your central manager, managed units, and GIM client.

You can run one of the following commands to find the current versions of the TLS that are enabled on your system:

- Run the `show tls enabled` CLI command to see which TLS versions are enabled.
- Run the `grdapi get_secured_protocols_info` API from a central manager to propagate down to all managed units. The command displays the enabled protocols (TLS 1.2 and TLS 1.3) and indicates if the TLS 1.2 protocols can be disabled.  
Messages display to indicate which components do not meet the requirements for disabling TLS 1.2. Warning messages are generated for managed units that are offline or unreachable.

For more information, see [show tls enabled](#) and [get\\_secured\\_protocols\\_info](#).

3. Depending on the status of your system, take one of the following steps:
- To enable TLS 1.3, and optionally disable TLS 1.2, run the following command:  
`grdapi enable_latest_tls`

- To enable both TLS 1.2 and TLS 1.3, run the following command:  
`grdapi enable_all_tls`

For more information, see [enable\\_all\\_tls](#) and [enable\\_latest\\_tls](#).

## Related reference

## Related information

---

- [show\\_tls\\_enabled](#)

## Global profile

---

The Global Profile page defines defaults that apply to all users.

## Getting started with the global profile

---

To open the Global Profile page, browse to Setup > Tools and Views > Global Profile.

Use the Global Profile page to set defaults for your Guardium® system. You can add your own header and footer to reports, upload your company logo, create a default message template, and much more.

Note: Whenever you change information on the Global Profile, you need to scroll to the end of the page and click **Apply** for the change to take effect.

## Changing settings for aliases and PDFs

---

You can change the following settings for aliases and PDF footers:

- Use aliases in reports unless otherwise specified: An alias provides a synonym that substitutes for a stored value of a specific attribute type. Aliases are commonly used to display a meaningful or user-friendly name for a data value. For example, Financial Server might be defined as an alias for IP address 192.168.2.18. When selected, Guardium uses available aliases for all reports.
- PDF footer text: PDF files created by various Guardium components (such as audit tasks) have a standard page footer. To customize the footer, enter your text into the PDF footer text box. PDF footer text that you define on a central manager or aggregator is not distributed to managed units.

## Managing alert message templates

---

Message templates determine the content of alerts. You can create multiple message templates from the Global Profile, and use them with different rules as needed. Note: For more information about creating and managing message templates, see [The alert message template](#).

- Default message template: Displays the default message template for alerts.
- No wrap: Select to remove word wrap from the message template. Use this feature to see where the line breaks appear in the message.
- Named template: Click Edit to create new templates and manage or edit existing named templates. For more information, see [The alert message template](#).

## Specifying a CSV separator

---

Specify a CSV separator for all CSV output (such as audit processes):

- CSV separator: Select Comma, Semicolon, Tab, or click Other to define your own separator.

## Adding text to the Guardium window

---

- HTML - left and HTML - right: Enter HTML-formatted text to include at the bottom of the Guardium window.  
To verify that your HTML displays as you expect, click .
- Create a login message and other elements to display when (or before) a user logs in:
  - Show login message: Select to display the login message (or clear to disable the display).
  - Login message: Add a plain text message to display each time that a user logs in.
  - Pre-login message (HTML): Add an HTML-formatted message that displays after a user opens the Guardium window but before they log in.  
Note: If you include an image, the image also displays in the pre-login message. For more information, see [Upload logo image](#).
  - Header and footer banner (HTML): Add HTML-formatted banners to the Guardium login page. By default, the header and footer display at the top and the lower left of the Guardium UI. However, you can use HTML to change the alignment, color, and other elements for your requirements.

## Managing other Guardium properties

---

- Concurrent login from different IP: By default, the same Guardium user can log in to an appliance from multiple IP addresses. Use this feature to disable concurrent logins from the same user. When disabled, each user can log in from only one IP address at a time. If a user closes their browser without logging out, the connection times out due to inactivity, so the user account is not blocked for long.  
Note: When this feature is enabled, Unlock displays. For support purposes, you can unlock the account to allow a second user to log in with this user account from a different IP address.
  - Data level security filtering: Enable this feature when specific Guardium users are responsible for specific databases. Use data-level filtering to filter results system-wide so that each user can see only the information from databases for which that user is responsible.  
Note: If data level security at the observed data level is enabled, then audit process escalation is allowed only to users at a higher level in the user hierarchy.
  - Default Filtering: If data-level security filtering is enabled, you can set the default filtering options for the logged-in viewer.
    - Show all: The logged-in viewer can see all of the rows in the result regardless of who these rows belong to. When used with the datasec-exempt role, allows an override of the data level security filtering.
    - Include indirect records: The logged-in viewer can see the rows that belong to the logged-in user, and all rows that belong to users in the user hierarchy under the logged-in user.
- Note: The datasec-exempt role is activated when data level security is enabled and the datasec-exempt role is assigned to a user. For more information, see [Understanding Roles](#).
- Restriction: Data Level Security and the Investigation Dashboard cannot be enabled concurrently.
- Escalate result to all users: When enabled (the default), audit process results (and PDF versions) are escalated to all users, even if data level security at the observed data level is enabled. If not enabled, then audit process escalation is allowed only to users at a higher level in the user hierarchy and to users with the datasec-exempt role. If disabled (cleared), and no user hierarchy is available, then no escalation is allowed.
  - Custom database table maximum size (MB): Set the size of the custom database table (in MB). The Default value is 4000 MB. In addition, click Current Usage to display the current values for InnoDB, MyISAM, and the combined total.  
Note: The custom size limit is tested before data is imported. If a data import exceed the new limit, Guardium prevents the next import.
  - FTP/SCP Ports Export: Change a port to send files over FTP or Secure Copy Protocol (SCP). You can change the ports for export and patch backup. The default port for FTP is 21. The default port for SSH/SCP/SFTP is 22.  
Note: A zero indicates that Guardium uses the default port.
  - Encrypt Must Gather output: Guardium collects certain data (MustGather information) that IBM support uses if something goes wrong. Select to encrypt MustGather output. Clear to compress, but not encrypt the output.  
You can also turn MustGather encryption on and off from the CLI. For more information, see [store\\_encrypt\\_must\\_gather](#).
  - Check for Guardium updates: When selected, information about relevant ad hoc Guardium patches, GPUs, CFPs, bundles, Sniffer patches, and security patches display when you click the  icon.  
Note: After you install a patch, it is removed from the list.
  - Datasource connection timeout (seconds): Set the datasource connection timeout. The default is 60 seconds.

When you are done making changes, click Apply to save your changes to the global profile.

## Uploading a new logo

You can add or delete a graphic on the Guardium window.

- To delete the current logo, click Delete.
- To add a file, click Browse to select a file to upload to theGuardium appliance. Then, click Upload.
- When you refresh your browser window, the new image is scaled to 60 x 54 pixels and displays in the upper right corner of the Guardium UI. If you have a pre-login message, the image also displays in the message.

Note: The file name cannot include any of the following characters: Single quotation mark ('), double quotation mark ("), less than sign (<), or greater than sign (>).

## Managing access by IP address

From a central manager or stand-alone machine, use Manage login access by IP address to limit access to the Guardium UI, CLI (via SSH), or both to specified IP addresses.

To specify IP addresses for an allowlist:

1. From Manage login access by IP address, click Manage to open Manage login access by IP address.  
From here, you can either add IP addresses one at a time, or click Import from CSV to import a list of IP addresses from a comma-separated value (CSV) file.
2. To add a single IP address, click the  icon to open the Add IP address to allowlist window.
  - a. Enter the IP address (IPv4 or IPv6) you want to include.
  - b. Select the login type: GUI, SSH (to log in to the CLI), or GUI and SSH.
  - c. Click OK to add the address.
3. To import a list of address from a CSV file:
  - a. Click Browse and select a CSV file that contains the list of IP address to add to the allowlist.
  - b. If necessary, set Field delimiter to the separator used in the CSV file. The default is a comma (,).
  - c. Click Load to add the values.
  - d. Select the column within the file to import.
  - e. Select the login type: GUI, SSH (to log in to the CLI), or GUI and SSH.
  - f. Click OK to add the addresses.

Note: To include different addresses for the GUI and SSH allow lists, use separate CSV files.
4. The addresses that you added display in the IP address table. Select whether to enforce the allowlist for GUI or SSH logins, or both, and then click Save.

Users can now log in only if their IP addresses are in the allowlist.

To manage IP addresses in the allowlist:

- To disable the allowlist (that is, allow login access for any IP address), clear Enforce allowlist... for either GUI or SSH logins (or both).
- To remove addresses from the allowlist, select the addresses to delete and click the  icon.

Note: Be careful not disable access from your current IP address. If you do disable access, you (or someone with access to the GUI) can use the [update\\_ip\\_restriction\\_allowlist](#) API to restore access.

- [The alert message template](#)

Message templates determine the content of alerts. You can create multiple message templates from the Global Profile, and use them with different rules as required.

## The alert message template

Message templates determine the content of alerts. You can create multiple message templates from the Global Profile, and use them with different rules as required.

Several message templates available, which allow you to define the following types of messages:

- Threshold Alerts: Send an alert when Guardium detects that a specified threshold is met or exceeded.
- Audit Process Report: Publish in audit process reports.
- Real-time Alerts: Send an alert immediately when Guardium detects a problem.
- Audit Process Email: Sends an email when an audit process runs. You can customize the email as needed. For more information, see [Custom email template in Building audit processes](#).

You can use the filtering checkboxes to filter the types of templates to view.

Several predefined message templates are available for ArcSight, enVision, and IBM QRadar (in LEEF format) security information and event management (SIEM) solutions. Guardium® includes two certified (agreed upon) templates to integrate with these SIEM solutions.

## Creating or updating named messages

To add, modify, or delete named message templates:

1. Click Edit to open the Named Template Finder window.
2. Click to open the Modify Named Template window. The current default message template displays in the Default message template text box.  
Alternatively, select one of the existing named templates and click to clone that template. You can then rename and edit your new template.
3. Enter a name and template type for your new template. Then, add or delete the message template variables to meet your requirements. For more information about the available message template variables, see [Table 1](#).  
Select No wrap to see where the line breaks appear in the message.
4. Click Save when you are done.
5. Changes take effect after you restart the inspection engines from the managed unit.  
Note: To restart the inspection engines, browse to Manage > Activity Monitoring > Inspection Engines and then click Restart Inspection Engines.

## Formatting real-time alerts

Customizing email for real-time alerts

Use the **store alerter email append\_name\_subject** and **store alerter email append\_subject\_body** CLI commands to customize emails from real-time alerts as follows:

- Control the appearance of the Prefix email subject with Guardium appliance name.
- Control the appearance of the email subject in the email body.
- Add naming template parameter %%applianceHostName to add the appliance hostname to Name Templates (in either the subject or the body).

Setting sender encoding

To encode outgoing messages (email and SNMP traps) in an encoding scheme other than UTF8, use the **store sender\_encoding** CLI command, as described in [store sender\\_encoding](#).

## Alert message template variables

Table 1. Alert message template variables.

Note: Only the following variables in the Alert template are available for correlation alerts.

- Subject: %%Subject[Guardium Alert. Severity: (%severity), Alert Name: %%alertName]  
Alert Name: %%alertName  
Alert Description: %%description  
Current value: %%alertQueryValue  
Base query value: %%alertBaseQueryValue  
Threshold: %%alertThreshold
- Query period: %%alertQueryFromDate - %%alertQueryToDate  
Alert Classification: %%classification  
Category: %%category  
Severity: %%severity
- Recommended Action: %%recommendation

| Variable | Description |
|----------|-------------|
|----------|-------------|

| Variable               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %%analyzedClientIP     | A client IP field populated by the Guardium Analyzer. Corresponds to GDM_ACCESS.ANALYZED_CLIENT_IP. If the Analyzed Client IP is not available when the SQL event is processed: <ul style="list-style-type: none"> <li>If the policy rule action is set to Alert only and SYSLOG notification, then %%analyzedClientIp is blank.</li> <li>A value for analyzedClientIp is not always available for encrypted Oracle traffic.</li> <li>For any other alert policy rule actions, the alert message might be delayed and sent later in the session.</li> </ul>                                                                                                                           |
| %%AppEventType         | The type of application event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| %%AppUserName          | Application username.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| %%severity          | Severity from the rule definition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| %%SourceProgram     | Source program name. For Db2 for IBM i, the %%SourceProgram returns job_user/job_name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| %%SQLNoValue        | SQL string with masked values. The value of SQL is replaced by a question mark (?) in the syslog.<br>For IMS z/OS users: The following values are available, similar to the %%SQLString values: prog=; job=; step=; tran=; job#=.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| %%SQLString         | SQL string (if any).<br>Note: For databases that generate custom queries, %%SQLString values are copied to %%SQLNoValue, where they are masked. These databases include, for Cloudera: HDFS, HBASE, and SOLR; for Hortonworks: HBASE, HDFS, KAFKA, SOLR, STORM, and YARN.                                                                                                                                                                                                                                                                                                                                                                                      |
| %%SQLTimestamp      | The time on the packet or request. %%SQLTimestamp displays in either seconds or milliseconds, based on the value of the alert_timestamp_unit CLI. The default is seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| %%Subject[ ]        | If you specify this variable, all of the text between the square brackets ([ ]), such as file name, email sender, or description, is included in the subject line of the email that is sent to the user.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| %%succeeded         | Messages that include this variable are delayed for 5 minutes by default. For more information, see the <a href="#">store alerter delay</a> CLI command. The value is replaced with the "FULL SQL"."Succeeded" value from Guardium report attributes.<br>Note: This variable does not return a value when used with a message template, which uses an <i>alert only</i> policy rule action that specifies the <i>syslog</i> notification type. For more information, see <a href="#">Alerting rule actions</a> .                                                                                                                                               |
| %%uid_chain         | For Linux or UNIX systems only, the UID chain that tracks a chain of users.<br>Messages that include this variable are delayed for 5 minutes by default. For more information, see the <a href="#">store alerter delay</a> CLI command. The value is then replaced with the "Session"."Uid Chain" value from Guardium report attributes. For more information, see <a href="#">UID chains</a> .<br><br>Note: This variable does not return a value when used with a message template, which uses an <i>alert only</i> policy rule action that specifies the <i>syslog</i> notification type. For more information, see <a href="#">Alerting rule actions</a> . |
| %%UnitOfWork        | Computed attribute that contains the CICS Unit of Work ID in hex to correlate CICS traffic across multiple S-TAP Entities (IMS, data sets, and Db2).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| %%Verb              | The SQL verbs that are relevant to the triggered rules in the alert messages. You can set the number of SQL verbs to include by setting the ALERT_VERB_NUM_LIMIT parameter from the <a href="#">modify_guard_param</a> command. The default is 10. For more information, see <a href="#">Alerter parameters</a>                                                                                                                                                                                                                                                                                                                                                |
| %%violationID       | Numeric representing the POLICY_VIOLATION_LOG_ID of this alert in GDM_POLICY_VIOLATION_LOG (this is the same as the Violation Log ID in the Policy Violations / Incident Management report).                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Example: Creating a real-time alert

The following example shows the general process of creating a Guardium real-time alert. Your process might be different.

1. Create a message template for your alert:
  - a. From the Named Template Finder in the Global Profile UI, select and clone a real-time alert template. You can use the filtering to select the template type that you want.
  - b. Name your new template and click Save to save it.
  - c. From the Named Template Finder, select your new template and click to make changes. Add or remove the message template variables (described in [Table 1](#)) as needed, and then save the changes.
2. Associate your alert with a policy:
  - a. Open Security Policies (Policy Builder for Data) and select or create a policy.
  - b. Create a rule for your policy (for example, a session level rule of *Database type = ORACLE*).
  - c. Under Rule action, add an action and specify your template as the Message Template.
  - d. Click OK to save the new Action, OK again to save the rule, and OK one more time to save the policy.
3. From the Guardium Alerter page, make sure that the alerter is running.
4. The next time Guardium starts, if Guardium fires the alert, a message is sent to the SYSLOG that contains the information that is specified in your alert message.

## Configuring the alerter

Configure and activate the alerter to send email messages, SNMP traps, and alert-related Syslog messages.

Other components create and queue messages for the Alerter. The Alerter checks for and sends messages based on the specified polling interval.

To configure, enable or disable individual correlation alerts, see [Correlation Alerts](#). To produce correlation alerts and appliance alerts, make sure that Anomaly Detection is started. To create real-time alerts, a security policy must be installed.

Mail/SNMP/SYSLOG messages are sent out according to their priority.

To open the Alerter page, go to Setup > Tools and Views > Alerter.

### Automatically activate the Alerter on startup

1. Select Active on Startup. Each time the appliance restarts, the Alerter is activated.
2. Click Apply.
3. If the Alerter is not running, click Restart to start it.

### Set the polling interval

The polling interval is the frequency that the Alerter checks for and sends messages. Enter the polling interval, in seconds.

### Configure the Alerter to send SMTP (email) messages

From the SMTP tab, configure email messages.

1. To use SMTP for alert emails, select Send alert emails using SMTP.
  2. Host, enter the IP address or hostname for the SMTP gateway.
  3. Under Port, enter the SMTP port number (the default is 25).
  4. If you selected Send alert emails using SMTP, click Test Connection to open the Test connection window. You can take one of the following actions:
    - Enter an email address to send the test alert and click OK to send a test email to the address.
    - Click OK without entering an address to test whether the connection is open (and return a message).
    - Click Cancel to cancel without testing.
  5. In Return-path email address, enter the return address for email that is sent by the system. This address is usually a monitored administrative account.
  6. Select Use STARTTLS for encryption to use STARTTLS to encrypt mail messages with TLS encryption.
  7. To use SMTP server authentication, select Assign SMTP credentials. In this case, you must specify the username and password to use for authentication.
    - Enter a valid username for your mail server.
    - Enter, and then reenter, the password for this user.
  8. Click Save to save the configuration.
- Note: The Alerter does not use the new configuration until it is restarted.
9. Click Restart to restart the Alerter with the new configuration.

### Configure the alerter to use SNMP

From the SNMP tab, you can configure SNMP traps for either SNMP v2c or v3.

To use SNMP for alert emails, select Send alert emails using SNMP and then select the SNMP version.

- For SNMP v2c, provide the following information:
    1. Under Primary host, enter the IP address or hostname to which to send the SNMP trap.
    2. Optionally, click Test Connection to verify the SNMP address and port (162). This only tests that access is available to specified host and port. The test does not verify that it is a working SNMP server. A dialog box displays that informs you of the success or failure of the operation.
    3. Under Trap community name and Re-enter trap community name, enter the community name for the trap.
    4. Optionally, select Secondary host to enable the ability to add a secondary host:
      - a. Under Secondary host, enter the IP address or hostname to which to send the SNMP trap.
      - b. Optionally, click Test Connection to verify the SNMP address and port.
      - c. Under Trap community name and Re-enter trap community name, enter the community name for the trap.
  - For SNMP v3, provide the following information:
    1. Under Primary host, enter the IP address or hostname to which to send the SNMP trap.
    2. Optionally, click Test Connection to verify the SNMP address and port (162). This only tests that access is available to specified host and port. The test does not verify that it is a working SNMP server. A dialog box displays that informs you if the operation was successful or failed.
    3. Under User name, provide the name of the SNMP user.
    4. Under Authentication protocol, select either the MD5 or SHA protocol. The default is MD5.
    5. Enter (and then re-enter) an authentication password.
    6. Under Encryption protocol, select either AES or DES encryption. The default is AES.
    7. Enter (and then re-enter) an encryption password.
  - Click Save to save the configuration.
- Note: The Alerter does not use the new configuration until it is restarted.
- Click Restart to restart the Alerter with the new configuration.

### Set up the external ticketing system

From the Alerter page, you can go to the External Ticketing System page to set up external tickets for alerts. For more information, see [Configuring an external ticketing system](#).

## Related concepts

---

- [The alert message template](#)
- 

## Facility and priority of syslog messages

---

The facility and priority of messages configured in the Guardium syslog can impact how they are consumed by the Security Incident Event Manager (SIEM).

You can send a few types of messages to the syslog:

- Policy Alerts. For more information, see [How to create a real-time alert](#).
- Correlation Alerts. For more information, see [Correlation alerts](#).
- Audit Process results. For more information, see [Building Audit Processes](#).
- Guardium® predefined alerts. See [Predefined alerts](#).

## Policy alerts and correlation alerts

---

When defining a policy or correlation alert, there are five levels of severity that can be picked from the drop down list:

- info
- low
- none
- med
- high

The syslog messages are assigned a specific facility and priority for each configuration of severity:

| Severity of Policy Rule | Facility | Priority |
|-------------------------|----------|----------|
| info                    | daemon   | info     |
| low                     | daemon   | warning  |
| none                    | daemon   | warning  |
| med                     | daemon   | error    |
| high                    | daemon   | alert    |

## Audit Process results

---

The Audit Process results are assigned the following facility and priority:

| Severity of Policy Rule | Facility | Priority |
|-------------------------|----------|----------|
| NA                      | user     | info     |

## Anomaly Detection

---

The Anomaly Detection process runs every polling interval to create and save, but not send, correlation alert notifications that are based on an alert's query.

This notification is run according to the schedule defined for each alert. See [Configuring the alerter](#) for more information about sending notifications.

The Anomaly Detection process uses the results of a correlation alert's query, which looks back over a specified period of time, and the correlation alert's threshold, to determine whether a condition is satisfied (an excessive number of failed logins, for example). See [Correlation Alerts](#) for more information.

In a Central Manager environment, the Anomaly Detection panel for each Guardium system can be used to turn off correlation alerts that are not appropriate for that particular Guardium system. Under Central Management, all correlation alerts are defined on the Central Manager, regardless of which Guardium system they were created or updated. These correlation alerts are the same for all Guardium system, and when activated, are activated on all Guardium system by default.

Note: The Alerter component must be configured and started to send a saved alert message to SYSLOG, email, or an SNMP trap.

Note: Anomaly Detection does not play a role in the production of real-time alerts, which are produced by security policies.

## Automatically activate Anomaly Detection on startup

---

1. Click Setup > Tools and Views > Anomaly Detection to open Anomaly Detection.
2. Mark the Active on Startup check box. Each time the Guardium system restarts, Anomaly Detection is activated automatically.
3. Click Apply.

## Set the frequency that Anomaly Detection checks for appliance issues

---

1. Click Setup > Tools and Views > Anomaly Detection to open Anomaly Detection.
2. Enter the Polling Interval in minutes.
3. Click Apply.

## Enable or Disable Active Alerts

---

To disable an alert globally in a central manager environment, use the alert builder: navigate to Protect > Database Intrusion Detection > Alert Builder and clear the Active check box in the Modify Alert panel.

To enable or disable an alert on a single Guardium system in a central management environment, follow these steps:

1. Log in to the UI of the Guardium system on which you want to disable one or more alerts.
2. Click Setup > Tools and Views > Anomaly Detection to open Anomaly Detection.
3. To disable an alert, select it from the Active Alerts box, and click Disable.
4. To enable an alert, select it from the Locally Disabled Alerts box, and click Enable.

## Stop or Restart Anomaly Detection

---

1. Click Setup > Tools and Views > Anomaly Detection to open Anomaly Detection.
  2. Click Stop to stop Anomaly Detection, or click Restart to restart it.
- 

## Session Inference

Session Inference checks for open sessions that have not been active for a specified period of time, and marks them as closed.

To configure the Session Inference options:

1. Click Setup > Session Inference to open Session Inference.
2. Mark the Active On Startup box to start Session Inference on startup of the Guardium® system.
3. In the Polling Interval box, enter the frequency (in minutes) with which Session Inference checks for open sessions. The default is 120 (minutes).
4. In the Max Inactive Period box, enter the number of minutes of inactivity after which a session is marked closed. The default is 720 (minutes).
5. Click Apply to store the values in the configuration database. Session Inference will not begin using a new configuration until it is restarted.
6. Click Restart to restart Session Inference with the new configuration.

To stop Session Inference, open the Session Inference panel and click Stop.

---

## Allow (approve) S-TAP connection to Guardium (S-TAP certification)

Use this function to control the specific S-TAP hosts whose clients are allowed ("approved") to access the Guardium® system.

### About this task

---

When enabled, only the specified S-TAP clients are allowed to access the Guardium system.

You can also control this feature with the CLI command **store\_stap\_approval** or with the GuardAPI command, **grdapic store\_stap\_approval**.

If you use the CLI command **store\_stap\_approval**, the new configuration takes effect after you run the command **restart inspection-core**.

View approved S-TAPs in Manage > Reports > Change Monitoring > Approved Tap Clients or Reports > Real-Time Guardium Operational Reports > Approved Tap Clients.

### Procedure

---

1. Access Manage > Activity Monitoring > S-TAP Certification.
2. Select S-TAP Approval Needed. This is the equivalent of the GrdAPI command **store\_stap\_approval**.
3. Specify the approved S-TAP host IP address (not host name) in the Approved S-TAP Clients section, and click Add. This is the equivalent of the GrdAPI command **add\_approved\_stap\_client**.
4. Repeat for each S-TAP host.

### Results

---

Note: In a Central Managed environment, after you add the IP addresses to approved S-TAPs, there is a wait time for synchronization that might take up to an hour. After synchronization is complete, the status of the approved S-TAPs appears green in Manage > Activity Monitoring > S-TAP Control.

## IP to Hostname Aliasing

The IP-to-Hostname Aliasing function accesses the Domain Name System (DNS) server to define hostname aliases for client and server IP addresses.

There are two separate sets of IP addresses: one for clients, and one for servers. When IP-to-Hostname Aliasing is enabled, alias names will replace IP addresses within Guardium® where appropriate.

1. Click Protect > Database Intrusion Detection > IP-to-Hostname Aliasing to open IP-to-Hostname Aliasing.
2. Mark the check box for Generate Hostname Aliases for Client and Server IPs (when available) to enable hostname aliasing.

A second check box can now be accessed. The name of this check box is Update existing Hostname Aliases if rediscovered.

3. Mark the check box to update a previously defined alias that does not match the current DNS hostname (usually indicating that the hostname for that IP address has changed). You may not want to do this if you have assigned some aliases manually. For example, assume that the DNS hostname for a given IP address is dbserver204.guardium.com, but that server is commonly known as the QA Sybase Server. If QA Sybase Server has been defined manually as an alias for that IP address, and the check box for Update existing Hostname Aliases if rediscovered is marked, that alias will be overwritten by the DNS hostname.
4. Click Apply to save the IP-to-Hostname Aliasing configuration.
5. Do one of the following:
  - Click Run Once Now to generate the aliases immediately.
  - Click Define Schedule to define a schedule for running this task. See [Scheduling](#) for more information.

To view the aliases defined, see [Aliases](#).

## Configure Permission to Socket connection

This topic applies to Custom Alerting Classes.

Follow this procedure to configure permissions for socket all connections that are used by custom classes.

1. Click Setup > Evaluations > Communication Permissions to open the Communication Permissions.
2. Click Add permission To Socket Connection to expand that pane.
3. Enter the IP address or Host name for the host.
4. Enter a Port number for the socket connection.
5. Enter a description.
6. Click Save.

## Managing access to Guardium

Access management consists of four tasks: account administration, maintenance, monitoring, and revocation.

Access Management is separate from system administration duties.

There are two predefined users on a Guardium® appliance: accessmgr and admin.

- *accessmgr* is the user name assigned to the access manager. By default, the access manager is the only user authorized to manage user accounts and security roles.
- *admin* is the user name assigned to the (primary) Guardium administrator. By default, the administrator does not have authority to manage user accounts or security roles. The admin user has a more extensive set of privileges.

Note: Admin and accessmgr roles can not be assigned to the same user. The same user may contain both of these roles through a legacy situation or as a result of an upgrade. However, current use will not allow the two roles to be assigned to the same user.

- User-DB Association

## Predefined Reports from Accessmgr

The following predefined reports are available from the Accessmgr user.

## User and Role Reports

Defining and modifying users (see [Managing users](#)) involves deciding both who will be using the Guardium system and to what roles (see [Understanding Roles](#)) they will be assigned. A role is a group of users, all of whom are granted the same access privileges.

The User and Role Reports consist of reports:

- User - Role: a report that shows, by user, the number of roles that user belongs to.
- All Roles - User: a report that shows, by role, the number of users that belong to that role.

Note: admin and access manager are pre-existing, other roles are created by the Access manager.

The following reports are available on a Central Manager or a standalone unit. If trying to use on a managed machine, an error message will appear. Servers Not Associated will show servers from ALL managed units in Central Manager systems.

## Datasources Associated

---

This report identifies Datasource Name, Host, Service Name, Login Name and Association Type. This information comes from the choices made in the User-Database Associations activity. See the Data User Security - Hierarchy and Associations help topic.

## Datasources Not Associated

---

This report is a list of datasources not associated with any users. This report identifies Datasource Name, Datasource Type, Host, and Service Name. This information comes from the choices made in the User-Database Associations activity. See the Data User Security - Hierarchy and Associations help topic.

## Servers Associated

---

This report identifies Server IP, Service Name, Login Name and Association Type. This information comes from the choices made in the User-Database Associations activity. See the Data User Security - Hierarchy and Associations help topic.

## Servers Not Associated

---

This report is a list of servers not associated with any users. This report identifies Server IP and Service Name. This information comes from the choices made in the User-Database Associations activity. See the Data User Security - Hierarchy and Associations help topic.

- [Understanding Roles](#)

Assign a role to a Guardium user to grant them specific access privileges. Some examples of roles are: CLI, admin, accessmgr, CAS, and user.

- [Access for default roles and applications](#)

This topic lists user interfaces and other tools associated with the default roles and applications used for access management.

- [Managing roles and permissions](#)

Roles and permissions provide different levels of access to users based on their job duties.

- [How to create a role with minimal access](#)

This topic explains how to create a new role with minimal access permissions, for example an auditor role that can only access the Audit Process To-Do List and view specific reports.

- [Managing users](#)

Use the Access Manager, assigned the username accessmgr to add user accounts, enable or disable user accounts, import members from LDAP, or edit user permissions. Open the User Browser and browse the user accounts by clicking Access > Access Management > User Browser

- [Managing Guardium credentials with CyberArk](#)

You can use CyberArk to manage your Guardium credentials. For more information on this application, access the CyberArk Marketplace web page and search for Guardium.

- [Creating a user who can run GuardAPI commands](#)

Create a user who has the proper roles and entitlements to run GuardAPI commands from the command-line interface (CLI).

- [Importing users from LDAP](#)

You can import Guardium user definitions from one or more LDAP servers by configuring an operation that imports the set of users who need Guardium access.

- [Data Security - User Hierarchy and Database Associations](#)

You can use data security features to create a hierarchy of users and associate users to specific databases and servers. Guardium data security features report on which users accessed what information, and ensure that only specific users see information that they are responsible for.

- [How to define User Hierarchies](#)

Use the UI from an access manager account to easily define user hierarchies.

---

## Understanding Roles

Assign a role to a Guardium user to grant them specific access privileges. Some examples of roles are: CLI, admin, accessmgr, CAS, and user.

The access manager defines roles and assigns them to users and applications. When a role is assigned to an application or the definition of an item (a specific query, for example), only those Guardium users who are also assigned that role can access that component.

When user definitions are imported from an LDAP server, the groups to which they belong can optionally be defined as roles. For more information, see [Importing users from LDAP](#).

Note: When assigning roles to a user, the admin and access manager role cannot be assigned to the same user.

Note: Custom-created roles cannot be combined with default-provided roles (examples are user, admin, accessmgr, cli, inv, datasec-exempt, review-only).

Note: Admin role and object owner have access to all objects by default.

Note: Taking a base role and customizing (with additional navigation items), and then copying this customized role, will result in a loss of the customization if the customized or copied role is reset to default.

---

## Default Roles

The Guardium system is pre-configured to support users who fall into four broadly defined default roles: admin, user, access manager, and investigations. The Guardium access manager can create new roles as well.

Note: Note: If data level security at the observed data level is enabled (see Global Profile settings), then audit process escalation is allowed only to users at a higher level in the Data Hierarchy (see Access Manager). The Datasec-exempt user can escalate, without restrictions, to anyone.

Table 1. Default Roles

| Default Role | Description                                                                                |
|--------------|--------------------------------------------------------------------------------------------|
| user         | Provides the default layout and access for all common users. This role can not be deleted. |

| Default Role   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| admin          | Provides the default layout and access for Guardium administrators. Do not confuse the admin role with the admin user, which is a special user account having the admin role, but also having additional powers that are reserved for the admin user account only. This role can not be deleted.                                                                                                                                                                                                                                                                                                         |
| accessmgr      | Provides the default layout and access for the access manager. This role can not be deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| cli            | Provides access to CLI. The admin user has default access to CLI. Everyone else must be given permission when users are created by access manager and roles specified. The access manager can define as many users in the system and give them the CLI role. These users have access to the CLI and all activities of their CLI sessions are associated with this user.<br><br>To run GrdAPI or CLI commands without admin rights, click the role CLI for Admin Console in the User Role Permissions selection.<br><br>See the topic, <a href="#">diag CLI Command</a> , on how to manage the diag role. |
| inv            | Provides the default layout and access for investigation users. An investigation user must have the restore-to database name of INV_1, INV_2 or INV_3, as the Last Name in their user definition. This is not enforced by the GUI, but is required for the application to function properly. When assigned, the user role must also be assigned. This role can not be deleted.<br><br>Note: The Ad-Hoc Process for run once now button is available on all report screens for all users except investigation (INV) user.                                                                                 |
| datasec-exempt | Data Security - Exempt. This role is activated when Data level security is enabled (see Global Profile in Administration Console) and the datasec-exempt role has been assigned. If the user has this role, a Show all check box appears in all reports. If checked, all sniffed data records are shown (no filter is applied). This role cannot be deleted in the Role Browser.                                                                                                                                                                                                                         |
| review-only    | A user that is specified by this role can view only results (Audit, Assessment, Classifier), Audit Results and the To Do List. This role cannot be deleted in the Role Browser.<br><br>Users with this role is allowed to enter comments in the audit process viewer (not workflow or comments/data per row, but comments at process/result level).<br><br>Users with this role cannot perform any changes/actions on any workflow automation result (escalate, reassign, etc).                                                                                                                          |

## Sample Roles

In addition to the default roles, a set of sample roles is also defined.

Table 2. Sample Roles

| Sample Role           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dba                   | Users who have a database-centric view of security, allowing access to database-related reports and tracking of database objects                                                                                                                                                                                                                                                                                                                                                                                                                          |
| infosec               | Users who have an information security focus, including tracking access to the database, and handling network requests, audits, and forensics                                                                                                                                                                                                                                                                                                                                                                                                             |
| netadm                | Users who have a network-centric view, including IP sources for database requests                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| appdev                | Application developers, architects, and QA personnel who have an application-centric focus and want to track and report on SQL streams generated by an application                                                                                                                                                                                                                                                                                                                                                                                        |
| audit                 | Auditors and others who need to view audit reports<br><br>Note: If trying to copy this role, an embedded message will appear explaining that not all aspects of this role can be copied. The message is: "Create a new role using the layout and permission from the "audit" role. Special privileges and actions associated with the "audit" role will not be copied."                                                                                                                                                                                   |
| audit-delete          | This role is used to track or log when an audit process result has been deleted. Users with the audit-delete role can delete reports. Admin users can also delete reports. Tracking is done through the User Activity Audit Trail report.                                                                                                                                                                                                                                                                                                                 |
| admin-console-only    | A user that is specified by this role can only access the admin console tab.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
